7. If desired, repeat Steps 5 and 6 to continue moving the previously selected objects.

   Regardless of whether you originally moved or copied the selected objects, subsequent translation vectors only move the objects from their position at the end of the previous step.
8. When you have finished translating objects, do one of the following:
   - Click mouse button 2 anywhere in the Abaqus/CAE window.
   - Select any tool in the Sketcher toolbox.
   - Click the cancel button  in the prompt area.

Additional information

- *Sketching simple objects*

- *Modifying objects*
- *Creating patterns, offsetting, and deleting objects*
- *Undoing and redoing sketching actions*

Rotating Sketcher objects about a point

Use the rotate tool from the Sketcher toolbox to rotate Sketcher objects—lines, arcs, circles, ellipses, fillets, or splines—through a specified angle about a specified point. You can choose to move the original objects or create copies and rotate them to the new location.

1. From the move and copy tools in the Sketcher toolbox, select the rotate tool . For a diagram of the tools in the Sketcher toolbox, see *The Sketcher tools*.
2. Select **Copy** or **Move** in the prompt area.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.
3. Select all the objects that you want to rotate. You can select sketch and construction geometry to move, or you can select sketch, construction, and reference geometry to copy; dimensions cannot be rotated.

   Tip: To select more than one object, hold down the **[Shift]** key as you click each object or drag a rectangle around the objects. To unselect an object, use **[Ctrl] + Click**. For more information, see *Selecting objects within the viewport*."
4. Click mouse button 2 to indicate that you have finished selecting objects.
5. Select a point for the center of rotation, or enter coordinates in the prompt area.
6. Enter the angle of rotation in the prompt area.

   Abaqus/CAE moves or copies the objects as specified.
7. If desired, repeat Steps 5 and 6 to continue moving the previously selected objects.

   Regardless of whether you originally moved or copied the selected objects, subsequent rotations only move the objects from their position at the end of the previous step.
8. When you have finished rotating objects, do one of the following:
   - Click mouse button 2 anywhere in the Abaqus/CAE window.
   - Select any tool in the Sketcher toolbox.
   - Click the cancel button  in the prompt area.

Additional information

- *Sketching simple objects*
- *Creating construction geometry*
- *Modifying objects*
- *Creating patterns, offsetting, and deleting objects*
- *Undoing and redoing sketching actions*

Enlarging or reducing Sketcher objects

Use the scale tool from the Sketcher toolbox to enlarge or reduce Sketcher objects—lines, arcs, circles, ellipses, fillets, or splines—about a specified point. You can choose to move the original objects or to create a scaled copy in the new location. If you choose to move objects, your changes are controlled by any constraints in the sketch and by the constraint solution method in the sketch options (for more information, see *Customizing the use of constraints in the Sketcher*). If you choose to create a copy, the movement of the copy is unrestricted.

1. From the move and copy tools in the Sketcher toolbox, select the scale tool . For a diagram of the tools in the Sketcher toolbox, see *The Sketcher tools*.
2. Select **Copy** or **Move** in the prompt area.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.
3. Select all the objects that you want to scale. You can select sketch and construction geometry to move, or you can select sketch, construction, and reference geometry to copy; dimensions cannot be scaled.

   Tip: To select more than one object, hold down the **[Shift]** key as you click each object or drag a rectangle around the objects. To unselect an object, use **[Ctrl] + Click**. For more information, see *Selecting objects within the viewport*."
4. Click mouse button 2 to indicate that you have finished selecting objects.
5. Select a center point about which to scale, or enter coordinates in the prompt area.
6. Enter the scale factor—values greater than `1.0` enlarge the moved or copied objects, values less than `1.0` reduce them.

   Abaqus/CAE keeps the selected point stationary in the viewport and enlarges or reduces the objects around it according to the scale factor.
7. If desired, repeat Steps 3 through 6 to continue scaling objects.

   Note:

   Subsequent scale operations are of the same type—**Copy** or **Move**—as you originally selected. To change the type, end the procedure and select the scale tool again.
8. When you have finished scaling objects, do one of the following:
   - Click mouse button 2 anywhere in the Abaqus/CAE window.
   - Select any tool in the Sketcher toolbox.
   - Click the cancel button  in the prompt area.

Additional information

- *Sketching simple objects*
- *Creating construction geometry*
- *Modifying objects*

- *Undoing and redoing sketching actions*

Moving or copying Sketcher objects about a mirror line

Use the mirror tool from the Sketcher toolbox to mirror Sketcher objects—lines, arcs, circles, ellipses, fillets, or splines—about a specified line. You can choose to move the original objects or to create a mirror copy in the new location. If you choose to move objects, your changes are controlled by any constraints in the sketch and by the constraint solution method in the sketch options (for more information, see *Customizing the use of constraints in the Sketcher*). If you choose to create a copy, Abaqus/CAE applies a mirror constraint between the original objects and the copies so that they will remain mirror images during any subsequent sketch edits.

1. From the move and copy tools in the Sketcher toolbox, select the mirror tool . For a diagram of the tools in the Sketcher toolbox, see *The Sketcher tools*.
2. Select **Copy** or **Move** in the prompt area.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.
3. Select an existing straight line in the sketch as the mirror line. You can select any straight edge from sketch, construction, or reference geometry.
4. Select all the objects that you want to mirror. You can select sketch and construction geometry to move, or you can select sketch, construction, and reference geometry to copy; dimensions cannot be mirrored.

   Tip: To select more than one object, hold down the **[Shift]** key as you click each object or drag a rectangle around the objects. To unselect an object, use **[Ctrl] + Click**. For more information, see *Selecting objects within the viewport*."
5. Click mouse button 2 to indicate that you have finished selecting objects.

   Abaqus/CAE moves or copies the objects as specified.
6. If desired, repeat Steps 4 and 5 to move or copy more objects about the same mirror line.
7. When you have finished moving and copying objects, do one of the following:
   - Click mouse button 2 anywhere in the Abaqus/CAE window.
   - Select any tool in the Sketcher toolbox.
   - Click the cancel button  in the prompt area.

Additional information

- *Sketching simple objects*
- *Creating construction geometry*

- *Creating patterns, offsetting, and deleting objects*
- *Undoing and redoing sketching actions*

Modifying objects

This section describes how to use the Sketcher tools to move and resize Sketcher objects.

In this section:

- *Dragging Sketcher objects*
- *Modifying Sketcher objects by trimming or extending edges*
- *Modifying Sketcher objects by automatically trimming edges*
- *Modifying Sketcher objects by splitting edges*
- *Modifying Sketcher objects by merging edges*

Dragging Sketcher objects

Use the **Drag** tool from the Sketcher toolbox to quickly move or resize a Sketcher object or to reposition dimension text. You can drag only one vertex, line, or dimension at a time. The object or dimension text that you drag snaps to the grilines when the **Snap to grid** option is selected; see *Turning snapping on or off* for more information.

If you drag a vertex or line, Abaqus/CAE modifies connected Sketcher objects according to the applied constraints—including dimensions and parameters—and according to the constraint solution method applied to drag operations. By default, the **Minimum move** constraint solution method, in which Abaqus/CAE moves the minimum number of entities to satisfy the constraints, is used (for more information, see *Customizing the use of constraints in the Sketcher*).

1. From the modify tools in the Sketcher toolbox, select the **Drag** tool . For a diagram of the tools in the Sketcher toolbox, see *The Sketcher tools*.

   Handles appear on all vertices in the viewport. Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.
2. Click and drag the selected vertex, edge, or dimension text to a new location.

   The selected object moves with the cursor unless constraints in the sketch do not allow the desired movement.
3. When you have finished dragging objects, do one of the following:
   - Click mouse button 2 anywhere in the Abaqus/CAE window.
   - Select any tool in the Sketcher toolbox.
   - Click the cancel button  in the prompt area.

Additional information

- *Modifying, copying, and offsetting objects*
- *Sketching simple objects*
- *Creating construction geometry*
- *Modifying objects*
- *Creating patterns, offsetting, and deleting objects*
- *Undoing and redoing sketching actions*

Modifying Sketcher objects by trimming or extending edges

Use the trim and extend tool from the Sketcher toolbox to trim or extend individual edges of Sketcher objects. You can trim or extend an edge at any intersection between the edge and other sketch, reference, or construction geometry. You can also trim or extend an edge at an extended intersection—an intersection that would exist only if another edge in the sketch was extended. You cannot trim or extend a fillet; if you trim or extend an edge that defines an endpoint of a fillet, Abaqus/CAE deletes the fillet.

1. From the modify tools in the Sketcher toolbox, select the trim and extend tool . For a diagram of the tools in the Sketcher toolbox, see *The Sketcher tools*.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

2. Select an edge near the portion that you want to keep.

   You can select any sketched or imported edge except for circles and ellipses. Circles and ellipses have only one edge, they cannot be extended or trimmed unless you first make them into one or more arcs.

   Tip: Use the Auto-trim tool to remove part of a circle or an ellipse, or use the split tool to split it into arcs. For more information, see *Modifying Sketcher objects by automatically trimming edges*, and *Modifying Sketcher objects by splitting edges*, respectively.

   You cannot extend spline curves. If you trim or split a spline curve, Abaqus/CAE removes the control points to retain the exact shape of the original curve; therefore, you can no longer edit the shape of the curve.

3. Move the cursor over other edges in the sketch.

   As you move the cursor, Abaqus/CAE highlights the edge that would be selected at the current cursor location. Abaqus/CAE also creates a preview of the extended or trimmed portion of the first edge by highlighting it a different color from the portion that will remain unchanged.

4. Click to select the highlighted edge.

   Abaqus/CAE trims or extends the first edge to meet the intersection point (or potential intersection point) with the second edge. Abaqus/CAE also splits the second edge if the intersection point is between its endpoints.

5. To trim or extend more edges, repeat the above steps beginning with Step 2.
6. When you have finished trimming and extending edges, do one of the following:

   - Click mouse button 2 anywhere in the Abaqus/CAE window.
   - Select any tool in the Sketcher toolbox.
   - Click the cancel button  in the prompt area.

Additional information

- *Sketching simple objects*
- *Creating construction geometry*
- *Modifying objects*
- *Creating patterns, offsetting, and deleting objects*
- *Undoing and redoing sketching actions*

Modifying Sketcher objects by automatically trimming edges

Use the Auto-trim tool from the Sketcher toolbox to delete unwanted portions of sketched edges. Edges are deleted between the two “trim points” closest to the cursor. The trim points include:

- Intersections with other edges, construction geometry, or reference geometry
- Endpoints
- Points used to define the circumference of circles

If the endpoints are the only trim points on an edge, Abaqus/CAE deletes the entire edge.

You cannot trim a fillet; if you trim an edge that defines an endpoint of a fillet, Abaqus/CAE deletes the fillet.

1. From the modify tools in the Sketcher toolbox, select the Auto-trim tool . For a diagram of the tools in the Sketcher toolbox, see *The Sketcher tools*.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.
2. Move the cursor over the edges in the sketch.

   As you move the cursor, Abaqus/CAE highlights the section that would be removed.
3. Click to remove the highlighted edge segment.

   Unlike when you use **Trim/Extend**, Abaqus/CAE does not split the intersecting edges.

   Note:

   If you trim a spline curve, Abaqus/CAE removes the control points to retain the exact shape of the original curve; therefore, you can no longer edit the shape of the curve.
4. When you have finished trimming edges, do one of the following
   - Click mouse button 2 anywhere in the Abaqus/CAE window.
   - Select any tool in the Sketcher toolbox.
   - Click the cancel button  in the prompt area.

Additional information

- *Sketching simple objects*
- *Creating construction geometry*
- *Modifying objects*
- *Creating patterns, offsetting, and deleting objects*
- *Undoing and redoing sketching actions*

Modifying Sketcher objects by splitting edges

Use the split tool from the Sketcher toolbox to split an individual edge of a Sketcher object into multiple edges. You can split an edge at any intersection between the edge and other sketch, reference, or construction geometry. If you use other sketch geometry to split an edge, Abaqus/CAE splits both edges at the intersection point. You can also split an edge at an extended intersection—an intersection that would exist only if another edge in the sketch was extended.

1. From the modify tools in the Sketcher toolbox, select the split tool . For a diagram of the tools in the Sketcher toolbox, see *The Sketcher tools*.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

2. Select the edge that you want to split; you can select any sketched or imported edge in Abaqus/CAE.

   Note:

   If you split a spline curve, Abaqus/CAE removes the control points to retain the exact shape of the original curve; therefore, you can no longer edit the shape of the curve.

3. Move the cursor over other edges in the sketch.

   As you move the cursor, Abaqus/CAE highlights the edge that would be selected at the current cursor location. Abaqus/CAE also circles the split point—the intersection point between the edge to be broken and the edge at the cursor position. If there is more than one possible split point between the selected edges, Abaqus/CAE circles the point that is closest to the cursor position.

4. Click to accept the indicated split point.

   Abaqus/CAE splits the first edge, creating two edges that share the split point as one endpoint. Abaqus/CAE also splits the second edge if it is sketch geometry and the split point lies between its endpoints.

   Note:

   If you split a circle or an ellipse, Abaqus/CAE uses the vertex on the edge as a second split point to create two arcs. If the split point indicated in the previous step is the same as the edge point, a warning appears in the message area and the curve is not broken.

5. To split more edges, repeat the above steps beginning with Step 2.
6. When you have finished splitting edges, do one of the following
   - Click mouse button 2 anywhere in the Abaqus/CAE window.
   - Select any tool in the Sketcher toolbox.
   - Click the cancel button  in the prompt area.

Additional information

- *Sketching simple objects*
- *Creating construction geometry*
- *Modifying objects*
- *Creating patterns, offsetting, and deleting objects*
- *Undoing and redoing sketching actions*

Modifying Sketcher objects by merging edges

Small gaps can occur in Sketcher objects when you import sketch geometry or when you use the Project Edges tool on edges that are not in a plane parallel to the sketch plane. The **Merge** tool from the Sketcher toolbox closes these small gaps by moving one or more vertices near the gap to a point on the other side.

Note:

When you merge edges, Abaqus/CAE can close the gap by moving one vertex to coincide with the other or by moving both vertices to a location between them. If you want to control the changes to your sketch, you can constrain the line or point that you want to retain its current location before performing the merge operation.

Abaqus/CAE enables you to choose the vertex that you want to remain stationary, and the merge operation moves any vertices within a specified tolerance radius across the gap to share the same point as your selected vertex. *Figure 1* shows a simple merge operation, closing the upper gap between two sketcher objects.

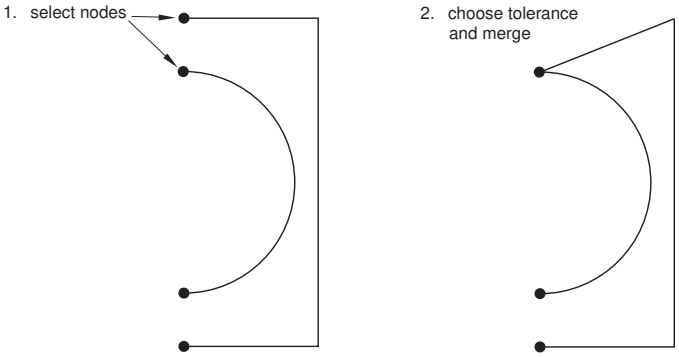

Figure 1: Merging edges

Note:

The Merge tool is intended only for closing small gaps. Merging edges to close larger gaps may change the sketch geometry significantly. If you want to move elements in a sketch over a large distance, use the drag tool to move vertices in your sketch to a new location. For more information, see *Dragging Sketcher objects*.

1. From the modify tools in the Sketcher toolbox, select the Merge tool. For a diagram of the tools in the Sketcher toolbox, see *The Sketcher tools*.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.
2. Select at least two vertices near the small gap.
3. Click **Done** in the prompt area.

   Abaqus/CAE prompts you for a **Tolerance** number for this merge operation.
4. Enter a value for the tolerance, or accept the default value of 0.001. Then either press Enter, or click mouse button 2.

   Abaqus/CAE allows you to increase the tolerance, but you should avoid merges that change the sketch geometry significantly.

   If any vertices are within the selected tolerance, Abaqus/CAE merges them to the location of the vertex you selected in Step 2.
5. To merge more edges, repeat the above steps beginning with Step 2.
6. When you have finished merging edges, do one of the following:

- Click mouse button 2 anywhere in the Abaqus/CAE window.
- Select any tool in the Sketcher toolbox.
- Click the cancel button  in the prompt area.

Additional information

- *Sketching simple objects*
- *Creating construction geometry*
- *Modifying objects*
- *Creating patterns, offsetting, and deleting objects*
- *Undoing and redoing sketching actions*

Repairing short edges, gaps, and overlaps

This section describes how to use the Sketcher tools to repair short edges in a sketch and to remove gaps and overlaps from a sketch.
These tools are intended for the repair of imported sketches, but you can use them to repair geometry in a native sketch as well. You should remove the gaps and overlaps in your sketch before repairing its short edges.

In this section:

- *Removing gaps and overlaps*
- *Repairing short edges*

Removing gaps and overlaps

Use the **Remove gaps and overlaps** tool to repair imported sketches that include gaps or overlaps.

Gaps or overlaps can occur when you import a sketch into Abaqus/CAE from a CAD system that measures sketch geometry using different tolerance values than Abaqus/CAE. The sketch in *Figure 1* includes a gap in the upper left and a small overlap at the midpoint of the top line.

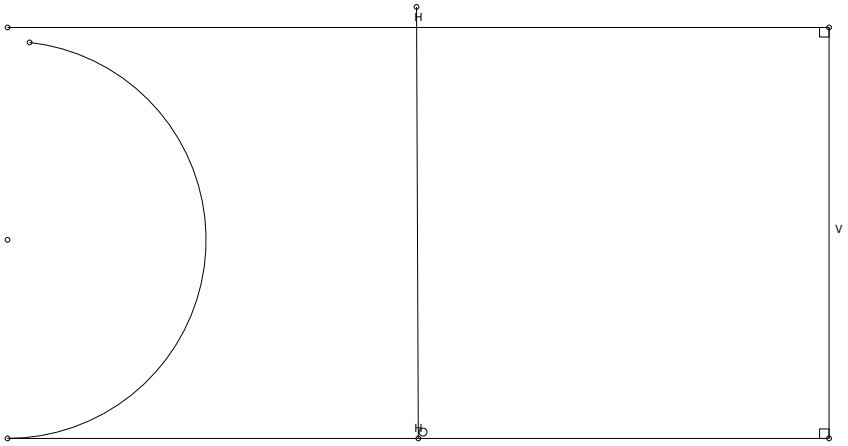

Figure 1: Simple imported sketch with a gap and an overlap.

You can repair the gap and overlap in this example by selecting the edges and specifying a tolerance value. When the size of the gap or the length of the overlap is less than the specified tolerance, Abaqus/CAE merges the vertices to close the gap.

Note:

During the removal of a gap or overlap, Abaqus/CAE can merge vertices by moving one vertex to coincide with the other or by moving both vertices to a location between them. If you want to control the changes to your sketch, you can constrain the line or point that you want to retain its current location before performing the gap/overlap removal.

In practice, you should remove gaps or overlaps from your sketch using an iterative process. Start by selecting the edges adjacent to the gaps or overlaps you want to remove and use the default length tolerance value of 0.001 for your first attempt. If all of the gaps or overlaps are not closed, reselect the edges and increase the tolerance. Repeat this process until Abaqus/CAE merges the selected vertices to close the gaps or overlaps.

1. From the modify tools in the Sketcher toolbox, select the **Remove gaps and overlaps** tool . For a diagram of the tools in the Sketcher toolbox, see *The Sketcher tools*.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

2. Select the edges between which you want to remove gaps and overlaps. You can **[Shift] + Click** or **[Ctrl] + Click** to specify edges individually, or you can drag-select to specify all of the edges within an area in your sketch.

   Abaqus/CAE colors the selected edges red.

3. Click mouse button 2 anywhere in the Abaqus/CAE window.

   Abaqus/CAE prompts you to select a tolerance value.

4. For your first attempt, accept the default tolerance value and click mouse button 2 anywhere in the Abaqus/CAE window. Abaqus/CAE removes the gaps and overlaps that are smaller than the default tolerance.
5. If you still have gaps and overlaps remaining that you want to remove, perform the following steps:
   a. Reselect the edges between which you want to remove gaps and overlaps.
   b. Increase the tolerance value in the prompt area.
   c. Click mouse button 2 anywhere in the Abaqus/CAE window.

      Abaqus/CAE removes the selected gaps or overlaps that are smaller than the default tolerance.

   d. Continue selecting edges and increasing the tolerance until Abaqus/CAE has removed all the gaps and overlaps that you want to remove from your model.
6. When you have finished removing edges and overlaps, do one of the following:
   - Click mouse button 2 anywhere in the Abaqus/CAE window.
   - Select any other tool in the Sketcher toolbox.
   - Click the cancel button  in the prompt area.

Additional information

- *Sketching simple objects*
- *Modifying objects*

Repairing short edges

Use the **Repair short edges** tool from the Sketcher toolbox to remove selected short edges from your sketch. Abaqus/CAE provides two methods for edge removal: you can either remove every edge that you select, or you can select multiple edges as candidates for removal and specify a length tolerance value. Edges shorter than the tolerance length are removed from the sketch.

If you remove short edges by specifying length tolerance values, you should perform the removals using an iterative process. Start by selecting the edges that you want to remove and use the default length tolerance value of 0.001 for your first attempt. If the short edges are not removed, reselect them and increase the tolerance. Repeat this process until the short edges are removed from the sketch.

You should repair the short edges in your sketch only after removing its gaps and overlaps. For more information, see *Removing gaps and overlaps*.

1. From the modify tools in the Sketcher toolbox, select the **Repair short edges** tool . For a diagram of the tools in the Sketcher toolbox, see *The Sketcher tools*.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

2. Specify the edges that you want to remove or, if you are specifying a length tolerance value, the edges you want to consider for removal. You can **[Shift] + Click** or **[Ctrl] + Click** to specify edges individually, or you can drag-select to specify all of the edges within an area in your sketch.

   Abaqus/CAE colors the selected edges red.

3. If you are removing short edges without specifying a tolerance, click **Done** in the prompt area.

   Abaqus/CAE removes the selected edges from the sketch.

4. If you are removing edges shorter than a specified length tolerance value, toggle on **Specify tolerance** in the prompt area and click **Done**. For your first attempt, accept the default tolerance value and click **Done** in the prompt area.

   Abaqus/CAE removes from the sketch any of the selected edges that are shorter than the length tolerance value.

5. To continue the removal of short edges by length tolerance value, perform the following steps:
   a. Reselect the edges that you want to consider for removal, and click **Done**.
   b. Leave **Specify tolerance** toggled on, and click **Done** again.
   c. Increase the length tolerance value in the prompt area.
   d. Click mouse button 2 anywhere in the Abaqus/CAE window.

      Abaqus/CAE removes from the sketch any of the selected edges that are shorter than the length tolerance value.

   e. Continue selecting edges and increasing the tolerance until Abaqus/CAE has removed all the short edges that you want to remove from your model.

6. When you have finished repairing short edges in your sketch, do one of the following:

   - Click mouse button 2 anywhere in the Abaqus/CAE window.
   - Select any other tool in the Sketcher toolbox.
   - Click the cancel button  in the prompt area.

Additional information

- *Modifying, copying, and offsetting objects*

- *Modifying objects*
- *Creating patterns, offsetting, and deleting objects*

Creating patterns, offsetting, and deleting objects

This section describes how to use the Sketcher tools to copy and delete Sketcher objects.

In this section:

- *Creating linear patterns of objects*
- *Creating radial patterns of objects*
- *Offsetting the edges of Sketcher objects*
- *Deleting Sketcher objects*

Creating linear patterns of objects

Use the linear pattern tool from the Sketcher toolbox to create a linear pattern of selected Sketcher objects. You can create a pattern that extends in one direction (for example, horizontally or vertically), or you can create a pattern that extends in two directions (for example, both horizontally and vertically). You can specify the following:

- The number of copies to create in each direction, including the selected objects. You can create a maxium of 1000 copies.
- The spacing between each copy along the specified direction.
- A line that defines the direction along which Abaqus/CAE generates the copies.

By default, Abaqus/CAE creates three copies in the positive *X*-direction and two copies in the positive *Y*-direction. The default spacing is 10% of the sketch sheet size. If you change the default settings, Abaqus/CAE retains those values while you work on the sketch. However, after you exit the Sketcher, Abaqus/CAE reverts to the original defaults. You cannot edit a pattern after you create it.

1. From the Sketcher toolbox, select the linear pattern tool . For a diagram of the tools in the Sketcher toolbox, see *The Sketcher tools*.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

2. Select the objects that you want to copy. Both sketch and *construction geometry* can be copied; *reference geometry* and dimensions cannot be copied.

   Tip: To select more than one object, hold down the **[Shift]** key as you click each object or drag a rectangle around the objects. To unselect an object, use **[Ctrl] + Click**. For more information, see *Selecting objects within the viewport*."

3. Click mouse button 2 to indicate that you have finished selecting objects.

   Abaqus/CAE displays the **Create Linear Pattern** dialog box.

4. From the **Create Linear Pattern** dialog box, configure the pattern in **Direction-1** (by default, **Direction-1** is the *X*-direction in the current grid rotation):

   a. Click the arrows to the right of **Number** to increase or decrease the number of copies to create, including the selected objects. The number of copies in the Sketch updates when you click the arrows and provides a preview of the setting.

      Alternatively, you can type in a number and press **[Enter]** to preview the setting. You can enter any number between 1 and 1000. If you enter a value of 1, Abaqus/CAE displays only the selected objects and does not create any copies of the selected objects; in effect, you are disabling copies in **Direction-1**.

   b. Enter the **Spacing** between each copy along the specified direction.

   c. By default, Abaqus/CAE creates the copies in a horizontal direction. If you want to change the direction in which Abaqus/CAE creates the copies, click **Angle** and select a line from the Sketch to define the new direction. You must pick a straight edge or a straight construction line. Abaqus/CAE calculates the spacing between each copy along the direction that you specify.

   d. By default, Abaqus/CAE creates the copies in the positive *X*-direction. Click **Flip** to reverse the direction in which Abaqus/CAE creates the copies.

5. To create copies in a second direction, enter a **Number** between than 1 and 1000 and specify the **Spacing**, the **Angle**, and the **Flip** direction for **Direction-2** (by default, **Direction-2** is the *Y*-direction in the current grid rotation). You must enter a **Number** greater than 1 for at least one direction.

6. In most cases you will want to preview the linear pattern that Abaqus/CAE will create as you enter values in the **Create Linear Pattern** dialog box. However, if you choose to create a large number of copies, the preview capability may impact the performance of the Sketcher. In this case you should toggle off the **Preview** button.
7. To copy more objects, repeat the above steps beginning with Step 2.
8. When you have finished copying objects, do one of the following:
   - Click mouse button 2 anywhere in the Abaqus/CAE window.
   - Select any tool in the Sketcher toolbox.
   - Click the cancel button  in the prompt area.

Additional information

- *Copying sketch objects to create patterns*
- *Modifying objects*
- *Undoing and redoing sketching actions*

Creating radial patterns of objects

Use the radial pattern tool from the Sketcher toolbox to create a radial pattern of selected Sketcher objects. You can specify the following:

- The number of copies to create in the radial pattern, including the selected objects. You can create a maxium of 1000 copies.
- The total angle between the original objects and the last copy in the pattern.
- The position of the center point of the circular pattern.

By default, Abaqus/CAE creates five copies around a complete circle (360°), and the center of the circle is located at the origin of the sketch. If you change the default settings, Abaqus/CAE retains those values while you work on the sketch. However, after you exit the Sketcher, Abaqus/CAE reverts to the original defaults. You cannot edit a pattern after you create it.

1. From the Sketcher toolbox, select the radial pattern tool . For a diagram of the tools in the Sketcher toolbox, see *The Sketcher tools*.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

2. Select the objects that you want to copy. Both sketch and *construction geometry* can be copied; *reference geometry* and dimensions cannot be copied.

   Tip: To select more than one object, hold down the **[Shift]** key as you click each object or drag a rectangle around the objects. To unselect an object, use **[Ctrl] + Click**. For more information, see *Selecting objects within the viewport*."

3. Click mouse button 2 to indicate that you have finished selecting objects.

   Abaqus/CAE displays the **Create Radial Pattern** dialog box.

4. From the **Create Radial Pattern** dialog box, configure the radial pattern:

   a. Click the arrows to the right of **Number** to increase or decrease the number of copies to create, including the selected objects. The number of copies in the Sketch updates when you click the arrows and provides a preview of the setting.

      Alternatively, you can type in a number and press **[Enter]** to preview the setting. You can enter any number between 2 and 1000.

   b. Enter the **Total angle** between the original objects that you selected and the final copy. The angle must be between –360° and +360°. A positive angle corresponds to a counterclockwise direction.

   c. By default, the center point of the circular pattern is the origin of the sketch. Click **Center** to change the location of the center point, and select a point from the sketch to define the new center point.

5. In most cases you will want to preview the radial pattern that Abaqus/CAE will create as you enter values in the **Create Radial Pattern** dialog box. However, if you choose to create a large number of copies, the preview capability may impact the performance of the Sketcher. In this case you should toggle off the **Preview** button.
6. To copy more objects, repeat the above steps beginning with Step 2.
7. When you have finished copying objects, do one of the following:

   - Click mouse button 2 anywhere in the Abaqus/CAE window.
   - Select any tool in the Sketcher toolbox.

- Click the cancel button  in the prompt area.

Additional information

• *Copying sketch objects to create patterns*
• *Modifying objects*
• *Undoing and redoing sketching actions*

Offsetting the edges of Sketcher objects

Use the offset tool from the Sketcher toolbox to offset edges. You select the edges, enter the offset distance, and choose the offset direction. Abaqus/CAE applies the offset distance perpendicular to each point along the edges to create the offset.

Note:

Edges containing features with dimensions of similar size to the offset distance will lose their details in the offset copy.

1. From the Sketcher toolbox, select the offset tool . For a diagram of the tools in the Sketcher toolbox, see *The Sketcher tools*.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.
2. Select a single group of connected edges to offset. Only sketch geometry can be offset; *construction geometry*, *reference geometry*, and dimensions cannot be offset.

   Tip: To select a group of edges that are connected end-to-end, choose **by chain** from the prompt area (for more information, see *Using the chain method to select edges in the Sketcher*). If necessary, you can then use the other selection methods in Abaqus/CAE to enhance your selection. For more information, see *Selecting objects within the viewport*."
3. Click mouse button 2 to indicate that you have finished selecting objects.
4. Specify an offset distance or accept the default value displayed in the prompt area.

   Abaqus/CAE displays a preview of the offset edges in the viewport.
5. Use the buttons that appear in the prompt area to accept or change the offset direction.
6. To offset more edges, repeat the above steps beginning with Step 2.
7. When you have finished offsetting edges, do one of the following:
   - Click mouse button 2 anywhere in the Abaqus/CAE window.
   - Select any tool in the Sketcher toolbox.
   - Click the cancel button  in the prompt area.

Additional information

- *Sketching simple objects*
- *Creating construction geometry*
- *Modifying objects*
- *Creating patterns, offsetting, and deleting objects*
- *Undoing and redoing sketching actions*

Deleting Sketcher objects

Use the delete tool from the Sketcher toolbox to remove Sketcher objects: lines, arcs, circles, fillets, splines, points, constraints, dimensions, or parameters.

1. From the Sketcher toolbox, select the delete tool  . For a diagram of the tools in the Sketcher toolbox, see *The Sketcher tools*.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

2. Select all the objects you want to delete. Select a filter from the prompt area to limit the available selections to **Geometry**, **Dimensions** (including parameters), or **Constraints**; the default filter, **Any**, does not limit your selection.

   Both sketch and *construction geometry* can be deleted; *reference geometry* cannot be deleted.

    **Tip:** To select more than one object, hold down the **[Shift]** key as you click each object or drag a rectangle around the objects. To unselect an object, use **[Ctrl] + Click**. For more information, see *Selecting objects within the viewport*."

3. When you have finished selecting objects, click mouse button 2.

   Abaqus/CAE deletes the selected objects and any associated dimensions or constraints.

    **Tip:** To restore accidentally deleted objects, click the *undo* tool  in the Sketcher toolbox.

4. To delete more objects, repeat the above steps beginning with Step 2.
5. When you have finished deleting objects, do one of the following:
   - Click mouse button 2 anywhere in the Abaqus/CAE window.
   - Select any tool in the Sketcher toolbox.
   - Click the cancel button  in the prompt area.

Additional information

- *Sketching simple objects*
- *Creating construction geometry*
- *Modifying objects*
- *Creating patterns, offsetting, and deleting objects*
- *Undoing and redoing sketching actions*

Undoing and redoing sketching actions

The Sketcher toolbox contains tools to undo and redo sketch actions.

Use the **Undo** tool  or the **Redo** tool  from the Sketcher toolbox to undo your previous operation or redo your most recently undone operation. For a diagram of the tools in the Sketcher toolbox, see *The Sketcher tools*.

Depending on your previous action, clicking the undo tool can have the following effect:

- Remove the object just created. Objects include sketch geometry (lines, arcs, circles, ellipses, fillets, splines, or points), construction geometry, or dimensions.
- Restore the sketch to its state prior to the editing operation just performed. Editing operations include copying entities, deleting entities, moving vertices, trimming edges, extending edges, breaking edges, and changing dimensions.
- Remove a retrieved stand-alone sketch, provided you have not positioned the sketch. Once you have positioned the retrieved sketch, clicking the undo tool moves the origin of the retrieved sketch back to the origin of the current sketch.

You can undo and redo several actions in a row. For example, if you sketch a circle and dimension its radius, your first undo operation removes the dimension and your second undo operation removes the circle. You can restore the circle by clicking the redo tool and restore its dimension by clicking the redo tool a second time. Abaqus/CAE stores a history of actions for the current sketch, and you can specify the maximum number of sketching operations to store (see *Setting the maximum number of recorded sketching operations*, for more information).

The **Undo** and **Redo** tools do not perform view manipulation operations. For example, if you sketch a circle, magnify the view, and click the undo tool, Abaqus/CAE deletes the circle (it does not resize the view).

Additional information

• *Deleting Sketcher objects*

Resetting the view

The Sketcher toolbox contains a tool for resetting the view.

Use the reset view tool  from the Sketcher toolbox to return to the original view. For a diagram of the tools in the Sketcher toolbox, see *The Sketcher tools*.

If you are unsure of the part's or assembly's orientation relative to the sketch plane, you can use the view manipulation tools to examine the sketch plane and the object on which you are sketching. When you click the reset view tool, Abaqus/CAE restores the view to the original view orientation displayed when you entered the Sketcher.

Additional information

- *Using the view manipulation tools*

Managing stand-alone sketches

This section describes how to manage stand-alone sketches while working in the Sketch module.

In this section:

- *Managing stand-alone sketches*
- *Creating stand-alone sketches*
- *Saving the current sketch as a stand-alone sketch*
- *Adding stand-alone sketches*

Managing stand-alone sketches

Stand-alone sketches are stored in your model and are independent of any particular part or the assembly. You can create a stand-alone sketch while working in the Sketch module, or you can save the current sketch as a stand-alone sketch while sketching. You can add a stand-alone sketch while creating or editing a feature or a partition, and an added sketch overlays the current sketch so that their origins are coincident.

You use the Sketch module to manage the stand-alone sketches defined in your model. To create, retrieve, copy, rename, and delete stand-alone sketches while working in the Sketch module, use one of the following:

- The **Create**, **Edit**, **Copy**, **Rename**, and **Delete** items listed under the **Sketch** menu on the main menu bar. Each item contains a submenu listing all the sketches in the current model.
- The **Sketch Manager** dialog box. The **Sketch Manager** contains functions identical to those listed under the **Sketch** menu, but with a convenient browser that lists all the sketches available in the current model. To display the **Sketch Manager** dialog box, select **Sketch->Manager** from the main menu bar.

Note:

The **Sketch** menu and the **Sketch Manager** are available only from the Sketch module. When you are sketching a feature in the Part module, for example, the **Sketch** menu and the **Sketch Manager** are not available.

Additional information

- *Managing stand-alone sketches*
- *Stand-alone sketches*

Creating stand-alone sketches

Stand-alone sketches are stored in your model and are independent of any particular part or the assembly. To create a new stand-alone sketch in the current viewport, select **Sketch->Create** from the main menu bar.

1. From the main menu bar, select **Sketch->Create**.

   The **Create Sketch** dialog box appears.

   Tip: You can also create a stand-alone sketch by clicking the sketch create tool  in the Sketch module toolbox.

2. In the **Create Sketch** dialog box, enter a name for the sketch. For information on valid names, see *Using basic dialog box components*.
3. In the **Create Sketch** dialog box, enter the approximate size of the sketch.

   The size that you enter is used by Abaqus/CAE to calculate the size of the sheet and the spacing of its grid. The approximate size should reflect the largest dimension of the sketch and must be between 10^{5} and 10^{-3} units. Abaqus/CAE does not require specific units, but the units must be consistent throughout the model.
4. Click **Continue** to close the **Create Sketch** dialog box.

   Abaqus/CAE starts the Sketcher and displays a square sheet on which you sketch; the width and height of the sheet are approximately equal to the value that you entered in the previous step. If you later find that your sketch extends beyond the edge of the sheet, you can change the sheet size using the Sketcher *customization options*.
5. When you have finished sketching, click **Done** in the prompt area.

Additional information

- *Managing stand-alone sketches*
- *Stand-alone sketches*

Saving the current sketch as a stand-alone sketch

While you are sketching, you can save the current sketch as a stand-alone sketch. Stand-alone sketches are maintained independent of any features; they can be subsequently retrieved into the Sketcher and will overlay any existing geometry.

Abaqus/CAE saves only items within the sketch. *Reference geometry* is not saved. Similarly, dimensions between vertices and lines from reference geometry are not saved.

1. From the Sketcher toolbox, select the save as tool . For a diagram of the tools in the Sketcher toolbox, see *The Sketcher tools*.
2. In the text field that appears in the prompt area, enter the name of the sketch.

   Abaqus/CAE saves the sketch and returns to the Sketcher.

Additional information

- *Managing stand-alone sketches*
- *Stand-alone sketches*

Adding stand-alone sketches

While you are sketching, you can add a stand-alone sketch so that its geometry overlays the current sketch. Abaqus/CAE positions the added stand-alone sketch so that its origin is coincident with the origin of the current sketch.

1. From the Sketcher toolbox, select the add sketch tool . For a diagram of the tools in the Sketcher toolbox, see *The Sketcher tools*.

   Abaqus/CAE displays the **Add Sketch** dialog box.

2. Select the sketch to add from the list of stand-alone sketches and click **OK** to close the **Add Sketch** dialog box.

   Abaqus/CAE does the following:

   - Positions the added sketch so that its origin is coincident with the origin of the current sketch.
   - Resizes the view so that both the current sketch and the added sketch are visible.

3. Use the buttons that appear in the prompt area to indicate how you will locate the added sketch.

   - Select **Translate** to translate the added sketch along a specified vector. You can define the beginning and the end of the translation vector by either selecting from the sketch or by typing the *X*- and *Y*-coordinates of each end.
   - Select **Rotate** to rotate the added sketch through a specified angle about a specified point. You can specify the point at the center of rotation by selecting from the sketch or typing the *X*- and *Y*-coordinates. The angle of rotation you specify must be between 360 and −360 degrees.
   - Select **Mirror** to mirror the added sketch about a selected line. You must specify the mirror line by selecting an existing straight line (not a line in the added sketch).
   - Select **Scale** to scale the spacing between the vertices of the added sketch by a specified amount about a specified point. You can specify the point by selecting from the sketch or by typing the *X*- and *Y*-coordinates.

   A preview of the added sketch is modified and positioned according to your specification.

4. If desired, repeat Step 3 to continue modifying or repositioning the added sketch.
5. Select **Done** in the prompt area.

   Abaqus/CAE adds the stand-alone sketch to the existing geometry.

Additional information

- *Stand-alone sketches*

Modeling techniques

This part discusses modeling techniques in Abaqus/CAE that span multiple Abaqus/CAE modules and that define special engineering features in an Abaqus/CAE model.

In this section:

- *Adhesive joints and bonded interfaces*
- *Bolt loads*
- *Composite layups*
- *Connectors*
- *Continuum shells*
- *Co-simulation*
- *Display bodies*
- *Eulerian analyses*
- *Fasteners*
- *Fracture mechanics*
- *Gaskets*
- *Imperfection*
- *Inertia*
- *Load cases*
- *Midsurface modeling*
- *Skin and stringer reinforcements*
- *Springs and dashpots*
- *Submodeling*
- *Substructures*

Adhesive joints and bonded interfaces

This section provides information on how to model adhesive joints and bonded interfaces.

In this section:

- *Modeling adhesive joints and bonded interfaces*
- *Embedding cohesive elements in an existing three-dimensional mesh*
- *Creating a model with cohesive elements using geometry and mesh tools*
- *Defining tie constraints between the cohesive layer and the surrounding bulk material*
- *Assigning cohesive modeling data*

Modeling adhesive joints and bonded interfaces

You can create a model using cohesive elements to model adhesive joints, fracture at bonded interfaces, and gaskets.

You can model:

- Adhesive joints – two components connected by a glue-like material that has a finite thickness.
- Fracture at bonded interfaces – crack propagation in glue material that is very thin and for all practical purposes may be considered to be of zero thickness.
- Gaskets (limited capability) – seal between two components. No specialized gasket behavior (typically defined in terms of pressure versus closure) is available. If you want to model special gasket behavior, use special-purpose gasket elements as described in *Gaskets*.

For more information, see *About Cohesive Elements*.

The two main approaches that you can use to include cohesive elements in your model are

- embedding one or more layers of cohesive elements in the mesh of an existing model; or
- creating the analysis model using the geometry and mesh tools.

You can model the connection at the interface between the cohesive layer and the surrounding bulk material by sharing nodes or by defining a tie constraint. The tie-constraint approach allows you to model the cohesive layer using a finer discretization than that of the bulk material and may be more desirable in certain modeling situations. For more information, see *Defining tie constraints between the cohesive layer and the surrounding bulk material*.

Like gasket elements, cohesive elements have an orientation associated with them. This orientation defines the thickness direction of the elements, and it should be consistent throughout the cohesive layer. Swept or offset meshing techniques should be used to generate the mesh in the cohesive layer because these tools produce meshes that are oriented consistently. You can also use the bottom-up sweep meshing method, but you must sweep in the direction of the element thickness to maintain the correct orientation. You should create a single layer of solid elements to model the cohesive region. The use of more than one layer through the thickness could produce unreliable results and is not recommended. You can generate the mesh in the surrounding bulk material using any of the mesh tools because these elements do not need to be oriented.

The general procedure for modeling adhesive joints and bonded interfaces involves the following steps:

1. Create a model, and assign a cohesive element type to the cohesive region in the Mesh module using one of the following approaches:
   - *Embedding cohesive elements in an existing three-dimensional mesh*
   - *Creating a model with cohesive elements using geometry and mesh tools*
2. In the Property module, define a material and a cohesive section that refers to the material, and assign the cohesive section to the cohesive region. See *Assigning cohesive modeling data* for more information.
3. To model progressive damage and failure of cohesive layers as discussed in *Defining the Constitutive Response of Cohesive Elements Using a Traction-Separation Description*, include the desired damage initiation and damage evolution information in the material definition (select **Mechanical->Damage for Traction Separation Laws->*damage type***). For more information, see *Defining damage*.

Embedding cohesive elements in an existing three-dimensional mesh

You can use the following procedure to embed a layer of cohesive elements:

1. In the Mesh module, use the solid offset mesh tool in the Edit Mesh toolset to embed elements in an existing mesh (see *Editing the entire mesh*). This approach generates a layer of hexahedral or wedge elements that share nodes with the surrounding bulk material. The offset mesh tool generates elements that are oriented consistently with a stack direction that is aligned with the offset direction. When prompted to select the element faces from which the offset mesh will be generated, select the interior element faces using the procedure described in *Selecting interior surfaces*.

   Note: When generating an embedded layer of elements, the thickness should be much less than that of the adjacent elements because the nodes are displaced when the offset layer is generated.

   You can create an offset mesh from only three-dimensional element faces. As a result, you can create only hexahedral- and wedge-shaped cohesive elements using an offset mesh. For example, you cannot create quadrilateral cohesive elements by offsetting from element edges.

2. In the Mesh module, use the element type assignment tool to assign the cohesive element type to the cohesive region. See *Element type assignment* for more information.

If your existing mesh is a native mesh, you should create a mesh part prior to adding cohesive elements. For more information, see *Creating a mesh part*.

If you want to use a finer mesh in the cohesive layer, you should construct the cohesive layer as a separate part. You should separate the mesh in the surrounding bulk material into two regions with the appropriate spacing to accommodate the cohesive layer. You can mesh the cohesive layer using the methods described in *Creating a model with cohesive elements using geometry and mesh tools*, and tie the cohesive layer to the surrounding bulk material. For more information, see *Defining tie constraints between the cohesive layer and the surrounding bulk material*.

Creating a model with cohesive elements using geometry and mesh tools

You can use the following procedure to create a model with cohesive elements using geometry and mesh tools:

1. In the Part module, define the geometry of the model. You should define the geometric region that represents the cohesive layer as a solid, even if the thickness of the layer is close to zero. To avoid numerical problems, it is recommended that you model the geometry using a value of 10^{-4} or greater for the thickness. If the actual thickness of the layer is less than this value, you should specify the actual thickness in the **Initial thickness** field of the cohesive section editor as described in *Creating cohesive sections*
2. In the Mesh module, mesh the surrounding bulk material. You can use any of the mesh tools to mesh the surrounding bulk material. See *Mesh generation* for more information.
3. In the Mesh module, mesh the cohesive region using one of the following methods:

Two- and three-dimensional models

Top-down swept or bottom-up meshing technique. You can assign the top-down swept meshing technique or the bottom-up meshing technique to mesh the cohesive region. The bottom-up meshing technique is available only for three-dimensional models (for more information, see *Bottom-up meshing*). Regardless of the meshing technique that you choose, you must sweep, extrude, or revolve the mesh in the thickness direction of the element to produce the correct element orientation. For a complex cohesive region, you may need to partition the model to create a group of sweep regions that you can align consistently. For more information, see *Selecting a meshing technique*, and *Specifying the sweep path*.

Three-dimensional models

Convert the cohesive region into a shell region, and use the offset meshing technique.

1. Convert the solid part to a shell using the **From solid** shell tool in the Part module.
2. Isolate a collection of faces that represents an idealized shell of the part using the **Remove faces** tool in the Geometry Edit toolset.
3. Mesh the simplified model with shell elements, and create a mesh part.
4. Use the mesh part to generate an offset mesh of solid hexahedral or wedge elements. The elements will be oriented through the thickness of the part, and you can verify this with the Query toolset.

For detailed instructions, see *Generating layers of solid elements offset from an existing mesh*.

4. In the Mesh module, use the element type assignment tool to assign the cohesive element type to the cohesive region. See *Element type assignment* for more information.

For example, *Figure 1* illustrates the layered composite specimen that is used in the benchmark problem *Delamination analysis of laminated composites*. An Abaqus Scripting Interface script that reproduces the composite specimen model using Abaqus/CAE is provided with this problem.

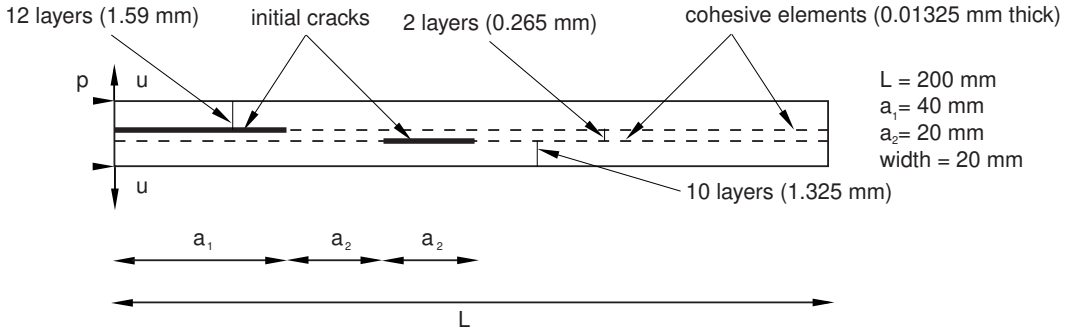

Figure 1: Model geometry for the Alfano delamination problem.

Defining tie constraints between the cohesive layer and the surrounding bulk material

If you want to model the cohesive layer using a mesh that is finer than the adjacent bulk material mesh, the cohesive layer should be generated as a separate mesh and tied to the bulk material using tie constraints (see *Defining tie constraints*). You should create a shell geometric model to represent the surface on one side of the cohesive layer and mesh that model with the desired mesh density. You can use this mesh to create a mesh part from which you can generate the offset mesh. For more information, see *Modeling with Cohesive Elements*.

You should use care when tying zero-thickness cohesive layers to the surrounding bulk material mesh. Use the following procedure to avoid problems:

1. Use the solid offset mesh tool to create the layer of cohesive elements along with the top and bottom surfaces. Abaqus/CAE appends **TopSurf** and **BottomSurf** to the surface name prefix when it creates the two surfaces on either side of the layer of cohesive elements.
2. Use the stack orientation query tool to distinguish the top (brown) and bottom (purple) faces of the cohesive elements.
3. Tie the surfaces of the surrounding bulk material mesh to the appropriate top and bottom cohesive surfaces. When you are prompted to select a surface from the cohesive surface, click **Surfaces** from the right side of the prompt line and select the appropriate surface. For example, select ***surface name*-BottomSurf** to tie the bottom (purple) face of the cohesive layer to the adjacent surface of the bulk material mesh.

Assigning cohesive modeling data

In the Property module, you can complete the cohesive modeling data as follows:

1. Create a cohesive section to define the section properties of adhesive layers at the interface between two bonded parts. You can model a negligibly thin layer of adhesive, a finite-thickness adhesive layer, or a gasket by selecting the constitutive behavior of the cohesive section as **Traction Separation**, **Continuum**, or **Gasket**, respectively. For more information, see *Creating cohesive sections*.
2. Define a material for the cohesive region. If you select the **Continuum** or the **Gasket** response in the cohesive section editor, you can use the material models available in the Property module to define the continuum material properties. Abaqus/CAE does not support the material models for the **Traction Separation** response. In this case you must add the material definition using the **Keywords Editor**, as described in *Adding unsupported keywords to your Abaqus/CAE model*.
3. Assign the cohesive section to the cohesive region. For more information, see *Assigning a section*.

Bolt loads

This section explains how to model tightening forces or length adjustments in bolts or fasteners.

In this section:

- *Understanding bolt loads*
- *Creating and editing bolt loads*

Understanding bolt loads

Bolt loads model tightening forces or length adjustments in bolts or fasteners.

Figure 1 shows a container (A) that is sealed by tightening the bolts that hold the lid, which places the gasket under pressure.

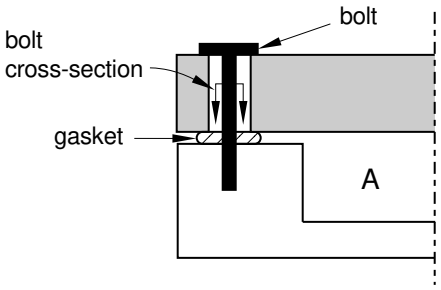

Figure 1: Modeling a pre-tensioned bolt.

You can model the tension in the tightened bolts by applying a bolt load to each one in the first step of the analysis. You define the load in terms of either a concentrated force or a prescribed change in length, and you apply the load across a bolt cross-section surface that you specify. In later steps you can modify the load to prevent further length changes so that the bolt acts as a standard, deformable component responding to other loadings on the assembly.

When you create a bolt load, you must specify the following:

A surface that defines the bolt cross-section

Abaqus/CAE applies the bolt load across the cross-section surface that you specify. The surface that defines the bolt cross-section must cut through the bolt geometry. Abaqus/CAE creates an “interior” surface at that location.

If you are working with bolt part instances made from native or imported geometry, Abaqus/CAE can create an interior surface by partitioning the bolt shank surface, or you can partition the bolt at the location where you want the cross-section to be defined. For example, a partition is selected as the bolt cross-section in *Figure 2*. For more information, see *The Partition toolset*.

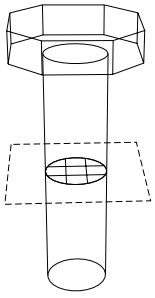

Figure 2: Using a partition to specify the bolt cross-section.

If you are working with orphan mesh elements, you must specify the cross-section surface by selecting element faces. For example, element faces define a cross-section surface for the mesh part shown in *Figure 3*.

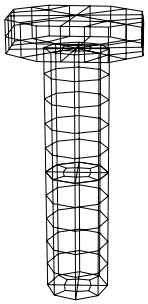

Figure 3: Using element faces to specify the bolt cross-section.

The element faces need to be selected from elements on only one side of the pre-tension section. You can use display groups to remove selected elements from the viewport to reveal the element faces of the cross-section surface. For more information on selecting surfaces, see *Selecting objects within the viewport*. For detailed information on selecting surfaces on wire part instances, see *Specifying a particular side or end of a region*.

Note:

You can apply bolt loads only to three-dimensional solid, two-dimensional solid, and three-dimensional wire part instances. Bolt loads on two-dimensional and axisymmetric wire part instances are unsupported.

A bolt axis

If you are defining a bolt load on a solid region, the surface normal of the surface that defines the bolt cross-section is used as the bolt axis by default. You can select a datum axis to indicate a different bolt axis direction (it need not be normal to the cross-section). If you are defining a bolt load on a wire region, the bolt axis direction is always assumed to be the direction of the tangent to the wire at the bolt cross-section.

Abaqus/CAE uses both the cross-section surface that you specify and the bolt axis to define the pre-tension section data and the pre-tension reference node used by Abaqus/Standard; see *Prescribed Assembly Loads* for more information. You can create the pre-tension section at the part level or the assembly level. To create the pre-tension section at the part level, the selected region must belong to a dependent part instance. If you create the pre-tension section at the part level, the bolt load is defined for all of the instances from the same part.

A method for applying the loading

When you create a bolt load, you must choose one of the following loading methods:

- Apply a force to the bolt. This method models tightening the bolt so that it carries a specified load.
- Adjust the bolt length. This method models tightening the bolt until its free length has changed by the specified value.
- Fix the bolt at its current length. This method is available only if you have already created the load in the first analysis step and are now editing it in a subsequent analysis step. This method allows the bolt length to remain unchanged so that the force in the bolt can change according to the response of the model.

A magnitude for the chosen method

If you are applying a force to the bolt, you must enter the force magnitude. If you are adjusting the bolt length, you must enter the length change.

You can create a bolt load only in the first analysis step, but you can modify the loading method or the magnitude of the load in subsequent steps. For example, you can apply a specific tension in the first step and then change the method in the second step to fix the bolt length.

You can obtain data from a bolt load using the field and history output request editors in the Step module. In the **Domain** section of the editor, select **Bolt load** and choose the desired bolt load from the menu that appears. For more information, see *Creating an output request*.

For detailed information on creating a bolt load, see *Creating and editing bolt loads*.

Creating and editing bolt loads

You can create bolt loads to model tightening forces or length adjustments in bolts or fasteners.

1. From the main menu, select **Load->Create**.

   Abaqus/CAE displays the **Create Load** dialog box.

2. In the **Create Load** dialog box, do the following:
   a. From the **Category** list, select **Mechanical**.
   b. From the **Types for Selected Step** list, select **Bolt Load**, and click **Continue**.

3. Select the method to specify the surface that defines the bolt cross-section.

   - Select **Interior Surface** to use a previously created interior surface.
   - Select **Bolt Shank Surface** to create an interior surface by partitioning the bolt shank surface.

4. If you selected the **Interior Surface** method, do the following:
   a. Select the interior surface or wire segment that indicates the location of the bolt load.

      - If you are working with native or imported geometry, use the mouse to select the interior surface or wire segment in the viewport. You can use a combination of drag select, **[Shift] + Click**, **[Ctrl] + Click**, and the angle method to select more than one face or edge. For more information, see *Selecting objects within the current viewport*.

        Tip: If you are unable to select the desired faces or edges, you can use the **Selection** toolbar to change the selection behavior. For more information, see *Using the selection options*.

      - If you are using orphan mesh elements, you must select element faces to specify the interior surface. You can use display groups to remove selected elements from the viewport to reveal the element faces of the cross-section surface. For more information, see *Using display groups to display subsets of your model*.

      When you have finished selecting, click mouse button 2.

   b. Choose the side on which the surface is defined using the techniques described in *Specifying a particular side or end of a region*. The side you select determines which elements are adjusted to produce the desired tightening load or length adjustment (see *Prescribed Assembly Loads* for details).

   Abaqus/CAE displays the bolt load editor.

5. If you selected the **Bolt Shank Surface** method, do the following:
   a. Select the bolt shank face to partition. You can only select a cylindrical face.
   b. In the prompt area, enter the cut position value to define the partition location.
   c. Click **Done**.

   Abaqus/CAE creates an interior surface by partitioning the selected face and displays the bolt load editor.

6. Click the arrow next to the **Method** field and select the loading method of your choice from the list that appears.
7. In the **Magnitude** field, enter the force magnitude (for the **Apply force** method) or the change in length (for the **Adjust length** method).

Note:

The **Fix at current length** method becomes available if you edit the load in a step that follows the step in which you create the load. If, while editing the load, you change the method to **Fix at current length**, the **Magnitude** field becomes unavailable.

8. If desired, specify an amplitude. (See *The Amplitude toolset* for more information.)
9. By default, the surface normal of the pre-tension section is fixed during analysis. Toggle on **Varying normal for pre-tension section** to write the FOLLOWER=YES for pre-tension section at part level. If you selected the **Pre-tension section at part level** option, it indicates that the normal is updated when performing a large-displacement analysis.
10. By default, the surface normal of the surface that defines the bolt cross-section is used as the bolt axis. If desired, you can define a different bolt axis direction.
    a. Select **Specify**.
    b. Select a datum axis.

    - To create a datum axis, click  and select two points in the viewport that define the axis. If desired, select **Make Independent** from the prompt area to create the datum as an independent feature.
    - Click , and select a datum axis that is aligned with the bolt centerline.

11. The pre-tension section is written at the assembly level. Toggle on **Pre-tension section at part level** to write the pre-tension section at the part level (applicable only for dependent part instances). If you selected the **Pre-tension section at part level** option, the bolt load is defined for all the instances from the same part.
12. Click **OK** to create the load and to exit the editor.

    Arrows appear in the viewport that represent the bolt load that you just created. For more information, see *Understanding symbols that represent prescribed conditions*.

Composite layups

This section provides information on modeling composite layups with Abaqus/CAE.

In this section:

- *An overview of composite layups*
- *Creating a composite layup*
- *Understanding composite layups and orientations*
- *Understanding composite layups and distributions*
- *Requesting output from a composite layup*
- *Viewing a composite layup*

An overview of composite layups

Figure 1 illustrates a single composite layup that contains three plies. Each ply is composed of a homogenous material of uniform thickness, with fibers oriented along a single orientation. However, a ply can also be an isotropic material, such as a foam core.

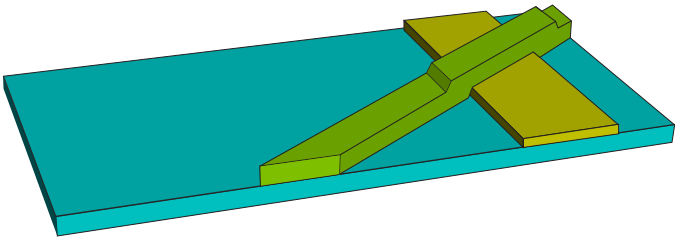

Figure 1: A composite layup.

A ply represents a single piece of material that is placed in a mold during the composites manufacturing process. A composite layup can contain a different number of plies in different regions. For example, the composite layup in *Figure 1* includes regions that contain a single ply, regions where two plies overlap, and a region where three plies overlap.

Figure 2 shows the same model that is depicted in *Figure 1* but defined using composite shell sections. The number of plies cannot change within a composite shell section. Therefore, four composite shell sections, each with a constant number of plies, are required to define this simple model. Section 1 contains a single ply, sections 2 and 3 each contain two plies, and section 4 contains three plies.

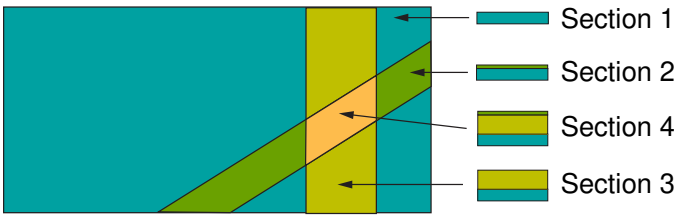

Figure 2: Composite shell sections.

Composite layups in Abaqus/CAE are designed to help you manage a large number of plies in a typical composite model. In contrast, composite sections are a product of finite element analysis and may be difficult to apply to a real-world application. Unless your model is relatively simple and all plies cover the same region, you will find it increasingly difficult to define your model using composite sections as you increase the number of plies. It can also be cumbersome to add new plies or remove or reposition existing plies.

The procedure for creating a composite layup with Abaqus/CAE mirrors the procedure for creating a real composite part—you start with a basic shape and then you add plies of different materials and thicknesses to selected regions and orient the plies to provide the greatest strength in a particular direction. The Abaqus/CAE composite layup editor allows you to easily add a ply, choose the region to which it is applied, specify its material properties, and define its orientation. You must specify ply names that are unique throughout the entire model to ensure the correct display of ply-based results. You can also read the definition of the plies in a layup from the data in a text file. This is convenient when the data are stored in a spreadsheet or were generated by a third-party tool. You can also suppress plies in your layup and experiment with the effect of adding and removing plies of different orientations.

It is important to specify the correct orientation of the fibers in a ply. Abaqus/CAE allows you to define a reference orientation for the layup as well as a reference orientation for each ply in the layup. In addition, you can specify the direction of the fibers in a ply relative to the reference orientation of the ply. By default, the coordinate system of a layup is the same as the coordinate system of the part; similarly, the coordinate system of a ply is the same as the coordinate system of the layup. Orientation definition is described in more detail in *Understanding composite layups and orientations*.

Using a composite layup to model a yacht hull, illustrates how you can analyze a complex three-dimensional model using the composite layup capability in Abaqus/CAE.

Creating a composite layup

Abaqus/CAE allows you to define composite layups for three types of elements: conventional shells, continuum shells, and solids. For detailed instructions, see the following sections:

- *Creating conventional shell composite layups*
- *Creating continuum shell composite layups*
- *Creating solid composite layups*

You create a composite layup in the Property module. The composite layup editor provides a table that you use to define the plies in the layup. For each ply you specify the ply's name, material, thickness, and orientation, as well as the number of integration points and the region of the model to which the ply is assigned. The composite layup editor's ply table is shown in *Figure 1*.

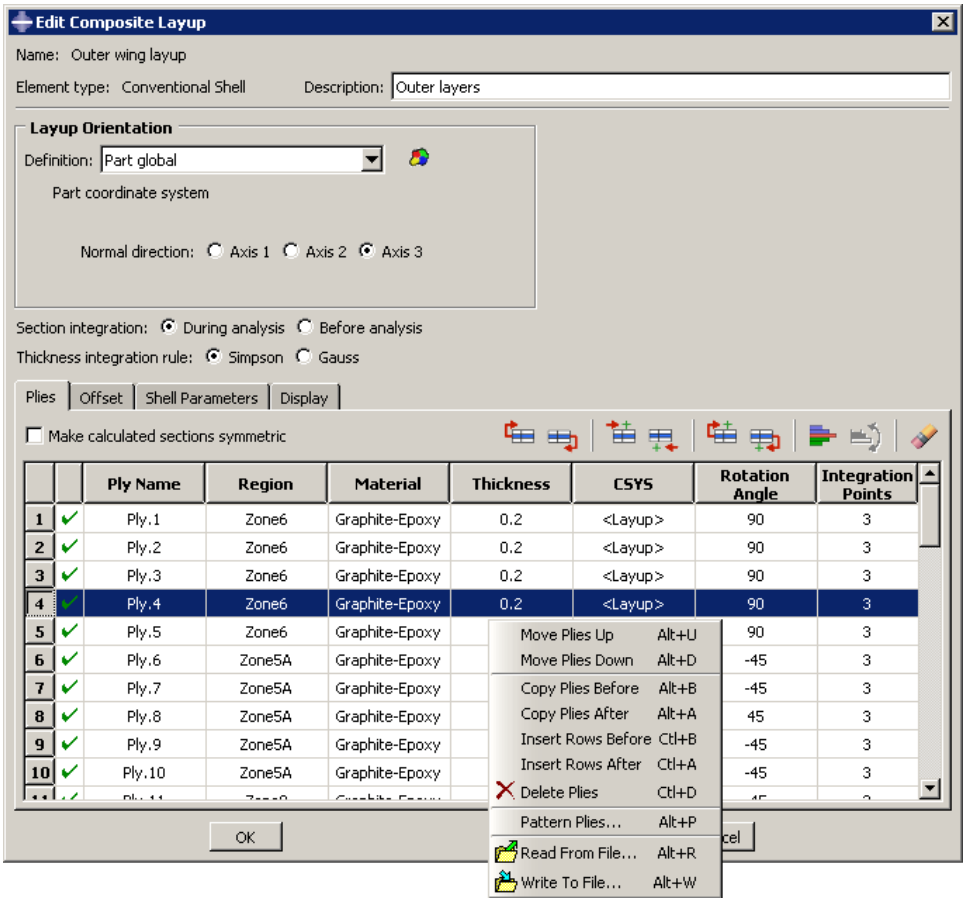

Figure 1: The ply table in the composite layup editor.

The ply table provides several options that make it easier for you to define a layup containing many plies; for example, the ply table allows you to do the following:

- Move or copy selected plies up or down in the table.
- Suppress or delete selected plies.
- Pattern a group of selected plies.
- Read ply data from or write ply data to an ASCII file. The data can define all the plies in the layup or only a subset of the plies in the layup.

The ability to suppress plies allows you to easily experiment with different configurations of plies in the composite layup and to see the effect on the results of an analysis of the model. For more information, see *Using the ply table when defining a composite layup*.

If you are defining a composite layup whose plies are symmetric about a central core, you only need to enter the bottom half of the layup in the ply table. When you apply the symmetry option, Abaqus automatically creates additional plies in the generated sections by repeating the entered plies (including the central ply) in reverse order.

You will probably have to partition your model to create the regions to which you will assign plies. You should create the partitions before you create the layup and start defining plies. You can select a region directly from the part in the current viewport, or you can create a named set that refers to the region and select the named set. Abaqus/CAE preserves any existing ply regions if you decide to add partitions and plies after you have defined a composite layup; for example, you can add plies to a layup that model a rib providing additional stiffness to a region. The region to which you assign a ply can be either Abaqus/CAE geometry or a mesh. You can combine plies assigned to geometry and plies assigned to a native mesh in a single composite layup.

Continuum shell and solid composite layups are expected to have a single element through the entire thickness across a combination of all the regions specified in the composite layup. Each single element through the thickness contains the multiple plies that you defined in the ply table. If the region to which you assign your continuum shell or solid composite layup contains multiple elements through the thickness, each element will contain all of the plies that you defined in the ply table and the analysis results will not be as expected.

If your model contains multiple continuum shell or solid elements through the thickness of a region, you can obtain correct results by defining a separate composite layup for each layer of elements. You can define a composite layup for each layer by selecting the elements of a native Abaqus/CAE mesh or the orphan elements when you specify the region of the layup. You must create a layup for each layer of elements.

If you have plies that overlap in your composite layup, you must enter the plies in the ply table in the order that they appear in the overlapping region. *Figure 2* illustrates a simple example of an overlapping region and the corresponding order of the plies in the ply table. The first ply in the ply table represents the bottom ply in the layup.

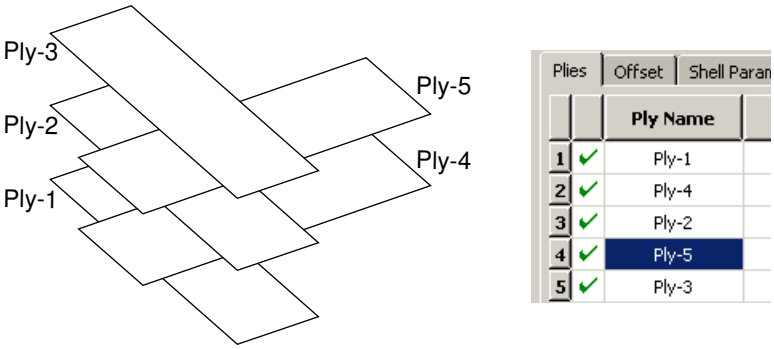

Figure 2: The order of the plies in the ply table.

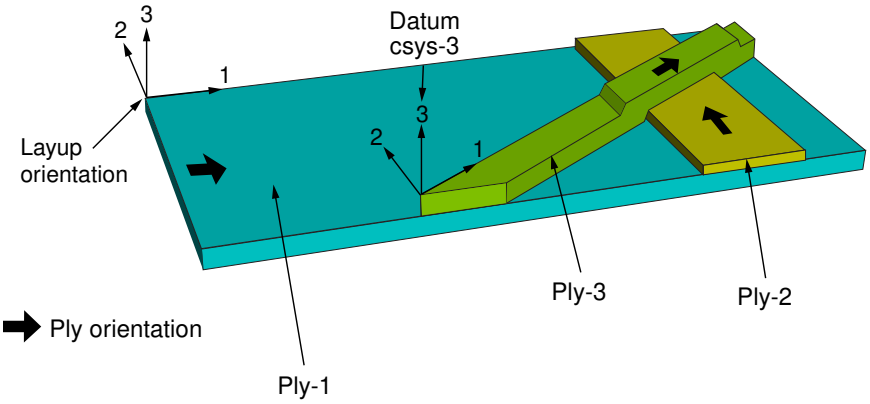
Under certain circumstances, Abaqus cannot determine the orientations of the composite ply for conventional shells. This can occur, for example, if your ply makes a sharp transition through an angle of 90°, and/or your part is aligned with one or more planes of the global coordinate system. To help you diagnose the problem region, Abaqus/CAE draws a collapsed coordinate system indicating regions for which the user-selected coordinate system and the geometric normal cannot be resolved into a valid orientation for display purposes. If this situation arises, you may be able to complete the analysis by splitting the ply into multiple plies at the transitions and by assigning orientations to each new ply.



If you apply a composite layup and assign a section assignment to the same region, Abaqus/CAE uses only the properties from the composite layup during the analysis. If you apply two or more composite layups to regions that overlap, Abaqus/CAE uses the properties of the last layup, where “last” refers to the alphabetical order of the names of the composite layups. The default color coding in the Property module uses yellow coloring to indicate a region with

overlapping composite layups and section assignments or to indicate a region with multiple overlapping composite layups.

Understanding composite layups and orientations

The orientation of the fibers within each ply of a composite layup plays an important role in determining the physical qualities of your model; however, defining this orientation in a model based on a real-world application is not straightforward.

Composite layups in Abaqus/CAE make the process more manageable by deriving the orientation of the fibers from three parameters that are relative to each other—the layup orientation, the ply orientation, and an additional rotation—as shown in *Figure 1*.

		Ply Name
1	✓	Ply-1
2	✓	Ply-2
3	✓	Ply-3

	CSYS	Rotation Angle	Integra Point
	<Layup>	0	3
	<Layup>	90	3
	Datum csys-3.3	0	3

Figure 1: Determining the ply orientation.

Layup orientation

The layup orientation defines the base or reference orientation of all the plies in the layup. In conventional and continuum shell layups, Abaqus projects the specified orientation onto the surface of the shell, aligning the direction of the layup orientation that you choose with the shell normal. In solid composite layups the orientation is not projected.

Abaqus/CAE provides several options for defining the layup orientation:

- **Part global**: By default, the layup orientation is the same as the orientation of the part.
- **Coordinate system**: You can create and select a datum coordinate system that defines the orientation.
- **Discrete orientation**: You can create a discrete orientation that provides an orientation value for each mesh element to define the orientation.
- **Discrete field**: You can create and select an orientation discrete field that defines a spatially varying orientation.
- **User-defined**: You can define the orientation in user subroutine *ORIENT*. This option is valid only for Abaqus/Standard analyses.
- **Normal direction**: For all options except **User-defined**, you can choose which axis defines the approximate normal direction of the composite layup.

- **Additional rotation**: If you choose a **Coordinate system**, **Discrete orientation**, or **Discrete field** to define the layup orientation, you can specify an angle (in degrees) that defines an additional rotation about the specified normal direction for the entire layup. You can use a scalar discrete field to specify a spatially varying additional rotation angle.

Ply orientation

The ply orientation defines the relative orientation of each ply. In conventional and continuum shell layups Abaqus projects the specified ply orientation onto the surface of the shell so that the ply normal direction is aligned with the shell normal and the layup stacking direction. In solid composite layups the plies are created with respect to the layup stacking direction, and the unprojected ply orientation defines the material orientation within a ply (see *Figure 2*).

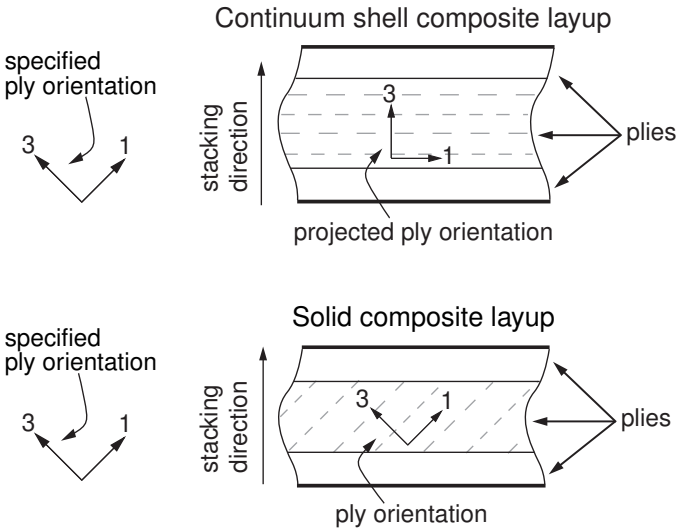


Figure 2: Plies and ply orientations for shell and solid composite layups.

Abaqus/CAE calculates the ply orientation from a combination of two variables that you can specify—the coordinate system (CSYS) and a rotation angle about the normal direction.

In cases where Abaqus/CAE attempts to draw coordinate systems for ply orientations in composite layups at singularity points of the system (i.e., points for which the user-selected coordinate system and the geometric normal from either geometry or elements cannot be resolved into a valid orientation for display purposes in Abaqus/CAE), the coordinate system will be drawn collapsed.

If the layup orientation is specified using a discrete field, no display is available for either the layup or ply orientation. For continuum shell elements, Abaqus/CAE does not project the displayed orientations onto the midplane surface. In both of these cases, you can perform a data check and view the output database in the Visualization module to verify the orientations. For more information, see *Performing a data check on a model*.

Coordinate system

Abaqus/CAE provides the following options for defining the coordinate system of the ply:

- **Layup**: By default, the coordinate system of the ply is the same as the coordinate system of the layup.
- **CSYS**: You can create and select a datum coordinate system that defines the coordinate system of the ply. If you choose to use a coordinate system for a ply, it overrides the layup orientation for that ply.

  You can also select the axis of the coordinate system that defines the normal direction of the ply. The axis that you choose appears as the last digit in the **CSYS** column in the layup table. For example,

`Datum csys1.3` indicates that you chose `Datum csys-1` to define the coordinate system of the ply, and you chose the `3-axis` to define the normal.

Rotation angle

The rotation angle defines the orientation of the fibers within each ply relative to the ply's coordinate system. For example, in a typical composite the fibers might be oriented at −45° or +90° relative to the coordinate system. You can also use a scalar discrete field to specify a fiber orientation that varies spatially across the ply. If you specify a rotation angle, the ply is rotated counterclockwise about the coordinate system normal, and the angle is measured relative to the 1-axis.

Figure 3 shows the orientation of four plies in a composite layup and the corresponding entries in the layup table.

		Ply Name	CSYS	Rotation Angle
1	✔	VerticalTape-1	<Layup>	0
2	✔	VerticalTape-2	<Layup>	90
3	✔	DiagonalTape-1	Datum csys-1.3	0
4	✔	DiagonalTape-2	Datum csys-1.3	90

Figure 3: Determining the orientation of each ply.

Abaqus/CAE determines the ply orientation as follows:

- You selected the layup orientation to define the coordinate system of **VerticalTape-1** and entered a rotation angle of 0°. The resulting ply orientation is along the 1-axis of the layup orientation.
- You selected the layup orientation to define the coordinate system of **VerticalTape-2** and entered a rotation angle of 90°. The resulting ply orientation is a rotation of 90° counterclockwise about the 3-axis (the normal direction) of the layup orientation. The rotation angle is measured relative to the 1-axis.
- You selected **Datum csys-1** to define the coordinate system of **DiagonalTape-1** and entered a rotation angle of 0°. The resulting ply orientation is along the 1-axis of **Datum csys-1**.
- You selected **Datum csys-1** to define the coordinate system of **DiagonalTape-2** and entered a rotation angle of 90°. The resulting ply orientation is a rotation of 90° counterclockwise about the 3-axis (the normal direction) of the datum coordinate system. The angle is measured relative to the 1-axis.

Understanding composite layups and distributions

A discrete field that is used by a composite layup is called a distribution. Because distributions are applied to specific elements and nodes, you can use a distribution only after you have meshed the part.
A discrete field is a spatially varying field where values are associated with a node or an element. The Discrete Field toolset allows you to create and manage discrete fields in Abaqus/CAE. In most cases you will use a third-party preprocessor that operates on meshed parts to create a distribution that can be applied to a composite layup. For more information, see *The Discrete Field toolset*.

You can use a distribution for the following:

- To define a spatially varying local coordinate system that specifies the overall orientation of the composite layup.
- To define an additional rotation for the layup orientation that is varying spatially across the layup.
- To define an additional rotation for a ply orientation that is varying spatially across the ply. You can use a distribution to define the ply orientation only in an Abaqus/Standard analysis.
- To define an overall shell thickness that varies spatially across a conventional shell composite layup.
- To define a ply thickness that varies spatially across a ply in a conventional shell composite layup. You can use a distribution to define the ply thickness only in an Abaqus/Standard analysis.
- To define a nodal thickness that varies spatially across a conventional shell composite layup.
- To define an offset that varies spatially across a conventional shell composite layup. You can use a distribution to define the offset only in an Abaqus/Standard analysis.

Requesting output from a composite layup

When you create a composite layup that will be integrated during the analysis, you can specify the number of integration points in each ply of the layup. By default, for shell sections integrated during the analysis Abaqus/CAE creates three integration points for each ply of a shell or continuum shell composite layup and one integration point for each ply of a solid composite layup. For pre-integrated shell sections, Abaqus/CAE creates three integration points for each ply in the layup, and you cannot change this value. *Figure 1* shows the integration point numbering for a composite layup with three plies and three integration points per ply.

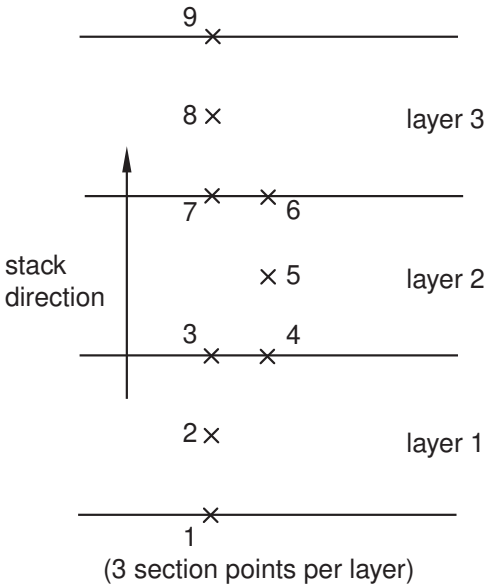

Figure 1: The integration point numbering for a composite layup with three plies.

If you do not create an output request, Abaqus writes field output data from only the top and bottom of a composite layup (the highest and lowest integration points), and no data are generated from the other plies. Therefore, if your model contains a composite layup and you want data from individual plies or interior integration points, you must create a new output request or edit the default output request and specify the composite layup from which variables will be output.

When you create an output request, Abaqus/CAE by default writes field and history data to the output database from only the middle section point in each ply of a composite layup. To change the default behavior, you can use the field and history output request editors to edit the output request and change the domain to a composite layup. You can then request field or history data from the top, middle, and/or bottom section point of each ply, from all section points, or from specified section points. For more information, see *Modifying field output requests*, and *Modifying history output requests*. You can request the following:

Selected

Abaqus/CAE writes field data to the output database from the selected section points of each ply (top, middle, and/or bottom). If a ply has an even number of section points and you request output from the middle section point, Abaqus/CAE generates data from the higher of the two section points that span the middle of the ply. For example, if a ply has four section points and you request output from the middle section point, Abaqus/CAE generates data from the third section point.

All

Abaqus/CAE writes field data to the output database from all of the section points of all of the plies.

Specify

Abaqus/CAE writes field data to the output database from specified section points. Section points are numbered sequentially from the bottom of the bottom ply to the top of the top ply, where the bottom ply is the first ply in the layup. For example, if you want output from the middle section point of each ply shown in *Figure 1*, you would enter `2,5,8`.

For more information, see *Understanding output requests*.

Viewing a composite layup

You can view a composite layup while you are creating it or after it has been analyzed. Abaqus/CAE provides the following tools for ply-based visualization of a composite layup:

Ply stack plot

A ply stack plot is a graphical representation of the plies from the selected region of a composite layup or a composite section. *Figure 1* illustrates a ply stack plot.

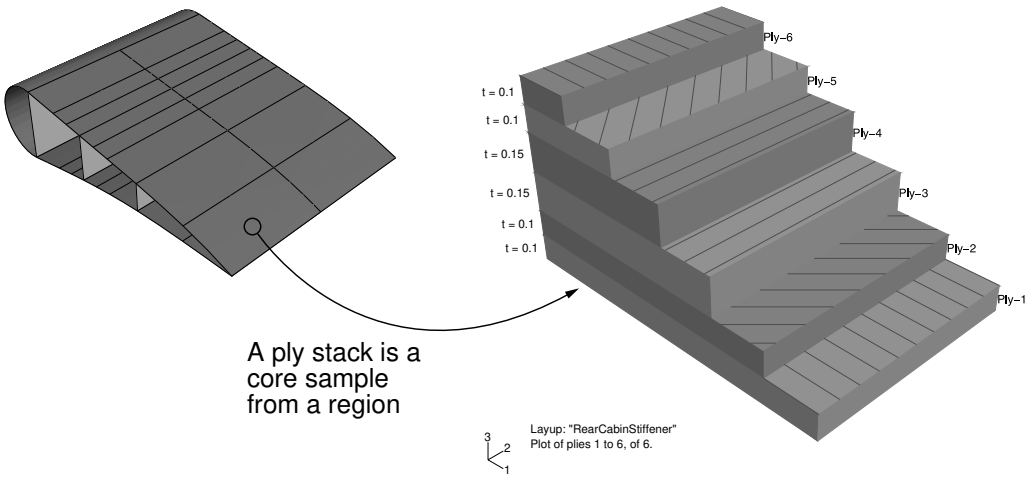

Figure 1: A ply stack plot.

The staircase appearance does not indicate ply drop-offs in the layup; it is simply a graphical representation that allows you to see the number of plies in the layup and, for example, the relative thickness of a ply, the material from which it is constructed, and the orientation of its fibers. If your composite layup contains many plies, the ply stack plot can become confusing and hard to interpret. To make the ply stack plot more readable, Abaqus/CAE provides options that allow you to view only a manageable number of plies.

The triad in a ply stack plot represents the element orientation system, and it shows the shell normal or stacking direction (the 3-direction) and the 1- and 2-directions for the plies. The fibers are always drawn in the 1–2 plane at an angle with respect to the 1-direction. In solid composite layups the fibers in a ply do not always run parallel to the 1–2 plane (e.g., if the 3-direction of the ply orientation and the element stacking direction are not aligned). In this situation the fibers in the ply stack plot are not a true depiction of the fibers in the layup, but rather a graphical representation of the rotation angles in the layup definition: the angle drawn in the ply stack plot is the rotation angle specified in the ply table measured about the element stacking direction axis. For more information, see *Understanding composite layups and orientations*.

Ply stack plots do not draw fibers for ply orientations that are based on a user-defined coordinate system or a rotation angle distribution. Abaqus/CAE displays an asterisk (for coordinate systems) or a caret (for rotation angle distributions) on such plies to signify that it cannot draw lines in the 1–2 plane that accurately represent the fiber direction for the ply. Similarly, if you use a discrete field distribution to define a ply's thickness, Abaqus/CAE draws the ply in the ply stack plot based on the average thickness of the other uniform plies in the layup and displays the discrete field name next to the plot (if thickness labels are turned on).

You can display a ply stack plot in the Property module after you have created a composite layup. You can also display a ply stack plot in the Visualization module after you have analyzed a model with a composite layup. For more information, see *Viewing a ply stack plot*.

Ply-based results

After you have analyzed a model with a composite layup, you can view a contour plot of results from individual plies of the layup, or you can view an envelope contour plot that looks for maximum or minimum values across all of the plies in the layup.

Results from individual plies

Ply-based results show the data from a selected ply in a composite layup. For a given ply, you can view data from the bottom, middle, or top of the ply, or you can view data from both the top and bottom plies. *Figure 2* illustrates a contour plot of strain (E11) from selected plies of a composite layup.

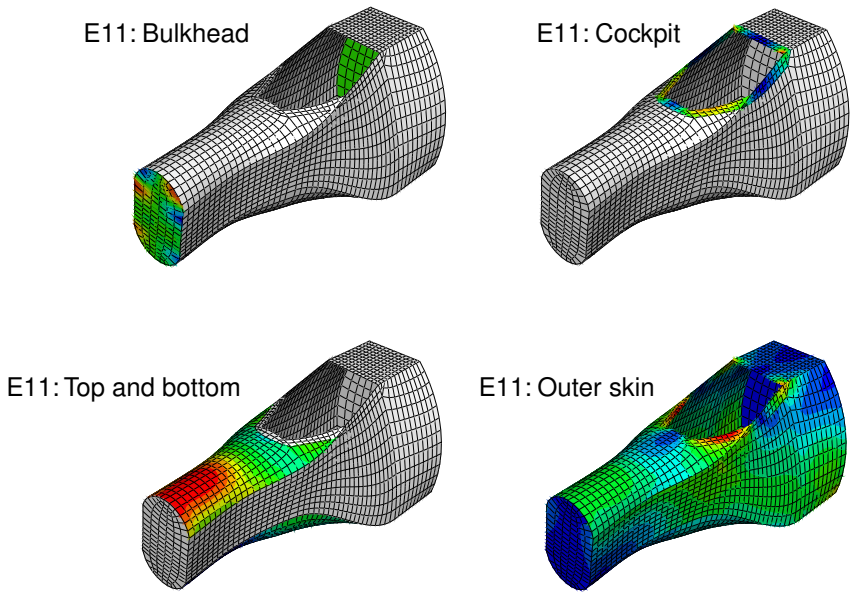

Figure 2: Contour plots from selected plies.

If the same ply name is used in multiple composite layup definitions within a model, viewing data for this ply displays results for all layups in which the ply name appears. To limit the results to a single ply within a single layup, you must first use a display group to limit the display to the individual composite layup (see *Selection methods for creating or editing a display group*), then plot the results for a section point within the desired ply (see *Selecting section point data by ply*).

Contour plots displaying output at both the top and bottom plies of a composite layup vary in appearance depending on the type of layup. In a conventional shell composite layup the two contours appear as a single double-sided shell with different contours on each side. In a continuum shell composite layup or solid composite layup the two contours appear as distinct single-sided contours at each section point location. *Figure 3* illustrates the difference between contour plots of conventional shell and continuum shell composite layups.

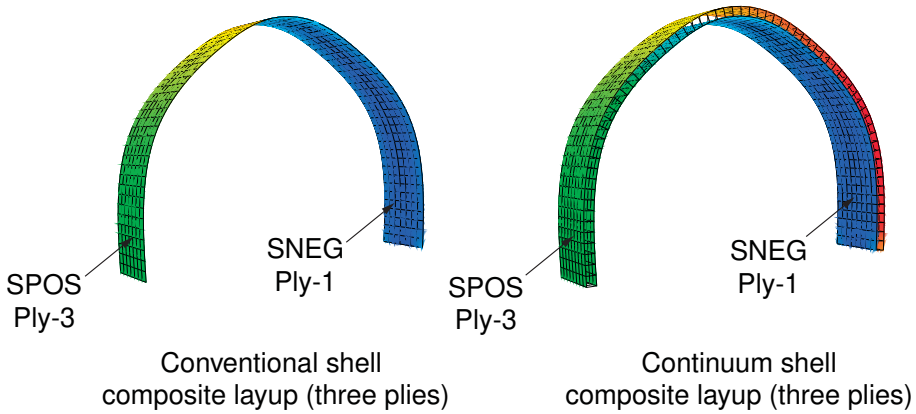

Figure 3: Contour plots of conventional shell and continuum shell composite layups.

Each layup contains three plies, and each plot is showing the output from the top of the top ply and from the bottom of the bottom ply. Stress (S11) is plotted in both cases. For more information, see *Selecting section point data by category*.

Envelope plots

An envelope plot allows you to view a contour plot of the highest or lowest value of a variable in your model, regardless of the ply in which it is occurring. The plies in an envelope plot that correspond with the extreme values are called the critical plies. You can choose the criterion that Abaqus/CAE applies (absolute maximum, maximum, or minimum) and the position in the ply at which Abaqus/CAE checks the value (integration point, centroid, element nodal).

For example, even though your composite layup can include a large number of plies, you can view only the critical plies and determine the highest strain that is occurring in each element of your model. You can decide if you want to reduce the strain in the critical plies by increasing the number of plies in a particular region or by reorienting existing plies. *Figure 4* shows the value of the strain (E11) in the critical plies of the model.

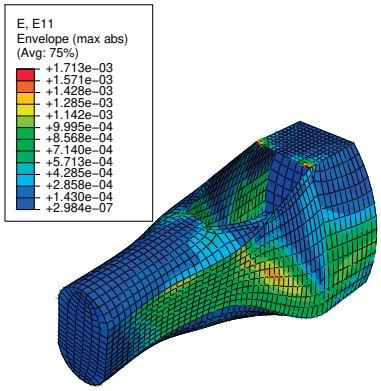

Figure 4: The value of the strain in the critical plies.

In addition, you can use the contour plot options to display a quilt contour plot where the color of each element indicates which ply is the critical ply, as shown in *Figure 5*.

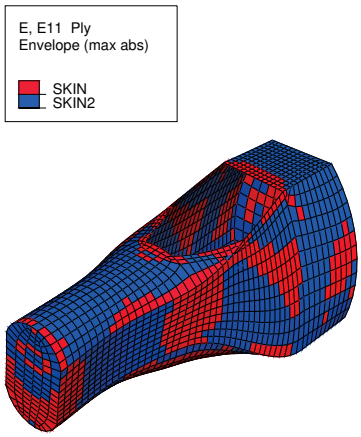

Figure 5: The critical plies.

Using a combination of the plots shown in *Figure 4* and *Figure 5*, you can determine both the value of the strain in the critical ply and the location of the critical ply in the layup. For more information, see *Selecting the field output to display*, and *Understanding how contour values are computed*.

If you do not create an output request, Abaqus/CAE writes field output data from only the top and bottom of a composite layup, and no data are generated from the other plies. To create an envelope plot that examines all of the plies in your model, you must create a new output request or edit the default output request and specify the composite layup and the plies and section points from which variables will be output.

In many cases, even though you change the position in the ply at which Abaqus/CAE checks the value, the same ply experiences the extreme value, and the contour plot does not change. However, the contour plot might change because the critical ply changed if:

- you have a small number of plies, and the results are changing rapidly through the thickness of the ply; or
- the material is nonlinear, and its stiffness changes abruptly under some conditions.

Through thickness X–Y plots

After you have analyzed a composite layup and determined which regions contain the critical plies, you can view the behavior of the plies across the layup with a through thickness X–Y plot. You can create an *X–Y* data object by reading field output results from the section points in a selected element of a shell region of your model. If you select an element in a composite layup, Abaqus/CAE plots data for each section point in each ply across the entire thickness of the layup. *Figure 6* illustrates a through thickness plot of the strain in the fiber direction through 13 plies of a composite layup. The strain is discontinuous because the orientation of the fiber changes between plies.

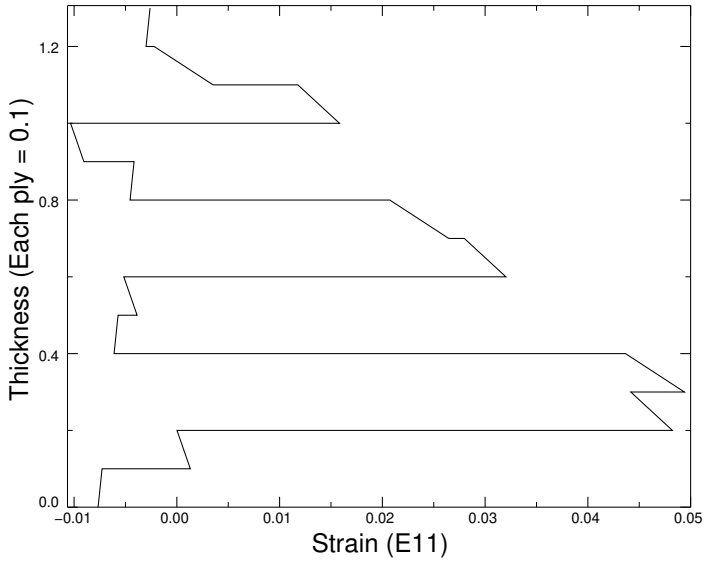

Figure 6: A through thickness X–Y plot.

For more information, see *Reading X–Y data through the thickness of a shell*.

Color coding

You can use color coding in all of the Abaqus/CAE modules to change the color of individual layups and plies. If you choose to color code by plies, Abaqus/CAE displays only one ply in a region, which by default is the last ply (in alphabetical order). To view a different ply, you can deactivate selected plies. For more information, see *Coloring geometry and mesh elements*.

Display groups

In the Visualization module you can use display groups to view the elements in only selected layups or plies. For more information, see *Selection methods for creating or editing a display group*.

Using a composite layup to model a yacht hull, illustrates how you can create and analyze a complex three-dimensional composite model and how you can use Abaqus/CAE to view the behavior of individual plies in the layup.

Connectors

This section provides information on how to model connectors.

In this section:

- *Modeling connectors*
- *What is a connector?*
- *What is a connector section?*
- *What is a CORM?*
- *What are connector behaviors?*
- *Creating the connector geometry, connector sections, and connector section assignments*
- *What is the relationship between reference points and connectors?*
- *Defining connector orientations in connector section assignments*
- *Requesting output from connectors*
- *Applying connector loads and connector boundary conditions*
- *Displaying connectors and connector output in the Visualization module*

Modeling connectors

The procedure for modeling and using connectors in Abaqus/CAE involves the following general steps:

1. Create reference points and datum coordinate systems to use when modeling connectors.
2. Create assembly-level wire features.
3. Create connector sections to define the connection types, connector behavior, and section data.
4. Create a connector section assignment that associates the connector section with the wires that you select and that specifies the orientations for the first and second points of the wires that you select.
5. In the Load module, prescribe connector loads and connector boundary conditions to simulate connector actuations and constrain material flow.
6. In the Step module, create field and history output requests for connectors.
7. In the Visualization module, plot connector output results; control the display of connector section assignments, wire endpoints, connection types, and current local orientations; and animate the time history of wire endpoints and local orientations.

What is a connector?

Connectors allow you to model mechanical relationships between two points in an assembly. The connection can be simple, such as a link, or the connection can impose more complicated constraints, such as constant velocity joints. The connector geometry is modeled using an assembly-level wire feature that contains one or more wires. The wires may connect two points in an assembly or connect a point to ground. You create a connector section that specifies the type of connection and connector behaviors, such as spring-like elasticity behavior. To complete the connector modeling, you create a connector section assignment that associates a connector section with the wires that you select and that specifies the orientations for the first and second points of the wires that you select. For more information on connectors, see *About Connectors*.

For example, *Figure 1* illustrates the crank mechanism that is used in the example problem *Crank mechanism*.

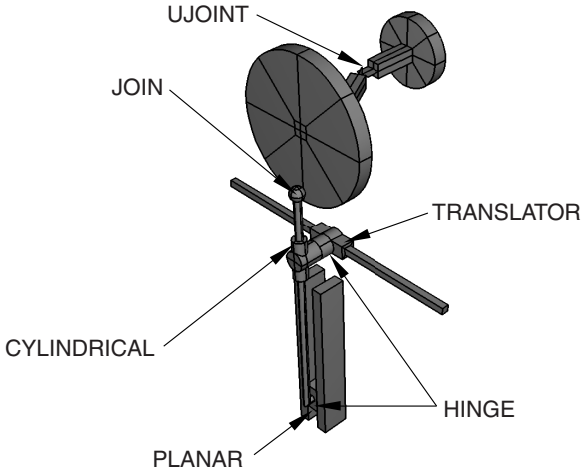

Figure 1: A crank mechanism modeled with connectors.

The model transmits a rotational motion through two universal joints and then converts the rotation into translational motion of two slides. An Abaqus Scripting Interface script that reproduces the crank mechanism model using Abaqus/CAE is provided with this example. The crank mechanism is modeled using nine part instances attached to each other through eight connectors modeled in Abaqus/CAE.

What is a connector section?

A connector section defines the connection type and may include connector behavior and section data. Abaqus provides several connection types—basic types, assembled types, complex types, and MPC types.

Basic types

Basic connection types include translational types and rotational types. Translational types affect translational degrees of freedom at both endpoints of the wires to which the connector section is assigned and may affect rotational degrees of freedom at the first or both endpoints of the wires. Rotational types affect only rotational degrees of freedom at both endpoints of the wires.

Assembled types

Assembled connection types are predefined combinations of basic connection types. For example, a HINGE connection type combines a JOIN connection type (translational) and a REVOLUTE connection type (rotational) to join the position of two points and provide a revolute constraint between their rotational degrees of freedom.

Complex types

Complex connection types affect a combination of degrees of freedom in the connection and cannot be combined with other connection types. They typically model highly coupled physical connections.

MPC types

MPC connection types are used to define multi-point constraints between two points.

Note:

Abaqus/CAE writes complete connector section data to the input file only when a connector section has a connector section assignment in the model database. If you plan to import a model from an input file and obtain connector sections, you must make sure that all of the connector sections have assignments in the model database.

For an overview of the connection types that are available in Abaqus/CAE, see *Understanding connector sections and functions*. For a description of each connection type and the equivalent basic connection types that define the kinematic constraints of assembled type connections, see *Connection Types* and *General Multi-Point Constraints*.

What is a CORM?

CORM is an abbreviation for component of relative motion: relative displacements and rotations local to a connector. Available components of relative motion are relative displacements and rotations that are not kinematically constrained. Depending upon the connection type, some of the components may be available and some may be constrained. When you are creating or modifying a connector section, Abaqus/CAE displays the available and constrained components of relative motion in the editor for the specified connection type. In addition to applying behaviors to the components of relative motion, you can prescribe connector loads and connector boundary conditions to the available components of relative motion of a connector (see *Applying connector loads and connector boundary conditions*). For more information on creating connector sections, see *Connector section editors*.

What are connector behaviors?

After you specify a connection type for a connector section, you can define behaviors for the components of relative motion. You can specify the following connector behaviors:

- Elasticity
- Damping
- Friction
- Plasticity
- Damage
- Stop
- Lock
- Failure
- Reference length
- Integration (Abaqus/Explicit analyses only)

For more information on behaviors, see *Connector behaviors*, and *Connector Behavior*.

Creating the connector geometry, connector sections, and connector section assignments

You create the assembly-level wire features, connector sections, and connector section assignments in the Interaction module to model a connector. Abaqus/CAE provides two methods for modeling connectors: you can use the **Connector Builder** to perform all the steps involved in creating a single connector, including creation of the wire feature, connector section, connector section assignment, and any desired reference points and datum coordinate systems; or you can create multiple connectors by creating the wires, connector sections, and connector section assignments in separate dialog boxes in the Interaction module. If you choose the latter technique, you should create the desired reference points and datum coordinate systems before you begin modeling the connectors.

The Model Tree, shown in *Figure 1*, is helpful for understanding the organization of the reference points, datum coordinate systems, and wire features that you created in assembly-related modules, as well as connector sections and connector section assignments that you created in the Interaction module. You can use the Query toolset in the Interaction module to obtain connector assignment information for selected wires.

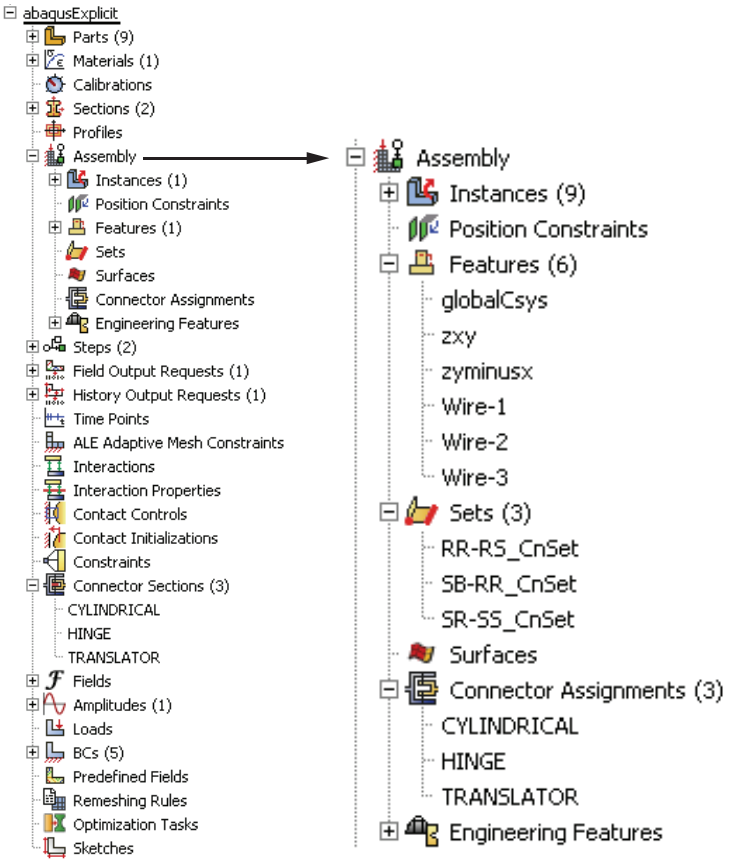

Figure 1: Wire features, connector sections, and connector section assignments in the Model Tree.

For detailed instructions, see the following sections:

- *Selecting a process for defining connector geometry*
- *Creating a single connector*
- *Creating or modifying wire features for multiple connectors*
- *Creating connector sections*
- *Creating and modifying connector section assignments*

- *Using the Query toolset to obtain connector assignment information*

What is the relationship between reference points and connectors?

The points that you can use to define an assembly-level wire feature can be one of the following:

- Vertex or node of a part instance
- Reference point of a part instance or of an assembly
- Ground

Using a reference point is often more convenient than using a point or node on the assembly because the same reference point can be used by a rigid body or coupling constraint. In the Part module you can use the Reference Point toolset to create one reference point on each part; additional reference points can be created in the Assembly module, Interaction module, and Load module.

You can use the Model Tree to rename reference points with more descriptive feature names. Descriptive names allow you to more easily associate reference points and wires in a complex model, as shown in *Figure 1*.

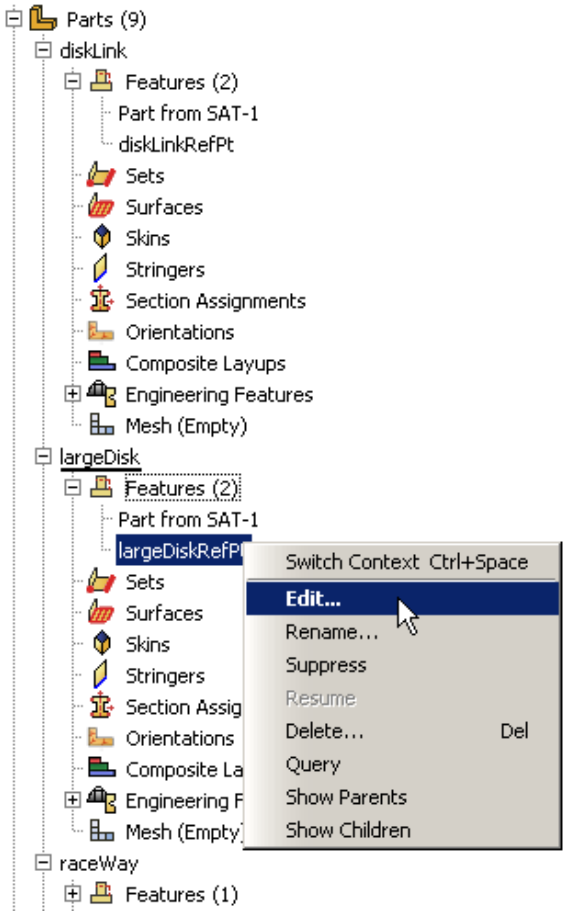

Figure 1: The Model Tree for the crank mechanism.

If you want to use different feature names and labels for a reference point on multiple instances of the same part, you must create the reference points in an assembly-related module. You can create a node on a mesh using the Edit Mesh toolset and then select the node to define an endpoint of an assembly-level wire; however, the node is not listed in the Model Tree and has no label in the viewport. For more information on creating and renaming reference points, see *The Reference Point toolset*. For more information on creating a node on a mesh, see *Manipulating nodes*.

Each reference point or node that defines an endpoint of an assembly-level wire needs to be associated with the model geometry, even if they are created in the Part module. In many cases you will create a rigid body constraint or a coupling

constraint (to distribute forces to an area instead of to a single point) between the reference point or node and a part instance. As a result, the motion of the wire endpoint will be constrained to the motion of the part instance. You create constraints in the Interaction module. For more information, see *Understanding constraints*.

Defining connector orientations in connector section assignments

When you model a connector, you may need to specify the orientation of the connector. Orientations for a connector may be required, optional, or not applicable, depending upon the connection type. In most cases the orientation will not be the same as the global coordinate system, and you must create a datum coordinate system that defines the connector's local orientation before you create a connector section assignment. Connector orientation requirements are described in *Connection Types*.

You can create datum coordinate systems in the Part module, Property module, Assembly module, Interaction module, Load module, and Mesh module. You can name a datum coordinate system when you create it. When you create a connector section assignment, you can select a datum coordinate system from the current viewport or you can select from a list of coordinate system names in a dialog box. Again, the Model Tree is helpful for understanding the organization of your datum coordinate systems. Datum coordinate systems are described in *Methods for creating a datum coordinate system*.

Requesting output from connectors

You can request field and history output for connectors by selecting a set that contains wires as the domain from which the output will be generated. In the Step module choose **Sets** as the domain type in the field output request editor or history output request editor; then select a set containing wires from the list of sets available. For more information, see *Creating and modifying output requests*.

Applying connector loads and connector boundary conditions

In the Load module you can apply a connector force or connector moment to the available components of relative motion of a connector to simulate connector actuation. Similarly, you can prescribe a connector displacement, connector velocity, or connector acceleration for the available components of relative motion of a connector. When you create these connector loads or boundary conditions, you select the wires to which you want to apply the prescribed condition. The best approach for selecting wires is to use the default geometry set name for the wire feature (see *Creating or modifying wire features for multiple connectors*, for more information). The wires that you select must be associated with a connector section assignment. If you select multiple wires, you must ensure that the connector sections assigned to the wires in the connector section assignments have the available components of relative motion for which you want to define forces or moments. If there are insufficient available components of relative motion for the connector force or connector moment, a message appears asking you to select different wires or to change the connection type.

You can also apply a connector material flow boundary condition to the endpoints of wires that are associated with connector section assignments. For more information, see *Creating loads*, and *Creating boundary conditions*.

Displaying connectors and connector output in the Visualization module

Abaqus/CAE displays connectors modeled using connector section assignments in the Visualization module. You can control the display of connectors using display groups. Each connector is listed as an element set in the output database. For more information on display groups, see *Creating or editing a display group*.

You can also use the **Entity Display** options in the **ODB Display Options** dialog box to control the display of symbols that represent connectors. You can control the following:

- The highlighting of wire endpoints
- The display of local orientation axes for connectors
- The display of connector type labels
- The size of the displayed symbols

For information on the symbols that represent connectors modeled in Abaqus/CAE, see *Understanding symbols that represent interactions, constraints, and connectors*. For more information on controlling the display of the symbols, see *Controlling the display of model entities*.

For example, you can use display groups to display four part instances and three connector element sets of the crank mechanism, as shown in *Figure 1*.

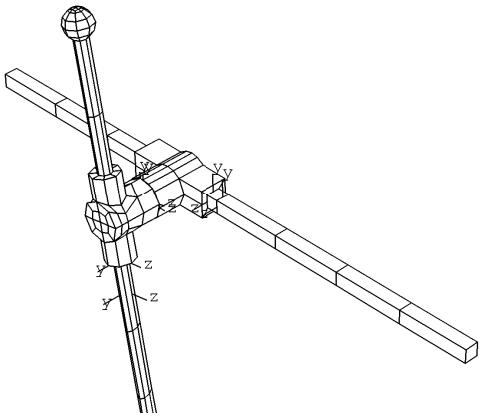

Figure 1: Selected part instance, connector, and connector symbol display in the Visualization module for the crank mechanism.

The highlighting of the wire endpoints and the display of connector type labels have been toggled off so that only the local connector orientations are displayed. You can produce a time history animation to view the changes in the connector orientations during the mechanism operation. For more information, see *Time history animation*.

For information on plotting connector output results, see *Contouring analysis results*, *Plotting analysis results as symbols*, and *X–Y plotting*.

The kinematics of connection types is formulated using an intrinsic coordinate system. The basis vectors of the intrinsic coordinate system are aligned with the directions associated with the components of relative motion. For some connection types (such as the CARTESIAN connection type), the intrinsic coordinate system aligns with the orientation directions at node *a* (see *Connection Types* for more information on connector orientation directions).

The components of connector vector output are resolved with respect to different coordinate systems depending on whether the output requested is field output or history output. For connector field output, the components of the vector are resolved with respect to the orientation directions at node *a*. However, if either of the two nodes is ground, the output of the axial connector is CTF1. For connector history output and connector field outputs with the "_LOCAL" suffix (for example, CTF_LOCAL, CTM_LOCAL), the components of the vector are resolved with respect to the intrinsic coordinate system. Therefore, except for the connection types whose intrinsic coordinate systems align with

the orientation directions at node *a*, plots of field output (symbol plots and contour plots) and history plots display different values for the requested connector vector components; the resultant is not affected by the choice of the coordinate system used to resolve the components.

Continuum shells

This section provides information on how to model continuum shells.

In this section:

- *Modeling continuum shells*
- *Meshing parts with continuum shell elements*

Modeling continuum shells

You use conventional shell parts to model structures in which the thickness is significantly smaller than the other dimensions, and you define the thickness in the Property module when you create the section.
In contrast, you assign continuum shell elements to solid parts, and Abaqus determines the thickness from the geometry of the part. From a modeling point of view continuum shell elements look like three-dimensional continuum solids, but their kinematic and constitutive behavior is similar to conventional shell elements. For example, conventional shell elements have displacement and rotational degrees of freedom, while continuum solid elements and continuum shell elements have only displacement degrees of freedom. For more information, see *About Shell Elements* and *Choosing a Shell Element*. *Figure 1* illustrates the differences between a conventional shell and a continuum shell element.

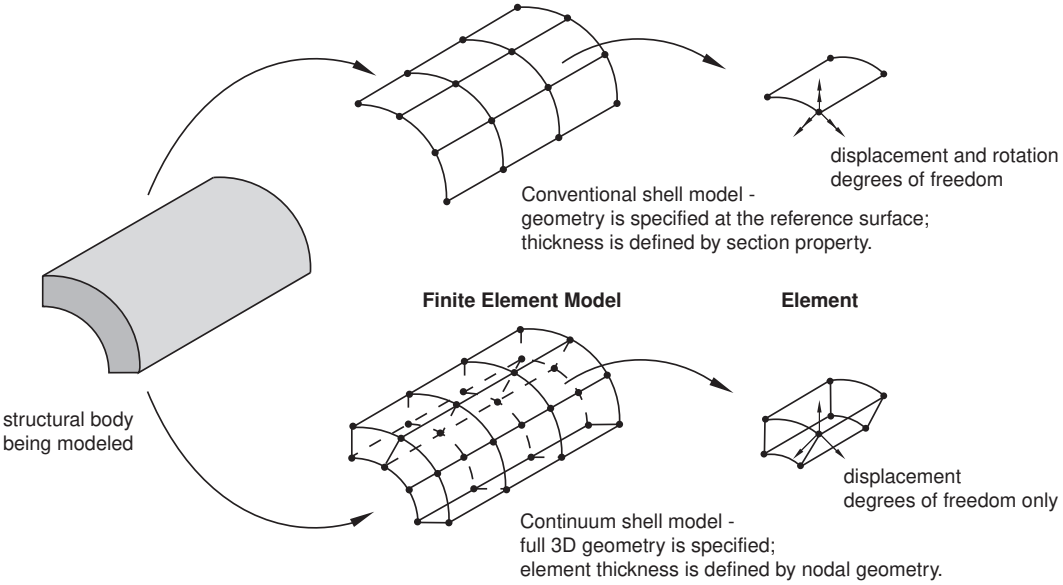

Figure 1: Conventional versus continuum shell element.

The general procedure for modeling continuum shells in three-dimensional space involves the following steps:

1. In the Part module, define the solid geometry.
2. In the Property module, assign a shell section to any solid regions to which you will assign continuum shell elements in the Mesh module. You must specify the thickness of a shell section; however, Abaqus uses this thickness only to estimate certain section properties, such as hourglass stiffness. Abaqus uses the actual thickness, based on the element nodal geometry, during the analysis. If the thickness of the solid region varies along its length, you should provide an approximate value of the thickness. For more information, see *Using a Shell Section Integrated during the Analysis to Define the Section Behavior*.
3. In the Mesh module, query the mesh stack orientation. If necessary, assign a stack orientation so that the continuum elements are aligned consistently from the bottom to the top of the stack. See *Applying a mesh stack orientation*, for more information.
4. In the Mesh module, assign a continuum shell element type to the region, and mesh the region with hexahedral or wedge elements. These are the only elements that can be stacked to form a continuum shell mesh.

Meshing parts with continuum shell elements

You use continuum shell elements to model shell-like solids with greater accuracy than conventional shell elements, as described in *About Shell Elements*. In addition, although you model a continuum shell with hexahedral- or wedge-shaped elements, the element formulations are still more computationally efficient than solid continuum elements.

When you are generating elements that will be assigned to continuum shell elements, the elements in the mesh must be oriented consistently. For example, *Figure 1* shows a swept mesh generated in the direction of the sweep path. The generated elements are stacked in the direction of the sweep path; however, if you plan to use continuum shell elements, the elements should be stacked through their thickness.

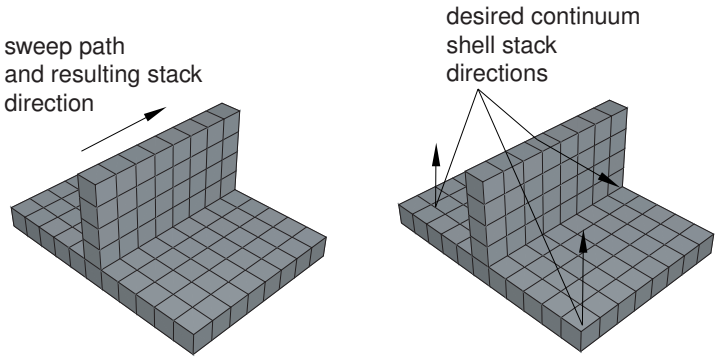

Figure 1: The resulting stack direction is not correct for continuum shell elements.

You can use the Query toolset to determine which faces are designated as the bottom face and the top face and to look for inconsistent orientations between elements. For more information, see *Obtaining general information about the model*. In some cases, you can partition the model and change the direction of the sweep path to obtain the correct orientation. Alternatively, you can assign an orientation unrelated to the sweep path. For more information, see *Applying a mesh stack orientation*.

Co-simulation

This section explains how to model and run a co-simulation in Abaqus/CAE.

In this section:

- *Overview of co-simulation*
- *What is a co-simulation?*
- *Linking and excluding part instances for a co-simulation*
- *Ensuring matching nodes at the interface regions*
- *Specifying the interface region and coupling schemes*
- *Identifying the models involved and specifying job parameters*
- *Viewing the results of the co-simulation*

Overview of co-simulation

The procedure for modeling and running a co-simulation in Abaqus/CAE involves the following general steps:

1. Create the models in a single model database.
2. Optionally, link part instances between models and exclude the linked instances from the analyses.
3. Optionally, ensure matching nodes at the interface regions.
4. In each model, create a co-simulation interaction to specify the interface region and coupling schemes.
5. Create a co-execution to identify the two models involved and specify the job parameters for each analysis.
6. Submit the co-execution to perform the co-simulation.
7. View the results of the co-simulation using overlay plots.

What is a co-simulation?

The co-simulation technique is a multiphysics capability that provides run-time coupling of Abaqus analysis programs. You can divide a model into multiple domains and use different analysis programs to obtain solutions for each domain. For Abaqus/Standard to Abaqus/Explicit co-simulation, each Abaqus analysis operates on a complementary section of the model domain where it is expected to provide the more computationally efficient solution. For example, Abaqus/Standard provides a more efficient solution for light and stiff components, while Abaqus/Explicit is more efficient for solving complex contact interactions.

You define the interface region across which fields are exchanged and the coupling schemes. For more information, see *Structural-to-Structural Co-Simulation*.

Additional information

• *Preparing an Abaqus Analysis for Co-Simulation*

Linking and excluding part instances for a co-simulation

For a co-simulation you may want to see the “whole” model involved in the co-simulation in a single viewport. To achieve this, you can link part instances in one model to part instances in the other model. For example, you can link part instances from the Abaqus/Standard model to part instances in the Abaqus/Explicit model. In this case, the linked part instances in the Abaqus/Standard model cannot be edited, their position is determined solely by the position of the part instance in the Abaqus/Explicit model, and they are available only for display purposes. Any changes to the part instances in the Abaqus/Explicit model are automatically updated in the linked part instances. You must exclude the linked part instances from the appropriate analysis; for example, the part instances in the Abaqus/Explicit model that are linked to the Abaqus/Standard model must be excluded from the Abaqus/Explicit analysis. For more information, see *Linking part instances between models*, and *Excluding part instances from an analysis*.

Ensuring matching nodes at the interface regions

You may have dissimilar meshes in regions shared in the model definitions. For Abaqus/Standard to Abaqus/Explicit co-simulation, you can improve solution stability and accuracy in some cases by ensuring that you have matching nodes at the interface (see *Dissimilar Mesh-Related Limitations*). This section describes the recommended modeling practices for ensuring matching nodes at the interface regions.

In general, you will create a skin or a stringer (depending on whether the interface region is a face or an edge) on the part that contains the interface region in the Abaqus/Explicit model, perform a variety of modeling techniques, and obtain a part instance to use to define a tie constraint in the Abaqus/Standard model.

Detailed instructions are provided in the following procedure.

1. In the Abaqus/Explicit model:
   a. In the Property module display the part that contains the interface region. If the interface region is a face, create a skin on the face. If the interface region is an edge, create a stringer on the edge. For more information, see *Skin and stringer reinforcements*.
   b. If the part is geometry based, mesh the part.
   c. Create a mesh part (even if you are working with a mesh part).
   d. Delete all of the elements in the newly created mesh part other than those on the skin or stringer. In addition, delete the associated unreferenced nodes using the Edit Mesh toolset.
2. In the Abaqus/Standard model:
   a. Copy the mesh part containing the skin or stringer from the Abaqus/Explicit model, and create an instance of the newly copied part.
   b. To simplify region selection procedures, create a named set or surface that contains the mesh part.
   c. In the Interaction module, create a tie constraint specifying the copied mesh part (using the named set or surface) as the main region and the interface region on the Abaqus/Standard model as the secondary region.
   d. In the Interaction module, define a Standard-Explicit co-simulation interaction and specify the mesh part (using the named set or surface) as the interface region. For more information, see *Specifying the interface region and coupling schemes*.
3. In the Abaqus/Explicit model:
   a. Delete the mesh part that contains the skin or stringer.
   b. Delete the skin or stringer from the part geometry.
   c. If the part is geometry based, remesh the part.
   d. In the Interaction module, define a Standard-Explicit co-simulation interaction and specify the interface region in the original Abaqus/Explicit part as the interface region.
4. Continue with the co-simulation procedure as described in *Overview of co-simulation*.

Specifying the interface region and coupling schemes

In each model, you define a co-simulation interaction to specify the interface region (region for exchanging data) and coupling schemes for the co-simulation. Only one co-simulation interaction can be active in each model, and the settings in each co-simulation interaction must be the same in each model. For more information, see *Defining a Standard-Explicit co-simulation interaction*.

Identifying the models involved and specifying job parameters

For co-simulation, the analyses are executed in synchronization with one another using the same functionality as that used for executing a single analysis job. In the Job module, you create a co-execution to identify the two analysis jobs involved in the co-simulation and to specify job parameters for each analysis, and you submit the co-execution to submit both jobs for analysis. For more information, see *Creating, editing, and manipulating co-executions*.

Viewing the results of the co-simulation

To display the results from the co-simulation, you can use the overlay plot functionality to display data from both output databases in the same viewport. For more information, see *Overlaying multiple plots*.

Display bodies

This section provides information on how to model display bodies.

In this section:

- *What is a display body?*
- *Should I mesh a display body?*
- *Displaying display bodies in the Visualization module*

What is a display body?

A display body is a part instance that will be used for display only. The part instance can be any instance containing geometry, mesh elements, or a combination of geometry and mesh. You do not have to mesh the part, and the part is not included in the analysis; however, when you view the results of the analysis, the Visualization module displays the part along with the rest of your model. In effect, a display body provides a more realistic view of your model in the Visualization module without the computational expense of including the part instance in the analysis. A display body behaves like a rigid part and does not deform. You cannot apply prescribed conditions, such as constraints, loads, or boundary conditions, to a display body.

You can associate the motion of a display body with selected control points (one point or three points), or you can specify that the display body remain fixed during the analysis. If the display body follows a single point, the display body will translate and rotate based on the translations and rotations of the single point. If the display body follows three points, the display body will translate and rotate based on the translation of the three points. For more information, see *Display Body Definition*.

For example, *Figure 1* shows a backhoe arm modeled with connectors.

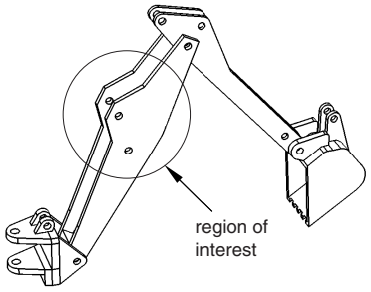

Figure 1: A backhoe arm modeled with connectors.

The region of interest is the main arm of the backhoe. The bucket interacts with the rest of the backhoe model only through the connectors and the mass and inertia of the bucket. As a result, the bucket can be modeled as a display body.

You create a display body by applying a display body constraint to a part instance. For the backhoe arm model you would first create the bucket part instance in the Part module. In addition, you would create a point part and position it at the centroid of the bucket in the assembly, as shown in *Figure 2* (see *Point parts*); a reference point is automatically created for the point part.

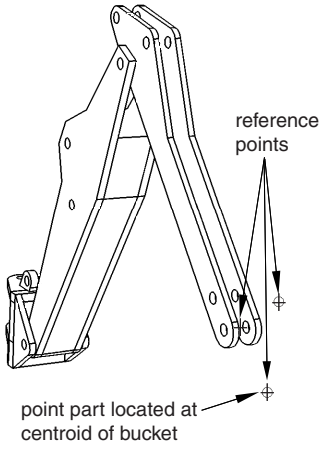

Figure 2: The mass and inertia of the bucket are modeled with a point part.

The other two reference points in the assembly serve as endpoints for a HINGE and an AXIAL connector; see *Connectors* for more information on connectors. In the Interaction module you would create a rigid body constraint to constrain the endpoints and the point part to move as a single rigid entity, as shown in *Figure 3*; see *Defining rigid body constraints*.

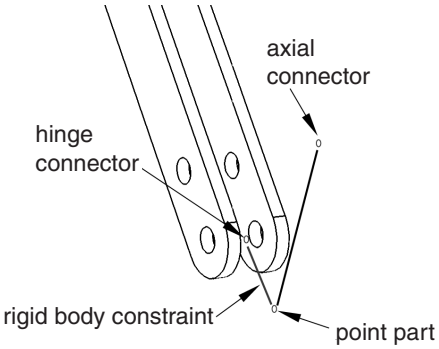

Figure 3: A rigid body constraint constrains the point part to the endpoints.

In addition, you would create a display body constraint to constrain the bucket part instance to the point part; see *Defining display body constraints*.

You do not have to mesh the bucket part instance, and it is not included in the analysis of the backhoe model. However, the bucket still appears when you view the results of the analysis in the Visualization module, as shown in *Figure 4*.

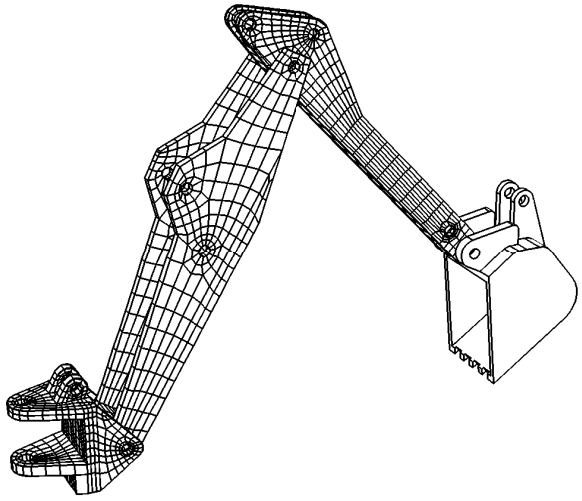

Figure 4: The bucket is modeled as a display body.

Display bodies are useful if your model contains a part that cannot be meshed and need not be analyzed. In general, an imported part that has invalid geometry cannot be used by Abaqus/CAE unless you choose to ignore the invalidity of the part (for more information, see *Working with invalid parts*). If you apply a display body constraint to the invalid part, you can continue to use the part in your model, although the part will not be included in the analysis. For more information, see *What is a valid and precise part?*.

Should I mesh a display body?

You do not have to mesh a display body. However, to display the part instance in the Visualization module, Abaqus/CAE computes a triangular mesh that models the surfaces of the part instance. This internal mesh is written to the input file and to the resulting output database; however, it is used only to render the display and is not included in the numerical analysis. By default, the Visualization module displays only the free edges of the meshed display body part instance, although you can change the visible edges displayed.

Similarly, if you do mesh a display body or if you use a mesh part to create a display body, Abaqus/CAE retains your mesh when the input file is generated; however, it is used only to render the display in the Visualization module and is not included in the numerical analysis.

Displaying display bodies in the Visualization module

You can use the **Display Body Options** in the Visualization module to customize the appearance of display bodies. The options available for display bodies are similar to the common and superimposed plot options in Abaqus/CAE: render style; edge visibility, color, and style; fill color; scaling; and translucency can all be customized. Similarly, display body options are plot state–independent; i.e., the options applied to display bodies are reflected in all plot states. For more information, see *Customizing the appearance of display bodies*.

Display body options apply to all display bodies in your model; to customize the appearance of individual display bodies, you can create display groups based on part instances (see *Creating or editing a display group*). Individual item coloring can also be applied to individual display body part instances to override the edge and/or fill colors specified as general display body options; see *Customizing the display color of individual objects* for more information.

Eulerian analyses

This section explains how to create Eulerian models in Abaqus/CAE.

In this section:

- *Overview of Eulerian analyses*
- *Assembling coupled Eulerian-Lagrangian models in Abaqus/CAE*
- *Defining contact in Eulerian-Lagrangian models*
- *Assigning materials to Eulerian part instances*
- *Using the volume fraction tool*
- *Eulerian mesh motion*
- *Viewing output from Eulerian analyses*

Overview of Eulerian analyses

Pure Eulerian analysis is a finite element technique in which materials are allowed to flow across element boundaries in a rigid mesh.
In the more traditional finite element formulation (also known as the Lagrangian technique), materials are closely associated with an element, and the materials move only with the deformation of the mesh. Because the element quality issues associated with a deformable mesh are not present in Eulerian analyses, the Eulerian technique can be very effective at treating problems involving very large deformations, material damage, or fluid materials. Eulerian analysis can be performed only in **Dynamic, Explicit** steps. For a detailed discussion of Eulerian capabilities and applications, refer to *Eulerian Analysis*.

The techniques for modeling pure Eulerian analyses in Abaqus/CAE are very different than those used to model pure Lagrangian analyses. Most notably, instead of defining several parts and assembling them into a complete model, Eulerian models typically consist of a single Eulerian part. This part, which can be arbitrary in shape, represents the domain within which Eulerian materials can flow. The geometry of bodies in the model is not necessarily defined by the Eulerian part; instead, materials are assigned to different regions within the Eulerian part instance to define the body geometries.

Figure 1 compares the same model created using Lagrangian and Eulerian techniques. In the Lagrangian model, two parts are modeled, and each part is assigned a unique section referencing a material. In the Eulerian model, a single Eulerian part is modeled and assigned an Eulerian section. The Eulerian section defines the materials that can be present within the part. Materials are then assigned to different regions within the instanced part; any region without a material assignment is treated as a void with no material properties.

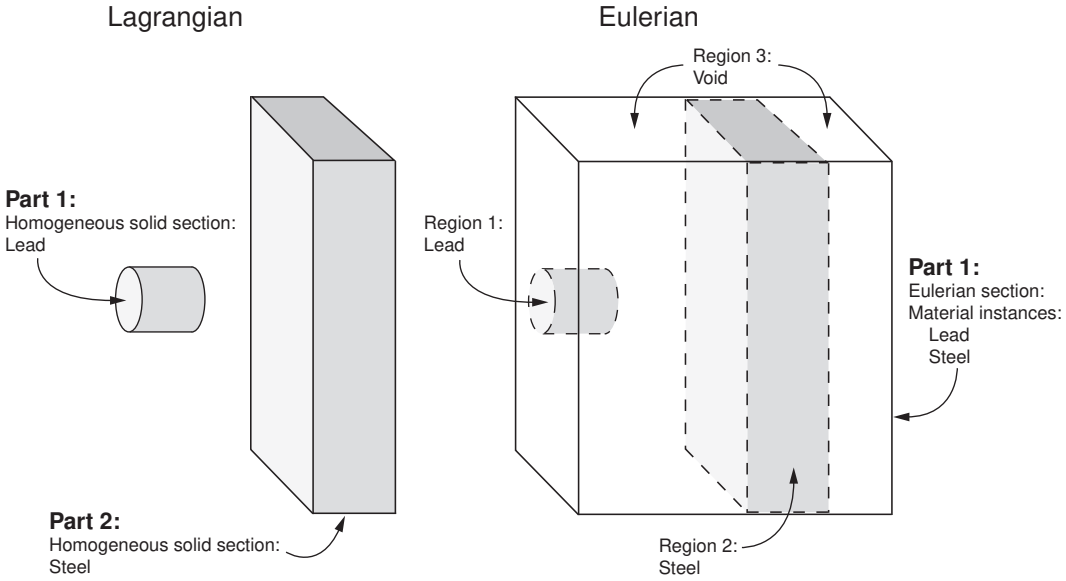

Figure 1: Two bodies modeled using Lagrangian and Eulerian techniques.

The Eulerian analysis technique can be coupled with traditional Lagrangian techniques to extend the simulation functionality in Abaqus:

- Arbitrary Lagrangian-Eulerian (ALE) adaptive meshing is a technique that combines features of Lagrangian and Eulerian analysis within the same part mesh. ALE adaptive meshing is typically used to control element distortion in Lagrangian parts undergoing large deformations, such as in a forming analysis. Most ALE adaptive meshing analyses can also be performed as pure Eulerian analyses, but some of the features associated with a Lagrangian mesh will be lost; for a more detailed comparison, see *About ALE Adaptive Meshing*.
- Coupled Eulerian-Lagrangian (CEL) analysis allows Eulerian and Lagrangian bodies within the same model to interact. Coupled Eulerian-Lagrangian analysis is typically used to model the interactions between a solid body

and a yielding or fluid material, such as a Lagrangian drill traveling through Eulerian soil or an Eulerian gas inflating a Lagrangian airbag. Eulerian-Lagrangian analysis is discussed in *Assembling coupled Eulerian-Lagrangian models in Abaqus/CAE*.

Viewing the results of Eulerian analyses requires some special techniques in the Visualization module. These techniques are discussed in detail in *Viewing output from Eulerian analyses*.

The procedure for creating Eulerian models in Abaqus/CAE involves the following general steps:

1. In the Part module, create an Eulerian-type part that defines the geometric region within which Eulerian materials can flow. For more information, see *Choosing the type of a new part*.
2. In the Part module, you may want to create partitions that represent the initial boundaries between different materials in the part. The partitions will affect the mesh of the part, and they are necessary only if you are assigning materials uniformly across a region. For more information about assigning materials in an Eulerian part, see *Assigning materials to Eulerian part instances*, and *Defining a material assignment field*.
3. In the Property module, define the materials in the model.
4. In the Property module, define and assign an Eulerian section for the model. The Eulerian section determines which materials can be present in the Eulerian part. The topology of the materials within the part will be defined in the Load module, as discussed in Step 7. For more information, see *Creating Eulerian sections*.
5. In the Assembly module, create an instance of the Eulerian part.
6. In the Step module, create a field output request for output variable EVF. This output is necessary to view the deformation of materials in an Eulerian model. For more detailed information, see *Viewing output from Eulerian analyses*.
7. In the Load module, create a material assignment predefined field that defines the topology of materials in the initial configuration of the Eulerian part instance. For more information, see *Assigning materials to Eulerian part instances*, and *Defining a material assignment field*.
8. In the Load module, define any loads or boundary conditions acting on the model. Because the mesh in an Eulerian part is rigid, traditional Lagrangian prescribed conditions do not move with the material deformations; loads and boundary conditions are imposed on any material that occupies (or moves into) the region to which the condition is prescribed. Zero-displacement boundary conditions can be used along the sides of an Eulerian part instance to prevent Eulerian material from entering or exiting the part. Boundary conditions and constraints based on nonzero nodal displacements are ignored in an Eulerian part instance; typically, velocity boundary conditions or predefined fields are used to prescribe initial motion in an Eulerian model. Specialized Eulerian boundary conditions can also be defined to control the flow of material across the boundaries of the Eulerian part (see *Defining an Eulerian boundary condition*). For more information about applying loads and boundary conditions to Eulerian models, see *Boundary Conditions*.
9. In the Mesh module, create a hexagonal mesh for the Eulerian part. EC3D8R elements are assigned to the mesh by default. After creating a regular mesh, you can trim any elements that are not expected to experience material flow to reduce the model size and improve performance of the analysis.

An example of a basic Eulerian model created in Abaqus/CAE is provided in *Eulerian analysis of a collapsing water column*. More complicated Eulerian modeling procedures, including complex material assignments and coupled Eulerian-Lagrangian interactions, are illustrated in *Impact of a water-filled bottle*.

Assembling coupled Eulerian-Lagrangian models in Abaqus/CAE

Abaqus allows you to create models that include both Eulerian part instances and Lagrangian part instances. During a coupled Eulerian-Lagrangian analysis, the Lagrangian mesh interacts with the materials in the Eulerian part. Coupled Eulerian-Lagrangian analyses typically offer better interpretation of contact conditions than pure Eulerian analyses, particularly for interactions between fluid and solid materials. During postprocessing, a solid Lagrangian body in a coupled Eulerian-Lagrangian analysis appears to maintain its shape better than a similar body in a pure Eulerian analysis.

Figure 1 compares a pure Eulerian analysis (top) and a coupled Eulerian-Lagrangian analysis (bottom) of a steel brick passing through a column of water.

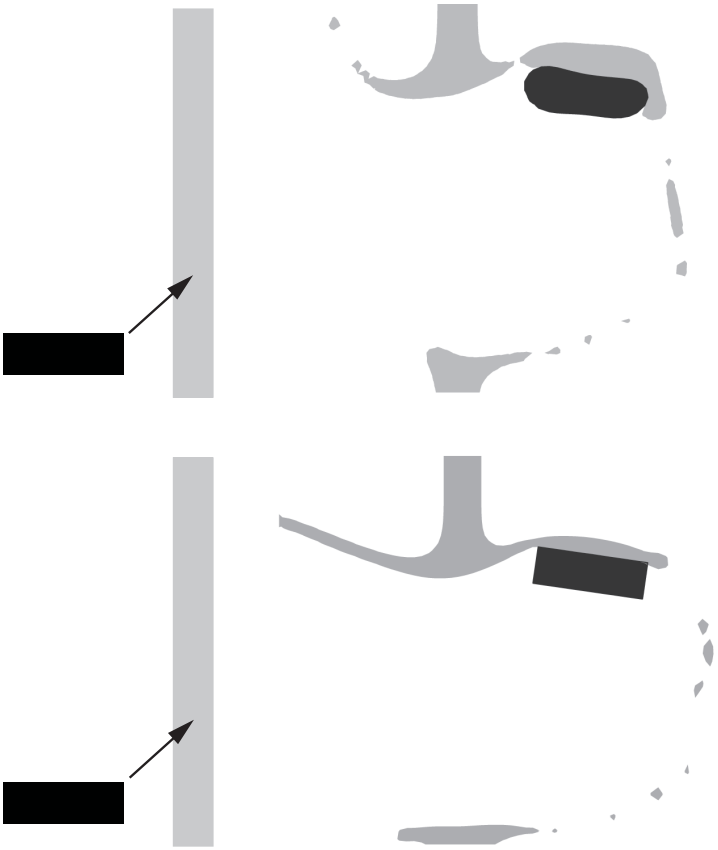

Figure 1: Comparison of a pure Eulerian analysis (top) and a coupled Eulerian-Lagrangian analysis (bottom).

In the Eulerian analysis the water tends to adhere to the sides of the brick, and the brick appears deformed in the final configuration. This apparent deformation is a result of the material volume fraction calculations used for Eulerian materials, as discussed in *Material Interfaces*. On the other hand, the Lagrangian brick maintains its shape as it passes through the Eulerian water, and the water flows around the brick.

Coupled Eulerian-Lagrangian analyses also allow you to capitalize on the strengths of both analysis techniques; for example, you can use the loads on a Lagrangian body moving through an Eulerian material to drive a detailed submodel of the Lagrangian body.

To assemble a coupled Eulerian-Lagrangian model in Abaqus/CAE, simply instance both Eulerian and Lagrangian parts in the same assembly. Coupled Eulerian-Lagrangian analyses can be performed only in **Dynamic, Explicit** steps. You must create a general contact definition to enable contact between Lagrangian and Eulerian parts. The general contact definition allows interactions between Lagrangian surfaces and Eulerian material instances in the model (see

Defining contact in Eulerian-Lagrangian models for more information). Other interactions, loads, boundary conditions, and predefined fields are applied to the Lagrangian and Eulerian parts in the usual manner.

In most cases the Lagrangian part is assembled inside of the Eulerian part instance. While Lagrangian and Eulerian elements and nodes can overlap, three-dimensional Lagrangian elements cannot occupy the same space as an Eulerian material instance. Therefore, Lagrangian parts must be instanced in an area of void within the Eulerian part instance (i.e., a region with no material assignment). To model a three-dimensional Lagrangian part instance that is completely surrounded by Eulerian material, use the volume fraction tool to create an Eulerian material assignment field that includes a void region corresponding to the Lagrangian part instance (see *Using the volume fraction tool* for details).

Defining contact in Eulerian-Lagrangian models

Contact in a coupled Eulerian-Lagrangian analysis must be defined using general contact. The general contact definition enables interactions between Lagrangian part surfaces and the surfaces of Eulerian material instances; contact between different Lagrangian parts in the model is also enabled.

In Abaqus/CAE you can use the global **All* with self** contact domain to enforce contact between all Lagrangian parts and all Eulerian material instances in the model. Alternatively, you can include or exclude contact between a Lagrangian surface and a particular Eulerian material instance. Eulerian material instances appear in the list of surfaces in the **Include Pairs** and **Exclude Pairs** dialog boxes, as shown in *Figure 1*. You can also assign unique contact properties between particular Lagrangian surfaces and particular Eulerian material instances in the **Individual Contact Property Assignments** dialog boxes.

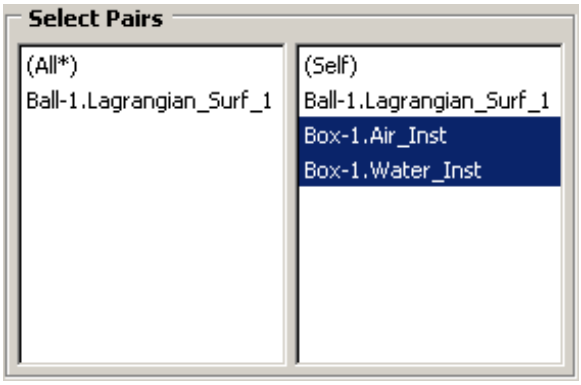

Figure 1: Eulerian material instances in the Edit Excluded Pairs dialog box.

True contact cannot be defined between different Eulerian material instances. A rudimentary contact condition is enforced because material instances cannot penetrate each other. However, material instances do not separate once they come into contact, which prevents the modeling of sliding or rebounding behavior. Contact output is not available for Eulerian material instances. For a detailed discussion of Eulerian analysis contact formulations, refer to *Interactions*. If the contact conditions between two materials are significant to your analysis, at least one of the materials should be modeled as a Lagrangian part.

Assigning materials to Eulerian part instances

In a pure Lagrangian analysis a section definition includes a reference to a single material. When you assign a section to a region or element in the Lagrangian part, that region or element is completely filled with the referenced material. The geometry of the region or element, therefore, defines the geometry of the material.

In a pure Eulerian analysis the relationship between the section definition and material is fundamentally different. An Eulerian section definition can reference a list of materials. When you assign the Eulerian section to an Eulerian part, you are defining which materials may be present in the part over the course of the analysis. The part, however, is initially empty of material. To introduce material to the initial state of an Eulerian part, you must use a material assignment predefined field.

Material assignment predefined fields rely on the concept of material volume fractions. During an Eulerian analysis, Abaqus tracks the material present in each element in terms of a volume fraction assigned to each material instance; the volume fraction represents the percentage of the element's volume that is occupied by a given material instance. For elements that are partially filled or filled with multiple materials, the exact geometric composition of the material within the element is not known; Abaqus interpolates the material volume fractions from adjacent elements to estimate the material boundaries within the element. These calculations are discussed in more detail in *Material Interfaces*.

In Abaqus/CAE the initial material volume fractions in an Eulerian part are specified by creating a material assignment predefined field in the Load module. The predefined field associates each region in an Eulerian part instance with a volume fraction for each material instance. The regions to which volume fractions are assigned can be cells (in geometry), mesh elements, or groups of elements. If you select a cell or a group of elements, the volume fraction values are propagated to each of the underlying Eulerian elements in the cell or group.

Volume fractions in a material assignment predefined field are expressed as a number between zero and one; a volume fraction of one indicates that the region is completely filled with the specified material. A volume fraction of less than one indicates that the region is only partially filled with the specified material; for example, a volume fraction of 0.25 means that the specified material instance occupies 25% of the region. As mentioned previously, Abaqus determines the material boundaries for partially filled elements based on the volume fractions in adjacent elements; to achieve greater control over the material boundaries within a region, you must refine the part mesh or redefine the region boundaries.

If material volume fractions are not defined for a region of an Eulerian part instance, that region is assigned a void. Similarly, if the volume fractions for all materials in a region do not sum to one, the remainder of the volume fraction in that region is assigned a void. Void regions do not have material properties, but other materials can flow into and through a void region during an analysis.

The material assignment predefined field effectively defines the topology of materials in the initial configuration of your model. The Eulerian part is typically arbitrary in shape; the material assignment predefined field adds to the part the Eulerian materials that will interact during the analysis. For example, consider the cross-section of the coupled Eulerian-Lagrangian model in *Figure 1*. The Eulerian part is simply an empty cube. Four regions defined on the part determine the slope of the earth and the amount of water in the tank, and material is assigned to these regions accordingly.

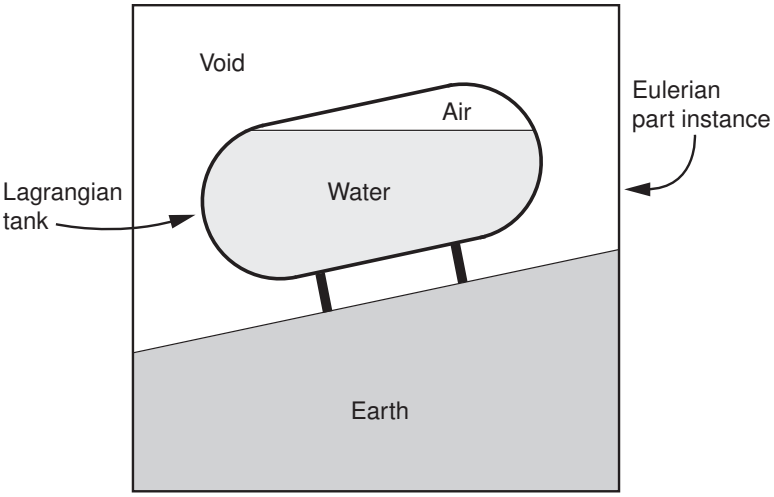

Figure 1: Material assignments in an Eulerian-Lagrangian model.

Material assignment predefined fields can be created only in the initial step of an Eulerian analysis. In subsequent steps the materials deform from their initial configuration and flow across the Eulerian mesh according to the forces present in the model.

Abaqus/CAE offers two techniques for defining material assignment predefined fields:

Uniform definitions

Uniform material assignment field definitions are created by selecting regions from an Eulerian part instance and directly specifying the volume fraction of each material instance within those regions. Geometry must be partitioned into separate cells representing the material regions. In part instances that include orphan elements you can select individual elements to act as regions.

Figure 2 illustrates a material assignment field created using uniform definitions. The Eulerian part is partitioned into three regions, and material volume fractions are defined in each region; each region is completely filled with a single material instance. Volume fractions are not defined for the void region, since void is the default material assignment.

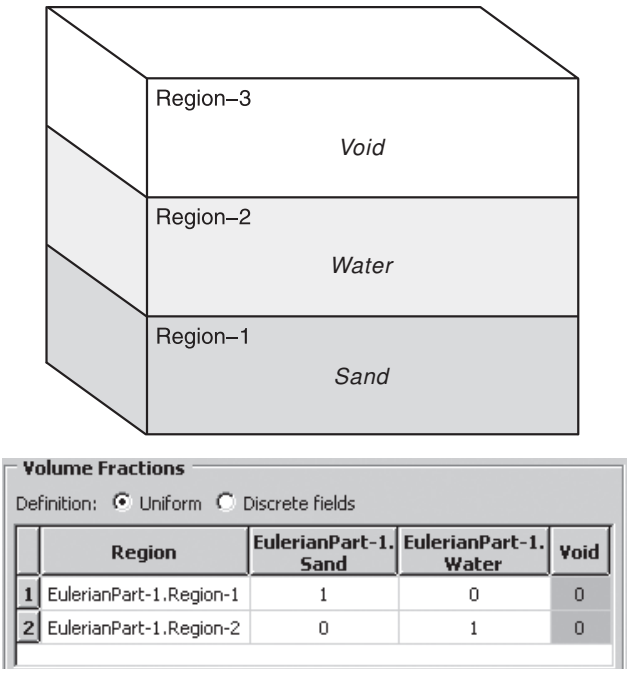

Figure 2: A uniform material assignment field.

The uniform material assignment definition should be used only for relatively simple regions that are uniformly filled with material. The partitions needed to create complex regions can negatively impact the quality of the Eulerian mesh, and partially filled regions are difficult to define and interpret, particularly when working with geometry.

For details on creating a uniform material assignment field in Abaqus/CAE, see *Defining a material assignment field*. An example of a uniform material assignment definition is illustrated in the Python script provided in *Deflection of an elastic dam under water pressure*.

Discrete field definitions

Material assignments for meshed geometry and orphan meshes can be defined using a scalar discrete field. For each material instance in the part you create a discrete field that associates individual elements with a volume fraction for that material instance. For more information on creating discrete fields, see *The Discrete Field toolset*.

When you are assigning materials using a discrete field, you still must select the region of the part instance to which the discrete field applies. If the discrete field includes data for elements outside of the selected region, these data are ignored. The default value associated with the discrete field is assigned to any elements within the selected region that are not explicitly listed in the discrete field.

Figure 3 shows a very simple example of a material assignment defined using discrete fields. The Eulerian part consists of four elements and two material instances. Two discrete fields, as defined in *Table 1*, are used to specify the material composition within the elements. The boundary between the water and the sand is an estimation based on interpolation of the material volume fractions in adjacent elements.

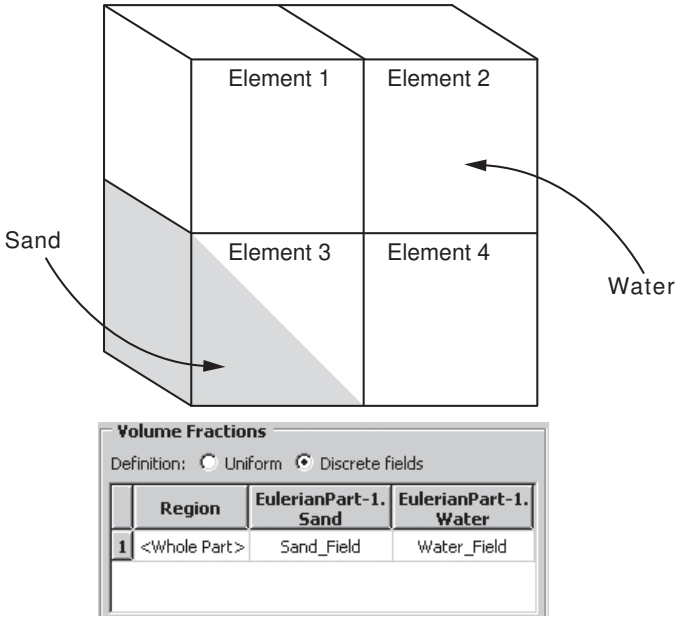

Figure 3: A discrete field material assignment.

Table 1: Volume fractions defined in discrete fields.

Discrete Field	Element 3	Default
Water_Field	0.5	1
Sand_Field	0.5	0

Note:

In any given element the sum of all material volume fractions should not be greater than one. Abaqus/CAE assigns volume fractions incrementally by reading the discrete fields in the **Volume Fractions** table from right to left; once the volume fraction for an element reaches one, additional volume fractions assigned to that element are ignored.

Since the discrete field can assign unique volume fractions to each individual element, it allows more complicated material boundaries than the uniform definition method without the need for excessive partitioning. The volume fraction tool in Abaqus/CAE creates discrete fields specifically for use in material assignment predefined fields. Through this tool, you can define complex Eulerian material regions using the part modeling techniques available in Abaqus/CAE. For more information, see *Using the volume fraction tool*.

For details on creating a discrete field material assignment in Abaqus/CAE, see *Defining a material assignment field*. An example of a discrete field material assignment definition (including the use of the volume fraction tool) is illustrated in the Python script provided in *Rivet forming*.

Using the volume fraction tool

The volume fraction tool creates a scalar discrete field by performing a Boolean comparison between an Eulerian part instance and a second part instance (the reference part instance) that intersects the Eulerian instance.
The comparison determines where the two part instances overlap, then assigns each element in the Eulerian instance a volume fraction based on the percentage of the element that is also occupied by the reference instance. The volume fraction is specified as a decimal between zero and one.

The discrete field that is created by the volume fraction tool can be used to assign material instances to the Eulerian part instance (see *Assigning materials to Eulerian part instances*). The topology of the assigned Eulerian material instance corresponds to the shape of the reference part instance within the Eulerian part instance.

Figure 1 and the following procedure summarize the process of using the volume fraction tool:

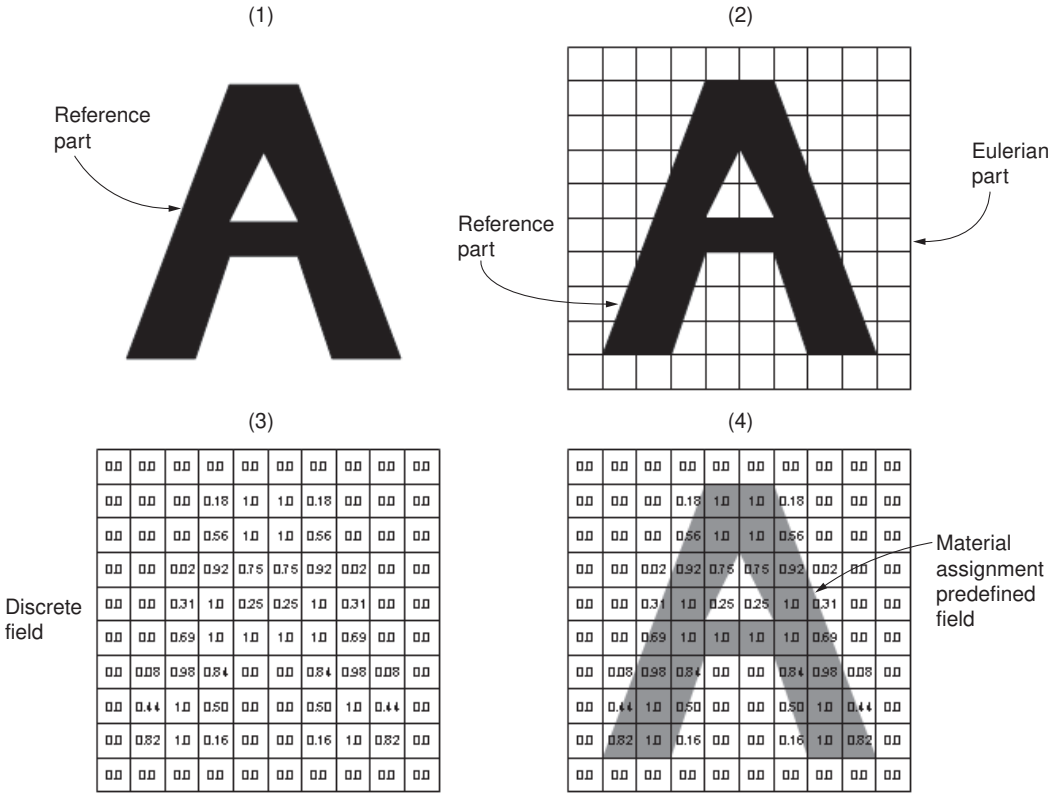

Figure 1: Procedure for using the volume fraction tool.

1. Using any of the modeling tools and techniques in Abaqus/CAE, create a reference part that corresponds to the geometry of the desired Eulerian material region.
2. Instance the reference part within the Eulerian part instance. The reference part instance should spatially correspond to the desired Eulerian material region.
3. Use the volume fraction tool to create a discrete field based on a comparison of the reference part instance and the Eulerian part instance.
4. Define a material assignment predefined field for the Eulerian part instance using the discrete field created by the volume fraction tool.

An option for the volume fraction tool controls whether the calculated discrete field represents the space inside the reference instance (the volume fraction is nonzero in elements that overlap the reference instance) or the space outside

the reference instance (the volume fraction is nonzero in elements that do not overlap or partially overlap the reference instance), as depicted in *Figure 2*.

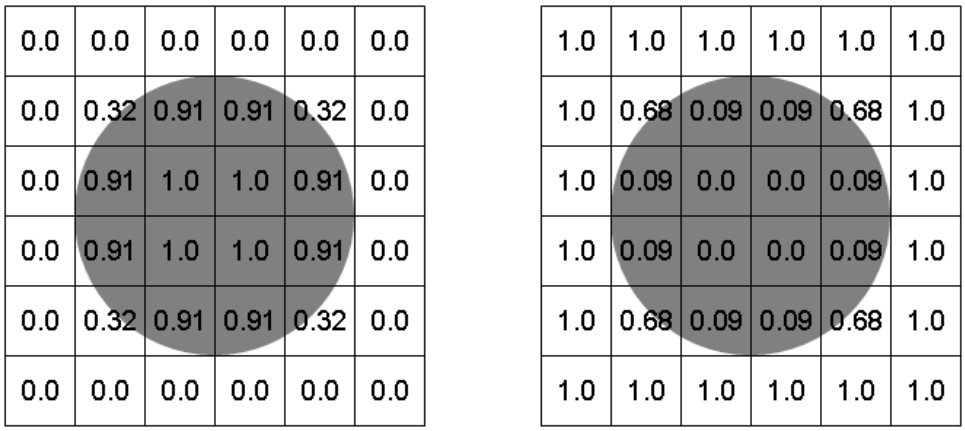

Figure 2: Discrete fields representing volume fractions inside (left) and outside (right) of the shaded reference region.

Typically, calculating the volume fraction outside of a reference instance is used to create an Eulerian material assignment around a Lagrangian part instance in a coupled Eulerian-Lagrangian analysis. Calculating the volume fraction inside of a reference instance is usually used to model complex material assignment fields within a pure Eulerian part instance; in this situation, the reference instance is suppressed after the Eulerian material is assigned. You can also calculate volume fractions inside of a reference instance to create an Eulerian material assignment on the inside of an enclosed Lagrangian shell in a coupled Eulerian-Lagrangian analysis.

To use the volume fraction tool, select **Tools->Discrete Field->Volume Fraction Tool** from the main menu bar. For step-by-step instructions for using the tool, refer to *Creating discrete fields for material volume fractions*.

The Eulerian part instance that is used by the volume fraction tool must be the same instance to which materials are assigned. The Eulerian part must be meshed before using the volume fraction tool. You should not edit the part mesh after creating the discrete field, as the element numbering in the discrete field may not conform to the elements in the updated mesh.

The reference part instance used by the volume fraction tool can include unmeshed geometry, a native mesh, or orphan elements; deformable, Eulerian, and discrete rigid parts are all allowed. The volume fraction tool always uses the mesh representation (if available) of the reference part instance when calculating the discrete field; if the reference instance is partially meshed, only the meshed portion of the instance is considered in the volume fraction calculation. The mesh on the reference instance should be fine enough to capture all important geometric details in the subsequent material assignment.

The reference part instance must be either a three-dimensional solid or a fully enclosed three-dimensional shell. The faces of a shell enclosure must define a single, continuous surface; features that create T-intersections with the surface faces (such as ribs or interior dividing panels) are not allowed (see *Figure 3*). An Eulerian element is considered to be inside a shell reference instance if it lies within the volume enclosed by the shell surface.

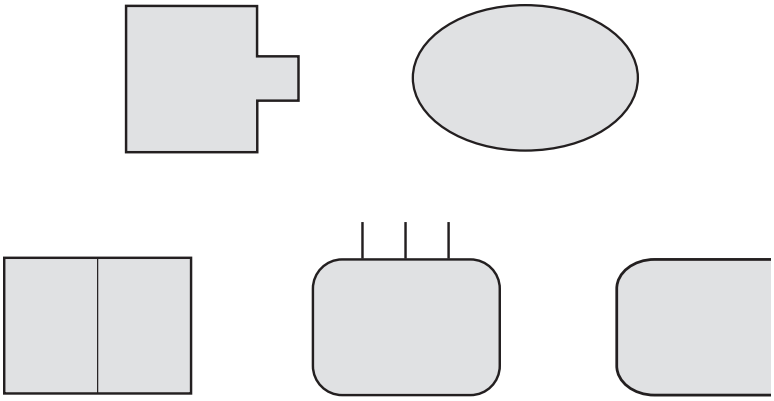

Figure 3: Cross-sections of acceptable reference shell parts (top) and unacceptable reference shell parts (bottom).

Eulerian mesh motion

Eulerian mesh motion is a technique that allows you to reduce the size of an Eulerian mesh for certain models, thereby improving the performance of the analysis. In some cases the Eulerian domain at the beginning of an analysis does not sufficiently capture the deformations in the model by the end of the analysis. Some typical examples include:

- An airbag where the inflator gas is modeled as an Eulerian material: the gas initially occupies a small region, but the region quickly expands as the airbag inflates.
- A projectile impact analysis where the projectile is modeled as an Eulerian material: the projectile initially occupies a region that is far from its ultimate destination.

In such cases it is possible to adjust the size and location of the Eulerian domain during the analysis so that it always captures a part or material of interest. By default, an Eulerian mesh is rigid and fixed in place; but enabling Eulerian mesh motion allows the Eulerian elements to scale and translate during the analysis. Eulerian mesh motion can follow the deformation of an Eulerian material instance (as shown in *Figure 1*) or a Lagrangian surface (as shown in *Figure 2*). The behavior of Eulerian mesh motion is described in detail in *Eulerian Mesh Motion*.

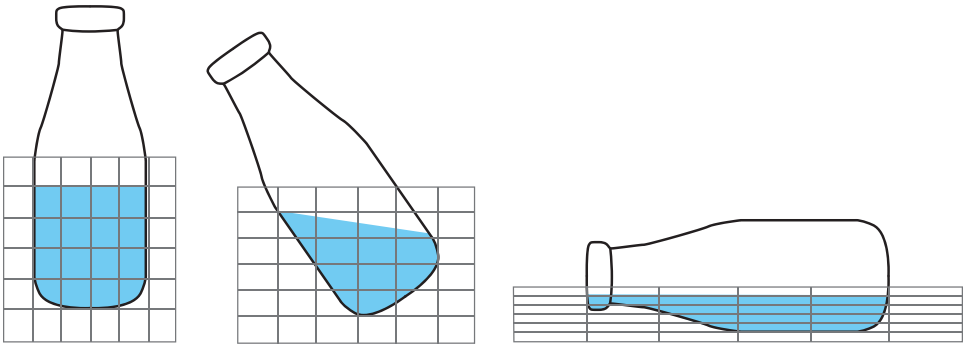

Figure 1: Eulerian mesh motion tracking a material instance.

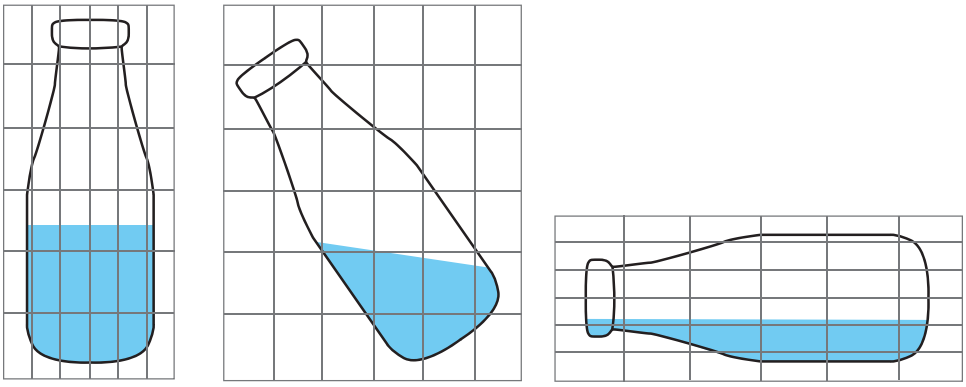

Figure 2: Eulerian mesh motion tracking a Lagrangian surface.

In Abaqus/CAE Eulerian mesh motion is defined as a boundary condition in the Load module. Restrictions can be imposed on the scaling and translation of the Eulerian mesh as part of the boundary condition definition. For more information about creating Eulerian mesh motion boundary conditions, see *Defining an Eulerian mesh motion boundary condition*.

Viewing output from Eulerian analyses

The results of an Eulerian analysis must be interpreted differently than those from a Lagrangian analysis. In particular, any results based on nodal displacements are meaningless in an Eulerian model because the Eulerian part is fixed and rigid. Details concerning how Eulerian results are written to the output database are available in *Output*.

Special steps must be taken in the Visualization module of Abaqus/CAE to view material instances within an Eulerian part. By default, Abaqus/CAE displays the full Eulerian part mesh in both undeformed and deformed plot states with no indication of the material instance boundaries within the mesh.

Visualization of material instances is based on output variable EVF, the Eulerian material volume fraction. Output variable EVF measures the amount of a particular material instance within an element as a relative fraction. An EVF value of one indicates that the element is completely filled with the specified material instance; an EVF value of zero indicates that the element is completely devoid of the specified material instance.

For elements that are partially filled or filled with multiple materials, Abaqus estimates a simple boundary between materials by interpolating the EVF values in adjacent elements. These simple boundaries may be slightly discontinuous across elements. To improve display of Eulerian materials, you should instruct Abaqus/CAE either to use a results averaging threshold of 100% or to compute scalars after averaging results; Abaqus/CAE remaps the material boundaries so they appear smooth and continuous across elements. For more information about results averaging, see *Controlling result averaging*; for a more detailed discussion of how Abaqus calculates Eulerian material boundaries, see *Material Interfaces*.

Output variable EVF is written to the output database if you request the **Preselected defaults** in the field output request editor (see *Modifying field output requests*). When you request output for EVF, Abaqus creates a separate material volume fraction output variable for each material instance in the model; for example, `EVF_WATER` is the volume fraction for the material instance named `Water`. An output variable named `EVF_VOID` is created to measure the volume fraction of empty regions in an Eulerian part.

The following techniques can be used in the Visualization module to view the initial and deformed states of material in an Eulerian part:

Contour plots

A contour plot of output variable EVF for a particular material instance allows you to visualize which areas of the model are occupied by the material during the analysis. Areas occupied by the material (EVF equal to one) appear as a uniform color from the top of the contour spectrum, while areas unoccupied by the material appear as a different color from the bottom of the contour spectrum; depending on your contour plot settings, the boundary of the material instance appears in a range of colors as EVF transitions from one to zero (see *Figure 1*).

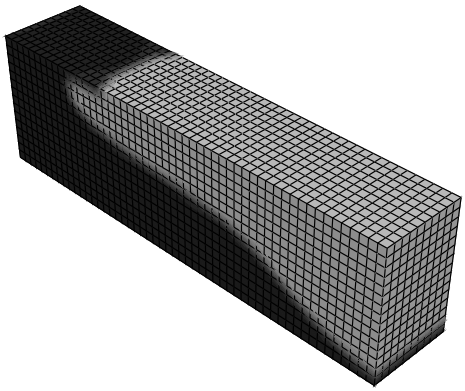

Figure 1: Contour plot of an Eulerian material instance.

Contour plots are of limited usefulness when visualizing Eulerian materials because the contours appear on the faces of the Eulerian parts. You cannot effectively visualize material volume fraction contours on the interior of Eulerian parts.

For further details on using contour plots in the Visualization module, see *Contouring analysis results*.

View cuts

To visualize the behavior of a material on the interior of an Eulerian part, activate a view cut along an isosurface of the EVF variable associated with that material instance. Abaqus/CAE automatically creates these isosurface view cuts for each material instance in the model, but you must activate them in the **View Cut Manager**. Using the view cut options, you can eliminate portions of the part that do not include a selected material by rendering them unfilled, rendering them translucent, or removing them from the display (see *Figure 2*).

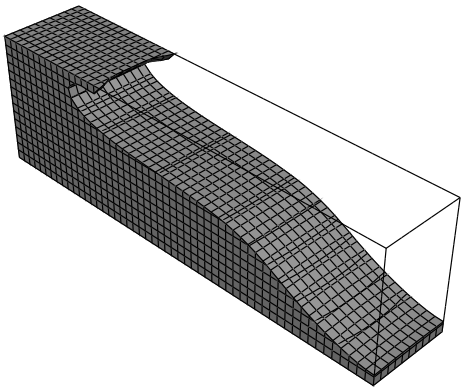

Figure 2: View cut along an Eulerian material instance isosurface.

If your Eulerian part includes regions without a material assignment, it may be helpful to activate an isosurface view cut based on the `EVF_VOID` output variable. By cutting away all regions in which `EVF_VOID` is greater than `0.5`, you are able to see the shape of materials within the part.

After activating an isosurface view cut based on the EVF variable, you can change the primary field output variable without affecting the view cut. This enables you to visualize results contours along the boundaries of material instances instead of on Eulerian part faces (see *Figure 3*).

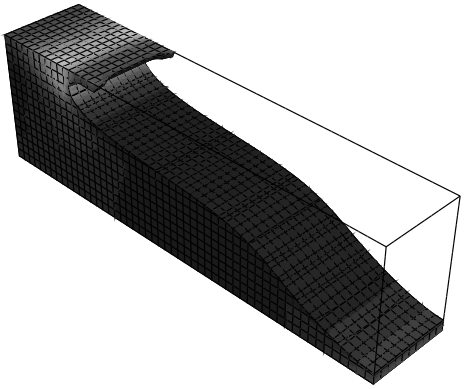

Figure 3: Contour plot of stresses in a cut Eulerian part.

Isosurface view cuts based on output variable EVF do not affect Lagrangian part instances in a coupled Eulerian-Lagrangian model. The Lagrangian parts remain visible when the cut is active. Therefore, this technique is useful for visualizing the interaction between a Lagrangian part and an Eulerian material instance.

For further details on using view cuts in the Visualization module, see *Cutting through a model*.

Combining view cuts and contour plots

In an Eulerian part that includes three material instances, you can use a combination of view cuts and contour plots to distinguish material instances in the undeformed and deformed model states. First, use an isosurface view cut to remove one of the material instances from the display, as discussed above. Then, create a contour plot of output variable EVF for one of the remaining material instances. The resulting colors in the model distinguish one material from the other. To produce a more defined boundary between the materials, you can reduce the number of contour intervals to two.

For example, *Figure 4* depicts an Eulerian model of a lead projectile impacting a brass plate. The void regions of the Eulerian part are cut away. A two-interval contour plot is applied, rendering the brass in one color and the lead (i.e., not brass) in another color. The resulting plot offers a useful generalization of the deformed shape of the projectile and plate.

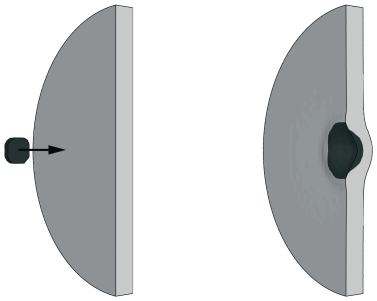

Figure 4: A contour plot is used to distinguished two Eulerian materials in a projectile impact analysis.

Currently there is no way to visually distinguish more than three Eulerian material instances simultaneously using Abaqus/CAE.

Color coding

Color coding cannot be used to visualize material behavior in Eulerian parts. The color coding tool in Abaqus/CAE does not recognize Eulerian section or material assignments. Color coding based on element sets is also ineffective for deformed shape plots because the Eulerian elements do not deform with the material.

However, in coupled Eulerian-Lagrangian models, color coding can distinguish between Eulerian and Lagrangian part instances or Eulerian and Lagrangian element types. When used with the visualization techniques discussed above, color coding can be helpful in distinguishing Lagrangian bodies from Eulerian materials in a model.

For further details on applying color coding to a model, see *Color coding geometry and mesh elements*.

Display groups

Certain types of coupled Eulerian-Lagrangian models involve a single Eulerian material instance throughout the Eulerian part; for example, a Lagrangian penetrator moving through a uniform Eulerian material. In these analyses the deformation of the Eulerian material is not as important as the interaction between the Eulerian material and the Lagrangian body. You can use a display group to remove the Eulerian elements from the display and visualize results (such as contact pressure or stress) on only the Lagrangian body.

For further details on using display groups, see *Using display groups to display subsets of your model*.

Fasteners

This section describes how to model fasteners.

In this section:

- *About fasteners*
- *Managing fasteners*
- *Creating point-based fasteners*
- *Creating discrete fasteners*
- *Creating assembled fasteners*

About fasteners

You use fasteners to model a point-to-point connection between two or more faces, such as a spot weld, a bolt, or a rivet.
You can use the Attachment toolset to create attachments that help you define fasteners; for more information, see *Understanding attachment points and lines*. You can create point-based fasteners, discrete fasteners, or assembled fasteners.

Both point-based and discrete fasteners can be modeled using connectors or beam MPCs. If you define connectors that use basic, assembled, or complex connection types, you can request output from your point-based or discrete fasteners through connector output variables. However, if you use beam MPCs, no output is available from your point-based or discrete fasteners.

In this section:

- *About point-based fasteners*
- *About discrete fasteners*
- *About assembled fasteners*

About point-based fasteners

Point-based fasteners make use of positioning points to create mesh-independent fasteners in Abaqus/Standard and Abaqus/Explicit, as described in *Mesh-Independent Fasteners*. A positioning point can be an attachment point, a reference point, or a node from an orphan mesh. Point-based fasteners modeling spot welds around the edge of a bracket are shown in *Figure 1*. The user first created attachment points at equally spaced intervals around the edge of the bracket. The attachment points were used to define the location of the fastener's positioning points.

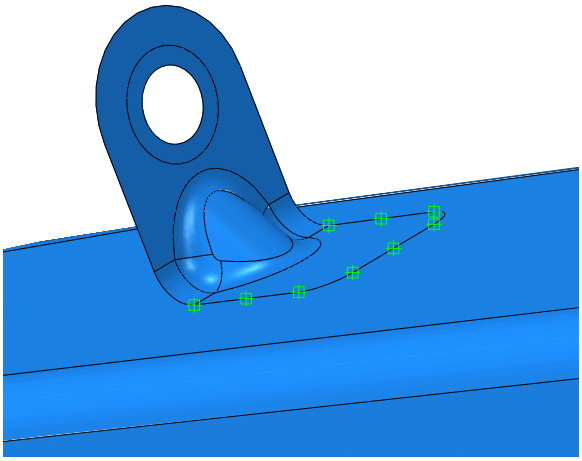

Figure 1: Point-based fasteners modeling spot welds.

A point-based fastener can connect selected faces with either connectors or rigid (beam) multi-point constraints. If you want to model a rigid connection, you can use rigid connectors or rigid multi-point constraints.

Connectors

If you use connectors to connect the faces, you can model either rigid, elastic, or inelastic connections with failure by using the generality of connector behavior definitions. You can use a rigid connector to model a rigid connection. However, if you are using rigid connectors and Abaqus detects two adjacent point-based fasteners that are sharing nodes, you must avoid overconstraining your model by defining some elasticity in the connector behavior to reduce the stiffness.

You can request output from connectors.

Rigid (beam) multi-point constraints

Rigid multi-point constraints are computationally cheaper than connectors and are less likely to result in an overconstrained model when two adjacent fasteners are sharing nodes. When Abaqus detects two adjacent fasteners that are sharing nodes and using rigid multi-point constraints, it uses a penalty distributing coupling formulation that relaxes, to a small degree, the constraint between the motion of the fastening point and its coupling nodes to avoid the overconstraint.

You cannot request output from multi-point constraints.

A point-based fastener uses distributing coupling constraints to connect the faces regardless of how you mesh the faces. When you submit a job for analysis, Abaqus uses your fastener definition to connect the faces with couplings and connectors. When you open the output database file in the Visualization module, you can display the couplings and connectors; however, outside the Visualization module, symbols are displayed only for the positioning points of the point-based fasteners.

If your model contains many fasteners (more than a thousand), point-based fasteners offer better performance than discrete fasteners. In addition, you may want to use point-based fasteners if you have a file from a CAD system that defines the coordinates of each positioning point. Point-based fasteners are available only for three-dimensional models. Point-based fasteners are used to model mesh-independent fasteners as described in *Mesh-Independent Fasteners*.

You can use the following two methods to create a point-based fastener, as shown in *Figure 2*:

- Select a positioning point and allow Abaqus/CAE to project the point to the closest face along a normal to the surface. The first fastening point is created where the normal intersects the closest face.
- Select a positioning point and specify the direction vector along which the point is projected. The first fastening point is created where the vector intersects the closest face.

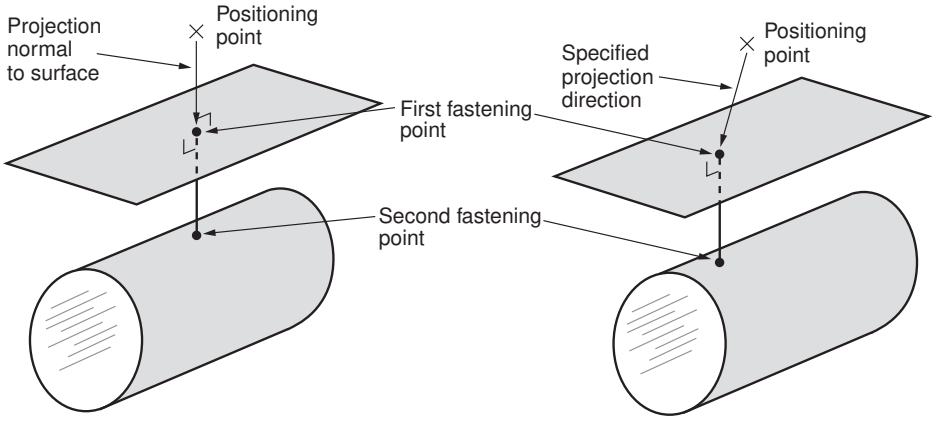

Figure 2: Creating point-based fasteners.

Abaqus creates the second (and subsequent) fastening points when you submit the job for analysis by projecting the first fastening point onto the other surfaces to be connected along the normal to the closest face.

About discrete fasteners

Discrete fasteners make use of attachment lines to create connectors and couplings between selected faces in Abaqus/Standard and Abaqus/Explicit. *Figure 1* shows a discrete fastener that uses attachment lines and connectors (**Beam** connection type) to model a spot weld across three surfaces. The user first created attachment lines at the locations of the spot welds. The attachment lines were used to define the location of the discrete fastener.

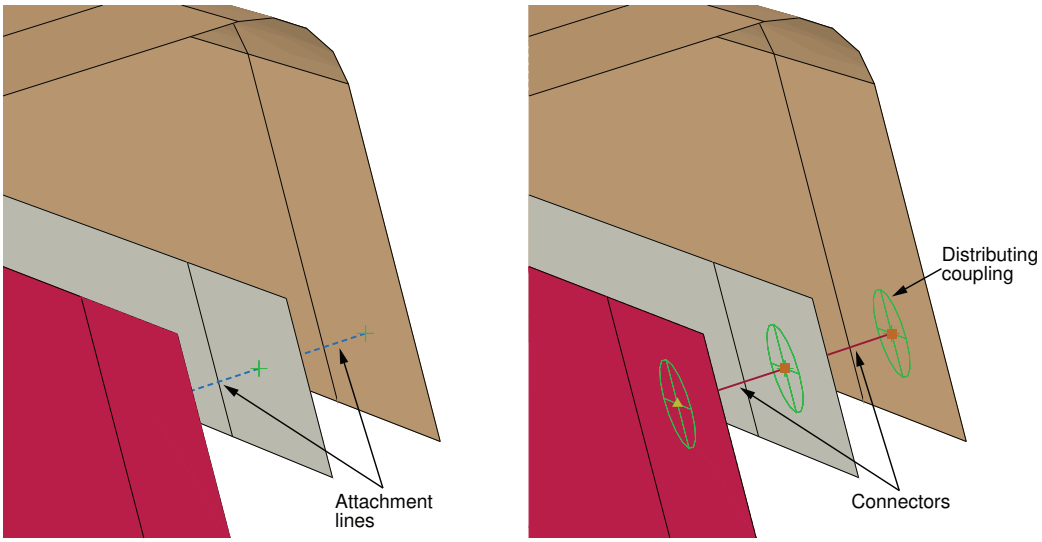

Figure 1: A spot weld across three surfaces modeled with a discrete fastener.

The process of creating an attachment line is similar to the process of creating point-based fasteners. You select a starting point and specify which of the two methods Abaqus/CAE will use to project the point onto the closest face. *Figure 2* shows the two methods for creating an attachment line that is used to define a discrete fastener.

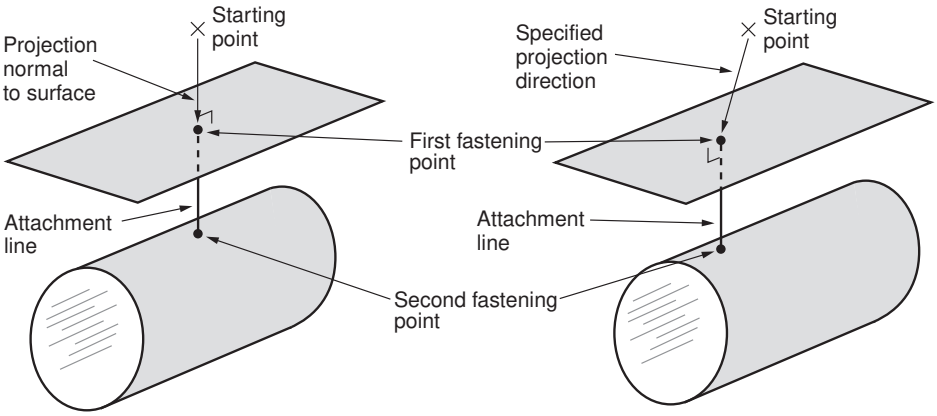

Figure 2: Creating an attachment line that is used to define a discrete fastener.

Abaqus/CAE projects the attachment line along a normal to the closest face. You can use the following two methods to determine the number of faces that are connected by the attachment line:

- Specify the number of projections or layers.
- Specify the maximum length of the projection.

For each attachment line, Abaqus/CAE determines the fastening points and applies a distributing coupling between each fastening point and its corresponding surface. After you assign a connector section to the attachment line, Abaqus/CAE creates a connector, and the discrete fastener is considered to be fully defined. You can control the

accuracy of the attachment line position on a faceted representation of a part instance by specifying the level of curve refinement in the Part module and the Property module. For more information, see *Controlling curve refinement*.

If your model is complex, Abaqus/CAE can create a chain of attachment lines connecting multiple surfaces that would be time consuming to create manually. In contrast with point-based fasteners, you can view attachment lines and discrete fasteners and their connectors and couplings outside the Visualization module.

If two surfaces are used by two attachment lines and share a common face, Abaqus/CAE merges the two faces into a single face when you submit the model for analysis. This results in better performance by Abaqus/Standard or Abaqus/Explicit, especially when the fasteners connect nodes across faces of a refined orphan mesh.

When you submit a job that contains a model with discrete fasteners for analysis, Abaqus/CAE writes special comment lines to the input file. These special comment lines, which are ignored by the Abaqus solvers, allow Abaqus/CAE to recreate the fully defined discrete fasteners upon import into Abaqus/CAE. For more information, see *Importing interactions, constraints, and fasteners*.

An example of creating discrete fasteners is illustrated in the Python script included in *Buckling of a column with spot welds*.

About assembled fasteners

Assembled fasteners let you efficiently assign complex fastener behaviors in a large number of model locations.

In this section:

- *The assembled fastener technique*
- *Using property generation scripts for assembled fasteners*
- *Output requests for assembled fasteners*
- *Assembled fasteners vs. point-based fasteners*

The assembled fastener technique

Using the assembled fastener technique, you can read in connector and constraint behaviors from a template model and assign these attributes in multiple locations in your main model.
For a large system such as an airframe or automobile, assembled fasteners allow you to define the fastener template once and then assign it many times in the main model. With the appropriate use of coupling constraints and adjust points constraints, secondary nodes in the template model can be automatically resized in the main model to accommodate the actual surface spacing.

The overall process for building assembled fasteners is as follows:

1. Build the template model containing your fastener-like construct: connector section assignments, tie constraints, coupling constraints, and solid or beam section assignments. You must assign names to all surfaces involved in constraints. You must also define a single-point set as the control point, which will be used to locate the template model copies in the main model.
2. Develop your main model, placing attachment points at the locations where you want the template fastener to be replicated. The template model control point will be mapped onto the locations of the attachment points in the main model (see *Figure 1*).
3. Working in your main model, use the **Create Fasteners** and **Edit Fasteners** dialog boxes to define how the template model will be read in, assigned, and oriented.
4. Optionally, use one or more property generation scripts to modify the properties copied into the main model from the template model. Multiple property generation scripts can be used with the same template model to achieve different results in separate assembled fastener objects. For example, you could use two scripts to apply different materials to the same fastener template. You can use the Abaqus Scripting Interface to write your property generation scripts; see *Creating and running your own scripts*, and the *Abaqus Scripting User's Guide*.

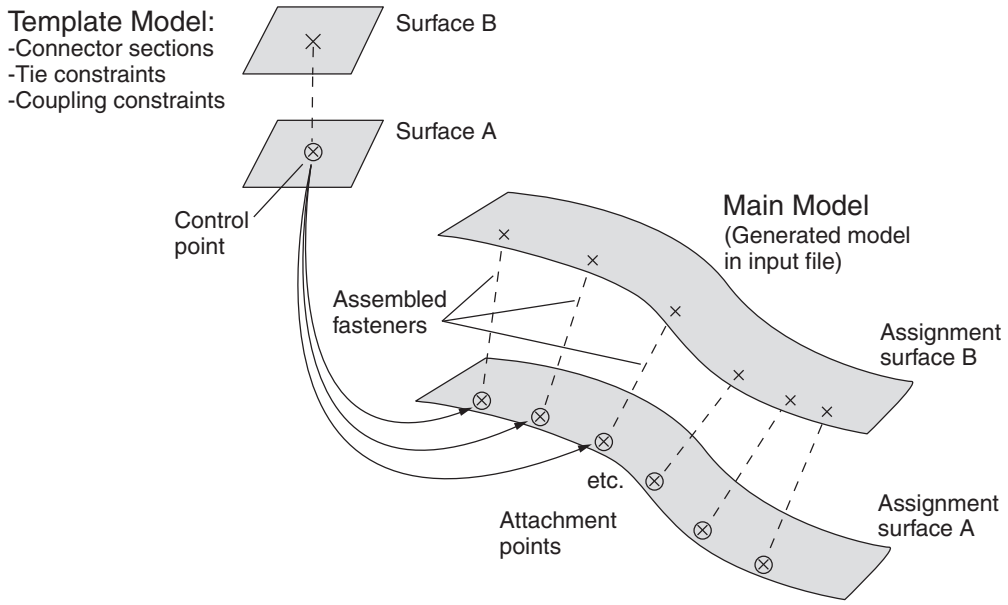

Figure 1: Replicating the template model in the main model.

The template model uses the global coordinate system, and the positive *Z*-axis direction of the fastener construct will be aligned with the selected normal direction in the main model.

Assembled fasteners are different from point-based (mesh-independent) and discrete fasteners in Abaqus/CAE. Assembled fasteners do not create individual fastener objects like point-based and discrete fasteners, but instead they allow you replicate fastener-like behavior in many places. You cannot view or manipulate the individual fasteners (at

each attachment point) in the main model while working in the Abaqus/CAEGUI; they are produced only in the input file generated by Abaqus/CAE. The template model sets are aggregated in the input file generated by Abaqus/CAE to help you manage models containing large numbers of assembled fasteners.

Assembled fastener template models are intended only to model fastener-like constructs and do not provide a generic subassembly capability. Only a few Abaqus/CAE features are supported in template models, such as connectors and mass inertia. No other Abaqus/CAE features are allowed in template models.

Table 1 lists the features that are supported and read from the template model into the main model. The actual model data are not transferred, only the constraints and behaviors.

Table 1: Features supported in assembled fastener template models.

Beam and solid parts (beam, solid, and cohesive elements)
Beam and solid section assignments (but not distributions or composite layups)
Connector section assignments
Tie constraints and coupling constraints (except for tie constraints generated due to incompatible meshes)
Adjust points constraints
Mass inertia

In particular, the Abaqus/CAE features and attributes listed in *Table 2* are not supported by assembled fasteners and are not read in from the template model.

Table 2: Features that are not supported in assembled fastener template models.

Point-based (mesh-independent) and discrete fasteners
Attachment points
Analytical rigid surfaces
Orphan mesh surfaces
Tie constraints generated internally due to incompatible meshes
Any constraint type other than tie, coupling, or adjust points

In addition, the following restrictions exist:

- Solid parts are allowed in the template model but material orientations are not.
- Beam parts are allowed in the template model, but beam orientations must be assigned using the same region as the beam section assignment.
- Solid and beam parts are allowed, but complex parts/assemblies may not work.
- Unmeshed constraint surfaces in the template model are allowed.
- Shell parts are not allowed in the template model, except as reference surfaces for constraints. These constraint surfaces will effectively be replaced with main model surfaces when the input file is generated by Abaqus/CAE. All constraint surfaces should be substituted with main model surfaces for correct behavior of the assembled fastener.
- Template model surfaces are not copied into the main model when the input file is generated by Abaqus/CAE. The only surfaces allowed in the template model are those that will have main model surfaces substituted for them.
- Constraint surfaces cannot be orphan mesh surfaces.
- Reference points are allowed in template models, but attachment points are not allowed.
- The modeling space of the template models must match the modeling space of the main model (see *Part modeling space*).

- Coupling constraints in the template model must constrain all degrees of freedom and must not specify a local coordinate system.
- Tie constraints in the template model must use a generic main surface and a secondary node region, not a secondary surface.
- Point mass and rotary inertia features are allowed in template models. However, for rotary inertia the local coordinate system will be ignored; thus, the only useful scenario is $I_{11} = I_{22} = I_{33}$, and $I_{12} = I_{13} = I_{23} = 0$. Essentially, the rotary inertia feature must have rotational symmetry.

The control point must be a predefined set containing a single vertex or node in your template model. You must create this set in the template model before creating the assembled fasteners in your main model. When the template model is read in, the control point will be placed at the locations of your attachment points in the main model.

The constraint surfaces in the template model must be mapped to corresponding surfaces in the main model to enable the constraint behavior in the main model. When you define the assembled fasteners in the main model, the **Edit Fastener** dialog box will automatically prepopulate the surface assignment table with any template model surfaces involved in tie constraints, coupling constraints, or adjust points constraints. The template surfaces are initially listed in ascending *Z*-axis order using the template model global coordinate system. You can change the order to coincide with your template fastener design; however, the ordering of the surfaces is not significant beyond the selection of the first surface, because the corresponding assignment surface normal is used to orient the assembled fastener. In the main model you must assign names to the surfaces that will be involved in the assembled fastener constraints.

At each attachment point in the main model, the template model is positioned and translated so that the template model control point coincides with the attachment point. The template model is rotated into the main model and oriented such that the positive *Z*-axis of the global coordinate system of the template model aligns with the coordinate system you specify (on the **Orientations** tabbed page of the **Edit Fasteners** dialog box). The default is to orient the template model copies according to the normal vector of the first surface in the main model. This default orientation from the first surface normal creates a *Z*-axis alignment at every attachment point. The *X*-axis is then computed by projecting the global *X*-axis onto the surface.

For any sets that you create in the template model, the main model will aggregate all of the sets' objects into a single set per assembled fastener. When the input file is generated by Abaqus/CAE, template model sets will be aggregated across all attachment points of the assembled fastener. For example, consider a template model that contains a connector section assignment for a wire set named *Wire-1-Set-1*, and that set contains a single wire. If the assembled fastener is then placed at 10 attachment points in the main model, the main model will have a set named *TM-1_Wire-1-Set-1* that contains 10 wires. However, Abaqus/CAE generates these aggregated sets only when it creates the input file. The aggregated sets are not directly visible in Abaqus/CAE.

Note:

The **Adjust control point to lie on surface** option can be useful in coupling constraints you create in assembled fastener template models; see *Defining coupling constraints*. The more general-purpose adjust points constraint can also be useful in assembled fastener template models; see *Defining adjust points constraints*.

The adjust points capability should not be used in assembled fastener template models when the main model attachment points are located at bolt hole center points. Any point along the bolt hole centerline will be moved (incorrectly) to a random location along the perimeter of the hole instead of being projected along the surface normal to the center of the hole.

Note: The size and shape of the template model surfaces do not matter, except with regard to the display of those surfaces during template model rendering from the **Edit Fasteners** dialog box. The recommended best practice is to make your template model surfaces square or rectangular in shape to facilitate rendering speed and accuracy in the main model. Circular template model surfaces or surfaces with any curvature will be rendered in a crudely approximate fashion in the main model.

Using property generation scripts for assembled fasteners

This section discusses how to use property generation scripts to modify template model properties.

In this section:

- *Property generation scripts*
- *Example property generation script*
- *Registering the property generation script*

Property generation scripts

Each assembled fastener can optionally reference a script that will modify the template model properties; for example, to use different materials in the assembled fasteners. These property generation scripts can be used to calibrate or adjust the fastener properties.
In Abaqus/CAE property definitions include material, profile, section, and connector section definitions.

You can use the Abaqus Scripting Interface to write your property generation scripts; see *Creating and running your own scripts*, and the *Abaqus Scripting User's Guide*.

This feature lets you use the same template model multiple times with different property generation scripts. The property definitions from the template model are copied into the main model and given names based on the original names plus a prefix. The default prefix is *TM-1* for the first assembled fastener you create, and *TM-2*, *TM-3*, etc., for subsequent ones. For example, a connector section named *BoltSection* in the template model will be named *TM-1_BoltSection* in the main model. You can change the prefix on the **Properties** tabbed page of the **Edit Fasteners** dialog box. Property prefix strings must be unique for all assembled fasteners you create.

Figure 1 shows an example in which two template models are used with three different property generation scripts.

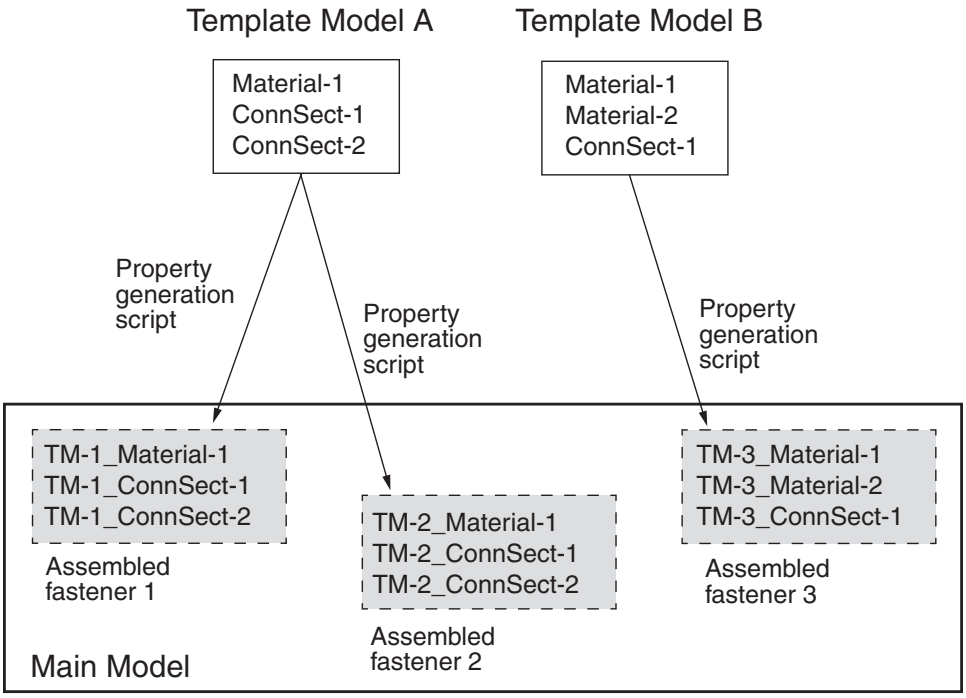

Figure 1: Using multiple property generation scripts.

Example property generation script

A complete example of a property generation script is provided in the blog post “Property generation scripts for assembled fasteners in Abaqus/CAE” in the *https://www.3ds.com/products-services/simulia/simulia-academic-program/learning-community/*. The script uses a method named `getSurfaceSections` that is useful for assembled fastener property scripts. This method accepts a surface name and returns a list of all section names found on the geometry underlying the named surface region; see *Assembly object*. The `getSurfaceSections` method can be used to obtain section information such as the material name and thickness, as shown in the code fragment below.

```
    def __init__(self, scriptName, modelName, fastenerName):
        self.scriptName   = scriptName
        self.modelName    = modelName
        self.fastenerName = fastenerName
        print 'Running script "%s" for "%s"' % (scriptName,
          fastenerName)
        assy = mdb.models[modelName].rootAssembly
        eo = assy.engineeringFeatures.fasteners[fastenerName]
        print eo.assignedSurfaces
        diameter = getInput('Enter %s bolt diameter:' % scriptName)
        print '  Bolt diameter: %s' % diameter
        for aSurf in eo.assignedSurfaces:
            sectNames = assy.getSurfaceSections(aSurf)
            print '  %s: %s' % (aSurf, sectNames)
            # No section assigned
            if (len(sectNames) > 0 and sectNames[0] == ''):
                continue
            for section in sectNames:
                sectObj = mdb.models[modelName].sections[section]
                if (type(sectObj) == HomogeneousShellSectionType):
                    print '    %s:  mat=%s, thk=%s' % \
                        (section, sectObj.material, sectObj.thickness)
```

Registering the property generation script

You provide the file name of the property generation script on the **Properties** tabbed page of the **Edit Fasteners** dialog box. The script is executed only when you click **OK** in the **Edit Fasteners** dialog box, not when Abaqus/CAE creates the input file. The property generation script is run only in the main model on the assembled fasteners, not in the template model.

To make your property generation scripts available from the **Edit Fasteners** dialog box, you must register each script similar to the way in which you register an Abaqus/CAE plug-in. The script must be registered before you startAbaqus/CAE. Any scripts that have been registered will be available from a pull-down list in the **Edit Fasteners** dialog box.

To register a property generation script, you must write a small registration script containing the following lines:

```
from abaqusGui import *
toolset = getAFXApp().getAFXMainWindow().getPluginToolset()
toolset.registerAsmbdFastenerScript('filename')
```

This registration script file must be named `registerAsmbFstnrScripts_plugin.py`. In the code replace *filename* with the name of your property generation script. The registration script informs Abaqus/CAE that you have a property generation script named *filename*`.py` that you wish to use with assembled fasteners.

Your property generation scripts and the registration script must be placed in your `abaqus_plugins` directory; see *Where are plug-in files stored?*, for the possible locations of the `abaqus_plugins` directory. For more details about registration scripts, see *What are the kernel and GUI registration commands?*.

Output requests for assembled fasteners

You can obtain both field output and history output from assembled fasteners in your main model. The output must be requested on named sets that you have defined in the template model.

1. In the Step module, working in your main model (not the template model), display the **Edit History Output Request** dialog box or the **Edit Field Output Request** dialog box; see the instructions in *Creating and modifying output requests*.
2. From the **Domain** list, choose **Assembled fastener set**.
3. From the **Fastener** list, choose the name of the assembled fastener for which you want output.
4. From the **Set** list, choose any set from the template model. The assembled fastener in your main model references the sets defined in the template model.
5. Continue selecting output variables and other options, and click **OK** to save your request.

Additional information

- *Creating assembled fasteners*
- *Understanding output requests*

Assembled fasteners vs. point-based fasteners

Assembled fasteners and point-based (mesh-independent) fasteners produce slightly different analysis results when used for the same fastener model. Assembled fasteners and point-based fasteners will generate different coupling nodes and coupling weights, leading to different solutions. The differences between point-based and assembled fasteners are described below and in *Figure 1* and *Figure 2*.

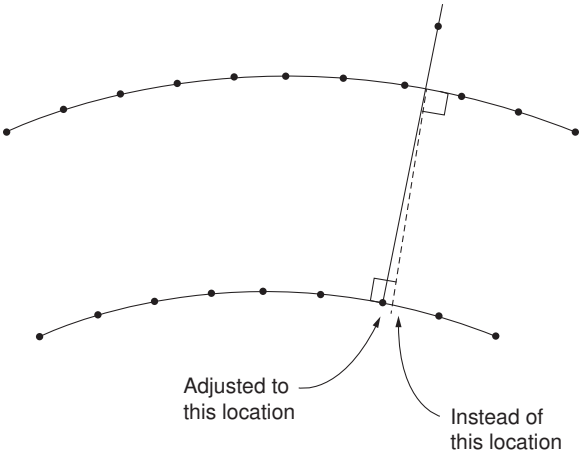

Figure 1: Adjustments for assembled fasteners vs. point-based fasteners.

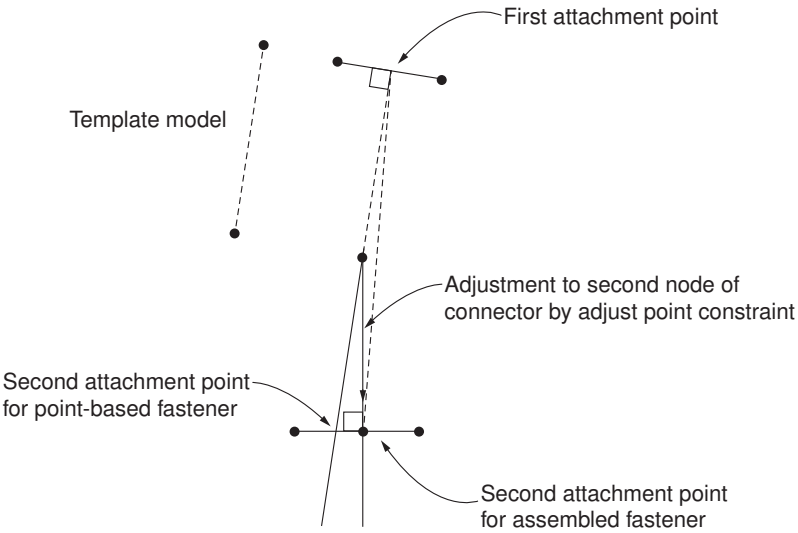

Figure 2: Location of attachment point for assembled fasteners vs. point-based fasteners.

Point-based fasteners

Abaqus looks at the first node of the connector and projects it onto the first surface (given the data line). Abaqus then moves normal to the facet, where it finds the first projection point and finds the subsequent projection points on the second surface.

Assembled fasteners

When the assembled fastener is instanced in the main model, Abaqus places the first node of the connector where the first projection point of the point-based fastener model is located. Both fastener types accomplish this

placement with normal projections. However, for assembled fasteners an adjust point constraint is performed on the second node of the connector; i.e., a normal projection onto the second surface. This action is not the same as moving normal to the first projection point facet unless the two normals align perfectly. Therefore, the second (subsequent) attachment points can be different for assembled fasteners versus point-based fasteners, which will lead to differences in the analysis solution.

In an ideal case where the two surfaces are placed exactly the same distance apart as the template model connector and are parallel to each other, Abaqus will get the same projection points for assembled fasteners and point-based fasteners. However, this situation will not be the case in general.

Managing fasteners

The **Fasteners Manager** allows you to create and manage fasteners. The manager includes a list of the names and types of fasteners that you have defined. The **Create**, **Edit**, **Copy**, **Rename**, and **Delete** buttons in the manager allow you to create new fasteners or to edit, copy, rename, and delete existing ones. The icons in the column along the left side of the manager allow you to suppress and resume existing fasteners. You can also initiate these procedures using the **Special->Fasteners** menu from the main menu bar in the Interaction module. After you select a management operation from the main menu bar, the procedure is exactly the same as if you had clicked the corresponding button inside the manager dialog box.

Additional information

- *Suppressing and resuming objects*
- *Creating point-based fasteners*
- *Creating discrete fasteners*

Creating point-based fasteners

You can create point-based fasteners in the Interaction module by picking each positioning point from the viewport or by reading the coordinates of the positioning points from a file.
You can allow Abaqus/CAE to project the positioning point to the closest face along a normal to the surface, or you can specify the direction vector along which the point is projected to the closest face. For more information, see *About fasteners*.

In this section:

- *Defining the surfaces where fasteners will be connected*
- *Defining the fastener attachment zone*
- *Defining the fastener properties*
- *Defining the fastener formulation*
- *Adjusting the fastener definition*

Defining the surfaces where fasteners will be connected

You use the **Domain** tabbed page to edit the positioning points and to select the target surfaces onto which Abaqus/CAE projects the points and the vector along which the points are projected.

1. From the **Edit Fasteners** dialog box, display the **Domain** tabbed page.
2. Choose the direction vector along which the positioning points will be projected onto the target surface.
   - By default, Abaqus/CAE creates the direction vector along which the positioning points will be projected along the normal to the closest face.
   - To change the direction vector, toggle on **Specify**, click , and select the points representing the start and end of the direction vector. Abaqus/CAE displays the direction vector.
3. Select the approach for the target surfaces.
   - Choose **Whole model** to use all of the surfaces in the model as the target surfaces.
   - Choose **Fasten specified surfaces by proximity** to specify the surfaces to be connected. The fastening point connectivity is defined by the relative positions of the surfaces along the direction vector.
   - Choose **Fasten in specified order** to specify a particular order of the target surfaces. The fastening point connectivity is determined by the direction vector.
4. Double click the first row in the target surfaces table, and select surfaces in the viewport. Click **Done** in the prompt area to indicate you have finished the surface selection.

   You can select multiple surfaces from the viewport to define a single surface region.
5. Click mouse button 3 anywhere on the target surfaces table to edit the selected surface, add a new surface, or delete a surface.

Additional information

- *Mesh-Independent Fasteners*
- *About fasteners*
- *Understanding attachment points and lines*

Defining the fastener attachment zone

You use the **Criteria** tabbed page to specify parameters that Abaqus uses to determine where to project the fasteners when you analyze the model.

1. From the **Edit Fasteners** dialog box, display the **Criteria** tabbed page.
2. Choose the **Attachment method**. In general, a positioning point should be located as close to the surfaces being connected as possible. Abaqus determines the actual fastening points where the fasteners are attached to the surfaces being connected by first projecting the positioning point onto the closest surface. You can choose from the following projection methods:

   - **Face-to-Face**
   - **Face-to-Edge**
   - **Edge-to-Face**
   - **Edge-to-Edge**

   The method that you should choose depends on how the surfaces are oriented relative to each other. For more information, see *Specifying the Positioning Points, Projection Method, and Fastening Points*.
3. Choose the method for specifying the distance from the positioning points within which the fastening points must lie.

   - Choose **Facet-based default** to allow Abaqus to compute a default search radius based on the facet thickness (for shell elements) or characteristic facet length (for non-shell elements) in the vicinity of each positioning point.
   - Choose **Specify**, and enter the maximum distance from the positioning point within which the fastening points will lie.

   For more information, see *Forming Fasteners on Surfaces inside a User-Specified Search Zone*.
4. Choose the maximum number of layers through which the fastening points will be projected.

   - Choose **All** to allow Abaqus to use the maximum possible number of layers.
   - Choose **Specify**, and enter the number of layers.

Additional information

• *Mesh-Independent Fasteners*
• *About fasteners*
• *Understanding attachment points and lines*

Defining the fastener properties

You use the **Property** tabbed page to define the radius of the fastener. You can also specify the connector section and the orientation of the local directions at each end of the connector.
Depending on the connection type, a local orientation for the first node of the connector is required, optional, or not applicable. Depending on the connection type, a local orientation for the second node of the connector is optional or not applicable. For the local orientation requirements for each connection type, see the summary tables in *Connection-Type Library*.

For a description of how you can combine connector orientations and fastener orientations, see *Defining the Fastener Orientation*.

1. From the **Edit Fasteners** dialog box, display the **Property** tabbed page.
2. Enter the **Physical radius** of the fastener to define the radius of its circular projection on the connected surfaces. Abaqus uses this information to define the geometric section properties of the fastener.
3. Display the **Section** tabbed page, and choose the method that you will use to model each fastener.

   - Choose **Connector section** and select a connector section to model the point-to-point connection with connectors. Like other uses of connectors in Abaqus/CAE, the connection can be fully rigid or allow for unconstrained relative motion in the local connector component directions. In addition, you can specify deformable behavior using a connector behavior definition that includes the effects of elasticity, damping, plasticity, damage, and friction.
   - Choose **Rigid MPC** to model a perfectly rigid fastener with a rigid, or beam, multi-point constraint (MPC).

   If you choose a connector section that uses a basic, assembled, or complex connection type to model the fasteners, you can request output of connector element output variables. However, if you use a beam MPC to model the fasteners, no output is available from the fasteners.
4. Display the **Connector Orientation 1** tabbed page to define the local directions for the first node of the connector. The **Connector Orientation 1** tabbed page is available only if you use a connector section to model the fasteners.
   a. In most cases Abaqus/CAE orients the nodes at both ends of the connector with the global coordinate system; however, some connection types that are referred to by the connection section require local directions. Click  to select a datum coordinate system that specifies local directions at the first node of the connector. Click  to create the datum coordinate system if it does not already exist.
   b. Do either of the following:

      - Choose **No modifications to CSYS** to use the selected datum coordinate system.
      - If desired, choose **Additional rotation angle** and specify an additional rotation angle and the axis about which Abaqus/CAE will apply the additional rotation. The additional rotation (in degrees) is applied to both directions orthogonal to the selected axis.
5. Display the **Connector Orientation 2** tabbed page to define the local directions for the second node of the connector. The **Connector Orientation 2** tabbed page is available only if you select a datum coordinate system that specifies local directions for the first node of the connector.

   a. Click  to select a datum coordinate system that specifies local directions for the second node of the connector. Click  to create the datum coordinate system if it does not already exist.
   b. Do one of the following:

- Choose **Use orientation 1** to define the same local directions that you specified on the **Connector Orientation 1** tabbed page.
- Choose **No modifications to CSYS** to use the selected datum coordinate system.
- If desired, choose **Additional rotation angle** and specify an additional rotation angle and the axis about which Abaqus/CAE will apply the additional rotation. The additional rotation (in degrees) is applied to both directions orthogonal to the selected axis.

Additional information

• *Connection Types*
• *Mesh-Independent Fasteners*
• *About fasteners*
• *Understanding attachment points and lines*

Defining the fastener formulation

You use the **Formulation** tabbed page to select the method that Abaqus/CAE uses to couple the motion of the fastening points to the selected surfaces. You can also constrain selected rotational degrees of freedom and choose the weighting method.

1. From the **Edit Fasteners** dialog box, display the **Formulation** tabbed page.
2. Choose the method to couple the motion of the fastening points to the average motion of the nodes on the surfaces that fall inside the influence radius.

   - Choose **Continuum distributing** (default) to use a general-purpose distributed coupling scheme.
   - Choose **Structural distributing** to augment the distributed coupling scheme to account for rotations of surface nodes such that a fastening point remains approximately on a shell surface on bending.

   For more information, see *Distributing Coupling Constraints*.
3. If desired, toggle off a rotational degree of freedom to remove its constraint. Abaqus/CAE always constrains all translational degrees of freedom in a fastener.
4. Choose the weighting method that Abaqus uses to modify the default weight distribution at the coupling nodes within the radius of influence.

   - Choose **Uniform** (default) to select a weight distribution that is uniform and equal to 1.0.
   - Choose **Linear** to select a weight distribution that decreases linearly with distance from the fastening point.
   - Choose **Quadratic** to select a weight distribution that decreases by a quadratic polynomial function with distance from the fastening point.
   - Choose **Cubic** to select a weight distribution that decreases by a cubic polynomial monotonic function with distance from the fastening point.

   For more information, see *Weighting Methods*.

Additional information

• *Mesh-Independent Fasteners*
• *About fasteners*
• *Understanding attachment points and lines*

Adjusting the fastener definition

You use the **Adjust** tabbed page to specify the orientation of the fastener. For a description of how you can combine connector orientations and fastener orientations, see *Defining the Fastener Orientation*. You can also specify how Abaqus will compute the radius of influence, which determines the group of nodes that will be associated with each fastening point.

1. From the **Edit Fasteners** dialog box, display the **Adjust** tabbed page.
2. By default, Abaqus determines the orientation of each fastener from the default local directions of the surface that is closest to the fastening point. Click  to select a datum coordinate system (**CSYS**) that specifies the orientation of the fastener. Click  to create the datum coordinate system if it does not already exist. The *z*-axis of the **CSYS** should be approximately normal to the surfaces that are being connected, and the local *x*- and *y*-axes should be approximately tangent to the surfaces that are being connected.
3. By default, Abaqus adjusts the orientation that you specified such that the local *z*-axis for each fastener is normal to the surface that is closest to the fastening point. Toggle off **Adjust CSYS to make Z-axis normal to closest surface** to use the selected coordinate system to define the local directions precisely.
4. Each fastening point is associated with a group of nodes on the surface in the immediate neighborhood of the fastening point called a region of influence. The motion of the fastening point is then coupled in a weighted sense to the motion of the nodes in this region by a distributed coupling constraint. Each region of influence contains a minimum of three nodes. Choose either of the following to define the region of influence:
   - Choose **Facet-based default** to allow Abaqus to compute an internal radius of influence based on the geometric properties of the fastener, the characteristic length of the connected facets, and the weighting method you selected. The default radius of influence is always chosen to be the largest of the internally computed radius of influence, the physical fastener radius, and the distance from the projection point to the closest node.
   - Choose **Specify**, and enter the radius of influence. If you specify a radius of influence that is smaller than the computed default radius of influence, Abaqus uses the computed value.

   For more information, see *Defining the Radius of Influence*.

Additional information

• *Mesh-Independent Fasteners*
• *About fasteners*
• *Understanding attachment points and lines*

Creating discrete fasteners

You can create discrete fasteners in the Interaction module by selecting the attachment lines that connect the desired surfaces.
For each attachment line, Abaqus/CAE determines the fastening points and applies a distributing coupling between the fastening points and their corresponding surfaces.

You must assign a connector section to each attachment line that you select. You can use any of the Abaqus connection types to model complex behavior of your fasteners, such as deformable connectors that include the effects of elasticity, damage, plasticity, and friction. In addition, you can assign different connector sections to different attachment lines.

1. From the main menu in the Interaction module, select **Special->Fasteners->Create**.

   Abaqus/CAE displays the **Create Fasteners** dialog box.

    **Tip:** You can also create discrete fasteners using the  tool in the Interaction module toolbox.

2. From the **Create Fasteners** dialog box that appears, select **Discrete** fasteners and click **Continue**.
3. Select the attachment lines that represent the location of the discrete fasteners, and click **Done**. For more information, see *Creating attachment lines by projecting points*.

   Abaqus/CAE displays the **Edit Fasteners** dialog box.

4. Choose the method to couple the motion of the fastening points to the average motion of the nodes on the surfaces that fall inside the influence radius.

   - Choose the **Coupling type** option **Continuum distributing** (default) to use a general-purpose distributed coupling scheme or **Structural distributing** to augment the distributed coupling scheme to account for rotations of surface nodes such that a fastening point remains approximately on a shell surface on bending.
   - Choose the **Rotational Coupling type** option **Rotational Continuum distributing** or **Rotational Structural distributing** (default).

   For more information, see *Distributing Coupling Constraints*.

5. If desired, toggle off a rotational degree of freedom to remove its constraint. Abaqus/CAE always constrains all translational degrees of freedom in a distributing coupling.
6. Choose the weighting method that Abaqus will use to modify the default weight distribution at the coupling nodes:

   - Choose **Uniform** (default) to select a weight distribution that is uniform and equal to 1.0.
   - Choose **Linear** to select a weight distribution that decreases linearly with distance from the fastening point.
   - Choose **Quadratic** to select a weight distribution that decreases by a quadratic polynomial function with distance from the fastening point.
   - Choose **Cubic** to select a weight distribution that decreases by a cubic polynomial monotonic function with distance from the fastening point.

   For more information, see *Weighting Methods*.

7. If desired, select or create a datum coordinate system that specifies the initial orientation of the local system in which the constrained degrees of freedom are defined. By default, the orientation of the constrained degrees of freedom is defined by the global coordinate system.
8. Specify the radius of influence centered about the fastening point. You can enter a value or allow Abaqus to use the entire surface to define the coupling constraint.

9. Click **OK** to close the **Edit Fasteners** dialog box.

   Abaqus/CAE displays the distributing coupling of the discrete fastener between the fastening points and connected faces. The radius of the circle reflects the specified radius of influence. If the coupling constraint definition uses the entire surface, the lines from the fastening point will extend past the circle. For orphan mesh models, you can modify the appearance of the distributing coupling by changing the face and edge density in the assembly display options; for more information, see *Controlling the display of attributes*.

10. Complete the discrete fastener definition by assigning a connector section to the attachment lines, as described in *Creating and modifying connector section assignments*.

    Abaqus/CAE displays the connector symbols for the discrete fastener.

Additional information

- *Coupling Constraints*
- *About fasteners*
- *Understanding attachment points and lines*

Creating assembled fasteners

You can create assembled fasteners in the Interaction module after you have developed your template model. For more information, see *About fasteners*.

In this section:

- *Mapping the template model surfaces to main model surfaces*
- *Orienting the geometry read in from the template model*
- *Modifying fastener properties in the main model*
- *Re-running a property generation script*

Mapping the template model surfaces to main model surfaces

You use the **Surfaces** tabbed page to assign the constraint surfaces from the template model to the corresponding target surfaces that will be fastened in your main model. The constraint surfaces must be mapped into the main model to enable the constraint behaviors in the main model.

All surfaces involved in the template model constraints must have assigned names. The corresponding target surfaces in the main model must also have names.

1. From the **Edit Fasteners** dialog box, display the **Surfaces** tabbed page.
2. In the **Constraint Surface Substitutions** table, assign each **Template Surface** to an **Assignment Surface** in the main model.

   The **Template Surface** column will be prepopulated with the names of any template model surfaces involved in tie constraints, coupling constraints, or adjust points constraints. If the template surfaces are ordered correctly, you can simply choose the main model surface names in the **Assignment Surface** column of the table. If you need to change the order of the template model surfaces that will be assigned, click in each table cell and then click the arrow that appears to display the list of available surface names. The template surfaces are initially listed in ascending *Z*-axis order, but you can change the order to coincide with your template fastener design. However, the ordering of the surfaces is not significant beyond the selection of the first surface, because the corresponding assignment surface normal is used to orient the assembled fastener.

   To choose the main model assignment surface for each template surface, click in the corresponding table cell and click the arrow that appears to choose from the list of available surfaces in the main model. If you have not assigned a name to any of the surfaces you need to use, click  (**Create Assignment Surface**) to define a new surface and add it to the list.
3. You can toggle on **Render template surfaces** to show the surfaces in the main model, if desired.

Orienting the geometry read in from the template model

You use the **Orientations** tabbed page to specify how the template fastener construct is oriented at each attachment point. The template model is rotated into the main model and oriented such that the global coordinate system of the template model aligns with the coordinate system you specify. The default is to orient the template model copies such that the positive *Z*-axis of the global coordinate system of the template model aligns with the normal vector of the first surface at every attachment point. This default orientation from the first surface normal creates a *Z*-axis alignment at every attachment point. The *X*-axis is then computed by projecting the global *X*-axis onto the surface. When the global *X*-axis is parallel to the normal or to the *Z*-axis alignment, then the *X*-axis is computed by projecting the global *Y*-axis onto the surface. Further, the *Y*-axis is computed by taking the cross product of the normal and the computed *X*-axis.

1. From the **Edit Fasteners** dialog box, display the **Orientations** tabbed page.
2. Choose the orientation option that Abaqus/CAE will use to orient the fastener template at each attachment point.

   - Choose **Compute orientation based on first surface normal** (default) to orient the fastener geometry such that the global coordinate system of the template model aligns with the normal vector of the first assignment surface in the main model.

     You can toggle on **Flip normal direction** to reverse the direction, if desired.
   - Choose **Specify uniform CSYS** to orient the fastener geometry with a coordinate system that you choose. Click  (**Edit**) to select from the existing datum coordinate systems in your main model.

     The default is to use the global coordinate system of the main model. Click  (**Create Datum CSYS**) to create a new coordinate system.

3. If desired, toggle on **Display orientation direction at attachment points** to show orientation triads at the attachment point of each assembled fastener. These visualization options are not available until you have selected the control point set and made the first surface assignment. Choose either of the following suboptions:

   - Toggle on **Display only the normal direction** to remove the 1-axis and the 2-axis from the triads, leaving only the surface normal vector.
   - Toggle on **Include template model surfaces every *x* points** to display sketched outlines of the constraint surfaces from the template model. Adjust the number ***x*** up or down to show the surfaces at every attachment point, every other point, every third point, etc. The surfaces will be color-coded according to the colors shown on this tabbed page and in the **Constraint Surface Substitutions** table on the **Surfaces** tabbed page.

     This option is helpful for positioning and orienting the template model correctly. If your template model surfaces are too large, however (relative to the main model dimensions), the resulting display may be too crowded. You may wish to go back and resize the surfaces in your template model if this is the case.

Modifying fastener properties in the main model

You use the **Properties** tabbed page to specify a property generation script to modify the properties copied into the main model from the template model. The script is executed by Abaqus/CAE only when you click **OK** in the **Edit Fasteners** dialog box, not when Abaqus/CAE creates the input file. See *Using property generation scripts for assembled fasteners*, for complete information.

Your property generation scripts must be registered before starting Abaqus/CAE; see *Registering the property generation script*. Any scripts that have been registered will be available for selection on the **Properties** tabbed page.

1. From the **Edit Fasteners** dialog box, display the **Properties** tabbed page.
2. By default, the properties copied into the main model from the template model are named with the prefix *TM-1* for the first assembled fastener you create. For example, a connector section named *BoltSection* in the template model will be named *TM-1_BoltSection* in the main model. Subsequent assembled fasteners will use the prefixes *TM-2*, *TM-3*, etc.

   If desired, you can change the name prefix used in the **Property prefix string** field. The property prefix string must be unique for each assembled fastener.
3. Toggle on **Specify a property generation script**, and select the filename of your script from the list.

Re-running a property generation script

You use the **Re-run** tabbed page to have Abaqus/CAE re-copy properties from the template model and then re-run the property generation script. The script currently specified on the **Properties** tabbed page is run. The action occurs when you click **OK** to close the dialog box.

The **Re-run** tabbed page is available only when you are editing an assembled fastener that has already been created.

Note:

Any time you make a change in the the **Edit Fasteners** dialog box, the re-run action occurs automatically when you click **OK**. You only need to use the **Re-copy template model properties and re-run script** option when no other changes have been made.

1. From the **Edit Fasteners** dialog box, display the **Re-run** tabbed page.
2. Toggle on **Re-copy template model properties and re-run script**.
3. Click **OK** to close the dialog box.

Fracture mechanics

You can do the following to model fracture mechanics with Abaqus/CAE:

- Create a seam crack that defines an edge or a face with overlapping nodes that can separate during an analysis.
- Use contour integral estimates to study the onset of cracking in quasi-static problems; however, a contour integral estimate does not predict how a crack will propagate. You can compute contour integrals for two- or three-dimensional models.
- Use the extended finite element method (XFEM) to study the initiation and propagation of a crack along an arbitrary, solution-dependent path without needing to remesh your model. XFEM is available only for three-dimensional solid and planar models and orphan meshes.
- Use the virtual crack closure technique (VCCT) to study the initiation and propagation of a crack along a known crack surface.
- Use the **Crack Manager** to create and manage your cracks.

In this section:

- *Seam cracks*
- *Using contour integrals to model fracture mechanics*
- *Using the extended finite element method to model fracture mechanics*
- *Using the virtual crack closure technique to model crack propagation*
- *Managing cracks*

Seam cracks

A seam defines an edge or a face with overlapping nodes that can separate during an analysis. You can include a seam crack in your model. Alternatively, you can refer to the seam when creating a contour integral; however, you cannot use a seam crack with the extended finite element method (XFEM).

In this section:

- *What is a seam?*
- *Creating a seam*

What is a seam?

A seam defines an edge or a face in your model that is originally closed but can open during an analysis. Abaqus/CAE places overlapping duplicate nodes along a seam when the mesh is generated. A seam cannot extend along the boundaries of a part and must be embedded within a face of a two-dimensional part or within a cell of a solid part. After you create a seam, you can determine its crack properties using a contour integral analysis. Because a seam modifies the mesh, you cannot create a seam on a dependent part instance.

Figure 1 shows a seam on the face of a planar part and the effect of applying a tensile load to the model. The duplicate nodes along the seam are independent of each other and are free to move.

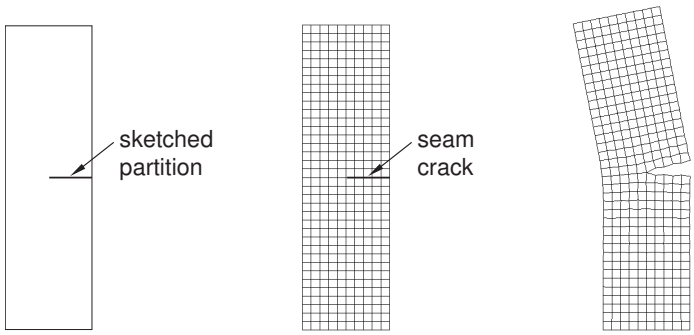

Figure 1: A seam embedded in a face.

Figure 2 shows a similar analysis of a seam embedded in a solid part. The seam was created by partitioning the solid with a sketch drawn on a datum plane.

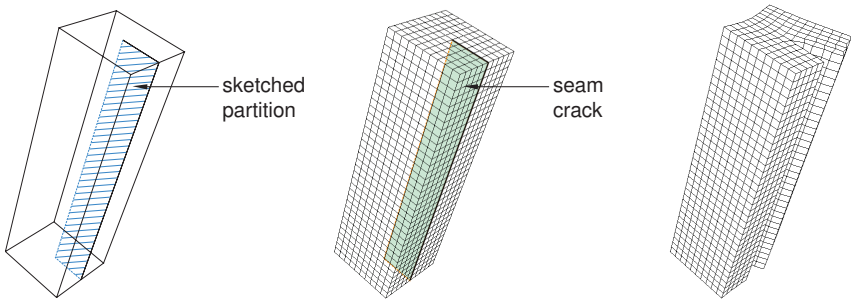

Figure 2: A seam embedded in a cell.

For detailed instructions, see *Creating a seam*, .

Creating a seam

You can use the **Special** menu in the Interaction module to define a seam in your model. A seam defines a region in your model that can open during an analysis. Abaqus/CAE places overlapping duplicate nodes along a seam when the mesh is generated. A seam cannot extend along the boundaries of a part and must be embedded within a face of a two-dimensional part or within a cell of a solid part. You can use the seam when you are selecting the crack front and the crack tip that will be used in a contour integral analysis. For more information, see *What is a seam?*.

1. From the main menu bar in the Interaction module, select **Special->Crack->Assign seam**.
2. From the model in the viewport, select the entities representing the seam. The entities must be embedded edges within a face of a two-dimensional part or embedded faces within a cell of a solid part; you cannot select any entities that lie on the boundary of the part.
3. Click mouse button 2 to indicate that you have finished selecting the seam.

   Abaqus/CAE creates the seam.
4. To include the seam in a contour integral analysis, follow the procedure described in *Creating a contour integral crack*.

Additional information

- *What is a seam?*
- *Fracture Mechanics*

Using contour integrals to model fracture mechanics

You can study the onset of cracking in a quasi-static model by selecting regions from your model that will be used to compute contour integral estimates.
During the analysis Abaqus/Standard writes the values of the contour integrals to the output database as history output. For a detailed description of contour integrals, see *Contour Integral Evaluation*. This section describes how you define a crack in Abaqus/CAE.

In this section:

- *Performing a contour integral analysis*
- *Defining the crack front*
- *Defining the crack tip or crack line*
- *Defining the crack extension direction*
- *Controlling the singularity at the crack tip for a small-strain analysis*
- *Contour integral output*
- *Meshing the crack region and assigning elements*
- *Controlling the singularity at the crack tip*
- *Creating a contour integral crack*
- *Modifying data for contour integrals*
- *Requesting contour integral output*

Performing a contour integral analysis

You can study the onset of cracking in quasi-static problems using contour integral estimates; however, a contour integral estimate does not predict how a crack will propagate.

You can compute contour integrals for two- or three-dimensional models, and you can choose to perform one of the following types of contour integral calculations:

- *J*-integral
- C_t-integral (for creep)
- *T*-stress (for linear materials)
- Stress intensity factors for linear homogeneous materials and for interfacial cracks lying on the interface between two linear homogeneous materials

For more information, see *Contour Integral Evaluation*.

You define cracks in the Interaction module. To perform a contour integral analysis, you must select the crack front, the crack tip or crack line, and the crack extension direction, as described in the following sections. The entities that you can select depend on whether the part is two- or three-dimensional and whether you are defining the part using geometry or using elements and nodes from an orphan mesh. In some cases the crack tip or the crack line is the same as the crack front that you selected, and Abaqus/CAE selects the crack tip or crack line for you.

A crack in a two-dimensional model is a region containing edges that are free to move apart. A crack in a three-dimensional model is a region containing faces that are free to move apart. The simplest approach to performing a contour integral analysis uses a region that already contains edges or faces that are free to move apart as the crack separates. Alternatively, you can model the crack as a line embedded in a face in a two-dimensional model or as a face embedded in a cell in a three-dimensional model. The embedded line or face is called a seam, and you can perform a contour integral analysis using a seam. When you mesh the model, Abaqus/CAE creates duplicate overlapping nodes on the seam; these coincident nodes are free to move apart as the seam separates. Seams are described in more detail in *What is a seam?*. *Figure 1* shows a two-dimensional model with existing edges that are free to move apart and a similar model with an embedded seam that is free to move apart.

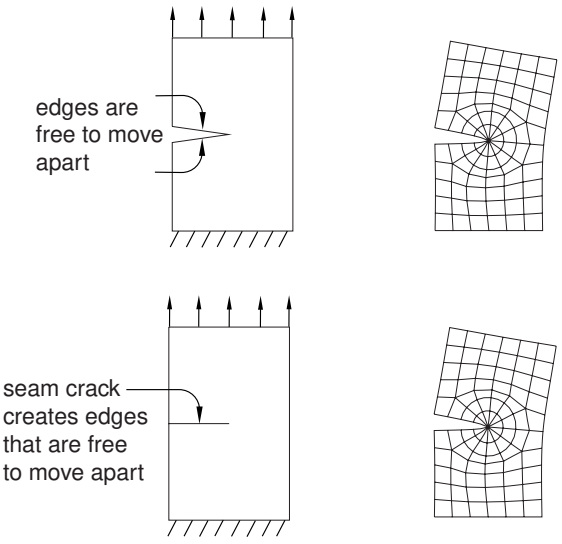

Figure 1: You can define a crack using an existing region or using a seam.

You can specify that the crack front is defined on a symmetry plane, in which case you need to model only half of the structure. Abaqus doubles the values calculated by the contour integral to arrive at the correct values. In most cases you need a refined mesh surrounding the crack. After you create a crack, you must use the **History Output Request**

editor to request that Abaqus write contour integral information to the output database. For more information, see *Contour integral output*.

For detailed instructions, see *Creating a contour integral crack*.

Defining the crack front

The first step in the procedure to configure a contour integral is to define the crack front by selecting entities from the assembly. The crack front is the forward part of the crack. Abaqus uses the crack front to compute the first contour integral using all of the elements inside the crack front and one layer of elements outside the crack front. You can request output for more than one contour integral, in which case Abaqus/CAE adds a single layer of elements to the group of elements that were used to calculate the previous contour integral. *Figure 1* illustrates how Abaqus/CAE computes successive contour integrals for a two-dimensional model by adding layers of elements.

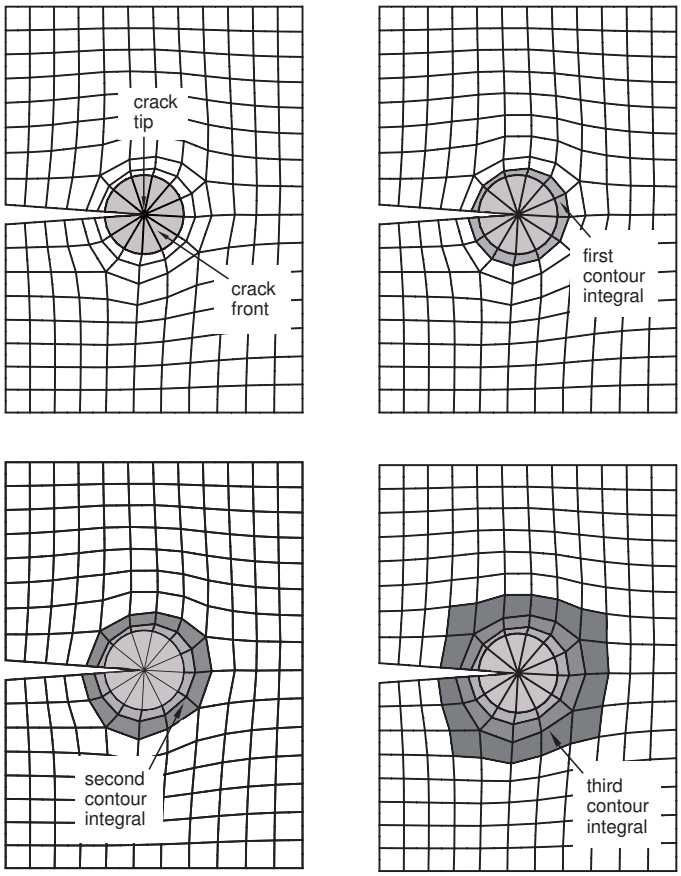

Figure 1: Successive contour integrals are calculated by adding a layer of elements.

If your part is three-dimensional, Abaqus computes contour integrals at each node along the crack line, as shown in *Figure 2*. For more information, see *Defining the Crack Front*.

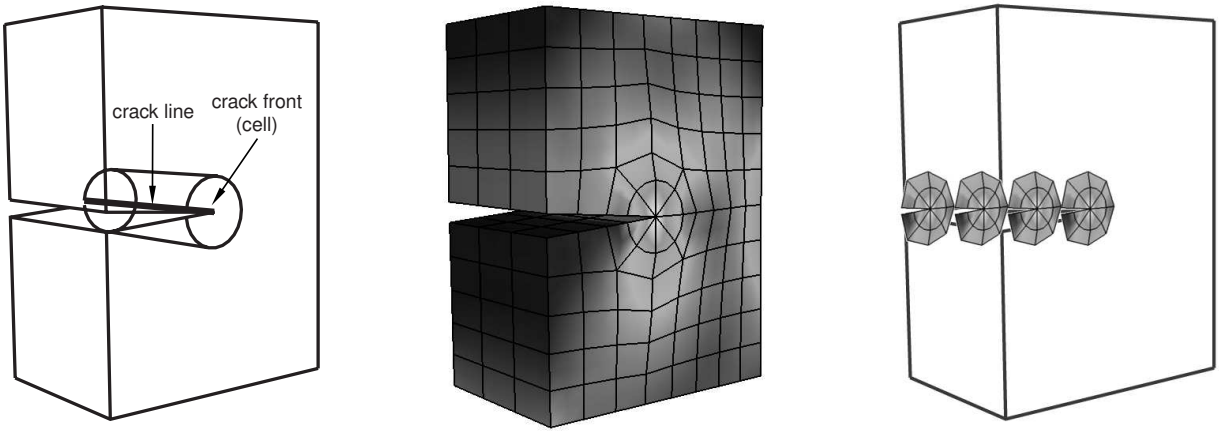

Figure 2: Abaqus computes the contour integral at each node along the crack line.

The entities from which you can select depend on whether the crack front is located in geometry or an orphan mesh and on the modeling space of the part.

Geometry

When you are defining the crack front on geometry, the entities that you can select depend on the modeling space of the part.

Two-dimensional geometry

If you are defining the crack front on two-dimensional geometry, you can select the following:

- A single vertex
- Connected edges
- Connected faces

Figure 3 shows the entities from which you can select when defining a crack front on two-dimensional geometry.

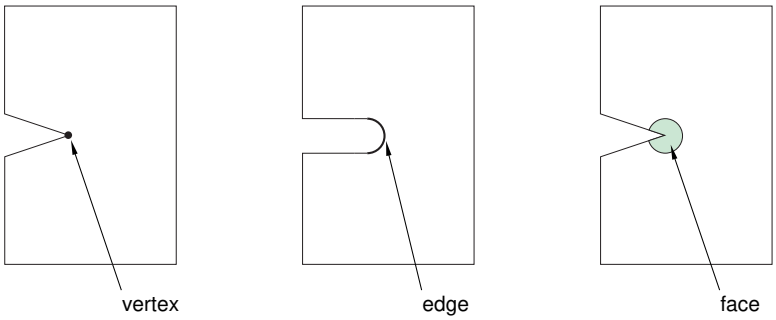

Figure 3: Selecting the crack front from two-dimensional geometry.

Three-dimensional geometry

If you are defining the crack front on three-dimensional geometry, you can select the following:

- Connected edges
- Connected faces
- Connected cells

Figure 4 shows the entities from which you can select when defining a crack front on three-dimensional geometry.

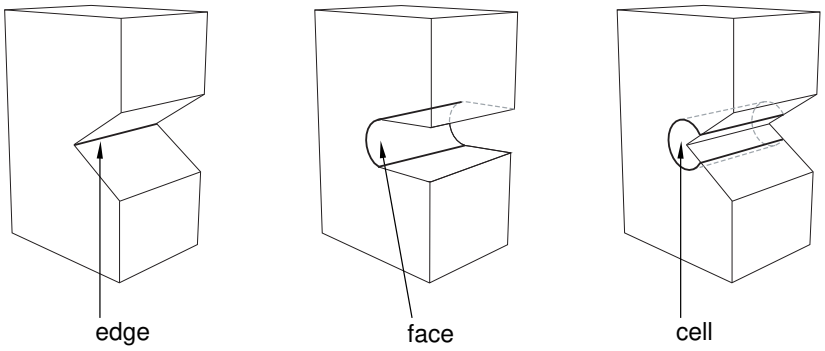

Figure 4: Selecting the crack front from three-dimensional geometry.

Mesh

When you are defining the crack front on an orphan mesh, you can select the elements or element edges or faces that define the crack front. Alternatively, you can select the nodes from the corresponding region. When you are defining the crack front on an orphan mesh, the entities that you can select depend on the modeling space of the part.

Two-dimensional orphan mesh

If you are defining the crack front on a two-dimensional orphan mesh, you can select the following:

- A single node
- Connected element edges
- Connected elements

Figure 5 shows the entities from which you can select when defining a crack front on a two-dimensional orphan mesh.

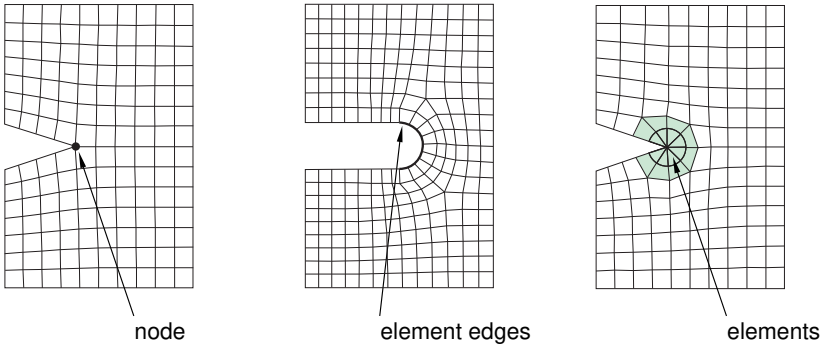

Figure 5: Selecting the crack front from a two-dimensional orphan mesh.

Three-dimensional orphan mesh

If you are defining the crack front on a three-dimensional orphan mesh, you can select the following:

- Connected element edges
- Connected element faces
- Connected elements

Figure 6 shows the entities from which you can select when defining a crack front on a three-dimensional orphan mesh.

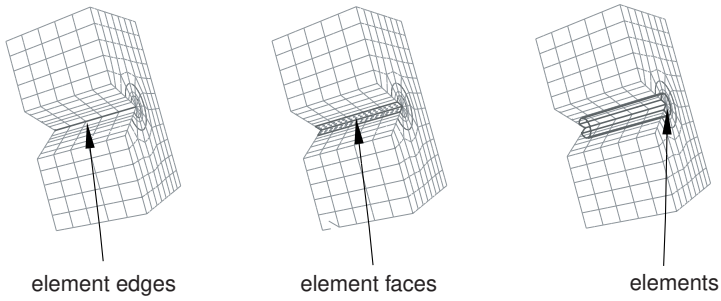

Figure 6: Selecting the crack front from a three-dimensional orphan mesh.

Defining the crack tip or crack line

After you have defined the crack front, the next step in the procedure to configure the contour integral is to define the crack tip or crack line by selecting entities from the assembly. The modeling space of your assembly governs whether you need to define a crack tip or a crack line for a contour integral analysis.

Two-dimensional

If your assembly is two-dimensional, you must define the crack tip by selecting a vertex or a node. The crack tip is the point on the crack front where you define the crack extension direction, $\mathbf{q}$. In some cases the desired vertex or node will not exist, and you must create it by partitioning the crack front.

If you selected a vertex or a node to define the crack front, the same vertex or node defines the crack tip.

Three-dimensional

If your part is three-dimensional, you must define the crack line by selecting edges or element edges that form a continuous line. The crack line is a series of connected edges along the crack front where you define the crack extension direction, $\mathbf{q}$. In some cases the desired edges will not exist, and you must create them by partitioning the crack front.

If you selected edges or element edges to define the crack front, the same edges define the crack line.

Selected edges (from an Abaqus/CAE native part or from an orphan mesh) must be connected, must connect one side of the crack front to the other, and must be included in the crack front.

Defining the crack extension direction

After you have defined the crack front along with the crack tip or crack line, Abaqus/CAE prompts you to specify the crack extension direction at the crack tip or along the crack line. You can specify the normal to the crack plane, $\mathbf{n}$; or you can specify the crack extension direction, $\mathbf{q}$, directly. For a detailed discussion of how Abaqus uses $\mathbf{n}$ or $\mathbf{q}$ to calculate the crack extension direction, see *Specifying the Virtual Crack Extension Direction*.

Normal to crack plane

If you select **Normal to crack plane**, you can define the normal by selecting points from the model that represent the start and the end of the normal to the crack plane. The crack plane contains the $\mathbf{q}$ vector that Abaqus needs to compute the contour integral. In many cases the crack plane represents the plane of symmetry of the crack.

You should define the normal to the crack plane only if the direction is the same at all points along the crack line. If the direction of the normal to the crack plane varies along the crack line, you cannot select a single normal that defines the crack extension direction at all points along the crack line.

To define the normal to the crack plane, you can select points from geometry (such as vertices, datum points, or midpoints), or you can select orphan mesh nodes. Alternatively, you can enter the coordinates of the points in the prompt area. If you select points from geometry and subsequently modify the part, Abaqus/CAE regenerates the points and updates the normal accordingly. If you are working with orphan mesh nodes, you must select nodes that represent the start and the end of the normal.

Abaqus calculates a crack extension direction, $\mathbf{q}$, that is orthogonal to the crack front tangent, $\mathbf{t}$, and the normal, $\mathbf{n}$. If required, you can flip the $\mathbf{q}$-direction vector.

q vectors

If you select **q vectors**, you can define the crack extension direction, $\mathbf{q}$, directly by selecting points from the model that represent the start and end of the $\mathbf{q}$ vector. If you are working with orphan mesh nodes, you must select nodes that represent the start and the end of the $\mathbf{q}$ vector. Alternatively, you can enter the coordinates of the points in the prompt area.

Figure 1 shows an example of a crack front formed by a circular arc along which the direction of the $\mathbf{q}$ vector is constantly varying. In contrast, the normal to the crack plane is constant. As a result, for this case you should define the crack extension direction by specifying the normal to the crack plane.

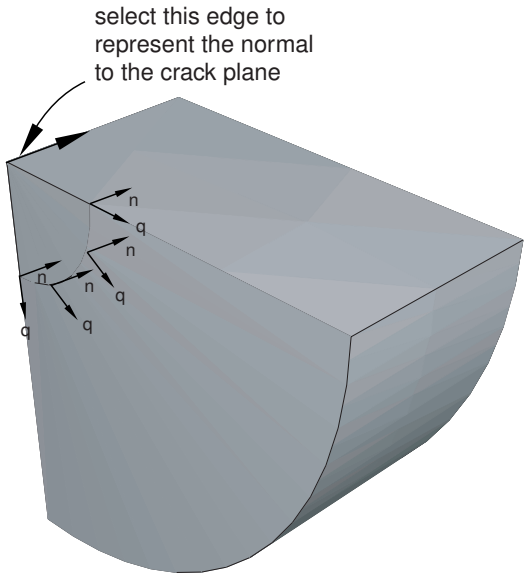

Figure 1: The direction of the $\mathbf{q}$ vector varies but the direction of the normal is constant.

Figure 2 shows a crack front formed by the edge of a truncated cone along which the directions of both the $\mathbf{q}$ vector and the normal to the crack plane are varying.

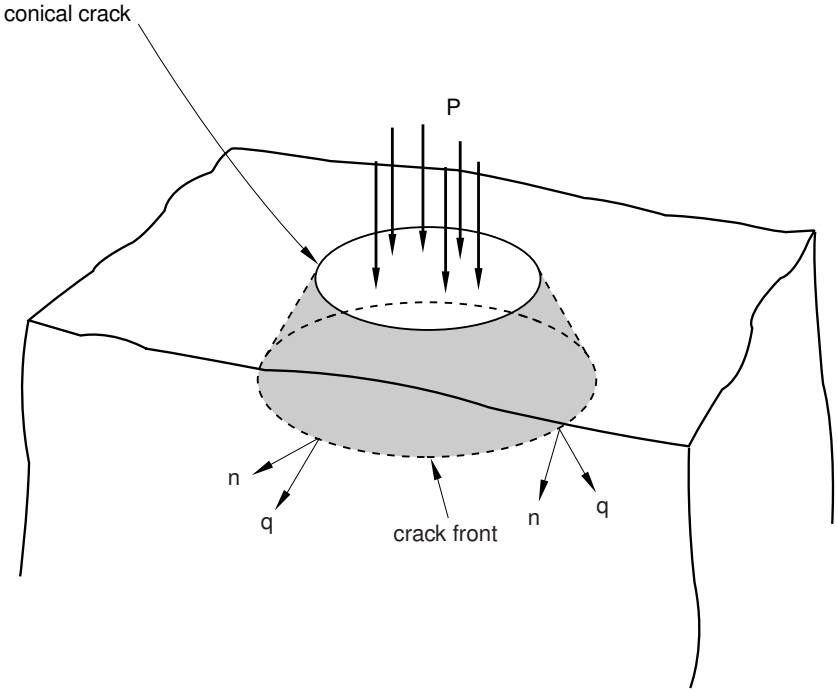

Figure 2: The directions of both the $\mathbf{q}$ vector and the normal vary along the crack front.

For this case you should do the following:

1. Define the contour integral, and use a single $\mathbf{q}$ vector to specify the crack extension direction.
2. Mesh the part, create a job, and write the model to an input file.

3. Import the input file, which will create an orphan mesh representation of the part.
4. Edit the crack that was imported with the model. Each node along the crack front will have the crack extension direction defined by the **q** vector that you specified in Step 1.
5. Use the Query toolset to determine the start and end coordinates of the **q** vector at each node, and edit the data defining the **q** vectors at each node along the crack front.

This technique is shown in *Figure 3*.

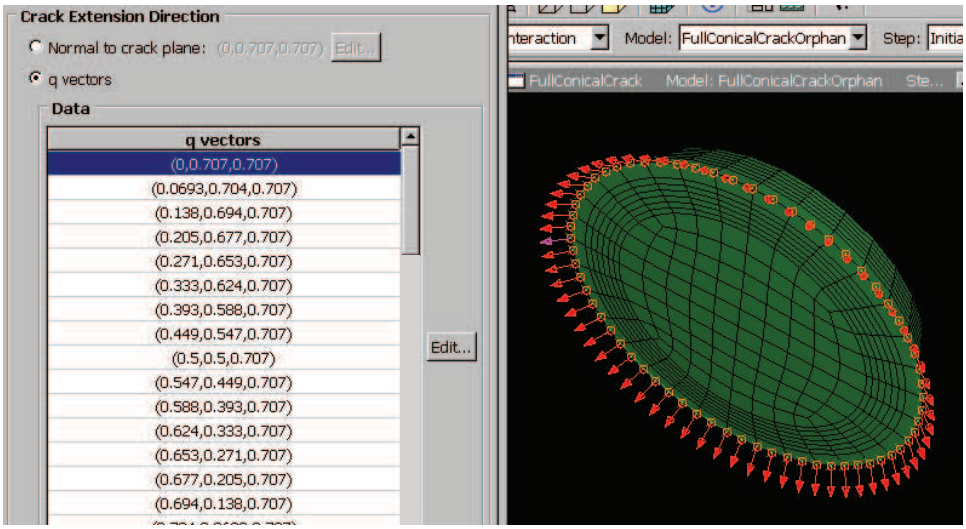

Figure 3: Entering the q vector at each node along the crack front.

Figure 3 is taken from *Contour integrals for a conical crack in a linear elastic infinite half space*. An Abaqus Scripting Interface script is provided with this example that illustrates how you can enter the **q** vector at each node along the crack front.

Controlling the singularity at the crack tip for a small-strain analysis

If the geometry of the crack region defines a sharp crack, the strain field becomes singular at the crack tip, as described in *Constructing a Fracture Mechanics Mesh for Small-Strain Analysis with the Conventional Finite Element Method*. Including the singularity in your model for a small-strain analysis improves the accuracy of the contour integral and the stress and strain calculations.

To include the singularity in your contour integral estimates, click the **Singularity** tab in the **Crack** editor and choose the desired position of the midside node and degenerate element control. For detailed instructions, see *Controlling the singularity at the crack tip*.

In addition, you must do the following in the Mesh module:

- If the assembly or part is two-dimensional, you must model the crack front with a ring of triangles and assign quadrilateral elements to the remainder of the contour integral region.
- If the assembly or part is three-dimensional, you must model the crack front with a ring of wedges and assign hexahedral elements to the remainder of the contour integral region.

When you mesh the crack front, Abaqus does the following:

- Converts the elements in the crack front to collapsed quadrilateral or hexahedral elements.
- If you modeled the crack front with a ring of second-order triangles or wedges, Abaqus moves the midside nodes to the specified position along the element edges that radiate out from the crack tip or crack line. (If you modeled the crack front with a ring of first-order triangles or wedges, Abaqus ignores the position that you specified for the midside nodes.)

A part instance that includes orphan mesh elements is always a dependent instance. As a result, you cannot adjust the midside nodes of these instances in the assembly. For more information, see *What is the difference between editing an orphan mesh, a meshed part, and a meshed part instance in the assembly?*. You must display the original orphan mesh and use the Edit Mesh toolset to adjust the position of the midsize nodes. For more information, see *Adjusting the position of midside nodes*. In addition, you cannot create collapsed elements from triangular and wedge elements of an orphan mesh.

Contour integral output

After you have defined the crack, you must use the **History Output Request** editor in the Step module to include the contour integral data in the output database generated by the analysis. The editor allows you to configure the following:

- The output frequency.
- The type of contour integral calculation to perform (*J*-integral, C_t-integral, stress intensity factors, or *T*-stress).
- The number of contours to evaluate.

Abaqus writes a history output variable to the output database for each contour integral that it calculates. *Figure 1* shows the format of the name of an output variable representing a contour integral.

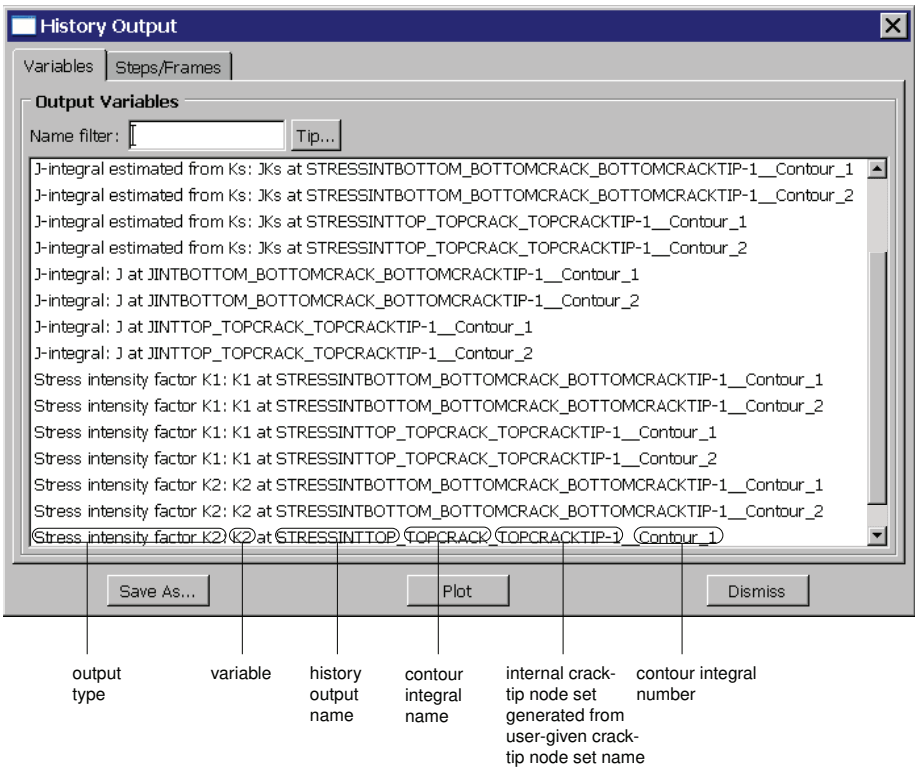

Figure 1: The format of a contour integral name in the output database.

For detailed instructions, see *Requesting contour integral output*. For more information, see *Modifying history output requests*, and *Contour Integral Evaluation*.

Meshing the crack region and assigning elements

Large stress concentrations occur at the crack tip. As a result, you should create a refined mesh around the crack tip to get accurate results for stresses and strains. In contrast, because the *J*-integral is an energy measure, you can obtain accurate *J*-values with a relatively coarse mesh. However, if the material becomes more nonlinear, you must create a finer mesh at the crack tip to maintain the accuracy of the *J*-values. You can control the density of the mesh at the crack tip by partitioning the region and by assigning mesh seeds to the resulting edges. For more information, see *Understanding seeding*.

For a large-strain analysis during which Abaqus will allow for nonlinear geometry, you should mesh the contour integral region with quadrilateral or hexahedral elements. For more information, see *Constructing a Fracture Mechanics Mesh for Finite-Strain Analysis with the Conventional Finite Element Method*.

However, for a small-strain analysis that does not allow for nonlinear geometry, you must allow for the singularity at the crack tip or crack line by meshing the region that defines the crack front with a ring of triangles or wedges. For more information, see *Controlling the singularity at the crack tip for a small-strain analysis*.

You must use the swept meshing technique to create wedge elements; however, there are limitations on the regions that Abaqus/CAE can mesh using the swept meshing technique, as described in *Swept meshing of three-dimensional solids*. As a result, if you cannot use the swept meshing technique, you cannot create wedge elements, and you cannot allow for the singularity at the crack line. In most cases you can ignore the singularity if your mesh is sufficiently refined to model the deformation around the crack tip or crack line and the resulting high strain gradients. You can also ignore the singularity if you are interested in only the contour integral output.

Controlling the singularity at the crack tip

If the geometry of the crack region defines a sharp crack, the strain field becomes singular at the crack tip, as described in *Constructing a Fracture Mechanics Mesh for Small-Strain Analysis with the Conventional Finite Element Method*. Including the singularity in your model for a small-strain analysis improves the accuracy of the contour integral and the stress and strain calculations.

1. Display the **Crack** editor using one of the following methods:
   - To configure a new contour integral, follow the instructions in *Creating a contour integral crack*.
   - To edit an existing contour integral, select **Special->Crack->Edit->*crack name*** from the main menu bar in the Interaction module.

2. To include the strain singularity in your contour integral estimates, click the **Singularity** tab in the **Crack** editor, and do one of the following:
   - To create a $1/\sqrt{r}$ strain singularity for an elastic fracture mechanics application:
     1. From the **Second-order Mesh Options** field, enter a value of 0.25 for the **Midside node parameter** to move the midside nodes to the $1/4$ points.
     2. From the **Degenerate Element Control at Crack Tip/Line** field, choose **Collapsed element side, single node**.
   - To create a $1/r$ strain singularity for a perfect plasticity fracture mechanics application:
     1. From the **Second-order Mesh Options** field, enter a value of 0.5 for the **Midside node parameter** to keep the midside nodes at the midside points.
     2. From the **Degenerate element control at Crack Tip/Line** field, choose **Collapsed element side, duplicate nodes**.
   - To create a combined $1/\sqrt{r}$ and $1/r$ strain singularity for a power law hardening material:
     1. From the **Second-order Mesh Options** field, enter a value of 0.25 for the **Midside node parameter**.
     2. From the **Degenerate element control at Crack Tip/Line** field, choose **Collapsed element side, duplicate nodes**.

3. Click **OK** to include the singularity in the contour integral estimation and to close the editor.

Note:

In most cases you must assign second-order triangle or wedge elements to the crack front region to include the singularity in your contour integral estimates. If you assign first-order elements, Abaqus ignores the value of the midside node setting in the **Singularity** tabbed page. However, if you assign first-order elements and choose **Collapsed element side, duplicate nodes** from the **Degenerate Element Control at Crack Tip/Line** field, you will create a $1/r$ strain singularity.

Creating a contour integral crack

You can use the **Special** menu in the Interaction module to create a contour integral crack. For more information, see *Fracture Mechanics*.

The entities that you select to define the contour integral depend on whether the part is two- or three-dimensional and whether you are defining the part using geometry or using orphan mesh elements and nodes.

1. From the main menu bar in the Interaction module, select **Special->Crack->Create**.
2. From the **Create Crack** dialog box that appears, select **Contour integral**.
3. Enter the name of the crack, and click **Continue** to close the dialog box.
4. From the model in the viewport, select the entities representing the crack front region. For a description of the entities to select, see *Defining the crack front*.
5. Click mouse button 2 to indicate that you have finished selecting the crack front region.
6. From the model in the viewport, select the entities representing the crack-tip region. In some cases, depending on the modeling space of your model and the entities that you selected to define the crack front, Abaqus/CAE selects the crack tip for you and skips to Step 7. For more information, see *Defining the crack tip or crack line*.

   From the prompt line, toggle on **Select mesh entities** to select entities from an orphan mesh.
7. Click mouse button 2 to indicate that you have finished selecting the crack-tip region.
8. From the prompt area, choose the method for defining the crack extension direction.

Normal to crack plane

Select **Normal to crack plane** to specify the normal to the crack plane, and select points representing the start and end of the normal.

q vectors

Select **q vectors** to specify the crack extension direction directly, and select points representing the start and end of the vector.

For more information, see *Defining the crack extension direction*.

Abaqus/CAE displays a blue arrow indicating the crack extension direction and, if specified, a red arrow indicating the normal to the crack plane and displays the **Edit Crack** dialog box.

9. Use the **Edit Crack** dialog box to configure the parameters that control a contour integral analysis.
   - Click the **General** tab of the dialog box to do the following:
     - Specify that the crack front is defined on a symmetry plane that models only half of the structure.
     - Change the entities that define the crack front or crack tip/line.
     - Change the method for defining the crack extension direction. You can also change the entities that define the crack extension direction and flip the crack extension direction (**q** vector).

     For more information, see *Modifying data for contour integrals*.
   - Click the **Singularity** tab of the dialog box to model a singularity of the strain field at the crack tip. For more information, see *Controlling the singularity at the crack tip*.
10. Click **OK** to configure the contour integral and to close the editor.

    Abaqus displays green crosses on the region to represent the crack front.

You must use the **History Output Request** editor in the Step module to include the contour integral data in the output database generated by the analysis. For more information, see *Contour integral output*, and *Modifying history output requests*.

Additional information

- *Using contour integrals to model fracture mechanics*
- *Fracture Mechanics*

Modifying data for contour integrals

If desired, you can modify the entities that you selected to define the crack front, the crack tip, and the crack extension direction that will be used to define a contour integral. You can also specify that the crack front is defined on a symmetry plane that models only half of the structure and flip the calculated crack extension direction, if desired. For more information, see *Symmetry with the Conventional Finite Element Method*.

1. Display the **Crack** editor using one of the following methods:
   - To configure a new contour integral, follow the instructions in *Creating a contour integral crack*.
   - To edit an existing contour integral, select **Special->Crack->Edit->*crack name*** from the main menu bar in the Interaction module.
2. Toggle on **On symmetry plane (half-crack model)** to specify that the crack front is defined on a symmetry plane that models only half of the structure. Abaqus doubles the change in potential energy calculated from the virtual crack front advance to compute the correct contour integral values.
3. If desired, click  to modify your selection of entities that define the crack front, crack tip, or crack line. If Abaqus/CAE selected the crack tip or crack line region to be the same as the crack front, you cannot edit the selection.
4. If desired, change the method for defining the crack extension direction. You can also click  to modify your selection of entities that define the crack extension direction.
5. If desired, you can click  to confirm or flip the calculated crack extension direction. In the prompt area, click **Yes** to confirm the **q**-vector direction or click **Flip** to reverse the direction.
6. Click **OK** to configure the contour integral and to close the editor.

   Abaqus displays green crosses on the region to represent the crack front.

   You must use the **History Output Request** editor in the Step module to include the contour integral data in the output database generated by the analysis. For more information, see *Contour integral output*, and *Modifying history output requests*.

Requesting contour integral output

You use the **History Output Request** editor in the Step module to request output from the contour integral analysis. You must select **Crack** from the **Domain** field. The editor then allows you to select the output frequency and the type of contour integral analysis to perform. For more information, see *Modifying history output requests*, and *Contour Integral Evaluation*.

You can also request contour integral output for an XFEM fracture analysis. For more information, see *Requesting contour integral output for XFEM*.

1. Enter the Step module.
2. From the main menu bar, select **Output->History Output Request->Create**.

   Abaqus/CAE displays the **Create History** dialog box.
3. From the **Create History** dialog box, enter the name of the output request and the step in which it will be created. Click **Continue** to close the dialog box.

   Abaqus/CAE displays the **History Output Requests** editor.
4. From the **Domain** field, select **Crack**, and select the desired contour integral.
5. From the fields that appear in the **History Output Requests** editor, enter the output frequency.
6. Enter the number of contours to evaluate. Abaqus/CAE computes the next contour integral by adding a single layer of elements to the region defined by the previous domain, as described in *Figure 1*. Each contour generates a value or a group of values for the contour integral.
7. If desired, toggle on **Step for residual stress initialization values**, and select the step from which Abaqus will read the stress data in the last available increment and use the data to calculate the residual stresses. If you select the initial step, the residual stresses are defined by the specified initial conditions. You cannot select a step that occurs after the step in which the history output request is created. For more information, see *Including the Effect of a Residual Stress Field on J-Integral Evaluation*.
8. Select the type of contour integral calculation to perform. You can select from the following:

J-integral

You use the *J*-integral in rate-independent quasi-static fracture analysis to characterize the energy release associated with crack growth. The *J*-integral can be related to the stress-intensity factor if the material response is linear. For more information, see *J-Integral*.

C_t-integral

You use the C_t-integral for time-dependent creep behavior, where it characterizes creep crack deformation under certain creep conditions, including transient crack growth. For more information, see *Ct-Integral*.

T-stress

You use the *T*-stress component to represent a stress parallel to the crack front. For more information, see *T-Stress*.

Stress intensity factors

You use the stress intensity factors K_I, K_{II}, and K_{III} in linear elastic fracture mechanics to characterize the local crack-tip stress and displacement fields. For more information, see *Stress Intensity Factors*.

If you request a contour integral calculation using stress intensity factors, Abaqus also computes the crack propagation direction at initiation. You must choose one of the following to indicate the crack initiation criteria:

- **Maximum tangential stress**
- **Maximum energy release rate**
- $\mathbf{K_{II} = 0}$

For more information, see *Crack Propagation Direction*.

9. Click **OK** to configure the contour integral analysis and to close the editor.

   For examples of how Abaqus names history output variables in the output database for each contour integral that it calculates, see *Contour integral output*.

Using the extended finite element method to model fracture mechanics

You can use the extended finite element method (XFEM) to study the initiation and propagation of a crack along an arbitrary, solution-dependent path without needing to remesh your model.
XFEM is available for three-dimensional solid and two-dimensional planar models; three-dimensional shell models are not supported.

In this section:

- *The extended finite element method (XFEM)*
- *Choosing the type of XFEM analysis*
- *Viewing an XFEM crack*
- *Creating an XFEM crack*
- *Deactivating and activating an XFEM crack growth*
- *Specifying a contact interaction property for XFEM*
- *Requesting contour integral output for XFEM*

The extended finite element method (XFEM)

You can study the onset and propagation of cracking in quasi-static problems using the extended finite element method (XFEM). XFEM allows you to study crack growth along an arbitrary, solution-dependent path without needing to remesh your model.
XFEM is available only for three-dimensional solid and two-dimensional planar models; three-dimensional shell models are not supported. You can use XFEM to study a crack in parts containing geometry, orphan mesh elements, or a combination of the two. You can choose to study a crack that grows arbitrarily through your model or a stationary crack. You define an XFEM crack in the Interaction module. You can specify the initial location of the crack. Alternatively, you can allow Abaqus to determine the location of the crack during the analysis based on the value of the maximum principal stress or strain calculated in the crack domain. For more information, see *Modeling Discontinuities as an Enriched Feature Using the Extended Finite Element Method*. Examples of XFEM models created in Abaqus/CAE are provided in *Modeling discontinuities using XFEM*.

To perform an XFEM crack analysis, you must specify the following:

Crack domain

To define the crack domain, you can select one or more cells from three-dimensional parts or one or more faces from two-dimensional planar parts. If you are defining the crack domain on an orphan mesh or a part containing both orphan and native mesh elements, you can select elements. The crack domain includes regions that contain any existing cracks and regions in which a crack might be initiated and into which a crack might propagate.

After you define the initial crack location, you can reduce the size of the crack domain by indicating that you want to use only elements in the vicinity of the crack geometry. You specify the number of element layers to include to prescribe a minimal enrichment zone automatically. The crack domain is defined using the elements intersected by the crack location. These elements are the initial set. The enrichment zone is built of elements in the neighborhood of the initial crack using the number of element layers that you specify. You can highlight the elements in the viewport and, if desired, save the highlighted elements to a set.

Crack growth

You can allow the crack to propagate along an arbitrary, solution-dependent path, or you can specify that the crack is stationary.

Initial crack location

To define the initial crack location, you can select faces from a three-dimensional solid or edges from a two-dimensional planar model. The initial crack location must be contained within the crack domain. A selected face can be a face of the solid, a face created by a partition, or a planar part instance. Similarly, a selected edge can be an edge of the solid, an edge created by a partition, or a wire part instance; you should not select a seam crack. You should not mesh the faces or edges that you selected to define the initial crack location. *Figure 1* shows examples of the crack domain and the crack location for two- and three-dimensional geometry and orphan meshes.

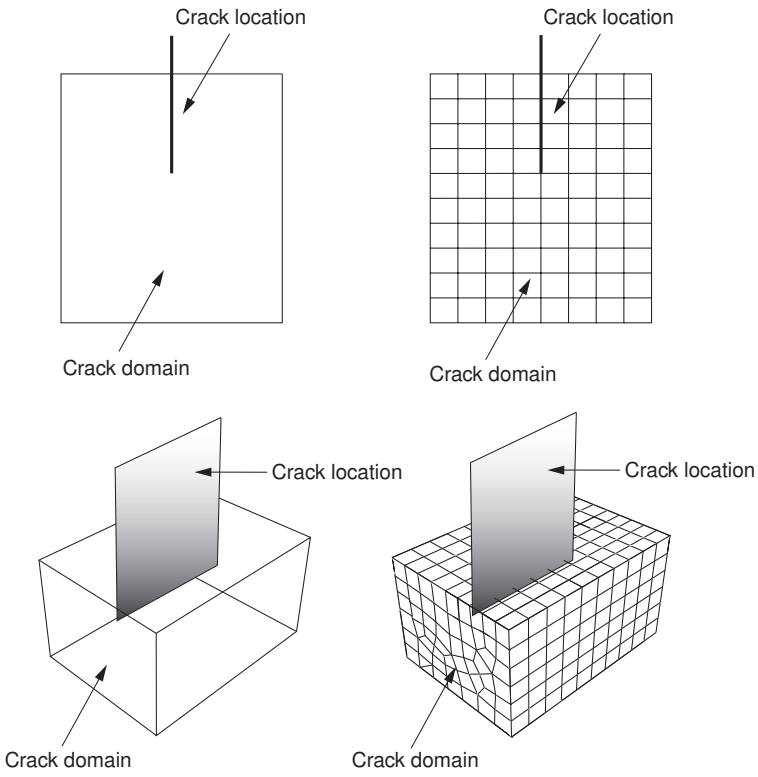

Figure 1: Defining a crack for XFEM.

Alternatively, you can choose not to define the initial crack location. Regardless of whether you define the initial crack location, Abaqus initiates the creation of cracks during the simulation by searching for regions that are experiencing principal stresses and/or strains greater than the maximum damage values specified by the traction-separation laws.

Enrichment radius

The enrichment radius is a small radius from the crack tip within which the elements will be used for calculating crack singularity for a stationary crack. Elements within the enrichment radius must be included in the cells or faces that you chose to represent the crack domain. You can allow Abaqus to calculate the radius (six times the typical element characteristic length in the enriched area), or you can specify its value.

Contact interaction property

You can choose to associate a contact interaction property with the XFEM crack that defines the contact of cracked element surfaces. For detailed information, see *Specifying a contact interaction property for XFEM*.

Damage initiation

You must specify the conditions that will initiate a crack by specifying damage initiation criteria in the material definition. You can specify a criterion based on either maximum principal stress or maximum principal strain. For more information, see *Maximum principal stress or strain damage*.

Analysis procedure

You can include an XFEM crack in a static analysis procedure. Alternatively, you can include an XFEM crack in an implicit dynamic analysis procedure to simulate the fracture and failure in a structure under high-speed impact loading. The XFEM-based crack propagation simulated in an implicit dynamic procedure can also be preceded or followed by a static procedure to model the damage and failure throughout the loading history.

For detailed instructions, see *Creating an XFEM crack*.

Choosing the type of XFEM analysis

Abaqus provides the traction-separation cohesive behavior approach and the linear elastic fracture mechanics (LEFM) approach for studying crack initiation and propagation using XFEM.

Traction-separation cohesive behavior

The traction-separation cohesive behavior approach is described in detail in *Modeling Moving Cracks with the Cohesive Segments Method and Phantom Nodes*. You can specify the material properties that define the evolution of damage leading to eventual failure. You apply the material to the section that is assigned to the crack domain. You can choose to associate a normal behavior contact interaction property with the XFEM crack that defines the contact of cracked element surfaces. For detailed information, see *Specifying a contact interaction property for XFEM*. To assist convergence as the material fails, you can introduce localized damping using the viscous regularization technique. For more information, see *Damage stabilization*.

Linear elastic fracture mechanics (LEFM)

The linear elastic fracture mechanics (LEFM) approach uses the modified Virtual Crack Closure Technique (VCCT) to calculate the strain energy release rate at the crack tip. The approach is more appropriate for brittle fracture problems and is described in detail in *Applying the VCCT Technique to the XFEM-Based LEFM Approach*. To use this approach, you must create a fracture criterion contact interaction property, as described in *Specifying fracture criterion properties for crack propagation*. If you specify localized damping in the contact interaction property, Abaqus will use the viscous regularization technique to assist convergence as the material fails. For more information, see *Specifying fracture criterion properties for crack propagation*.

Viewing an XFEM crack

When you are creating your model, you must request field output for the signed distance function, PHILSM. When you open an output database file containing the PHILSM output variable, Abaqus/CAE creates a view cut along the XFEM crack (where the value of the signed distance function is zero). Therefore, when you display a deformed or contour plot, the cracked elements in the enriched region are visible, as shown in *Figure 1*.

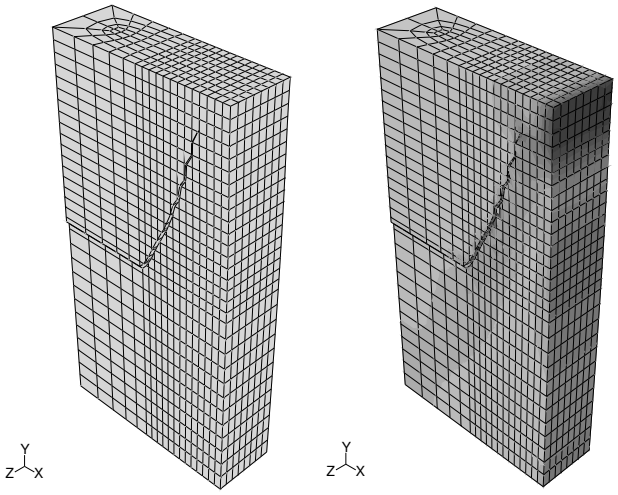

Figure 1: Viewing an XFEM crack.

You can perform a time history animation of a contour plot and view the onset of damage calculated by XFEM. The animation also allows you to view the propagation of the damage through the enriched region as the analysis progresses. Turning on translucency allows you to see the progression of the crack through interior elements. For more information, see *Changing the translucency*.

To view the initial crack front, you can create an isosurface cut shape with PSILSM selected as the current primary field output variable. For more information, see *Creating or editing a view cut*.

If you want to investigate the crack in more detail, you can create a contour plot of the signed distance function (PHILSM) and determine in which elements the signed distance values are negative or positive. The crack surface is situated in the elements where the value of PHILSM transitions from a negative number to a positive number. In addition, you can use the  option in the **View Cut Manager** to view only the surface where the value of the signed distance function is zero, which corresponds with the surface of an XFEM crack. For more information, see *Understanding view cuts*.

Creating an XFEM crack

You can use the **Special** menu in the Interaction module to create an extended finite element method (XFEM) crack.

1. From the main menu bar in the Interaction module, select **Special->Crack->Create**.
2. From the **Create Crack** dialog box that appears, select **XFEM**.
3. Enter the name of the crack, and click **Continue** to close the dialog box.
4. From the model in the viewport, select the entities representing the crack domain. You can select cells from a three-dimensional part instance or faces from a two-dimensional part instance. If you have an orphan mesh or an instance containing both orphan mesh and native mesh elements, you can select elements to represent the crack domain. You should select the entities that contain an existing crack along with any entities into which a crack might propagate.
5. Click mouse button 2 to indicate that you have finished selecting the crack domain.

   The **Edit Crack** dialog box appears.
6. You can reduce the size of the crack domain. This option is available only if you specify the crack location. Do the following:
   a. Toggle on **Shrink crack domain using crack location**.
   b. Specify the number of element layers to include to prescribe a minimal enrichment zone automatically.
   c. Click **Preview** to highlight the elements in the viewport and, if desired, save the highlighted elements to a set.
7. Do either of the following:
   - Toggle on **Allow crack growth** to define a crack that grows along an arbitrary path through your model as the solution progresses.
   - Toggle off **Allow crack growth** to define a stationary crack that cannot grow.
8. If you chose to allow crack growth, you can do either of the following to specify the crack location:
   - Toggle off **Crack location**, indicating that you will allow Abaqus to determine the location of the crack based on the damage initiation criterion that you specified.
   - Toggle on **Crack location** and click  to specify the crack location by selecting interior faces from a three-dimensional model or edges from a two-dimensional planar part. You should not select a seam crack.
9. If you chose to prevent crack growth, do the following:
   a. Click  to specify the crack location by selecting interior faces from a three-dimensional model or edges from a two-dimensional planar part. You should not select a seam crack.
   b. To specify the enrichment radius, do either of the following:
      - Choose **Analysis default**, to allow Abaqus to determine the enrichment radius. The default radius is three times the typical element characteristic length in the enriched area.
      - Choose **Specify** and enter a value. The value should be the radius from the crack tips within which the elements are used to calculate the crack singularity.
10. Choose the type of XFEM analysis:
    - By default, Abaqus will use the traction-separation cohesive behavior approach. You can select or create a contact interaction property that specifies the compressive and frictional behavior of the

cracked faces based on a small-sliding contact formulation. For more information, see *Defining surface-to-surface contact*.

- If you create a fracture criterion contact interaction property, Abaqus will use the linear elastic fracture mechanics (LEFM) approach. For more information, see *Specifying fracture criterion properties for crack propagation*.

11. Click **OK** to configure the XFEM crack and to close the editor.

Abaqus displays green crosses to represent the crack domain and the crack location.

To view the crack growth in the Visualization module, you must use the **Field Output Request** editor in the Step module and request that Abaqus writes the signed distance function PHILSM to the output database during the analysis. For more information, see *Viewing an XFEM crack*, and *Modifying field output requests*.

Additional information

- *Fracture mechanics*
- *Modeling Discontinuities as an Enriched Feature Using the Extended Finite Element Method*

Deactivating and activating an XFEM crack growth

By default, XFEM crack growth is active in all steps. However, if an analysis that includes XFEM crack growth fails to converge, you can deactivate the crack in a selected step and allow the analysis to reach equilibrium before reactivating the crack in a subsequent step.

1. Create an interaction in the initial step. For more information, see *Creating interactions*.
2. Select an interaction type of **XFEM crack growth**, and click **Continue**.
3. From the **Edit Interaction** dialog box, select the XFEM crack that you want to activate or deactivate. You can select only cracks that allow crack growth.
4. Click **OK** to create the interaction.
5. Open the **Interaction Manager**. For more information, see *Managing objects in the Interaction module*.
6. Select the XFEM crack growth interaction in the desired step, and click **Edit**.
7. From the **Edit Interaction** dialog box, toggle off (or on) **Allow crack growth** to deactivate (or activate) the XFEM crack growth in the selected step, and click **OK**.

   The **Interaction Manager** displays **Modified** to indicate the status of the XFEM crack growth in that step. Abaqus propagates the state of the XFEM crack growth (activated or deactivated) to subsequent steps.

Specifying a contact interaction property for XFEM

When you are configuring an XFEM analysis, you can select a contact interaction property that defines the compressive behavior of the crack surfaces. This section describes the settings in the contact interaction property that apply to XFEM crack growth. For more information, see *Understanding interaction properties*.

1. From the main menu bar, select **Interaction->Property->Create**.
2. In the **Create Interaction Property** dialog box that appears, do the following:
   - Name the interaction property.
   - Select the **Contact** type of interaction property.
3. Click **Continue** to close the **Create Interaction Property** dialog box.
4. From the menu bar in the contact property editor, select **Mechanical->Normal Behavior**.
5. From the **Constraint enforcement method** field, select **Penalty (Standard)** to enforce contact constraints using the penalty method.
6. Toggle off **Allow separation after contact** if you want to prevent surfaces from separating once they have come into contact.
7. Choose the **Linear** enforcement behavior in the **Behavior** field to use the linear penalty method for the enforcement of the contact constraint.
8. Specify the contact stiffness in the **Stiffness value** field.
   - Choose **Use default** to have Abaqus calculate the penalty contact stiffness automatically.
   - Choose **Specify**, and enter a positive value for the linear penalty stiffness.
9. Specify a factor by which to multiply the chosen penalty stiffness in the **Stiffness scale factor** field.
10. Specify the **Clearance at which contact pressure is zero**. The default value is 0.
11. Click **OK** to create the contact property and to exit the **Edit Contact Property** dialog box.

Requesting contour integral output for XFEM

You use the **History Output Request** editor in the Step module to request contour integral output from the XFEM crack. You must select **Crack** from the **Domain** field. The editor then allows you to select the output frequency and the type of contour integral analysis to perform. For more information, see *Modifying history output requests*, and *Contour Integral Evaluation*.

1. Enter the Step module.
2. From the main menu bar, select **Output->History Output Request->Create**.

   Abaqus/CAE displays the **Create History** dialog box.
3. From the **Create History** dialog box, enter the name of the output request and the step in which it will be created. Click **Continue** to close the dialog box.

   Abaqus/CAE displays the **History Output Requests** editor.
4. From the **Domain** field, select **Crack**, and select the desired XFEM crack.
5. Select the frequency at which the history output will be generated.
6. Enter the number of contours to evaluate. Abaqus/CAE computes the next contour integral by adding a single layer of elements to the region defined by the previous domain. Each contour generates a value or a group of values for the contour integral.
7. If desired, toggle on **Step for residual stress initialization values** and select the step from which Abaqus will use the stress data in the last available increment to extract the residual stresses. If you select the initial step, the residual stresses are defined by the specified initial conditions. You cannot select a step that occurs after the step in which the history output request is created. For more information, see *Including the Effect of a Residual Stress Field on J-Integral Evaluation*.
8. Select the type of contour integral calculation to perform. You can select from the following:

J-integral

You use the *J*-integral in rate-independent quasi-static fracture analysis to characterize the energy release associated with crack growth. The *J*-integral can be related to the stress-intensity factor if the material response is linear. For more information, see *J-Integral*.

C_t-integral

You use the C_t-integral for time-dependent creep behavior, where it characterizes creep crack deformation under certain creep conditions, including transient crack growth. For more information, see *Ct-Integral*.

T-stress

You use the *T*-stress component to represent a stress parallel to the crack front. For more information, see *T-Stress*.

Stress intensity factors

You use the stress intensity factors K_I, K_{II}, and K_{III} in linear elastic fracture mechanics to characterize the local crack-tip stress and displacement fields. For more information, see *Stress Intensity Factors*.

If you request a contour integral calculation using stress intensity factors, Abaqus also computes the crack propagation direction at initiation. You must choose one of the following to indicate the crack initiation criteria:

- **Maximum tangential stress**
- **Maximum energy release rate**
- $\mathbf{K_{II} = 0}$

For more information, see *Crack Propagation Direction*.

9. Click **OK** to configure the contour integral analysis and to close the editor.

   For examples of how Abaqus names history output variables in the output database for each contour integral that it calculates, see *Contour integral output*.

Using the virtual crack closure technique to model crack propagation

You can use the virtual crack closure technique (VCCT) to study the initiation and propagation of a crack along a known crack surface.
Modeling crack propagation using VCCT is available only for Abaqus/Standard models (three-dimensional solid and shell and two-dimensional planar and axisymmetric models).

In this section:

- *The virtual crack closure technique*
- *Creating a VCCT crack for Abaqus/Standard*

The virtual crack closure technique

You can study the onset and propagation of cracking in quasi-static problems using the virtual crack closure technique (VCCT). VCCT uses the principles of linear elastic fracture mechanics (LEFM) , so it is appropriate for problems in which brittle crack propagation occurs along predefined surfaces.
VCCT is based on the assumption that the strain energy released when a crack is extended by a certain amount is the same as the energy required to close the crack by the same amount.

You can include a VCCT crack in a static or quasi-static analysis procedure. Alternatively, you can include a VCCT crack in an implicit dynamic analysis procedure to simulate the fracture and failure in a structure under high-speed impact loading. VCCT is available only for Abaqus/Standard (three-dimensional solid and shell and two-dimensional planar and axisymmetric models). You can use VCCT to study a crack in parts containing geometry, orphan mesh elements, or a combination of the two. You define a VCCT crack in the Interaction module. You can specify the location of the surfaces that are initially bonded. For more information, see *Modeling Discontinuities as an Enriched Feature Using the Extended Finite Element Method*.

Creating VCCT or enhanced VCCT crack propagation models that converge to a successful solution requires some understanding of the principles behind VCCT. See *Tips for Using the VCCT or Enhanced VCCT Criterion in Abaqus/Standard*, for information that will help you create models that can be analyzed successfully.

For detailed instructions, see *Creating a VCCT crack for Abaqus/Standard*.

Creating a VCCT crack for Abaqus/Standard

You can create a virtual crack closure technique (VCCT) crack that can be analyzed by Abaqus/Standard by doing the following:

- Create a contact interaction property that specifies the fracture criterion. The fracture criterion interaction property specifies the criterion for crack propagation along initially partially bonded surfaces. You can choose between the following crack propagation criteria:
  - The virtual crack closure technique (**VCCT**) criterion, which uses the principles of linear elastic fracture mechanics. For more information, see *VCCT Criterion*.
  - The enhanced virtual crack closure technique (**Enhanced VCCT**) criterion, in which you can control the onset and growth of a crack using two different critical fracture energy release rates. The enhanced virtual crack closure technique is available only in an Abaqus/Standard analysis. For more information, see *Enhanced VCCT Criterion*.
- Create a surface-to-surface contact interaction that models the potential crack surfaces using main and secondary contact surfaces. The initially bonded region defines a region of the secondary surface that is initially bonded with the main surface. The unbonded portion of the secondary surface behaves as a regular contact surface. For detailed information, see *Defining Initially Bonded Crack Surfaces in Abaqus/Standard*.
- Activate the crack propagation capability to specify that crack propagation can occur between the two surfaces that are initially partially bonded. The crack continues to propagate along the interface between the main and secondary surfaces. The virtual crack closure technique cannot model crack initiation from a surface that is not already cracked; therefore, you must specify a clearance between the secondary and main surfaces that models a preexisting flaw at the beginning of the crack surface.

  For more information, see *Crack Propagation Analysis*.

1. Create a contact interaction property that defines the mechanical fracture criterion, as described in *Specifying fracture criterion properties for crack propagation*.
   a. Choose the crack propagation criteria (**VCCT** or **Enhanced VCCT**).

   Note:

   The **Direction of crack growth relative to 1–direction** option applies only to enriched regions that will be used by the extended finite element method (XFEM) for crack propagation.

   b. Specify the critical energy release rates for crack onset and propagation.
2. Create a surface-to-surface contact interaction that specifies the main and secondary surfaces (the region that contains the potential crack surfaces), as described in *Defining surface-to-surface contact in an Abaqus/Standard analysis*.
   a. Select a discretization method of **Surface to surface**.
   b. From the **Bonding** tabbed page, toggle on **Limit bonding to secondary nodes in subset**, and choose the set that specifies the initially bonded nodes of the secondary surface. The unbonded portion of the secondary surface behaves as a regular contact surface.
   c. Select the contact interaction property that defines the mechanical fracture criterion.
3. Activate the **VCCT** crack propagation capability.
   a. From the Interaction module main menu, select **Special->Crack->Create**.
   b. From the **Create Crack** dialog box that appears, select **Debond using VCCT**.
   c. Enter the name of the crack, and click **Continue** to close the dialog box.

The **Edit Crack** dialog box appears.

d. From the **Edit Crack** dialog box, do the following:

1. Select the step in which the crack propagation is initiated.
2. Select the surface-to-surface contact interaction that specifies the main and secondary surfaces.
3. Specify how the traction between the surfaces defined in the contact pair interaction is released after debonding occurs:
   - Choose **Step** (default) to release the traction during the increment that follows debonding.
   - To avoid a sudden loss of stability, choose **Ramp** to release the traction gradually during succeeding increments that follow debonding.
4. You can specify the rate at which crack propagation information is written to the data (`.dat`) file. If the step is using automatic time incrementation, the value is the suggested time increment to use for the first increment just after debonding starts. If the step is using fixed time incrementation, the value is the time increment after debonding starts if Abaqus/Standard finds it needs a smaller time increment than its current value. The time increment size will be modified as required until debonding is complete.

e. Click **OK** to configure the VCCT crack and to close the editor.

4. If desired, edit the general solutions control and adjust the **VCCT Linear Scaling** to accelerate convergence. For most crack propagation simulations using VCCT or the enhanced VCCT criterion, the deformation can be nearly linear up to the point of the onset of crack growth; past this point the analysis becomes very nonlinear. In this case linear scaling can be used to effectively reduce the solution time to reach the onset of crack growth. For more information, see *Customizing general solution controls*.

- *Crack Propagation Analysis*

Managing cracks

The **Crack Manager** allows you to create and manage cracks. The manager includes a list of the names and types of cracks that you have defined. The **Create**, **Edit**, **Copy**, **Rename**, and **Delete** buttons in the manager allow you to create new cracks or to edit, copy, rename, and delete existing ones. The icons in the column along the left side of the manager allow you to suppress and resume existing cracks. You can also initiate these procedures using the **Special->Crack** menu from the main menu bar in the Interaction module. After you select a management operation from the main menu bar, the procedure is exactly the same as if you had clicked the corresponding button inside the manager dialog box.

Additional information

- *Suppressing and resuming objects*
- *Fracture mechanics*

Gaskets

This section provides information on how to model gasket behavior.

In this section:

- *Modeling gaskets*
- *Defining materials for gaskets*
- *Assigning gasket elements to a region*

Modeling gaskets

Gaskets are thin sealing components that are positioned between structural components.
(For detailed information on gasket theory, see *Gasket Elements*.) The general procedure for modeling gaskets in three-dimensional space involves the following steps:

1. In the Part module, define the solid geometry. Gasket parts are typically very thin, flat solids.
2. In the Property module, define a gasket material. The material can be a regular material or one that includes special gasket behaviors. See *Defining materials for gaskets*, for more information.
3. In the Property module, define a gasket section that refers to the gasket material. Then assign the gasket section to the gasket region.
4. In the Interaction module, establish appropriate tie constraints or contact interactions between the gasket surfaces and the surfaces of adjacent regions.
5. In the Mesh module, assign the top-down swept meshing technique or the bottom-up meshing technique to the gasket region. Regardless of the meshing technique that you choose, you must sweep, extrude, or revolve the mesh in a direction normal to the gasket plane to produce gasket elements with the correct orientation. See *Specifying the sweep path*, or *Bottom-up meshing*, for more information.
6. In the Mesh module, assign a gasket element type to the gasket region, and mesh the region.

When you model gaskets with solids, you can use one or a combination of the following techniques to define the interaction between the gaskets and surrounding regions:

- You can create a separate gasket part and then use tie constraints or contact interactions to couple the gasket part instance to the other part instances.
- You can create a thin region within a part and then assign a gasket section and element type to that region. This approach is recommended if compatibility between the gasket mesh and the meshes of adjacent regions is important.

Additional steps are necessary if the gasket model is composed of several layers and inserts. For example, *Figure 1* illustrates a gasket modeled as a solid layer with an embedded shell-like insert.

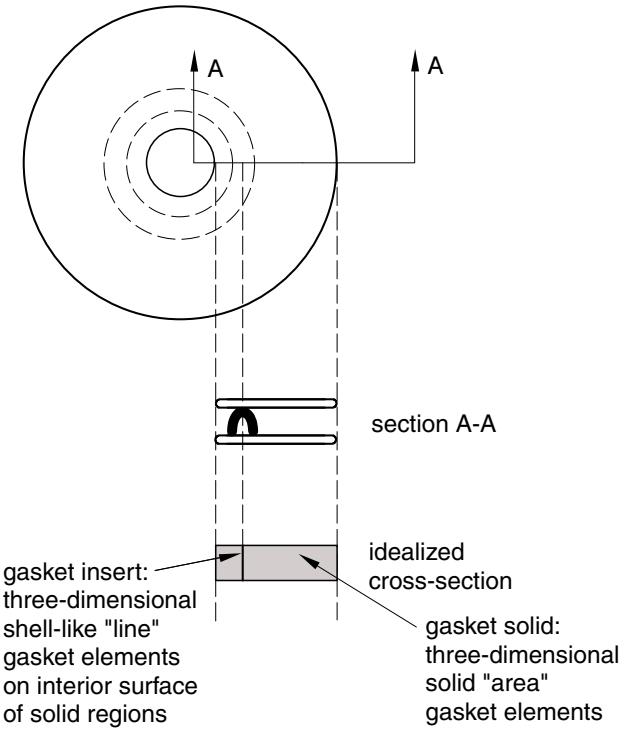

Figure 1: Idealized gasket model.

The Abaqus/CAE representation of the idealized gasket model is shown in *Figure 2*.

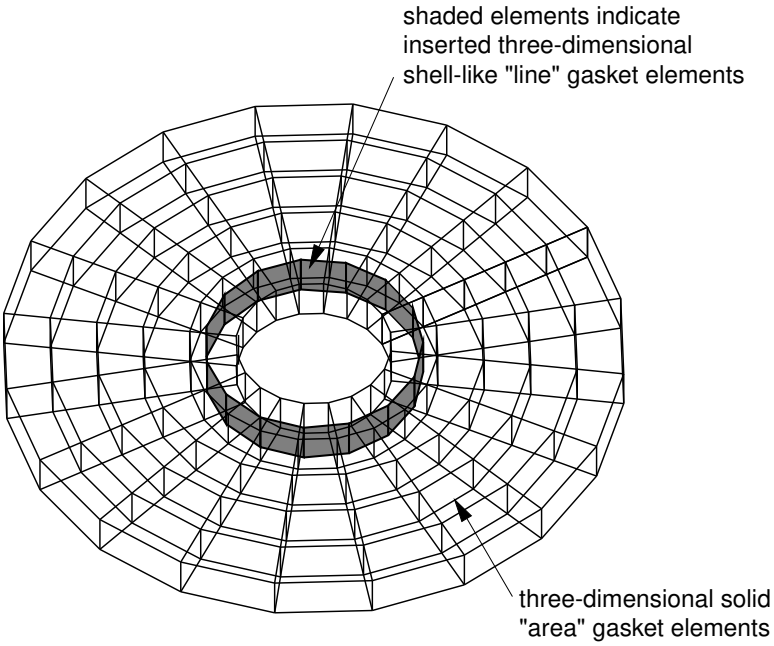

Figure 2: A three-dimensional view of the gasket model and its elements.

If you are working with gaskets composed of several layers and inserts, you must perform the following additional tasks:

1. Use the Partition toolset to partition the solid gasket region so that an internal surface is created at the position of the insert.
2. In the Property module, define a skin reinforcement on the internal surface that represents the insert. (See *Defining skin reinforcements*, for more information.) The gasket sections that you assign to the solid and to the insert are usually different, as are their materials.
3. No meshing is required (or allowed) for the insert skin, but you must assign a three-dimensional “line” gasket element type to the skin in the Mesh module. See *Assigning element types to skin or stringer reinforcements*, for more information.

Defining materials for gaskets

You can create two types of materials to include in gasket section definitions: materials with gasket-specific behaviors and general-use materials. The type of material that you create depends on your requirements for the gasket behavior.

- Create a material using the special gasket behaviors if you want the thickness-direction, transverse shear, and membrane behaviors to be uncoupled. Gasket behavior materials are valid only for gasket sections. For detailed information on this approach to defining gasket behavior, see *Defining the Gasket Behavior Directly Using a Gasket Behavior Model*.
- Create a general-use material if you want to consider only the thickness-direction behavior. General-use materials are valid in gasket sections as well as in other types of sections. For detailed information on this approach to defining gasket behavior, see *Defining the Gasket Behavior Using a Material Model*.

You create a gasket-specific material by entering data for one or more of the behaviors found in the **Other->Gasket** submenu. Data entered for any other behavior in the material editor are ignored, with the following exceptions:

- You can include the **Expansion** behavior (located in the **Mechanical** menu) in a gasket behavior material definition.
- You can include the **Creep** behavior (located in the **Mechanical->Plasticity** menu) in a gasket behavior material definition.
- You can include the **Depvar** and **User Output Variables** behaviors (located in the **General** menu) in a gasket behavior material definition.

You create a general-use material by entering data for any behaviors that are valid for gasket sections except those found in the **Other->Gasket** submenu. (If you enter data for a behavior found in the **Other->Gasket** submenu, you automatically create a gasket behavior material.) For information on which material behaviors are valid for general-use materials included in gasket section definitions, see *Gasket Elements*.

Assigning gasket elements to a region

If the region is a shell, you must assign the swept meshing technique; if the region is a solid, you can assign any meshing technique. For solid regions you can define a stack orientation that is independent of the mesh technique. (For more information, see *Applying a mesh stack orientation*.) The swept meshing technique ensures that the elements are stacked in a manner suitable for gasket modeling. When you sweep mesh shell regions or solid regions that have not been assigned a stack orientation, the axis of each gasket element is coincident with the sweep path direction; therefore, you can control gasket element alignment by specifying an appropriate sweep path.

For example, the part instance shown in *Figure 1* has three possible sweep paths, and each path has two possible sweep directions. If you mesh this part instance using gasket elements, you can choose from six possible gasket axis orientations. For more information, see *Swept meshing*, and *Specifying the sweep path*.

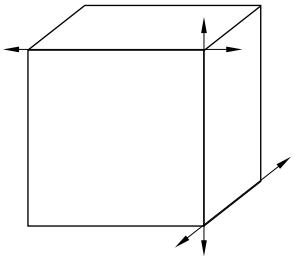

Figure 1: For shell regions, you must choose a sweep path and direction that provides an appropriate gasket axis orientation for your model.

In addition, you can assign gasket elements to orphan mesh elements. You can use the Query toolset to verify that the gasket elements are aligned correctly for regions where the gasket axis has more than one possible orientation. If necessary, you can use the Edit Mesh toolset to change the mesh stack orientation. For more information, see *Orienting the stack direction*. You can use these tools with hexahedral, wedge, and quadrilateral elements because these are the only elements that can be stacked to form a continuum shell or gasket mesh. If you have assigned second-order gasket elements to the region, you must first change the assignment to conventional elements before you reorient the stack direction. You can then convert the region back to a gasket mesh by reassigning second-order gasket elements.

Imperfection

This section provides information on how to model different types of imperfection. You can define imperfection in the Interaction module.

In this section:

- *Defining imperfections*
- *Managing imperfections*
- *Defining file imperfections*
- *Defining input imperfections*
- *Defining data imperfections*
- *Editing the region to which a file imperfection applied*

Defining imperfections

You can define an imperfection for an assembly in the Interaction module.

You can specify the following types of imperfections:

File imperfection

You can define a file imperfection that uses results files from a previous analysis on an assembly. For more information, see *Introducing a Geometric Imperfection into a Model*.

Input imperfection

You can define an input imperfection that uses imperfection data specified in an alternate input file on an assembly. For more information, see *Introducing a Geometric Imperfection into a Model*.

Data imperfection

You can define a data imperfection that uses data lines in the input file specifying components of imperfection for a given node on an assembly. For more information, see *Introducing a Geometric Imperfection into a Model*.

Select **Special**->**Imperfection**->**Create**: ***type*** from the Interaction module to define imperfection. Select **Edit** from the same menu to make changes to an existing definition.

Imperfection definitions appear in the Model Tree in the **Engineering Features** container under the assembly.

When you define a file imperfection, you can select objects from the viewport to identify the region on which to apply the imperfection. By default, a node set is created that contains the selected objects. You can change this behavior by toggling off the option to create a set or surface in the prompt area. A default name is provided in the prompt area, but you can enter a new name.

For detailed instructions on creating this type of engineering feature, see the following sections:

- *Defining file imperfections*
- *Defining input imperfections*
- *Defining data imperfections*

Managing imperfections

The **Imperfection Manager** allows you to create and manage imperfection definitions.

The manager includes a list of the names and types of imperfections that you have defined. The **Create**, **Edit**, **Copy**, **Rename**, and **Delete** buttons in the manager allow you to create new imperfection definitions or to edit, copy, rename, and delete existing ones.

The icons in the column on the left side of the manager allow you to suppress and resume existing imperfection definitions. You can also initiate these procedures using the **Special->Imperfection** menu from the main menu bar in the Interaction module.

After you select a management operation from the main menu bar, the procedure is the same as if you had clicked the corresponding button inside the manager dialog box.

Additional information

- *Suppressing and resuming objects*
- *Defining file imperfections*
- *Defining input imperfections*
- *Defining data imperfections*
- *Editing the region to which a file imperfection applied*

Defining file imperfections

You can define file imperfections on an assembly.

1. From the main menu bar in the Interaction module, select **Special->Imperfection->Create**.
2. In the **Create Imperfection** dialog box that appears, name the imperfection, select **File Imperfection**, and click **Continue**.
3. Select the points for which you want to define a file imperfection using one of the following methods:
   - Select the points in the viewport. When you have finished selecting, click mouse button 2.
   - To select from a list of existing sets, do the following:
     1. Click **Sets** on the right side of the prompt area to display the **Region Selection** dialog box containing a list of available sets.
     2. Select the set of interest, and click **Continue**.

     Note: The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

   The **Edit Imperfection** dialog box appears.
4. Select **Result file**, which is an `.odb` file that is to be used in the imperfection definition.
5. Select the **Step** and **Increment** of the results file from which the displacement data are to be read to define the imperfection.
6. In the **Data** table, enter the following:

Mode Number

Enter the mode number.

Scaling Factor

Enter the scaling factor. Repeat this row in the table as often as necessary to specify the imperfection as a linear combination of mode shapes.

7. Click **OK** to save your data and to close the dialog box.

• *Introducing a Geometric Imperfection into a Model*

Defining input imperfections

You can define input imperfection on an assembly.

1. From the main menu bar in the Interaction module, select **Special->Imperfection->Create**.
2. In the **Create Imperfection** dialog box that appears, name the imperfection, select **Input imperfection**, and click **Continue**.
3. Select **System**.
4. Select **Input file**, which is an `.odb` file that is used in the imperfection definition.
5. Click **OK** to save your data and to close the dialog box.

• *Introducing a Geometric Imperfection into a Model*

Defining data imperfections

You can define data imperfection on an assembly.

1. From the main menu bar in the Interaction module, select **Special->Imperfection->Create**.
2. In the **Create Imperfection** dialog box that appears, name the imperfection, select **Data imperfection**, and click **Continue**.
3. Select **System**.
4. In the **Imperfection Data** table, enter the following:

Node Number

Enter the node for which the imperfection is to be specified.

Components

Enter the `comp1`, `comp2`, and `comp3` component values for the imperfection in the selected system.

5. Click **OK** to save your data and to close the dialog box.

• *Introducing a Geometric Imperfection into a Model*

Editing the region to which a file imperfection applied

You can edit the region to which a file imperfection is applied.

1. From the main menu bar in the Interaction module, select **Special->Imperfection->Edit->*file imperfection name*** to display the **Edit Imperfection** dialog box.
2. In the top part of the dialog box, click .
3. Edit the region using one of the following methods:
   - Select and unselect objects in the viewport. When you have finished editing the region, click mouse button 2. For more information, see *Selecting objects within the viewport*.
   - To select from a list of existing sets, do the following:
     1. Click **Sets** on the right side of the prompt area.

        Abaqus/CAE displays the **Region Selection** dialog box containing a list of available sets.
     2. Select the set of interest, and click **Continue**.

Note: The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

4. In the dialog box, finish editing the imperfection definition as desired and click **OK**.

Inertia

This section provides information on how to model different types of inertia for regions on a part or on an assembly. You can define inertia in the Property module or in the Interaction module.

In this section:

- *Defining inertia*
- *Managing inertia*
- *Defining point mass and rotary inertia*
- *Defining nonstructural mass*
- *Defining heat capacitance*
- *Editing the region to which inertia is applied*

Defining inertia

Inertia can be defined for a part in the Property module or for an assembly in the Interaction module

You can specify the following types of inertia:

Point mass/inertia

You can define lumped mass and rotary inertia at a point on a part or on an assembly. You can also define mass and inertia proportional damping. In an Abaqus/Standard analysis, you can define composite damping. For more information, see *Point Masses*, and *Rotary Inertia*.

Nonstructural mass

You can define nonstructural mass for a region on a part or on an assembly. For more information, see *Nonstructural Mass Definition*.

Heat capacitance

You can define concentrated heat capacitance at a point on a part or on an assembly. For more information, see *Point Capacitance*.

Select **Special->Inertia->Create**: ***type*** from the main menu bar in the Property module or the Interaction module to define inertia. Select **Edit** from the same menu to make changes to an existing definition.

Inertia definitions appear in the Model Tree in the **Engineering Features** container under the part (if created in the Property module) or under the assembly (if created in the Interaction module).

When you define inertia, you can select objects from the viewport to identify the region on which to apply the inertia. By default, a set or surface is created that contains the selected objects. You can change this behavior by toggling off the option to create a set or surface in the prompt area. A default name is provided in the prompt area, but you can enter a new name.

When you apply inertia to regions of the model, you can choose to display symbols in the viewport that indicate where you have applied the inertia. If you apply inertia to geometry, symbols appear at the vertices. If you apply inertia to an orphan mesh, symbols appear at the nodes. For information about graphical symbol types, see *Symbols used to represent special engineering features*. For information about controlling the visibility of these symbols, see *Controlling the display of attributes*.

For detailed instructions on creating this type of engineering feature, see the following sections:

- *Defining point mass and rotary inertia*
- *Defining nonstructural mass*
- *Defining heat capacitance*

Managing inertia

The **Inertia Manager** allows you to create and manage inertia definitions.

The manager includes a list of the names and the types of inertia that you have defined.

The **Create**, **Edit**, **Copy**, **Rename**, and **Delete** buttons in the manager allow you to create new inertia definitions or to edit, copy, rename, and delete existing ones.

The icons in the column along the left side of the manager allow you to suppress and resume existing inertia definitions. You can also initiate these procedures using the **Special->Inertia** menu from the main menu bar in the Property module or the Interaction module. After you select a management operation from the main menu bar, the procedure is the same as if you had clicked the corresponding button inside the manager dialog box.

Additional information

- *Suppressing and resuming objects*
- *Defining point mass and rotary inertia*
- *Defining nonstructural mass*
- *Defining heat capacitance*
- *Editing the region to which inertia is applied*

Defining point mass and rotary inertia

You can define lumped mass and rotary inertia at a point on a part or on an assembly.
You can also define proportional damping for point masses and rotary inertia. In an Abaqus/Standard analysis, you can define composite damping. For more information, see *Point Masses* and *Rotary Inertia*.

1. From the main menu bar in the Property module or the Interaction module, select **Special->Inertia->Create**.
2. In the **Create Inertia** dialog box that appears, name the inertia, select **Point mass/inertia**, and click **Continue**.
3. Select the points for which you want to define mass and rotary inertia using one of the following methods:

   - Select the points in the viewport. When you have finished selecting, click mouse button 2.

     If the model contains a combination of orphan mesh elements and geometry, select one of the following from the prompt area:

     - Select **Geometry** to define the point mass and rotary inertia for the geometric portions of a part or assembly or for a reference point.
     - Select **Mesh** to define the point mass and rotary inertia for orphan mesh components.

       You can use the angle method to select a group of nodes from an orphan mesh. For more information, see *Using the angle and feature edge method to select multiple objects*.

   - To select from a list of existing sets, do the following:

     1. Click **Sets** on the right side of the prompt area to display the **Region Selection** dialog box containing a list of available sets.
     2. Select the set of interest, and click **Continue**.

     Note: The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

   The **Edit Inertia** dialog box appears. The region to which you are applying the point mass and rotary inertia is highlighted in the viewport.
4. From the **Mass** portion of the **Magnitude** tabbed page, do the following:

   - For isotropic mass, toggle on **Isotropic** and specify the magnitude of the mass.
   - For anisotropic mass, toggle on **Anisotropic** and specify the mass components M_{11}, M_{22}, and M_{33}.

5. In the **Rotary Inertia** portion of the page, specify the moments of inertia (units ML^2).
   a. Toggle on **Specify off-diagonal terms** if you want to specify products of inertia.
   b. Enter values for the rotary inertia.

I11

Rotary inertia about the local 1-axis, I_{11}.

I22

Rotary inertia about the local 2-axis, I_{22}.

I33

Rotary inertia about the local 3-axis, I_{33}.

c. If applicable, enter values for the products of inertia.

I12

Product of inertia, I_{12}.

I13

Product of inertia, I_{13}.

I23

Product of inertia, I_{23}.

6. If you want to change the coordinate system (**CSYS**) for the rotary inertia, click  and use one of the following methods:

- Select an existing datum coordinate system in the viewport.
- Select an existing datum coordinate system by name.
  1. From the prompt area, click **Datum CSYS List** to display a list of datum coordinate systems.
  2. Select a name from the list, and click **OK**.
- Click **Use Global CSYS** from the prompt area to revert to the global coordinate system.

By default, the global coordinate system is used to define the rotary inertia.

7. Use the **Damping** tabbed page to define proportional damping for point masses or rotary inertia. For an Abaqus/Standard analysis, you can also define composite damping. You can specify values for both proportional damping for point masses and composite damping or for both proportional damping for rotary inertia and composite damping; however, Abaqus uses only the damping that is relevant to the particular dynamic analysis procedure being performed. If different damping values are needed for point masses and rotary inertia, you must create separate inertia definitions.

- In the **Alpha** field, enter the α_R factor to create proportional damping for point masses or rotary inertia in a direct-integration dynamic analysis, in a mode-based analysis that supports nondiagonal damping in Abaqus/Standard, or in an explicit dynamic analysis. This value is ignored in a modal dynamic analysis that does not support nondiagonal damping. The default value is 0.0.
- In the **Composite** field, enter the fraction of critical damping, ξ_α, to be used when calculating composite damping factors for the modes in a modal dynamic analysis. This value is ignored in a direct-integration dynamic analysis and in mode-based analyses that support nondiagonal damping in Abaqus/Standard. The default value is 0.0.

8. Click **OK** to save your data and to close the dialog box.
   Symbols appear in the viewport that represent the point mass and rotary inertia that you just created.

Additional information

- *Controlling the display of attributes*
- *Symbols used to represent special engineering features*

Defining nonstructural mass

You can define nonstructural mass for a region on a part or on an assembly.
For more information, see *Nonstructural Mass Definition*.

1. From the main menu bar in the Property module or the Interaction module, select **Special->Inertia->Create**.
2. In the **Create Inertia** dialog box that appears, name the inertia, select **Nonstructural mass**, and click **Continue**.
3. Select the region for which you want to define nonstructural mass using one of the following methods:

   - Select the region in the viewport. When you have finished selecting, click mouse button 2.

     If the model contains a combination of orphan mesh elements and geometry, select one of the following from the prompt area:

     - Select **Geometry** to define the nonstructural mass for the geometric portions of a part or assembly or for a reference point.
     - Select **Mesh** to define the nonstructural mass for orphan mesh components.

       You can use the angle method to select a group of nodes from an orphan mesh. For more information, see *Using the angle and feature edge method to select multiple objects*.

   - To select from a list of existing sets, do the following:

     1. Click **Sets** on the right side of the prompt area to display the **Region Selection** dialog box containing a list of available sets.
     2. Select the set of interest, and click **Continue**.

     Note: The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

   The **Edit Inertia** dialog box appears. The region to which you are applying the nonstructural mass is highlighted in the viewport.
4. Choose the **Units** that you will use to specify the nonstructural mass magnitude. The available types depend on the type of region that you selected.

   - Select **Total Mass** to specify the magnitude in the form of a total mass value.
   - Select **Mass per Volume** to specify the magnitude in the form of mass per unit volume.
   - Select **Mass per Area** to specify the magnitude in the form of mass per unit area.
   - Select **Mass per Length** to specify the magnitude in the form of mass per unit length.

5. Enter the nonstructural mass magnitude in the **Magnitude** field in the units that you chose in the previous step.
6. If you specify the mass in the form of a total mass value and the region as a set, you can choose the **Distribution** method for distributing the mass over the region.

   - Select **Mass Proportional** to distribute the total mass among the members of the set in proportion to the structural mass. The underlying structural density is scaled uniformly over the region, and the center of mass is not altered.

- Select **Volume Proportional** to distribute the total mass among the members of the set in proportion to the volume in the initial configuration. A uniform value is added to the underlying structural density over the region. If the region has a nonuniform structural density, its center of mass might be altered.

7. Click **OK** to save your data and to close the dialog box.

   Symbols appear in the viewport that represent the nonstructural mass that you just created.

Additional information

- *Controlling the display of attributes*
- *Symbols used to represent special engineering features*

Defining heat capacitance

You can define concentrated heat capacitance at a point on a part or on an assembly.
For more information, see *Point Capacitance*.

1. From the main menu bar in the Property module or the Interaction module, select **Special->Inertia->Create**.
2. In the **Create Inertia** dialog box that appears, name the inertia, select **Heat capacitance**, and click **Continue**.
3. Select the points for which you want to define heat capacitance using one of the following methods:

   - Select the points in the viewport. When you have finished selecting, click mouse button 2.

     If the model contains a combination of orphan mesh elements and geometry, select one of the following from the prompt area:

     - Select **Geometry** to define heat capacitance for the geometric portions of a part or assembly or for a reference point.
     - Select **Mesh** to define heat capacitance for orphan mesh components.

       You can use the angle method to select a group of nodes from an orphan mesh. For more information, see *Using the angle and feature edge method to select multiple objects*.

   - To select from a list of existing sets, do the following:

     1. Click **Sets** on the right side of the prompt area to display the **Region Selection** dialog box containing a list of available sets.
     2. Select the set of interest, and click **Continue**.

     Note: The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

   The **Edit Inertia** dialog box appears. The region to which you are applying the heat capacitance is highlighted in the viewport.
4. **Optional:** Toggle on **Use temperature-dependent data**, and enter the temperature.
5. **Optional:** Specify the **Number of field variables**, and enter the value for the first field variable, the value of the second field variable, etc.
6. In the **Data** table, enter the following:

   ### Capacitance

   Enter the capacitance magnitude, ρcV (density × specific heat × volume).
7. Click **OK** to save your data and to close the dialog box.

   Symbols appear in the viewport that represent the heat capacitance that you just created.

Additional information

- *Controlling the display of attributes*
- *Symbols used to represent special engineering features*

Editing the region to which inertia is applied

You can edit the region to which inertia is applied.

1. From the main menu bar in the Property module or Interaction module, select **Special->Inertia->Edit->*inertia name*** to display the **Edit Inertia** dialog box.
2. In the top part of the dialog box, click .
3. Edit the region using one of the following methods:
   - Select and unselect objects in the viewport. When you have finished editing the region, click mouse button 2. For more information, see *Selecting objects within the viewport*.
   - To select from a list of existing sets, do the following:
     1. Click **Sets** on the right side of the prompt area.

        Abaqus/CAE displays the **Region Selection** dialog box containing a list of available sets.
     2. Select the set of interest, and click **Continue**.

Note: The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

4. In the dialog box, finish editing the inertia definition as desired and then click **OK**.

   The symbols representing inertia in the viewport change to appear on the newly edited region.

Load cases

This section provides information on how to use load cases.

In this section:

- *What is a load case?*
- *Managing load cases*
- *Load case editors*
- *Viewing load case output*
- *Defining a load case*

What is a load case?

A load case is a set of loads and boundary conditions used to define a particular loading condition. You can use one or more load cases to study the linear responses of a structure subjected to different loading conditions in the following types of analyses: static perturbation, direct steady-state dynamic, SIM-based steady-state dynamic (mode-based and subspace-based), and substructure generation. A load case analysis is generally much more efficient than the equivalent multiple step analysis since it takes advantage of the principal of linear superposition.

You can define load cases directly in terms of loads and boundary conditions or in terms of combinations of previously defined load cases. You use the Load module to define load cases directly in terms of loads and boundary conditions. You use the Visualization module to define load case combinations of previously defined load cases during postprocessing. Load case output is stored in separate frames in the output database (`.odb`), and you can create results for load case combinations by combining the results from multiple frames.

You use the **Load Case** menu in the Load module to create load cases that include previously defined loads and boundary conditions. You can use a nonzero scale factor to scale the magnitude of individual loads and boundary conditions within a load case. You may include a load or boundary condition only once within each load case. If a step contains load cases, you must include each load and boundary condition in the step in one or more load cases. By default, Abaqus/CAE includes all boundary conditions propagated or modified from the base state in each load case you create but allows you to modify this behavior for individual load cases. You can use the boundary condition manager to deactivate unused propagated boundary conditions in a step containing load cases.

In steps containing load cases Abaqus supports only field output requests. The field output requests created in the Step module apply to all load cases in the step. You can use the Visualization module to view and manipulate load case results (see *Viewing load case output*).

For more information on load cases, see *Multiple Linear Load Case Analysis*. For more information on creating loads and boundary conditions in the Load module, see *Creating and modifying prescribed conditions*.

Additional information

• *Suppressing and resuming objects*

Managing load cases

The **Load Case Manager** allows you to organize and manipulate load cases associated with a given model. You access the manager in the Load module by selecting **Load Case->Manager** from the main menu bar. The **Load Case Manager** is shown in *Figure 1*.

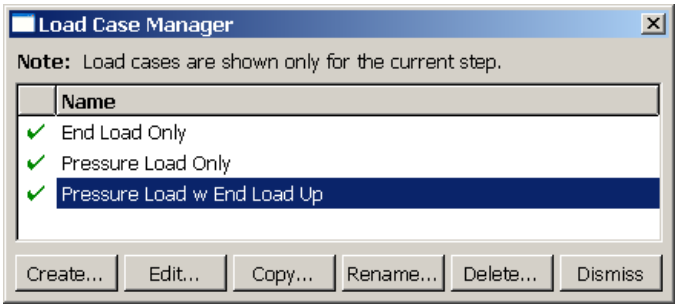

Figure 1: The Load Case Manager.

The icons in the column along the left side of the manager allow you to suppress and resume existing load cases. The **Create**, **Edit**, **Copy**, **Rename**, or **Delete** buttons in the manager allow you to create new load cases or to edit, copy, rename, and delete existing ones. You can also initiate the create, edit, copy, rename, and delete procedures by using the **Load Case** menu in the main menu bar. After you select a management operation from the main menu bar, the procedure is exactly the same as if you had clicked the corresponding button inside the manager dialog box.

For detailed instructions on creating and editing load cases, see *Defining a load case*.

Additional information

- *Managing objects*
- *Suppressing and resuming objects*

Load case editors

After you enter the Load module and create loads and boundary conditions, you can select **Load Case->Create** from the main menu bar to create a load case. A **Create Load Case** dialog box appears in which you can provide a name for the load case and select the step in which the load case will be created. When you click **Continue** in the **Create Load Case** dialog box, the load case editor appears.

The top panel of the load case editor displays the name of the load case and the current analysis step. The load case editor contains two tabbed pages with tables that allow you to select the loads and boundary conditions to define the load case. By default, Abaqus/CAE includes all boundary conditions propagated or modified from the base state in each load case that you create. You can toggle off this behavior on the **Boundary Condition** tabbed page.

Click  at the bottom of each tabbed page to select loads and boundary conditions from a list. You can enter a scale factor to scale the magnitude of individual loads and boundary conditions. If you enter a negative scale factor for a load, the load will be applied in the opposite direction. You can also enter the names of the loads and boundary conditions and the scale factors directly in the tables. During load case creation, Abaqus/CAE sorts the names of the loads and boundary conditions alphabetically and lists the names in the load case editor. You can highlight selected loads and boundary conditions in the viewport.

For example, you can define a set of load cases to analyze the response of a cantilever beam subjected to an end load and a uniform pressure load. The cantilever beam model is shown in *Figure 1*.

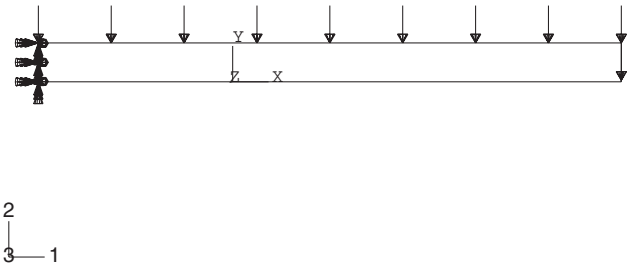

Figure 1: Cantilever beam model with end load, pressure load, and encastre boundary condition.

An encastre boundary condition is applied in the initial step, and the end load and pressure load are applied in a static, linear perturbation step.

You can create a load case that contains only the end load and another that contains only the pressure load. In addition, you can create a load case that contains both the pressure load and the end load with the end load applied in the opposite direction (scale factor value of −1), as shown in *Figure 2*.

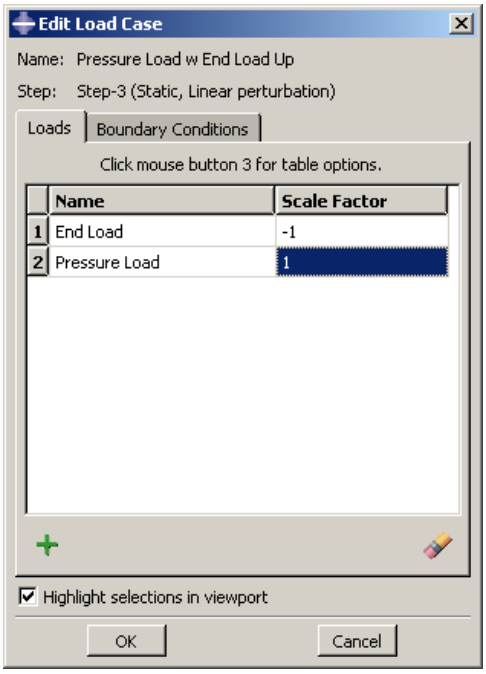

Figure 2: Load case definition that includes loads for the cantilever beam model.

By default, each load case contains the encastre boundary condition propagated from the base state, as shown in *Figure 3*.

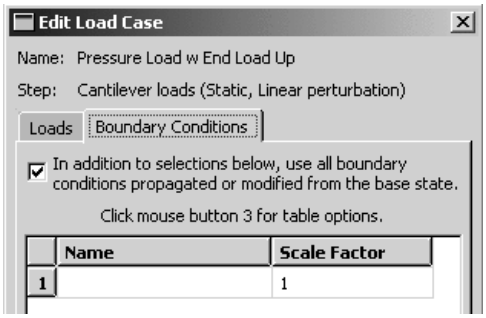

Figure 3: Load case definition that includes boundary conditions propagated from the base state for the cantilever beam model.

The **Load Case Manager** in *Figure 1* shows the three load cases created for the cantilever beam model.

Additional information

- *What is a load case?*

Viewing load case output

Load case output is stored in separate frames in the output database (`.odb`). You use the Visualization module to view and manipulate load case output. The load case name is displayed in the state block for each frame containing load case output. For example, *Figure 1* shows the deformed plot for the `Pressure Load w End Load Up` load case of the cantilever beam model (see *Load case editors*).

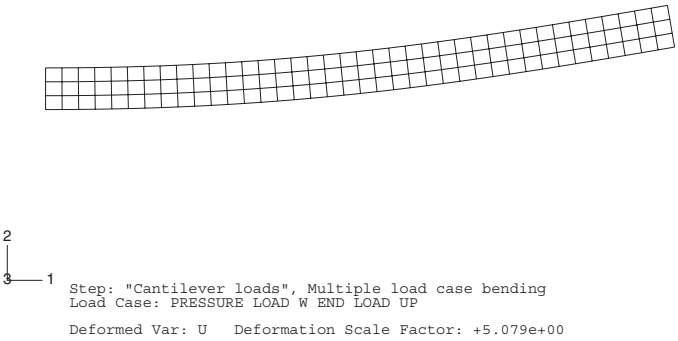

Figure 1: Results from a load case analysis.

In the Visualization module you can linearly combine output from several load cases to represent an actual loading environment. You can also obtain the minimum or maximum value of a selected field variable over some or all load cases.

For example, you can combine the output from the `End Load Only` and `Pressure Load Only` load cases for the cantilever beam model to create new field output with a load case name of `Both loads`, as shown in *Figure 2*.

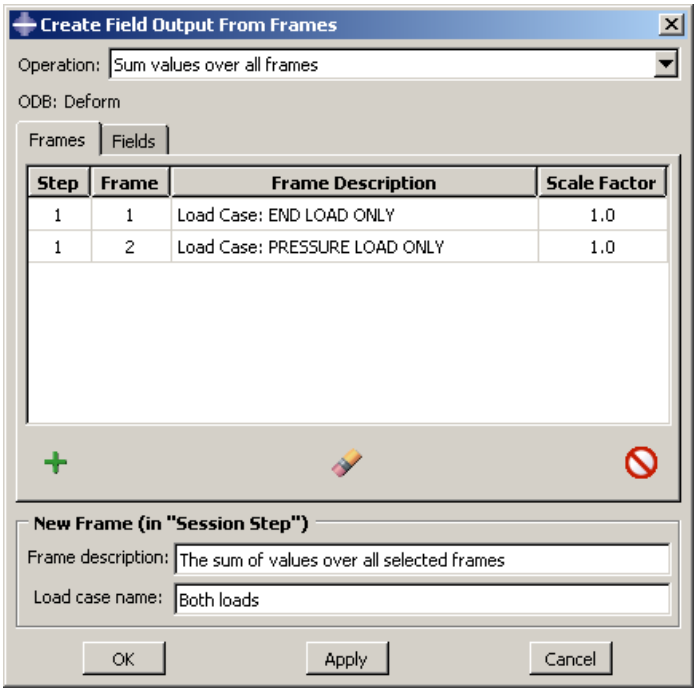

Figure 2: Creating new field output by combining the output from two load cases (frames).

The new field output is contained in a frame of the session step and is available from the **Field Output** dialog box. *Figure 3* shows a plot of the combined deformation results.

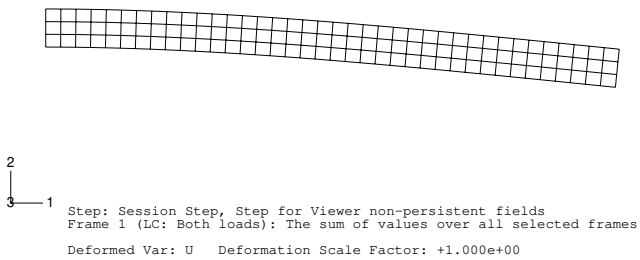

Figure 3: Combined deformation results from both load cases.

For detailed information on manipulating load case output, see *Combining results from several frames*.

Additional information

- *Creating and saving new field output*

Defining a load case

You use the **Load Case** menu in the Load module to define a load case. You can create load cases in static perturbation, direct steady-state dynamic, SIM-based steady-state dynamic (mode-based and subspace-based), and substructure generation analyses. You must create the individual loads and boundary conditions in the Load module prior to creating a load case. For more information, see *Creating loads*, and *Creating boundary conditions*.

1. From the main menu bar in the Load module, select **Load Case->Create**.

   Tip: You can also create a load case using the tool in the Load module toolbox.

2. In the **Create Load Case** dialog box that appears, do the following:
   a. Name the load case. For more information about naming objects, see *Using basic dialog box components*.
   b. Select the step. You can define a load case only during the following steps: static, linear perturbation; steady-state dynamic, direct; SIM-based steady-state dynamic (modal and subspace); and substructure generation.
   c. Click **Continue**.

   The load case editor appears.

3. If you want to include loads in the load case, click the **Loads** tab. Specify the loads using one of the following methods:

   - Click at the bottom of the page to display a list of the loads available for the selected step.
     1. From the **Load Selection** dialog box, select the loads from the list (see *Selecting multiple items from lists and tables*, for more information). The selected loads are highlighted in the viewport.
     2. In the **Scale factor** field, enter a nonzero value to scale the magnitude of the selected loads. Enter a negative value to apply the selected loads in the opposite direction. The default value of the scale factor for each load is 1.0.
     3. Click **OK** to save your selections and to close the **Load Selection** dialog box.
   - Enter data in the table using the keyboard.
     1. Enter the name of a previously defined load.
     2. Enter a nonzero value to scale the magnitude of the load. Enter a negative value to apply the load in the opposite direction. The default value of the scale factor is 1.0.
     3. Repeat the previous steps to specify all the loads to include in the load case.

   The load case editor displays the loads and scale factors included in the load case. To highlight loads in the viewport, click the table row headings to select the loads in the editor (see *Selecting multiple items from lists and tables*, for more information) and toggle on **Highlight selections in viewport**. Suppressed loads are not highlighted in the viewport. To remove loads from the table, click the table row headings to select the loads and click .

4. If you want to include boundary conditions in the load case, click the **Boundary Conditions** tab to display the boundary conditions page. By default, Abaqus/CAE will include all boundary conditions propagated or modified from the base state in each load case you create. You can toggle off this behavior at the top of the boundary condition page. Specify the boundary conditions using one of the following methods:

- Click  at the bottom of the page to display a list of the boundary conditions available for the selected step.

  1. From the **Boundary Condition Selection** dialog box, select the boundary conditions from the list (see *Selecting multiple items from lists and tables*, for more information). The selected boundary conditions are highlighted in the viewport.
  2. In the **Scale factor** field, enter a nonzero value to scale the magnitude of the selected boundary conditions. The default value of the scale factor for each boundary condition is 1.0.
  3. Click **OK** to save your selections and to close the **Boundary Condition Selection** dialog box.

- Enter data in the table using the keyboard.

  1. Enter the name of a previously defined boundary condition.
  2. Enter a nonzero value to scale the magnitude of the boundary condition. The default value of the scale factor is 1.0.
  3. Repeat the previous steps to specify all the boundary conditions to include in the load case.

The load case editor displays the boundary conditions and scale factors included in the load case. The scale factor is relevant only if the boundary condition has a nonzero value. To highlight boundary conditions in the viewport, click the table row headings to select the boundary conditions in the editor (see *Selecting multiple items from lists and tables*, for more information) and toggle on **Highlight selections in viewport**. Suppressed boundary conditions are not highlighted in the viewport. To remove boundary conditions from the table, click the table row headings to select the boundary conditions and click .

5. Click **OK** to save your load case definition and to close the editor.

Midsurface modeling

This section explains midsurface modeling and how you can use it to simplify thin solid models for analysis.

In this section:

- *Understanding midsurface modeling*
- *Understanding the reference representation*
- *Creating shell faces for the midsurface model*
- *Examples of creating a midsurface model*
- *Creating and editing midsurface models*

Understanding midsurface modeling

Midsurface modeling is a technique for creating a simplified shell representation of a solid model. Midsurface modeling can reduce the computational expense of analyzing a complete solid model when a shell model with a defined thickness and fewer details is suitable for the required analysis.

The midsurface modeling process relies on an accurate solid model as the starting point. Midsurface modeling is best suited to thin solids or thin-walled solids where wall thickness is constant or where reasonable approximations of the wall thickness at each point can be made easily. You can apply midsurface modeling to any solid cell within a model; you need not apply it to the entire model. If you apply midsurface modeling to only a portion of a solid model, Abaqus/CAE automatically creates shell-to-solid coupling constraints to couple the motion of the midsurface shell edges to that of the remaining solid model faces. Shell-to-solid coupling constraints will not be created if the angle between the shell surface and the solid face deviates significantly from 90°.

Besides reduced expense, you might use a midsurface model in place of a solid model to better account for bending response in thin sections of the model. Shell elements are designed to manage bending loads within the thickness of a single element, whereas a single solid element will have little or no resistance to bending.

Creating a midsurface model in Abaqus/CAE is a manual process. The procedure presented below provides an overview of the general steps involved. The tasks within each step may vary depending on the complexity and completeness of the original solid model and the analysis requirements. Some steps, such as Step 4 below, may not be required or may be completed in a different order from what is presented here.

1. Assign midsurface regions on the solid part. Use the **Assign Midsurface Region** tool to select one or more cells from the solid part to begin creating a midsurface model. For more information, see *Assigning a midsurface region*.

   Abaqus/CAE removes the selected cells from the active representation and creates a reference representation containing the selected cells.

2. Create new shell faces to replace the solid geometry that you moved to the reference representation.

   You can use tools in the Geometry Edit toolset or the shell feature creation tools to add shell features to the midsurface model. For more information, see *The Geometry Edit toolset* and *Adding a shell feature*, respectively. The offset faces tool in the Geometry Edit toolset is the most common face creation method for midsurface models. The offset process creates new faces based on selected geometry and automatically assigns a shell thickness based on the offset parameters.

3. Assign thicknesses to the new shell features.

   The **Assign Thickness and Offset** tool allows you to assign shell thicknesses to the new midsurface geometry (for more information, see *Assigning thicknesses and offsets*). The tool allows you to assign thicknesses to individual faces, and you can also use it to edit thicknesses that Abaqus/CAE assigned automatically for faces created using the offset process. You must still assign a section to the new faces in the Property module. During the section assignment process you can make a final decision whether to use the thickness defined with the section properties or to use the definition from the geometry. You can toggle the shell thickness display in all part and assembly-based modules to see the thickness in the viewport (for more information, see *Visualizing shell thicknesses*).

4. Revise any analysis attributes that were associated with the solid geometry that was used to create the reference representation.

   Analysis attributes such as loads, boundary conditions, or interactions cannot be applied to geometry in the reference representation. Any attributes that were associated with the solid geometry before it was moved to the reference representation will be associated with an empty region if the geometry is no longer part of the active representation. For more information, see *Understanding the reference representation*.

Understanding the reference representation

A reference representation is an alternative representation of a part or a subset (one or more cells) of a part that is not used in the analysis. The reference representation retains the original solid model geometry, and, like reference geometry in the Sketcher, you can use entities from the reference representation as tools to construct a simpler version of the part. The reference representation is most commonly used to construct a midsurface model. When used with the offset face tool to create faces for the midsurface model, the offset calculations between the reference representation and the new faces also allow Abaqus/CAE to automatically compute shell thicknesses and element offsets in the midsurface model.

Abaqus/CAE creates a reference representation when you assign a midsurface property to one or more cells in a solid part. The selected cells are removed from the active representation of the part and added to the reference representation. The reference representation appears by default in the Part module and is colored translucent brown. You cannot change the color of the reference representation, but you can toggle it on or off in all modules using the **Show Reference Representation** tool  located with the visible object tools in the main toolbar. You can also toggle translucency of the reference representation on or off using the display options (for more information, see *Controlling edge visibility*.

You can use the reference representation with the shape creation tools or with the tools in the Geometry Edit toolset to help construct new geometric entities in the active representation. For example, you can offset faces in the reference representation or you can select a planar face from the reference representation as the sketch plane to create a new shell face using the extrude method. You can use the geometry in the reference representation to define partitions—select an edge and a vertex from the reference representation as the point and normal to partition a cell—or create datum entities. You can also use reference representation geometry to position entities and define constraints in the Assembly module.

You cannot edit the geometry within the reference representation, and you cannot assign analysis attributes such as loads, boundary conditions, and interactions to it. When you create a reference representation, any analysis attributes that were applied to the solid cells before you created the reference representation will now be associated with an empty region. You can edit the empty regions to associate the analysis attributes with geometry—solid geometry or shell geometry that you create for the midsurface model—that is part of the active representation. Alternatively, you can suppress or delete the analysis attributes. If you do not make any changes to the affected analysis attributes, Abaqus/CAE will display a warning message when you submit the job in the Job module.

Creating shell faces for the midsurface model

Once you have a reference representation, you must manually build a shell model to replace the solid cells that have been removed from the model.
You can use the shell feature tools and the tools in the Geometry Edit toolset (for more information, see *Adding a shell feature* and *The Geometry Edit toolset*, respectively) to create and edit shell faces.

This section discusses some special conditions that may apply when you use these tools to create faces for a midsurface model.

In this section:

- *Using the offset face tool for midsurface modeling*
- *Using the extend faces tool for midsurface modeling*

Using the offset face tool for midsurface modeling

You can use the offset face tool from the Geometry Edit toolset to create midsurface faces. The offset face tool creates new faces at an offset distance from an original set of faces. The offset faces are created using a similar process to that used for offsetting objects in the Sketcher (for more information, see *Offsetting objects*). Use of the offset face tool is discussed in detail in *Offset faces*.

In addition to the basic task of creating new shell faces, the offset face tool offers two functions that are helpful for creating a midsurface model:

- The offset distance is used by Abaqus/CAE to assign a thickness to the new shell faces.
- The auto trim option automatically trims the new faces to the reference representation.

Once you have selected the faces to offset, you can enter a value for the offset distance or select a set of target faces that represents the distance through the desired shell thickness and have Abaqus/CAE calculate an offset. Abaqus/CAE calculates the distance between faces being offset and the target faces. You can offset to half the average distance or a fraction of the distance to the closest or farthest point on the target faces.

The difference in using each of the calculated offset distances is shown in *Figure 1*. The part has three different thicknesses. The thinnest face is at the top, the thickest in the middle, and the vertical face on the right has a thickness between the other two. The three outer faces of the reference representation were selected to be offset, and the three inner faces are the target faces. The view on the left shows the default **Half the average distance** method, and the offset is approximately the full thickness of the top face. The middle view shows the **Fraction distance to closest point on face** method with the fractional distance set to `0.5`. The top target face is closest to the top offset face, so Abaqus/CAE offsets the new faces by `0.5` times this distance. The view on the right shows the **Fraction distance to farthest point on face** method with the fractional distance again set to `0.5`. The middle (angled) target face is farthest from the middle offset face, so Abaqus/CAE offsets the new faces by `0.5` times this distance—the top offset face is cut off where it would extend through the reference representation of the original solid part because the **Auto trim to reference representation** option was used.

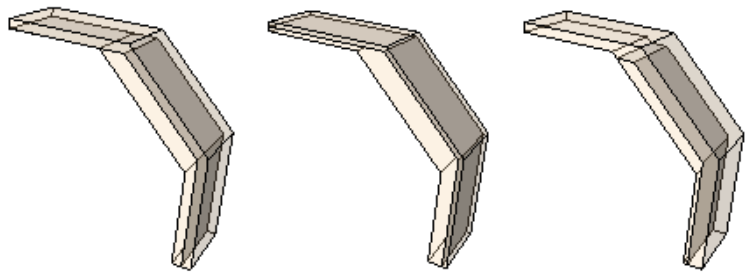

Figure 1: Differences in the offset distance based on the three target face calculation methods.

Abaqus/CAE automatically associates the new offset shell faces with a thickness based on the offset calculations. If you selected target faces to calculate the offset distance, Abaqus/CAE also automatically recalculates the offset for any changes in the geometry of the top and bottom face sets. Use the **Assign Thickness and Offset** tool and the **Render shell thickness** option to edit and view the thicknesses assigned to the shell faces. For more information, see *Assigning thicknesses and offsets*, and *Visualizing shell thicknesses*.

If you use the auto trim option while offsetting faces, Abaqus/CAE offsets the faces and extends the outer edges of the new faces by an amount equal to the offset distance. The new faces are then trimmed where they intersect with the reference representation. *Figure 2* shows a possible effect of using the auto trim option. The reference representation contains a cell, and the larger circular face of the cell was picked for the offset operation. Using the auto trim option, the new face is trimmed to the boundary of the conical face of the reference representation.

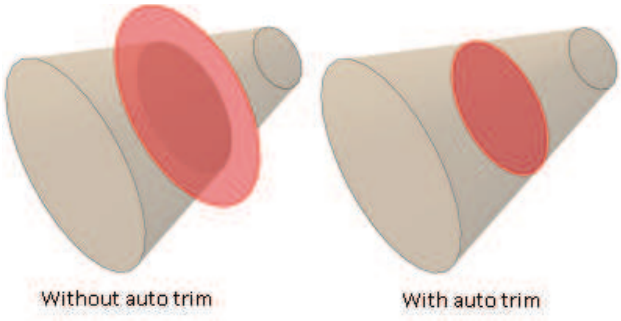

Figure 2: The auto trim option trims to the outer faces of the reference representation.

Additional information

- *Offset faces*
- *Extend faces*

Using the extend faces tool for midsurface modeling

You can use the extend faces tool from the Geometry Edit toolset to create midsurface faces. The extend faces tool extends existing shell faces, so for midsurface modeling it must be used after you have created one or more shell faces. Use of the extend faces tool is discussed in detail in *Extend faces*.

You can extend faces by selecting individual edges to extend the faces in one or more directions, or you can specify faces to extend the faces along all exterior edges. There are also several methods for determining the extension distance; the **Up to reference representation** option is intended specifically for midsurface modeling.

When you use the **Specify edges of faces to extend** option to extend faces along a set of edges, the extend faces operation may fail. If this occurs, try reducing the number of selected edges and then using a second operation to extend the faces along the remaining edges.

Additional information

- *Extend faces*

Examples of creating a midsurface model

This section provides examples of creating midsurface models from solid models. In the first example the solid part has reasonably uniform thickness, and creation of the midsurface model is relatively easy. The second example is more complex and requires multiple steps to create a midsurface model that accurately represents the original solid model.

In this section:

- *Midsurface modeling of a stamped bracket*
- *Midsurface modeling of a complex part*
- *Creating the shell representation of the beam*

Midsurface modeling of a stamped bracket

This example shows how you can use the midsurface modeling tools in Abaqus/CAE to convert a solid model of a bracket to a shell representation of the same part.

The solid model

The model in this example is a 175.0 mm long bracket that is stamped from a 3.0 mm thick plate of mild steel, as shown in *Figure 1*. A default mesh of the solid part results in one or two elements through the thickness of the bracket that will not perform well in bending. Modeling a shell representation of the bracket will provide a more accurate bending response.

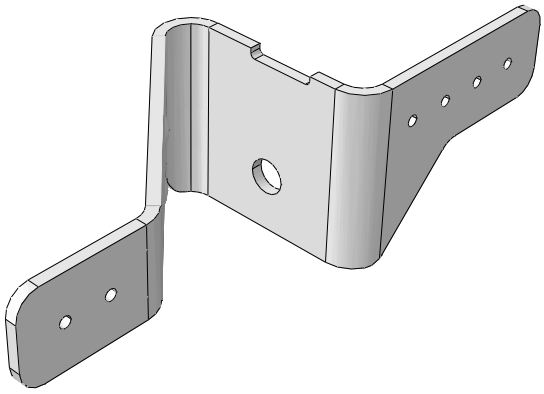

Figure 1: The solid model of the bracket.

Assign the midsurface region

Use the **Assign Midsurface Region** tool in the Part module to remove geometry from the active representation of the model and to create a reference representation of the original solid geometry, as shown in *Figure 2*.

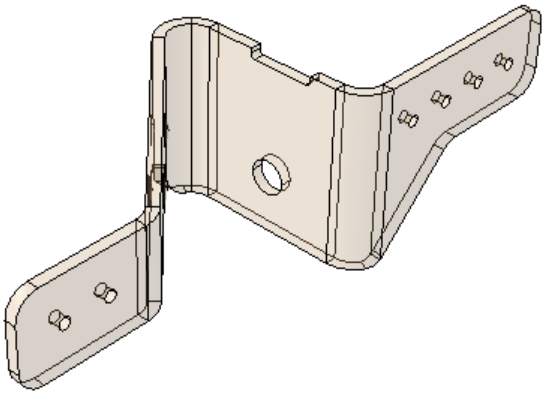

Figure 2: The reference representation of the bracket.

The reference representation is an abstract representation of the original bracket. It retains the original geometry of the bracket, but it cannot be used in the analysis. The reference representation appears by default in the Part module; you can toggle the view off and on using the **Show Reference Representation** tool  located with the visible object tools in the main toolbar. For more information, see *Understanding the reference representation*, and *Assigning a midsurface region*.

Create the shell representation

You must create a shell representation of the bracket that can be analyzed by Abaqus. The most commonly used tool for creating a midsurface shell model is the offset face tool, located with the other face tools in the Geometry Edit toolset. The offset face tool allows you to select one or more faces from the reference representation and to create new faces that are offset from the original faces. You can enter a fixed distance, or you can select target faces that Abaqus/CAE uses to calculate the distance. If you select target faces, the resulting shell thickness varies if the distance between the face to offset and the target face is not constant. Abaqus/CAE calculates the nodal thickness and the element offset for each node and element when you analyze the model. The **Offset Faces** dialog box is shown in *Figure 3*.

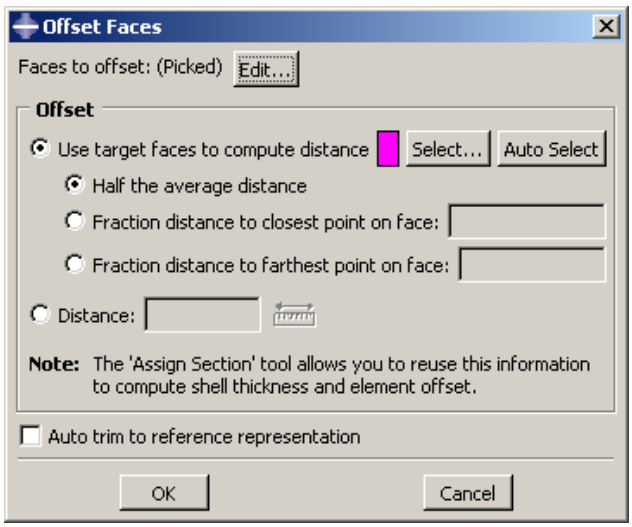

Figure 3: The Offset Faces dialog box.

For more information, see *Methods for editing faces*, and *Adding a shell feature*.

Figure 4 shows the selected faces to offset and the selected target faces. The **by angle** selection method was used to select the inner group of face as the faces to offset and the outer group of faces as the target faces.

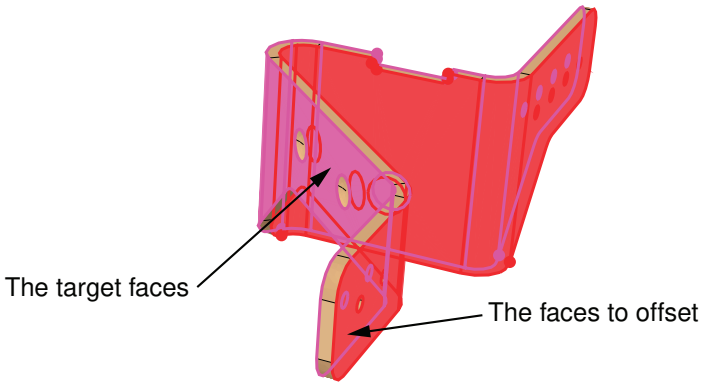

Figure 4: The faces to offset and the target faces.

In this example you select the default option of **Half the average distance** from the **Offset Faces** dialog box, and Abaqus/CAE creates faces that are half the average distance between the faces to offset and the target faces.

By default, **Auto trim to reference representation** is toggled off in the **Offset Faces** dialog box. However, the auto trim option was active for this step, so Abaqus/CAE trimmed the offset faces to align with the reference representation. In some cases the trimming operation fails, which results in a slight misalignment between the new faces and the reference representation and a warning message from Abaqus/CAE. Even when trimming fails, the resulting shell face is often still a reasonable approximation of the reference representation; so you may be able to ignore the warning message. For more information, see *Using the offset face tool for midsurface modeling*.

Assign a shell section

You use the Property module to create a shell section and to assign it to the new face. When you create the shell section, you can enter an arbitrary value for the shell thickness. When you subsequently assign the section to the shell, you specify that the thickness and the shell offset are calculated from the geometry in the **Edit Section Assignment** dialog box, as shown in *Figure 5*. Abaqus/CAE ignores the thickness value that you entered for the shell section.

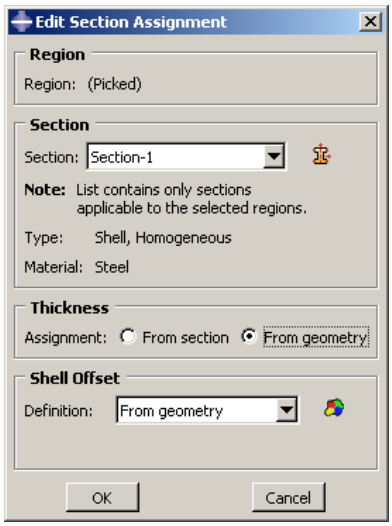

Figure 5: The Edit Section Assignment dialog box.

For more information, see *Assigning a section*.

If desired, you can toggle on **Render shell thickness** from the **Part Display Options** to view the thickness of the shell, as shown in *Figure 6*.

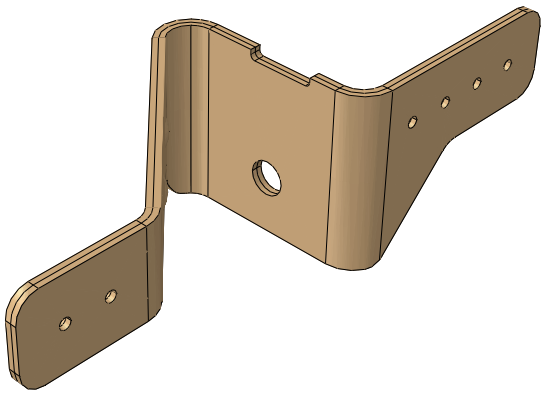

Figure 6: Viewing the shell thickness.

Mesh the part

Abaqus/CAE colors the shell part pink in the Mesh module to indicate it can be meshed using the free meshing technique, as shown in *Figure 7*.

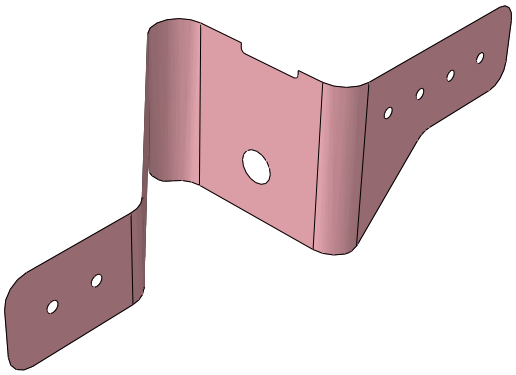

Figure 7: Free meshing can be applied to the part.

You apply automatic virtual topology to the part to remove small details from the original part and to remove details that were created during the face trimming operation, as described in *Creating virtual topology automatically*.

You apply default seeding and mesh controls, and the resulting mesh is shown in *Figure 8*.

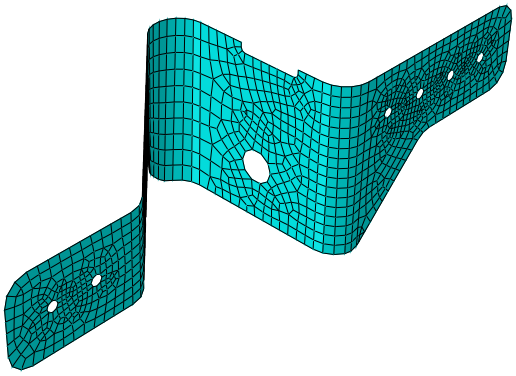

Figure 8: The resulting mesh.

Midsurface modeling of a complex part

This example uses several techniques and tools to create the midsurface model for a reinforced structural component.

The solid model

The model in this example is the structural beam shown in *Figure 1*. The reinforcing ribs, different thicknesses, and asymmetrical shape of the beam do not allow for a simple beam section representation. The complexity of the part combined with its thin cross-sections make it a good candidate for replacement with a midsurface model. As in the previous example, bending performance will be improved by using a shell model for the mesh instead of thin solid sections.

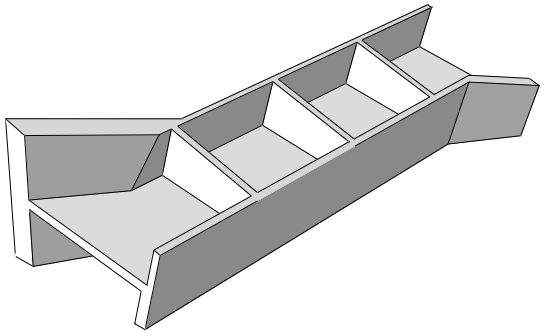

Figure 1: The solid model of the reinforced beam.

Assign the midsurface region

Use the **Assign Midsurface Region** tool in the Part module to remove geometry from the active representation of the beam and to create a reference representation of the original solid geometry, as shown in *Figure 2*. The reference representation is an abstract representation of the original part. It retains the original geometry of the part, but it cannot be used in the analysis. The reference representation appears by default in the Part module; you can toggle it off and on using the **Show Reference Representation** tool  located with the visible object tools in the main toolbar. For more information, see *Understanding the reference representation*, and *Assigning a midsurface region*.

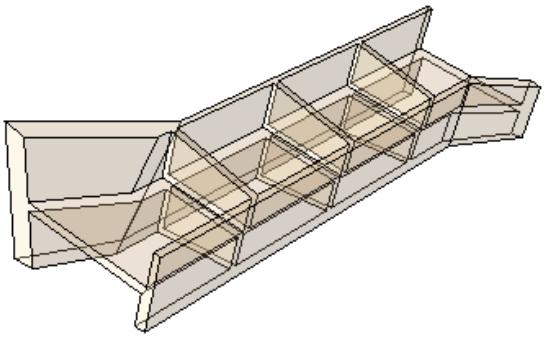

Figure 2: The reference representation of the beam.

Create the shell representation

You must create a shell representation of the beam that can be analyzed by Abaqus. Creating a shell for this part requires multiple steps and tools. There may be several equally valid ways to produce an accurate shell representation for a model. See *Creating the shell representation of the beam*, to use tools from the Geometry Edit toolset to create the new shell faces.

Assign thicknesses

All the original solid geometry has now been replaced with shell geometry. To complete the model, you should verify that the shells have appropriate thickness information. Click the assign thickness and offset tool . Abaqus/CAE highlights any shell faces that do not have thickness data. In this case, since the shell faces were all created using the offset, extend, and blend tools, all of the faces already have thickness data assigned. If there were faces without thickness data, you would select each face and, using the **Compute thickness from opposite faces** method in the **Assign thickness and Offset** dialog box, pick appropriate top and bottom faces from the reference representation to create the missing thicknesses.

To view the model with shell thicknesses, you can toggle on **Render shell thickness** in the **Part Display Options** dialog box (for more information, see *Visualizing shell thicknesses*). As shown in *Figure 3*, the resulting view includes the variations in thickness that were in the original solid model.

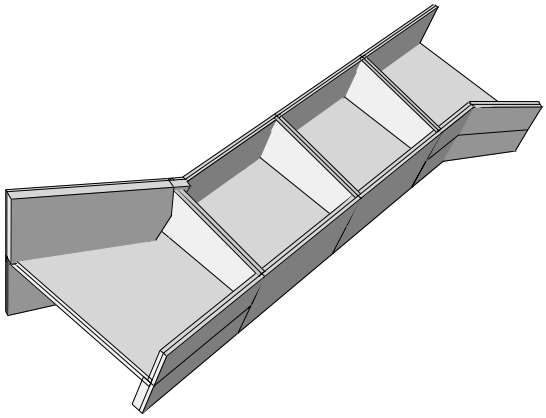

Figure 3: Shell faces with thickness displayed.

Assign a shell section

Use the Property module to create a shell section and assign it to the midsurface model. When you create the shell section, you can enter an arbitrary value for the shell thickness. When you subsequently assign the section to the shell, you specify that the thickness and the shell offset are calculated from the geometry in the **Edit Section Assignment** dialog box. Abaqus/CAE ignores the thickness value that you entered for the shell section and uses the thicknesses assigned to the faces in the Part module. For more information, see *Assigning a section*. *Figure 4* shows the completed midsurface model with section thicknesses after section assignment in the Property module. The geometry is identical to that in *Figure 3*.

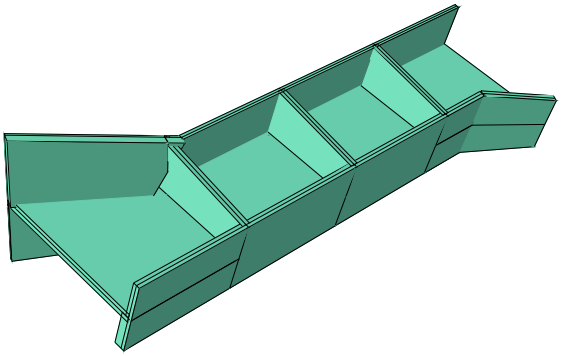

Figure 4: The completed midsurface geometry with shell thicknesses.

Mesh the part

Abaqus/CAE colors the shell part pink in the Mesh module to indicate it can be meshed using the free meshing technique, as shown in *Figure 5*.

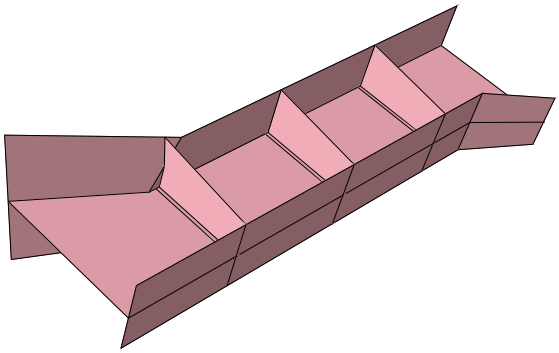

Figure 5: Free meshing can be applied to the part.

Before seeding and meshing the part, you can apply automatic virtual topology to remove small details that are not needed in the mesh (for more information, see *Creating virtual topology automatically*). The default automatic virtual topology settings should remove the blended face edges and other small details that would unnecessarily constrain the part mesh.

Note:

Automatic virtual topology may fail if neighboring faces have inconsistent normals. If this occurs, return to the Part module and use the tool in the Geometry Edit toolset to repair the face normals.

Apply default seeding and mesh controls, and generate the mesh on the part. The resulting mesh is shown in *Figure 6* with the shell thickness displayed.

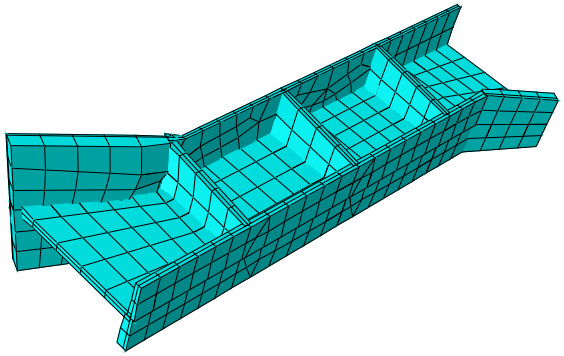

Figure 6: The resulting mesh with shell thickness rendering.

Creating the shell representation of the beam

You must create a shell representation of the beam that can be analyzed by Abaqus. Creating a shell for this part requires multiple steps and tools. There may be several equally valid ways to produce an accurate shell representation for a model. The following steps use tools from the Geometry Edit toolset to create the new shell faces.

1. Use the offset face  tool to create shell faces for the vertical upper left side of the beam.

   Select faces from the reference representation to create the offset shell. Use **Auto Select** to select the target faces. The faces to offset and the target faces are shown in red and magenta, respectively, in *Figure 1*.

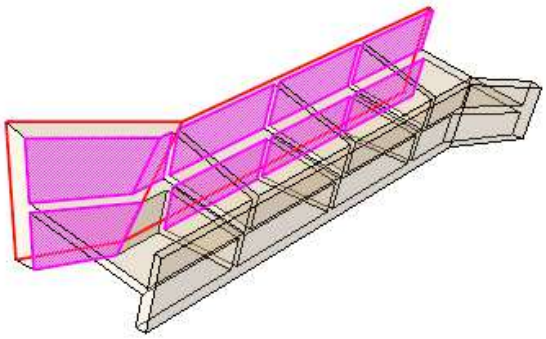

Figure 1: Selected faces to create the offset for the upper left side.

The faces to offset are the two outer vertical faces toward the rear. The target faces are the nine faces, mostly unconnected, that comprise the inner surface of the same beam wall. The **Fraction distance to closest point on face** method is used with an entry of `0.5` to create the offset with half the thickness of the thinner main portion along the top of the beam. Using this option prevents the thicker sections at the left and along the bottom of the beam from creating an offset larger than the thinner portion. The **Auto trim to reference representation** option is used for this step. This operation extends the faces during the offset process and then trims them along the edges of the reference representation. Auto trim may fail when multiple offset and target faces are selected; if auto trim fails, Abaqus/CAE displays a warning indicating the failure. You can use the extend faces tool to extend the new faces to meet the edges of the reference representation. The resulting offset faces are shown in *Figure 2*.

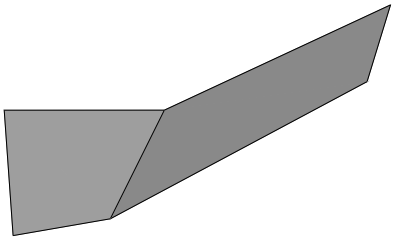

Figure 2: The resulting offset faces.

2. Repeat the process from Step 1 to create offset faces for the opposite side of the beam.

   The resulting shell model now contains the two outer surfaces of the beam, as shown in *Figure 3*.

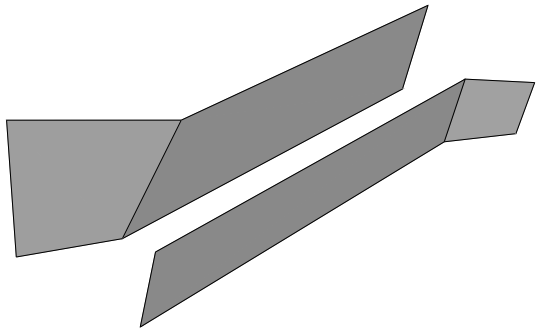

Figure 3: The offset faces from the first and second steps.

3. Create offset faces for the four horizontal sections that connect the two side walls.

   You can create the faces in a single offset operation by selecting the four top faces to offset and using **Auto Select** to select the corresponding bottom faces. In this case **Auto trim to reference representation** is toggled off, so the new faces are not extended and trimmed. The shell model of the horizontal faces is shown in *Figure 4*. (The faces created in Step 2 have been suppressed for clarity.) Notice the gaps between the horizontal faces where they meet the vertical reinforcement ribs in the original part. Similar gaps exist between the horizontal shell faces and the side walls created in the previous two steps.

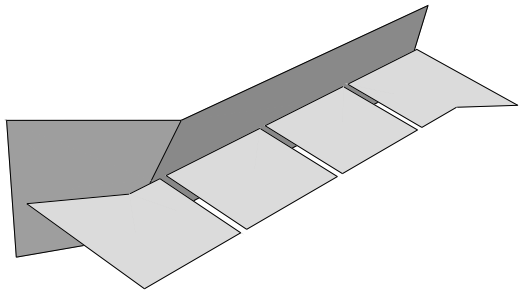

Figure 4: The horizontal offset faces.

4. Repeat the process from Step 3 to create offset faces for the vertical ribs that connect the sides of the beam.

   The midsurface shell model now contains faces representing nearly all of the solid geometry, as shown in *Figure 5*. However, there are gaps between most of the faces due to the thickness of the original solid structure.

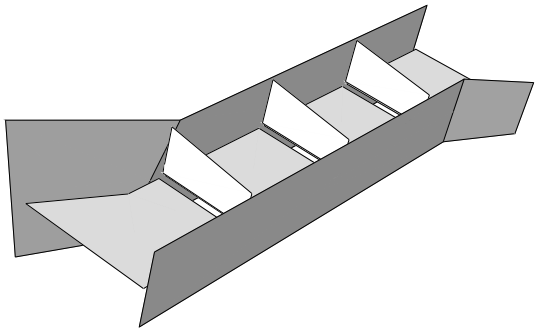

Figure 5: The midsurface model with gaps between the faces.

5. Close the gaps between the vertical ribs and the beam sides.

   Use the extend faces tool to extend the six vertical ribs to intersect with the sides. The selected faces and target faces are shown in magenta and yellow, respectively, in *Figure 6*.

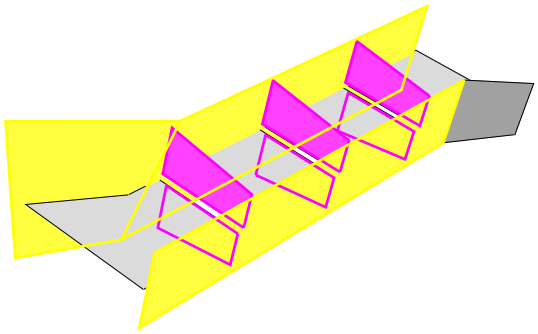

Figure 6: Specifying the faces to extend and the target faces.

When you click **OK**, Abaqus/CAE updates the highlighting to indicate the edges along which the faces will be extended, as shown in *Figure 7*, and displays a warning dialog box with options allowing you to accept the selection, to extend all edges of the selected faces, or to cancel the extend faces procedure.

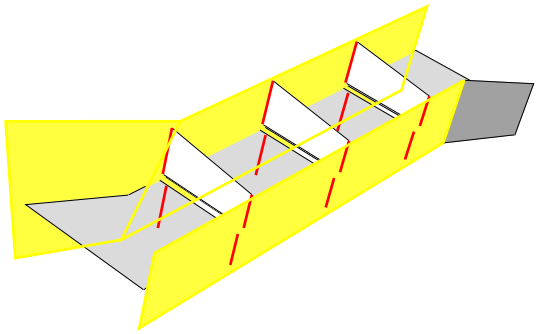

Figure 7: The edges where the vertical faces will be extended.

6. Use the extend faces tool to extend the horizontal faces to intersect with the sides of the beam.

In this case, use the **Specify edges of faces to extend** method with **Up to target faces** to pick the edges and faces, respectively, shown in *Figure 8*. When Abaqus/CAE highlights the edges indicating the areas that will be extended, the four edges indicated by arrows in the figure are removed from the selection because they do not completely match the target faces. Click **No** to use the previous selection of edges.

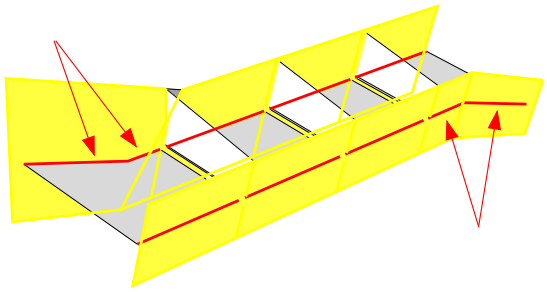

Figure 8: The edges along which the horizontal faces will be the extended.

7. Close the remaining gaps between the horizontal and vertical connecting sections of the beam. You can use either the blend faces tool or the extend faces tool to complete the midsurface model by closing the remaining gaps between the horizontal and vertical connecting sections of the beam.

   a. Use the extend faces tool with the selections shown in *Figure 9*.

   Toggle on **Trim to extended underlying target surfaces** so that Abaqus/CAE will extend and trim the vertical faces to their implied intersections with the selected target face.

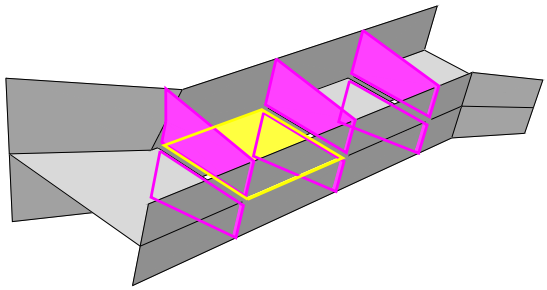

Figure 9: Filling the gaps between the vertical reinforcing ribs.

   b. Use the blend faces tool to fill the remaining gaps.

   The tool must be used three times to fill the three remaining gaps in the model.

Creating and editing midsurface models

The typical process for creating a midsurface model in Abaqus/CAE begins with the solid model. From the solid model, you select cells for which you want to create a midsurface model. Assigning these solid cells as a midsurface region creates a reference representation in the viewport from which you can create shell faces for the midsurface model. You can use tools from the Geometry Edit toolset to create the shell faces, then you can assign thicknesses to the new shells. When you assign thicknesses and offsets to the shell geometry, the default settings typically center the shell representation within the thickness.

In this section:

- *Assigning a midsurface region*
- *Assigning thicknesses and offsets*
- *Assigning thickness to shell faces*
- *Visualizing shell thicknesses*

Assigning a midsurface region

To begin creating a midsurface model, you select the solid model regions that you would like to represent as shells. When you assign a midsurface region to one or more cells of a solid model, Abaqus/CAE creates an **Assign Midsurface** feature and moves the selected cells from the active representation of the part to the reference representation. The reference representation works similarly to reference geometry in a sketch—using the Geometry Edit toolset, you can select points and edges from the reference representation to create points, edges, and faces in the midsurface model. The new midsurface geometry that you create becomes part of the active representation that will be meshed and analyzed.

1. From the main menu bar, select **Tools->Midsurface->Assign**.

   Tip: You can also assign midsurface regions using the  tool, located with the midsurface tools in the Part module toolbox.

2. Select the solid cells from which you want to create the midsurface model.

   You can select individual cells from the viewport or select an existing set of solid cells. For more information on using the selection methods in Abaqus/CAE, see *Selecting objects within the viewport*.

   Abaqus/CAE creates an **Assign midsurface** feature containing the selected cells and displays them as translucent in the viewport.

3. Repeat Step 2 to assign more midsurface regions, or click **Done** to end the procedure.

Additional information

- *Editing techniques*

Assigning thicknesses and offsets

Like all shell faces in Abaqus/CAE, midsurface model faces require a defined thickness. After you have created the shell geometry for the midsurface model, the **Assign Thickness and Offset** tool provides a method to accurately capture the thickness of the solid model that you are replacing. You can also use this tool to edit thicknesses assigned automatically by Abaqus/CAE. For example, you can edit the thickness of faces that were created using the face offset process (for more information, see *Offset faces*). Abaqus/CAE automatically derives the shell thickness for offset faces from the parameters used in the offset operation.

There are two ways to assign a thickness to shell faces in Abaqus/CAE. You can apply a shell thickness definition by using the section properties in the Property module, or you can assign thicknesses by selecting faces and editing their thicknesses with the **Assign Thickness and Offset** tool in the Part module. During the section assignment process you select which method Abaqus/CAE uses to assign thickness to a particular set of geometric faces. (For more information on section assignments, see *Assigning a section*.)

Note:

Thickness data assigned in the Part module—either automatically or using the **Assign Thickness and Offset** tool—appear as **From geometry** in the thickness section of the **Edit Section Assignment** dialog box in the Property module. You cannot use thickness data assigned in the Part module to calculate the offset in an Abaqus/Explicit analysis.

Additional information

- *Editing techniques*

Assigning thickness to shell faces

Defining the thickness in the Part module allows you to define where the midsurface of the solid lies with respect to the shell faces of the midsurface model. The default thickness definition places the midsurface in the center of the thickness. However, you can select surfaces to define a top and bottom thickness, effectively creating an offset between the midsurface and the middle of the shell thickness. Selecting top and bottom faces allows you to easily define different thicknesses at each node and define a different shell offset for each element. This freedom is useful when you use a midsurface model to approximate thin solid models with varying thickness. Using top and bottom faces also allows Abaqus/CAE to automatically update thickness data if you edit the model geometry.

1. From the main menu bar, select **Tools->Midsurface->Assign Thickness and Offset**.

   Tip: You can also assign thicknesses and offsets using the  tool, located with the midsurface tools in the Part module toolbox.

   Shell faces are colored yellow if they are not currently associated with a thickness.

2. If the part contains multiple shell faces, select the faces to which you want to assign thicknesses and offsets (for more information, see *Selecting objects within the viewport*").
3. When you have finished making selections from the viewport, click mouse button 2 to commit your selections.

   Abaqus/CAE opens the **Assign Thickness and Offset** dialog box.
4. If necessary, click the **Edit** button next to **Faces to assign thickness** to change the selections you made in the previous steps.
5. Use one of the following methods to assign a thickness to the selected faces:

Enter or Measure the thickness

Enter a value for thickness, or click  to measure a distance in the viewport and enter it as the thickness.

Compute thickness from opposite faces

Toggle on this option, and click **Select** to select the top and/or bottom faces from the viewport.

Abaqus/CAE highlights the faces in the viewport and calculates the thickness.

If you select only top or only bottom faces, Abaqus/CAE applies the same thickness to both sides of the target shell faces. If you select both top and bottom faces, Abaqus/CAE calculates the thickness and an offset value so that the selected shell faces are not centered within the thickness.

6. Click **OK** to apply the thickness and offset (if used) to the target faces and to close the dialog box.

You can view the thickness of faces in the model by toggling on **Render shell thickness** in the Abaqus/CAE display options. For more information, see *Visualizing shell thicknesses*, and *Controlling shell thickness display*.

Visualizing shell thicknesses

You can view the thickness of your midsurface model in Abaqus/CAE. The thickness representation uses the offsets and thicknesses defined on the part or through the section assignment properties to create the new model view. Visualizing the part thickness along with the reference representation can help you determine whether the midsurface model accurately represents the solid model that you are replacing.

An axisymmetric shell section (smooth curved face) and an extruded shell where faces are joined along a straight edge are shown in *Figure 1*. As shown in the figure, shell thickness is accurately displayed for smooth curved shells; however, where shell faces are joined along edges, the displayed thickness contains gaps and overlaps at the corners between faces.

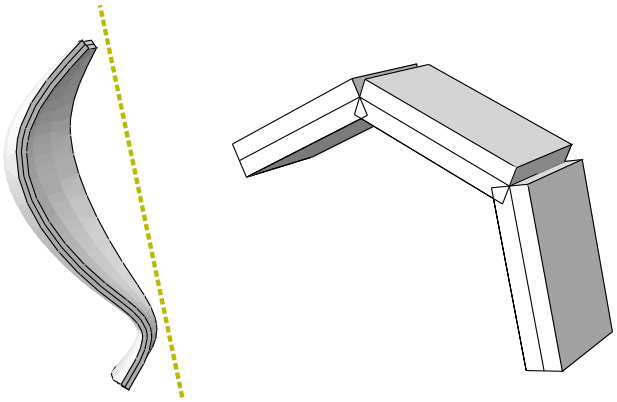

Figure 1: Displaying shell thickness on a smooth curved face and faces joined along edges.

To activate shell thickness display, see *Controlling shell thickness display*.

Additional information

- *Editing techniques*

Skin and stringer reinforcements

This section provides information on how to model skin and stringer reinforcements.

In this section:

- *Defining skin reinforcements*
- *Defining stringer reinforcements*
- *Managing skin and stringer reinforcements*
- *Generating elements on a skin or stringer reinforcement*
- *Assigning element types to skin or stringer reinforcements*
- *Using offset meshes to create skin reinforcements*
- *Assigning surface properties to skins and stringers*
- *Creating and editing skin reinforcements*
- *Creating and editing stringer reinforcements*

Defining skin reinforcements

A skin reinforcement defines a skin that is bonded to the surface of an existing part and specifies its engineering properties. The surface can be a face of a three-dimensional solid part, any edge of an axisymmetric part, or any face of a two-dimensional part. The part can include geometry and orphan mesh elements; however, skin reinforcements must be defined separately for the geometry and the orphan mesh elements. You should think of a skin as a property of a part or region, in the same way a section is a property of a part or region.

The composite beam shown in *Figure 1* is an example of how you might use a skin reinforcement in your model.

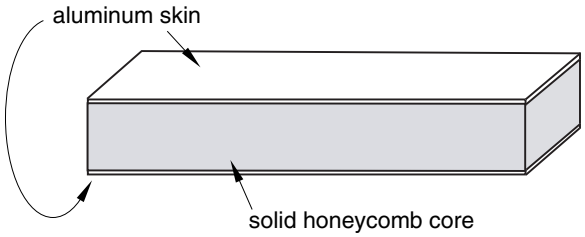

Figure 1: A composite beam modeled by a solid honeycomb core and an aluminum skin.

The beam has a solid honeycomb core and an aluminum skin on the upper and lower faces. You can create a solid part representing the honeycomb and add a skin reinforcement representing the aluminum layers. In the Mesh module you assign solid elements to the honeycomb and shell elements to the skin. The solid and shell elements share the same nodes.

Select **Special->Skin->Create** from the main menu bar in the Property module to define one or more skins. Select **Edit** from the same menu to make changes to an existing definition. All skins you create also appear in the Model Tree in a **Skins** container under the part. Skins are not displayed in the viewport by default, but you can make them visible by color coding them in the viewport. See *Coloring geometry and mesh elements*, for more information.

If you create a skin on a geometry region, Abaqus/CAE updates the skin if you make minor modifications to the underlying geometry. If you edit orphan nodes or elements with a skin, Abaqus/CAE updates the skin if you edit or delete nodes or elements; however, it does not update the skin if you create new nodes or elements.

You may need to select the skin in subsequent modeling operations; for example, to:

- Assign a homogeneous shell section, a composite shell section, a membrane section, a surface section, or a gasket section to a skin. Section assignments are performed in the Property module.
- Assign a material orientation or rebar reference orientation to a skin. Both of these orientation assignments are performed in the Property module.
- Assign a normal direction to a skin in the Property module. Although you cannot assign a normal direction to a skin directly, you can assign a normal direction to a face, which updates the normal direction of all skins defined on that face.
- Prescribe a body force to the skin in the Load module.
- Prescribe a thermal flux on the skin in the Load module. In practice, you perform this modeling operation by applying a thermal flux load to the underlying face or faces. Abaqus/CAE applies the load to all skins on that face during the analysis.
- Assign an element type to the skin in the Mesh module.
- Request field data output or history data output for the skin in the Step module.
- Create a display group to view the stress values on the skin elements in the Visualization module. While you cannot specifically select skins by name in the **Create Display Group** dialog box, you can find them in this dialog box by searching for elements that share the same element type, section assignment, or another property as the skin elements in your model. This process can help you narrow down the list of elements to the skins you want to include.

When you are prompted to select a region for these modeling operations, select **Skins** from the list of object types in the **Selection** toolbar, and select the skin region from the viewport. For more information, see *Filtering your selection based on the type of object*.

When performing contact calculations, Abaqus/CAE considers a geometric surface's skin reinforcements only in certain cases; for example, when you specify general contact for all exterior surfaces, a default all-inclusive surface is defined automatically in Abaqus that will consider skin reinforcements. Skin reinforcements can significantly influence contact calculations, due to skin thickness and potential effects on numerical quantities such as contact penalty stiffness. To explicitly include skin reinforcements in a contact definition, you can create a set on the skin reinforcement and then use the set to define an element-based secondary surface in a contact pair definition in an Abaqus/Standard analysis or use the set to define a node-based secondary surface in a contact definition in an Abaqus/Explicit analysis.

For detailed information on creating a skin, see *Creating and editing skin reinforcements*.

Defining stringer reinforcements

A stringer reinforcement defines a stringer that is bonded to the edge of an existing part and specifies its engineering properties. You can select an edge of a three-dimensional solid part or an edge of a two-dimensional planar part. The part can include geometry and orphan mesh elements; however, stringer reinforcements must be defined separately for the geometry and the orphan elements. You should think of a stringer as a property of a part or region, in the same way a section is a property of a part or region.

The steel-reinforced beam shown in *Figure 1* is an example of how you might use stringer reinforcements in your model.

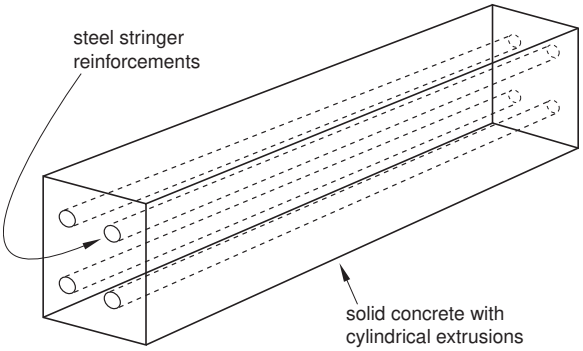

Figure 1: A concrete beam modeled with steel stringer reinforcements.

The beam has a concrete core with four cylindrical extrusions that run the length of the beam. A steel stringer with a circular profile has been created in each extrusion to provide support along the length of the beam. You can create a solid part representing the beam and add four stringer reinforcements representing the steel reinforcements. In the Mesh module you assign solid elements to the concrete and line elements to the stringers. The solid and line elements share the same nodes.

Select **Special->Stringer->Create** from the main menu bar in the Property module to define one or more stringers. Select **Edit** from the same menu to make changes to an existing definition. All stringers you create also appear in the Model Tree in a **Stringers** container under the part. Different stringers can share the same section, and multiple stringers can be placed on an edge of a part. Stringers are not displayed in the viewport by default, but you can make them visible by color coding them in the viewport. See *Coloring geometry and mesh elements*, for more information.

If you create a stringer on a geometry region, Abaqus/CAE updates the stringer if you make minor modifications to the underlying geometry. If you edit orphan nodes or elements with a stringer, Abaqus/CAE updates the stringer if you edit or delete nodes or elements; however, it does not update the stringer if you create new nodes or elements.

You may need to select the stringer in subsequent modeling operations; for example, to:

- Assign a section, beam section orientation, material orientation, or tangent direction to a stringer. All of these activities are performed in the Property module.
- Prescribe a body force or line load to the stringer in the Load module.
- Prescribe a thermal flux on the stringer in the Load module. In practice, you perform this modeling operation by applying a thermal flux load to the underlying edge or edges. Abaqus/CAE applies the load to all stringers on that edge during the analysis.
- Assign an element type to the stringer in the Mesh module.
- Request field data output or history data output for the stringer in the Step module.
- Create a display group to view the stress values on the stringer elements in the Visualization module. While you cannot specifically select stringers by name in the **Create Display Group** dialog box, you can find them in this dialog box by searching for elements that share the same element type, section assignment, or another property as

the stringer elements in your model. This process can help you narrow down the list of elements to the stringers you want to include.

When you are prompted to select a region for these modeling operations, select **Stringers** from the list of object types in the **Selection** toolbar, and select the stringer from the viewport. For more information, see *Filtering your selection based on the type of object*.

When performing contact calculations, Abaqus/CAE considers a geometric surface's stringer reinforcements only in certain cases; for example, when you specify general contact for all exterior surfaces, a default all-inclusive surface is defined automatically in Abaqus that will consider stringer reinforcements. Stringer reinforcements can significantly influence contact calculations, due to stringer thickness and potential effects on numerical quantities such as contact penalty stiffness. To explicitly include stringer reinforcements in a contact definition, you should create a set on the stringer reinforcement and then use the set in a contact definition.

For detailed information on creating a stringer, see *Creating and editing stringer reinforcements*.

Managing skin and stringer reinforcements

The **Skin Manager** and **Stringer Manager** allow you to create and manage skin and stringer reinforcements, respectively. These managers each include a list of the names of skins or stringers that you have defined. The **Create**, **Edit**, **Rename**, and **Delete** buttons in the manager allow you to create new skins and stringers or to edit, rename, and delete existing ones. You can also initiate these procedures using the **Special->Skin** menu and **Special->Stringer** menu from the main menu bar in the Property module. After you select a management operation from the main menu bar, the procedure is exactly the same as if you had clicked the corresponding button inside the manager dialog box.

Note:

If you rename a skin or stringer after you have assigned sections, orientations, normals, or other properties to it, the assignments become invalid.

Additional information

- *Creating and editing stringer reinforcements*

Generating elements on a skin or stringer reinforcement

You can use the Mesh module to generate two-dimensional elements on a skin reinforcement on a face of a three-dimensional part instance. Similarly, you can generate one-dimensional elements on a stringer reinforcement on an edge of an axisymmetric part instance. Abaqus/CAE generates the skin or stringer elements when the underlying geometry is meshed; you cannot mesh a skin or stringer reinforcement independently.

Figure 1 shows a three-dimensional part instance with a skin reinforcement on the top surface.

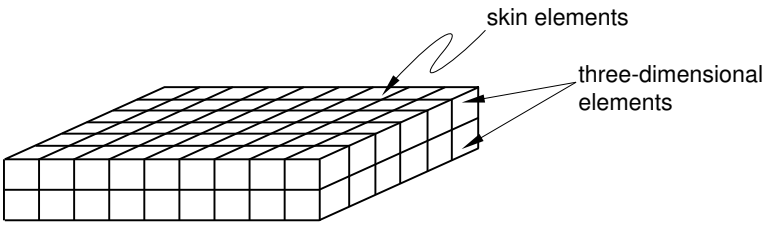

Figure 1: A three-dimensional part instance with a skin reinforcement.

When the part instance is meshed, the skin or stringer elements and the three-dimensional elements share the same nodes and mesh topology. If you assign a different geometric order to the skin elements, you should also change the order of the underlying elements. For more information, see *Assigning element types to skin or stringer reinforcements*.

If you create a skin or stringer on an orphan mesh, the skin or stringer elements and the underlying orphan mesh elements share the same nodes and mesh topology. If you delete an orphan mesh element, Abaqus/CAE automatically regenerates any skins or stringers associated with the deleted element. After regeneration, these skins or stringers have new element ID numbers, so this regeneration renders invalid any sets that include the skins or stringers. Therefore, if you delete elements from an orphan mesh, you should update any set definitions that include skins or stringers formerly associated with the deleted elements.

Assigning element types to skin or stringer reinforcements

You use the Property module to create a skin or stringer reinforcement on a part in your model. You use the Mesh module to assign an element type to a skin or stringer reinforcement. When you are prompted to select the regions to be assigned element types, you must select either **Skins** or **Stringers** from the list of object types in the **Selection** toolbar.

When you create a skin or a stringer for a geometric part, Abaqus/CAE adds an attribute to the geometric entity. This attribute is used when you mesh the part to generate skin or stringer elements, and these elements share nodes with the underlying elements of the part.

You can use stringer reinforcements in a buckling analysis, and you can use skin reinforcements in a coupled structural-acoustic analysis. If the acoustic medium adjoins a structure, structural-acoustic coupling occurs at the interface. It is recommended that you use surface-based tie constraints to enforce the coupling; however, if you are conducting a structural-acoustic submodeling analysis where the acoustic domain forms the submodel, you must line the interface portion of the submodel boundary with acoustic-structural interface (ASI) elements to enforce the coupling. You can line the interface with ASI elements by creating a skin at the interface and assigning ASI elements to the skin. For detailed information about using skins to create ASI elements on geometry and orphan meshes, see the Dassault Systèmes Knowledge Base at *http://support.3ds.com/knowledge-base/*.

Using offset meshes to create skin reinforcements

As an alternative approach, you can use the mesh offset tool in the Edit Mesh toolset to create a skin reinforcement by sharing the nodes of the offset shell with the underlying orphan mesh. However, the equivalent offset shell does not appear in the Model Tree as a skin because using the offset shell to represent a reinforcement skin is just one of many potential uses of the offset shell. If you are creating more than one layer of reinforcement skins, you should specify a distance of zero between the layers so that the layers can share nodes.

Assigning surface properties to skins and stringers

If you want to apply a surface property such as a pressure load to a skin or a stringer, you must apply the property to its underlying surface or edge instead. Because skins and stringers share nodes with the surfaces or edges to which they apply, Abaqus/CAE automatically propagates any applied surface properties to skins and stringers as well. For more information about defining surface properties, see *Assigning sections, orientations, normals, and tangents to a part*.

Creating and editing skin reinforcements

During the initial creation of a skin, you select one or more faces that you want to reinforce and, if desired, the number of skins that you want to create.
After the skin is created, you can modify it in the following ways:

- In the Property module, you can modify a skin by assigning it a section (a homogeneous shell section, a composite shell section, a membrane section, a surface section, or a gasket section), a material orientation, or a rebar reference orientation. You can also reverse the normal direction of a skin by assigning a normal direction to its underlying face. When you reverse the normal direction for a face, all skins assigned to that face inherit the new normal direction as well.
- In the Mesh module, you can assign an element type to the skin. When you are prompted to select the regions to be assigned element types, you must select **Skins** from the list of object types in the **Selection** toolbar. If you assign a shell section to a skin, you must assign shell elements to the skin. Similarly, if you assign a membrane, surface, or gasket section, you must assign membrane, surface, or gasket elements.

Abaqus/CAE names skins automatically, but you can rename them from the **Skin Manager**, the **Special** menu, or from the Model Tree. If you create multiple skins at once, Abaqus/CAE appends a unique identifier to the name to identify each skin.

You can obtain data from a skin by using the field and history output request editors in the Step module. In the **Domain** section of the editor, select **Skin** and choose the desired skin from the menu that appears. For more information, see *Creating an output request*.

1. From the main menu bar in the Property module, select **Special->Skin->Create**.

   
   Tip: You can also click the  tool in the Property module toolbox.

2. Use one of the following methods to select the faces to which you want to add skin reinforcements:

Selecting individual faces:

1. Click the arrow next to the **Select entities on which to create a skin** field in the prompt area, and select **individually** from the list that appears.
2. Select a face to which you want to add skin reinforcement.
3. **[Shift] + Click** on additional faces to add them to your selection.
4. If necessary, **[Ctrl] + Click** on selected faces to unselect them.
5. When you have finished selecting faces, click mouse button 2.

Specifying an existing set:

1. Click **Sets** on the right side of the prompt area.

   Abaqus/CAE displays the **Region Selection** dialog box containing a list of sets that you have created.
2. Select the set of faces to which you want to add skin reinforcement, and click **Continue**.

Note: The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

Selecting faces using the angle method:

1. Click the arrow next to the **Select entities on which to create a skin** field in the prompt area, and select **by face angle** from the list that appears.
2. Enter an angle (from 0° to 90°), and select a face. Abaqus/CAE selects every adjacent face from the selected face until the angle between the faces is equal to or exceeds the angle that you entered. (See *Using the angle and feature edge method to select multiple objects* for more information.)
3. After you use the **by face angle** method, you can **[Shift] + Click** on additional faces to add them to your selection or **[Ctrl] + Click** on selected faces to remove them from your selection. (See *Combining selection techniques* for more information.)

Tip: You can use the **Selection** toolbar to limit the types of objects that you can select in the viewport. For more information, see *Selecting objects within the viewport*.

3. If desired, toggle on **Multiple skins** in the Prompt area to create more than one skin reinforcement for the selected face or faces.
4. Click **Done** to create the skin. If you are creating multiple skins, enter the number of skin layers you want to create, and click mouse button 2.

Additional information

- *Assigning a section*
- *Assigning a material orientation*
- *Assigning a rebar reference orientation*
- *Assigning shell/membrane normal directions*

Creating and editing stringer reinforcements

You can create a stringer immediately after you define the part; stringers do not initially require material or section assignments.
After you have created a stringer, you can then assign it a section, beam section orientation, material orientation, and tangent direction using the options under the **Special** menu in the Property module. You can also assign an element type to the stringer in the Mesh module. When you are prompted to select the regions to be assigned element types, you must select **Stringers** from the list of object types in the **Selection** toolbar.

You can create multiple stringers at a time on the same edge. Abaqus/CAE treats these stringers as different layers of stringer reinforcement, and you can assign different qualities to each one.

Abaqus/CAE names stringers automatically, but you can rename them from the **Stringer Manager**, the **Special** menu, or from the Model Tree. If you create multiple stringers at once, Abaqus/CAE appends a unique identifier to the name to identify each stringer.

You can obtain data from a stringer by using the field and history output request editors in the Step module. In the **Domain** section of the editor, select **Stringer** and choose the desired stringer from the menu that appears. For more information, see *Creating an output request*.

1. From the main menu bar in the Property module, select **Special->Stringer->Create**.

   Tip: You can also click the tool in the Property module toolbox.

2. Use one of the following methods to select the edges to which you want to add stringer reinforcement:

Selecting individual edges:

1. Click the arrow next to the **Select entities on which to create a stringer** field in the prompt area, and select **individually** from the list that appears.
2. Select an edge to which you want to add stringer reinforcement.
3. **[Shift] + Click** on additional edges to add them to your selection.
4. If necessary, **[Ctrl] + Click** on selected edges to unselect them.
5. When you have finished selecting edges, click mouse button 2.

Specifying an existing set:

1. Click **Sets** on the right side of the prompt area.

   Abaqus/CAE displays the **Region Selection** dialog box containing a list of element sets that you have created.
2. Select the set of entities to which you want to add stringer reinforcement, and click **Continue**.

Note:

The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

Selecting edges using the angle method:

You can use this method to select geometric edges only. This method is not available for selecting orphan mesh element edges.

1. Click the arrow next to the **Select entities on which to create a stringer** field in the prompt area, and select **by edge angle** from the list that appears.
2. Enter an angle (from 0° to 90°), and select an edge or another entity. Abaqus/CAE selects every adjacent edge from the selected edge until the angle between the edges is equal to or exceeds the angle that you entered. (See *Using the angle and feature edge method to select multiple objects* for more information.)
3. After you use the **by edge angle** method, you can **[Shift] + Click** on additional edges to add them to your selection or **[Ctrl] + Click** on selected edges to remove them from your selection. (See *Combining selection techniques* for more information.)

Tip: You can use the **Selection** toolbar to limit the types of objects that you can select in the viewport. For more information, see *Selecting objects within the viewport*.

3. If desired, toggle on **Multiple stringers** to create more than one stringer for the selected edge or edges.
4. Click **Done** to create the stringer. If you are creating multiple stringers, enter the number of stringers you want to create, and click mouse button 2.

Additional information

- *Assigning a section*
- *Assigning a beam orientation*

Springs and dashpots

This section provides information on how to model springs and dashpots.

In this section:

- *Defining springs and dashpots*
- *Managing springs and dashpots*
- *Creating springs and dashpots connecting two points*
- *Editing springs and dashpots connecting two points*
- *Creating springs and dashpots connecting points to ground*
- *Editing the region to which springs and dashpots connecting points to ground are applied*

Defining springs and dashpots

You can define springs and dashpots that exhibit the same linear behavior. You can also define both spring and dashpot behaviors on the same set of points. If you define both spring and dashpot behaviors, they act in parallel. You can model springs and dashpots using the following connectivity types:

- Connect two points and follow the line of action between the points
- Connect two points and act in a fixed direction (Abaqus/Standard analyses only)
- Connect points to ground (Abaqus/Standard analyses only)

For more information, see *Springs*, and *Dashpots*.

Select **Special->Springs/Dashpots->Create** from the main menu bar in the Property module or the Interaction module to define springs and dashpots. Select **Edit** from the same menu to make changes to an existing definition. Springs and dashpots created on a part are instanced along with the part.

If you want to include the spring and dashpot results data in the output database generated by the analysis, you must use the **History Output Request** editor in the Step module. Springs and dashpots appear in the Model Tree in the **Engineering Features** container under the part (if created in the Property module) or under the assembly (if created in the Interaction module).

For detailed information, see the following sections:

- *Modifying history output requests*
- *Creating springs and dashpots connecting two points*
- *Editing springs and dashpots connecting two points*
- *Creating springs and dashpots connecting points to ground*
- *Editing the region to which springs and dashpots connecting points to ground are applied*

Managing springs and dashpots

The **Springs/Dashpots Manager** allows you to create and manage springs and dashpots. The manager includes a list of the names and types of springs and dashpots that you have defined. The **Create**, **Edit**, **Copy**, **Rename**, and **Delete** buttons in the manager allow you to create new springs and dashpots or to edit, copy, rename, and delete existing ones. The icons in the column along the left side of the manager allow you to suppress and resume existing springs and dashpots. You can also initiate these procedures using the **Special->Springs/Dashpots** menu from the main menu bar in the Property module or the Interaction module. After you select a management operation from the main menu bar, the procedure is exactly the same as if you had clicked the corresponding button inside the manager dialog box.

Additional information

- *Suppressing and resuming objects*
- *Creating springs and dashpots connecting two points*
- *Editing springs and dashpots connecting two points*
- *Creating springs and dashpots connecting points to ground*
- *Editing the region to which springs and dashpots connecting points to ground are applied*

Creating springs and dashpots connecting two points

You can define springs and dashpots that connect two points and exhibit the same linear behavior independent of field variables.
For more information, see *Springs* and *Dashpots*.

You can obtain history data of stress and strain from a spring/dashpot by using the history output request editor in the Step module. In the **Domain** section of the editor, select **Springs/Dashpots** and choose the desired spring/dashpot from the menu that appears. For more information, see *Creating an output request*.

1. From the main menu bar in the Property module or the Interaction module, select **Special->Springs/Dashpots->Create**.
2. In the **Create Springs/Dashpots** dialog box that appears, name the springs/dashpots, select **Connect two points**, and click **Continue**.
3. Select the first point for the first spring/dashpot using one of the following methods:
   - Select the point in the viewport. (For more information, see *Selecting objects within the viewport*.)

     Tip: The  **Select the Entity Closest to the Screen** tool in the **Selection** toolbar is toggled off by default. If you make an ambiguous selection, Abaqus/CAE highlights the point and displays a description of the point in the lower left corner of the viewport. Use the **Next** and **Previous** buttons to cycle through the possible selections, and click **OK** to confirm your selection.

     If the model contains a combination of geometry and mesh components, select one of the following from the prompt area:

     - Select **Geometry** to define the spring/dashpot for geometry or for a reference point.
     - Select **Mesh** to define the spring/dashpot for a mesh.

   - To select from a list of existing sets, do the following:
     1. Click **Sets** on the right side of the prompt area to display the **Region Selection** dialog box containing a list of available sets.
     2. Select a set that contains only one point, and click **Continue**.

        Note:

        The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

4. Select the second point for the first spring/dashpot using one of the methods described in the previous step.

   The first spring/dashpot point pair and a dashed line connecting them are highlighted in the viewport.
5. Continue selecting pairs of points for additional springs/dashpots as described in the previous steps. When you have finished selecting point pairs, click **Done** in the prompt area.

   The **Edit Springs/Dashpots** dialog box appears. The point pairs that you selected to define each spring/dashpot are listed in the **Spring/Dashpot Point Pairs** table.
6. From the **Spring/Dashpot Point Pairs** table, you can do the following:

- To define additional springs/dashpots with the same behavior, click  and repeat the point selection procedures described in the previous steps to define the first and second points of each spring/dashpot.
- To edit a point in the table, select the point in the table, double-click on it or click , and reselect a point. The selection highlighting in the viewport is updated to show the newly edited point.
- To identify a specific spring/dashpot in the viewport, select the desired row number. The highlighted dashed line connecting the selected point pairs appears bolder in the viewport.
- To remove springs/dashpots from the table, select the desired row numbers and click .
- To remove all springs/dashpots from the table, click .

7. Click the arrow next to the **Axis** field, and select an option from the list that appears:
   - Select **Follow line of action** to have the axis of each spring/dashpot follow the line of action of the two points.
   - Select **Specify fixed direction** to specify the degree of freedom at each point on the spring/dashpot (Abaqus/Standard analyses only).
8. If you selected **Specify fixed direction**, do the following in the **Direction** portion of the dialog box:
   - Click the arrow next to the **Point 1 degree of freedom** field, and select the degree of freedom with which the springs/dashpots are associated at their first point.
   - Click the arrow next to the **Point 2 degree of freedom** field, and select the degree of freedom with which the springs/dashpots are associated at their second point.
   - The global coordinate system determines the default spring/dashpot orientations. To specify an orientation for the springs/dashpots, click . Specify the orientation for the springs/dashpots using one of the following methods:
     - Click **Datum CSYS List** from the prompt area to select a name from a list of datum coordinate systems.
     - Select a datum coordinate system in the viewport.
     - Click **Use Global CSYS** from the prompt area to use the global coordinate system.

     Abaqus/CAE displays the local coordinate system specified for springs/dashpots in the viewport.
9. In the **Property** portion of the dialog box, check the appropriate box to include:
   - **Spring stiffness**. Enter the force per relative displacement for springs.
   - **Dashpot coefficient**. Enter the force per relative velocity for dashpots.

   If you define both spring and dashpot behaviors, they act in parallel.
10. Click **OK** to create the springs/dashpots and to close the **Edit Springs/Dashpots** dialog box.

    Symbols appear in the viewport that represent the springs/dashpots that you just created.

Additional information

• *Editing springs and dashpots connecting two points*

- *Controlling the display of attributes*
- *Symbols used to represent special engineering features*

Editing springs and dashpots connecting two points

You can edit springs and dashpots that connect two points to add more point pairs, delete point pairs, or edit a point of an existing point pair.

1. From the main menu bar in the Property module or the Interaction module, select **Special->Springs/Dashpots->Edit->*name*** to display the **Edit Springs/Dashpots** dialog box.

   The symbols representing springs/dashpots are highlighted in the viewport.

2. From the **Spring/Dashpot Point Pairs** table, you can do the following:

   - To define additional springs/dashpots with the same behavior, click  and repeat the point selection procedures described in the previous steps to define the first and second points of each spring/dashpot.
   - To edit a point in the table, select the point in the table, double-click on it or click , and reselect a point. The selection highlighting in the viewport is updated to show the newly edited point.
   - To identify a specific spring/dashpot in the viewport, select the desired row number. The highlighted dashed line connecting the selected point pairs appears bolder in the viewport.
   - To remove springs/dashpots from the table, select the desired row numbers (**[Shift] + Click** to select multiple rows) and click . **[Ctrl] + Click** a row number to unselect it.
   - To remove all springs/dashpots from the table, click .

3. Finish editing the springs/dashpots definition as desired, and click **OK**.

   The symbols representing springs/dashpots in the viewport appear on the newly edited points.

Additional information

- *Controlling the display of attributes*
- *Symbols used to represent special engineering features*

Creating springs and dashpots connecting points to ground

In an Abaqus/Standard analysis you can define springs and dashpots that connect points to ground and exhibit the same linear behavior independent of field variables.
For more information, see *Springs* and *Dashpots*.

You can obtain history data of stress and strain from a spring/dashpot by using the history output request editor in the Step module. In the **Domain** section of the editor, select **Springs/Dashpots** and choose the desired spring/dashpot from the menu that appears. For more information, see *Creating an output request*.

1. From the main menu bar in the Property module or the Interaction module, select **Special->Springs/Dashpots->Create**.
2. In the **Create Springs/Dashpots** dialog box that appears, name the springs/dashpots, select **Connect points to ground**, and click **Continue**.
3. Select the points to connect to ground using one of the following methods:

   - Select the points in the viewport. (For more information, see *Selecting objects within the viewport*.)

     Tip: The **Select the Entity Closest to the Screen** tool in the **Selection** toolbar is toggled off by default. If you make an ambiguous selection, Abaqus/CAE highlights the point and displays a description of the point in the lower left corner of the viewport. Use the **Next** and **Previous** buttons to cycle through the possible selections, and click **OK** to confirm your selection.

     If the model contains a combination of geometry and mesh components, select one of the following from the prompt area:

     - Select **Geometry** to define the spring/dashpot for geometry or for a reference point.
     - Select **Mesh** to define the spring/dashpot for a mesh.

   - To select from a list of existing sets, do the following:

     1. Click **Sets** on the right side of the prompt area to display the **Region Selection** dialog box containing a list of available sets.
     2. Select the set of interest, and click **Continue**.

        Note:

        The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

   The **Edit Springs/Dashpots** dialog box appears.
4. In the **Direction** portion of the dialog box, do the following:

   - Click the arrow next to the **Degree of freedom** field, and select the degree of freedom with which the springs/dashpots are associated.
   - The global coordinate system determines the default spring/dashpot orientations. To specify an orientation for the springs/dashpots, click . Specify the orientation for the springs/dashpots using one of the following methods:

- Click **Datum CSYS List** from the prompt area to select a name from a list of datum coordinate systems.
- Select a datum coordinate system in the viewport.
- Click **Use Global CSYS** from the prompt area to use the global coordinate system.

Abaqus/CAE displays the local coordinate system specified for springs/dashpots in the viewport.

5. In the **Property** portion of the dialog box, check the appropriate box to include:
   - **Spring stiffness**. Enter the force per relative displacement for springs.
   - **Dashpot coefficient**. Enter the force per relative velocity for dashpots.

   If you define both spring and dashpot behaviors, they act in parallel.
6. Click **OK** to create the springs/dashpots and to close the **Edit Springs/Dashpots** dialog box. Symbols appear in the viewport that represent the springs/dashpots that you just created.

Additional information

• *Editing the region to which springs and dashpots connecting points to ground are applied*
• *Controlling the display of attributes*
• *Symbols used to represent special engineering features*

Editing the region to which springs and dashpots connecting points to ground are applied

You can edit the region to which springs and dashpots that connect points to ground are applied (Abaqus/Standard analyses only).

1. From the main menu bar in the Property module or Interaction module, select **Special->Springs/Dashpots->Edit->*name*** to display the **Edit Springs/Dashpots** dialog box.
2. In the top part of the dialog box, click .
3. Edit the region using one of the following methods:
   - Select and unselect points in the viewport. When you have finished editing the region, click **Done** in the prompt area. (For more information, see *Selecting objects within the viewport*.)
   - To select from a list of existing sets, do the following:
     1. Click **Sets** on the right side of the prompt area.

        Abaqus/CAE displays the **Region Selection** dialog box containing a list of available sets.
     2. Select the set of interest, and click **Continue**.

     Note:

     The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.
4. In the dialog box, finish editing the springs/dashpots definition as desired and then click **OK**.

   The symbols representing springs/dashpots in the viewport change to appear on the newly edited region.

- *Symbols used to represent special engineering features*

Submodeling

You use submodeling to study in detail an area of interest in your model; for example, a region of high stress. In most cases you will mesh the region of interest with a finer mesh, and the submodel can provide an accurate, detailed solution. You can also change the modeling space from a shell global model to a more representative solid submodel—shell-to-solid submodeling.

Creating a submodel is a two-step process. First you create and analyze the global model. You then create the submodel and drive the boundaries of the submodel with time-dependent variables that were saved during the analysis of the global model. You can drive submodel boundaries either with boundary conditions or in some cases with stresses from the global model. Submodeling is described in detail in *About Submodeling*. *Shell-to-solid submodeling and shell-to-solid coupling of a pipe joint*, includes an example of a submodel created using Abaqus/CAE.

In this section:

- *Analyzing the global model*
- *Creating a submodel*
- *Removing regions*
- *Creating the submodel boundary condition*
- *Creating the submodel load*
- *Modifying the submodel*
- *Analyzing the submodel*
- *Checking the results from the submodel*

Analyzing the global model

You first obtain results for the entire model using a relatively coarse mesh and perhaps simplified geometry. This model is called the global model. Data from the output database that is generated by the global model are used to drive the submodel. As a result, the output requests in the global model must include the driven variables. You can also drive a submodel using the global model results stored in a results file that was generated from the Abaqus execution procedure.

Creating a submodel

When you have successfully analyzed the global model and generated an output database or a results file containing the global model results, you are ready to create the submodel. You start by copying the global model to a new model that you will use to define the submodel. To copy a model, select **Model**->**Copy**->***global model name*** from the main menu bar. Enter the name of the submodel in the **Copy Model** dialog box that appears and click **OK**. The copied model becomes the current model.

You must select the output database or results file from the global analysis that will be used to drive the submodel. From the main menu bar, select **Model**->**Edit Attributes**->***submodel name***. From the **Edit Model Attributes** dialog box that appears, click the **Submodel** tab, and do the following:

- Toggle on **Read data from job**, and enter the name of the output database or results file containing the global model that will drive the submodel. You must provide the file extension (`.odb` or `.fil`) if both an output database and a results file exist and they use the same name.
- In addition, if your shell global model is driving a solid submodel, toggle on **Shell global model drives a solid submodel**.
- Click **OK** to close the **Edit Model Attributes** dialog box.

Removing regions

Remove regions from the submodel that you are not interested in analyzing. Only the regions of interest should remain. You can use several techniques to remove regions from a part.

- Use the cut tools in the Part module. For more information, see *Adding a cut feature*.
- Use the Geometry Edit toolset to remove faces. For more information, see *Editing techniques*.
- You can delete the part in the Part module and create a new part with the same name. You can then create geometric features that represent the submodel; however, you must position the new features in the same location as the original part. For a discussion of the tolerances between the submodel and the global model, see *About Submodeling*. The new part and the original part must be created in three-dimensional modeling space.

  Creating a new part is a useful technique for converting a shell global model to a solid submodel. You can delete the shell part from the copied model and create a new solid part in the same location. You must take care to ensure that the part defined in the solid submodel is contained within the part defined in the shell global model.

Creating the submodel boundary condition

The most common submodeling technique is node-based submodeling, which uses a nodal results field (including displacement, temperature, or pressure degrees of freedom) to interpolate global model results onto the submodel nodes. Node-based submodeling is also a more general technique. To use node-based submodeling, you create a submodel boundary condition.

If you apply a submodel boundary condition to nodes that are constrained by either a displacement/rotation boundary condition or a connector displacement boundary condition on the global model in a previous step and the global model's boundary condition is fixed using the **Fixed at Current Position** method, Abaqus/CAE disregards the submodel boundary condition for those nodes and retains the specifications in the boundary condition on the global model instead. Abaqus/CAE reports this replacement of boundary conditions in the data file for the analysis.

1. Enter the Load module and select **BC->Create** from the main menu bar.
2. From the list of steps, select the step during which the submodel boundary condition will be applied.
3. From the **Category** field, select **Other**.
4. From the **Types for Selected Step** field, select **Submodel** and click **Continue**.
5. From the model, select the regions to which the boundary condition will be applied. In most cases you apply the boundary condition to the edges and faces that were created when you cut away regions from the global model. You can prescribe other boundary conditions to the same regions; for example, a symmetry boundary condition. The prescribed boundary conditions take precedence over the submodel boundary condition.
6. From the **Edit Boundary Condition** dialog box that appears, do the following:
   a. In the **Driving region** field, do one of the following:
      - Select **Automatic** to allow Abaqus/CAE to create the driving region by searching all regions in the global model that lie in the vicinity of the submodel.
      - Select **Specify** to specify a set name that will be used as the driving region. You must give the complete name of the set. The syntax for the set name is `assembly_name.part_name-1.set_name`, assuming that you are defining the driving region on the first instance of the part.

   b. If you are driving a solid submodel with a shell global model, you must enter the maximum value of the shell thickness in the global model in the **Shell thickness** field.
   c. In the **Exterior tolerance** field, do the following:
      - Enter the **absolute** exterior tolerance. This is the absolute value by which a driven node of the submodel may lie outside the elements of the global model. The default value is the relative exterior tolerance.
      - Enter the **relative** exterior tolerance. This is the fraction of the average element size in the global model by which a driven node of the submodel may lie outside the elements of the global model. The default value is .05.

      For more information, see *About Submodeling*.
   d. If you are driving a solid submodel with a solid global model or if you are driving a shell submodel with a shell global model, you must enter a comma-separated list indicating the degrees of freedom that are being driven; for example, `1,2,3`. You cannot leave this field blank.
   e. If you are driving a solid submodel with a shell global model, you can provide the thickness of the center zone size around the shell midsurface. The default value is 10% of the maximum shell thickness in the global model as defined in the **Shell thickness** field.
   f. In the **Global step number** field, enter an integer representing the step number in the global analysis from which the values of the driven variables will be read.

g. If you created the boundary condition in a static, linear perturbation step, you can specify the increment in the global analysis step that will be the basis for calculating the values for the driven variables. The default value of zero corresponds to the last increment of the previous step.

h. If the time period of the submodel analysis is different from the time period of the global analysis, you can choose to scale the time period of the global step to match the time period of the submodel step. For example, Abaqus determines the displacements of the global model at a time 20% into the global step and applies those displacements at a time 20% into the submodel step.

If you do not choose to scale the time period of the global step to match the time period of the submodel step, Abaqus applies the displacements of the global model at the same time during the submodel step. For example, Abaqus determines the displacements of the global model one second into the global step and applies those displacements one second into the submodel step. This behavior is probably not desired if the two time periods are different. You choose to scale the time period by toggling on **Scale time period of global step to time period of submodel step**.

i. If you want Abaqus to ignore driven nodes found to lie outside the region of elements of the global model after accounting for the exterior search tolerance, toggle on **Intersection only**. This parameter is available only for node-based submodeling.

Additional information

- *Defining a displacement/rotation boundary condition*
- *Defining a connector displacement boundary condition*

Creating the submodel load

The surface-based submodeling technique is an alternative submodeling technique that uses the stress field to interpolate global model results onto the submodel integration points on the driven element-based surface facets. To use surface-based submodeling, you create a submodel load.

1. Enter the Load module and select **Load->Create** from the main menu bar.
2. From the list of steps, select the step during which the submodel load will be applied.
3. From the **Category** field, select **Other**.
4. From the **Types for Selected Step** field, select **Submodel** and click **Continue**.
5. From the model, select the regions to which the load will be applied. In most cases you apply the load to faces that were created when you cut away regions from the global model. If you are applying the load to a face of a shell, Abaqus/CAE asks you to specify the side of the face to which the load will be applied. For more information, see *Specifying a particular side or end of a region*.
6. From the **Edit Load** dialog box that appears, do the following:
   a. In the **Driving region** field, do one of the following:
      - Select **Automatic** to allow Abaqus/CAE to create the driving region by searching all regions in the global model that lie in the vicinity of the submodel.
      - Select **Specify** to specify a set name that will be used as the driving region. You must give the complete name of the set. The syntax for the set name is `assembly_name.part_name-1.set_name`, assuming that you are defining the driving region on the first instance of the part.

   b. In the **Exterior tolerance** field, do the following:
      - Enter the **absolute** exterior tolerance. This is the absolute value by which a driven node of the submodel may lie outside the elements of the global model. The default value is the relative exterior tolerance.
      - Enter the **relative** exterior tolerance. This is the fraction of the average element size in the global model by which a driven node of the submodel may lie outside the elements of the global model. The default value is .05.

      For more information, see *About Submodeling*.
   c. In the **Global step number** field, enter an integer representing the step number in the global analysis from which the values of the driven variables will be read.

Modifying the submodel

You can make the following modifications to the submodel:

- You can use the Step module to change the analysis procedure. The submodel can use either a general procedure or a linear perturbation procedure. For more information, see *About Submodeling*.
- In the Load module you must remove any loads, boundary conditions, or initial conditions that were applied to regions of the global model that were removed.
- If a boundary condition is applied outside the region to which you applied the submodel boundary condition, you must ensure that it corresponds to the loading of the global model.
- Similarly, if a load is applied to the submodel, you must ensure that it corresponds to the loading of the global model.
- In most cases you will apply a more refined mesh to the submodel in the Mesh module. You can change the element type assigned to the submodel; however, you cannot change the dimensionality. Both the global model and the submodel must be either two-dimensional or three-dimensional.

Analyzing the submodel

To analyze your submodel in the Job module, do the following:

- Create a new job using the model containing the submodel.
- Submit the new job for analysis.

Checking the results from the submodel

After the analysis is complete, you can use the Visualization module to overlay contour plots from the submodel and the global model. For a meaningful comparison, the layers of the overlay plots should use the same legend scale and the same deformation scale factor. For more information, see *Overlaying multiple plots*.

You should check the following:

The submodel location

You should check that the position of the submodel is correct, relative to the global model. You can check the relative positions using overlay plots from the global and submodel output databases. Alternatively, you can check the relative positions in the Assembly module before you submit the submodel for analysis by creating temporary instances of the parts in the global model. You can view the position of the assembly in the global model relative to the position of the assembly in the submodel. You can then delete or suppress the instances of the parts in the global model before you mesh and analyze the submodel.

The submodel response does not influence the global response

You should check that the submodel response has insignificant impact on the global response. This is the fundamental assumption of submodeling. You can check this by creating overlay contour plots of variables like stress and strain. The contours should be reasonably continuous across the submodel boundary.

Substructures

This section explains how to integrate substructures into your analysis in Abaqus/CAE.

In this section:

- *Using substructures in Abaqus/CAE*
- *Generating a substructure*
- *Specifying the retained nodal degrees of freedom and load cases for a substructure*
- *Importing a substructure into Abaqus/CAE*
- *Using substructure part instances in an assembly*
- *Activating load cases during substructure usage*
- *Recovering field output for substructures*
- *Visualizing substructure output*

Using substructures in Abaqus/CAE

Substructures are collections of elements that have been grouped together, so the internal degrees of freedom have been eliminated for the analysis.
Using a substructure makes model definition easier and analysis faster when you analyze a model that contains identical pieces that appear multiple times (such as the teeth of a gear), because you can use a substructure repeatedly in a model. Substructures are connected to the rest of the model by the retained degrees of freedom at the retained nodes. Factors that determine how many and which nodes and degrees of freedom should be retained are discussed in *Generating Substructures*. Substructure definition in your model follows two sets of steps.

In this section:

- *Creating substructures in your model database*
- *Including substructures in your analysis*

Creating substructures in your model database

You can create substructures in Abaqus/CAE by following these general steps:

1. Create or open the model database in which you want to specify substructures in Abaqus/CAE.
2. In the Step module, create a **Substructure generation** step. Abaqus/CAE converts the entire model into a single substructure. For more information, see *Generating a substructure*.
3. In the Load module, create **Retained nodal dofs** boundary conditions to determine which degrees of freedom will be retained as external degrees of freedom on the substructure. You can also define a load case in the substructure generation step if you want to apply a load to the substructure at a location other than its retained degrees of freedom. For more information, see *Specifying the retained nodal degrees of freedom and load cases for a substructure*.
4. In the Job module, create a new job and submit the analysis.

   When you perform an analysis of an assembly that includes substructure data, Abaqus/CAE creates separate output databases for the results of each substructure part instance and does not include the results from the substructure part instances in the output database for the assembly. The Visualization module provides tools that enable you to integrate the results from the substructure components back into the results from the assembly; for more information, see *Visualizing substructure output*.

Including substructures in your analysis

Substructure usage should be performed in a different model than substructure generation. You can include substructures in your analysis in Abaqus/CAE by following these general steps:

1. Import each substructure that you want to use in your model database from the corresponding `.sim` file. For more information, see *Importing a substructure into Abaqus/CAE*.
2. In the Assembly module, instance each substructure part that you want to add to the assembly, and position the substructure part instances in the desired locations in the assembly. *Using substructure part instances in an assembly*, explains the capabilities and limitations of substructure part instances.
3. In the Load module, activate substructure load cases by creating a **Substructure load** definition. For more information, see *Activating load cases during substructure usage*.
4. In the Step module, create a field output request with **Substructure** as the **Domain**, then select the substructure sets for which you want to recover field data. For more information, see *Recovering field output for substructures*.
5. In the Interaction module, apply constraints to attach the substructure part instance to the rest of the assembly.

Generating a substructure

The first step in substructure definition is the addition of a **Substructure generate** step in your analysis. The substructure generation step enables you to create a substructure in your model database and, if desired, specify substructure-related options such as the writing of the recovery matrix, stiffness matrix, mass matrix, and load case vectors to a file. These options are described later in this section.

A single analysis can include multiple substructure generate steps, and Abaqus/CAE creates corresponding output database files for each step. Multiple preloading steps can precede every substructure generation step in your analysis. If you want to specify retained eigenmodes for substructure generation, you must also include a frequency extraction step in the analysis.

You cannot have a substructure generation step in a model that contains model instances.

Substructure identifier

You must specify a unique identifier for each substructure you create. Substructure identifiers must begin with the letter Z followed by a number that cannot exceed 9999.

Recovery options

You can recover the field output data for a substructure during the usage-level analysis, but you must specify the recovery region during substructure generation. Substructure recovery can be performed only on the sets included in the recovery region. You can specify that recovery be performed on the whole model or for an individual node set or element set. While performing the substructure recovery in the usage model, Abaqus/CAE must have access to the substructure's `.mdl`, `.prt`, and `.stt` files. For more information about these file types, see *Generating Substructures*.

Generation options

You can control several aspects of the substructure generation process, including calculation of gravity load vectors, evaluation of frequency-dependent material properties, and generation of a reduced mass matrix, reduced structural damping matrix, and viscous damping matrix.

Retained eigenmodes

You can specify retained eigenmodes for generation of a coupled acoustic-structural substructure. When you choose to specify retained eigenmodes, Abaqus/CAE enables you to specify eigenmodes by mode range or by frequency range.

Damping

You can specify several global damping controls and substructure damping controls. For global damping you can choose to apply damping settings to acoustic or mechanical options; for substructure damping you can specify separate controls for viscous and structural damping.

Additional information

- *Configuring a substructure generation procedure*

Specifying the retained nodal degrees of freedom and load cases for a substructure

After you defined the substructure generation step or steps for your analysis, you must define a **Retained nodal dofs** boundary condition for a substructure. The retained degrees of freedom for a substructure node are the degrees of freedom that are external and are available for use in the analysis; all other degrees of freedom for the specified node are assumed to be internal to the substructure and do not factor into the analysis. When you import a substructure from this analysis into a model for substructure usage, Abaqus/CAE displays these nodes as light blue crosses, which enables you to pick them easily from a part instance or assembly.

If you want to apply a load to the substructure at a location other than its retained degrees of freedom, you can define a load case in the substructure generation step.

Additional information

- *Defining a retained nodal DOFs boundary condition*
- *Defining a load case*

Importing a substructure into Abaqus/CAE

You can include substructure definitions in a model database and begin to use them for modeling by importing the substructures as new part definitions. Substructure data are available in `.sim` files, and the substructure identifier is included in the file name; for example, in an analysis in which the substructure is named `FAN` and the substructure identifier is `Z400`, the substructure database file is named `FAN_Z400.sim`.

The `.sim` file from which you import a substructure must reside in the same directory as the supporting Abaqus files to which the `.sim` database refers; these supporting files might include data in the formats `.prt`, `.mdl`, or `.stt`.

Substructure import also requires an output database (`.odb`) file for mesh display.

Additional information

- *What kinds of files can be imported and exported from Abaqus/CAE?*
- *Importing a substructure into a model database as a part*

Using substructure part instances in an assembly

Once you import substructure parts into your model database, you can add them to your assembly by instancing them in the same manner you would for any part. Substructure part instances are displayed in a translucent color in the viewport.

You can move and apply constraints to substructure part instances; however, substructure part instances have the following modeling limitations:

- You cannot assign sections to a substructure part instance.
- You cannot apply attributes to a substructure part instance.
- Substructure part instances are not eligible for definition of contact pairs.
- Gravity loads are the only load definition that can be applied to substructure part instances.

Additional information

• *Creating and manipulating part and model instances*

Activating load cases during substructure usage

The **Substructure load** definition enables you to activate the substructure load cases that are specified during the substructure generation step. As you activate a load case, you can scale its load definitions or apply an amplitude to them.

Additional information

• *Defining a substructure load definition to activate a substructure load case*

Recovering field output for substructures

You can specify that Abaqus/CAE write field output data for one or more substructure sets in your analysis.

From the field output editor, select **Substructure** from the **Domain** field, then click  to open the **Select Substructure Sets** dialog box. This dialog box lists only the substructure sets that were defined while generating the substructure. You cannot recover data for sets that you define on substructure part instances in Abaqus/CAE.

Additional information

• *Modifying field output requests*

Visualizing substructure output

Abaqus/CAE creates separate output database (`.odb`) files for each substructure part instance used in the analysis, so you must perform some additional steps if you want to display substructure results in context with the rest of the assembly. The Visualization module provides the following tools that enable you to incorporate substructure results into the rest of the model:

- You can use an overlay plot to display plots of substructure data in the same viewport as a plot of the rest of the assembly.
- You can use the **Combine ODBs** plug-in to combine the data in one or more substructure output database files with the data from the rest of the assembly.

Additional information

- *Producing and modifying overlay plots*
- *Combining data from multiple output databases*

Viewing results

This part describes how to use the Visualization module (also licensed separately as Abaqus/Viewer) to view your model and the results of your analysis.

In this section:

- *Visualization module basics*
- *Viewing diagnostic output*
- *Selecting model data and analysis results to plot*
- *Plotting the undeformed and deformed shapes*
- *Contouring analysis results*
- *Plotting analysis results as symbols*
- *Plotting material orientations*
- *X–Y plotting*
- *Viewing results along a path*
- *Animating plots*
- *Querying the model in the Visualization module*
- *Probing the model*
- *Calculating linearized stresses*
- *Viewing a ply stack plot*
- *Generating tabular data reports*
- *Customizing plot display*
- *Customizing viewport annotations*

Visualization module basics

You can use the Visualization module to view your model and the results of your analysis.

In this section:

- *Understanding the role of the Visualization module*
- *Entering and exiting the Visualization module*
- *Understanding plot states and plot customization*
- *Understanding toolsets in the Visualization module*
- *Understanding Visualization module performance*

Understanding the role of the Visualization module

The Visualization module provides graphical display of finite element models and results. It obtains model information from the current model database or model and result information from an output database. You can control what information is placed in the output database by modifying output requests in the Step module. (For more information, see *What is an output request?*.) You can view data from a model database using a contour plot or a symbol plot; you can view model and results data from an output database by producing any of the plots described in this section.

Undeformed shape

An undeformed shape plot displays the initial shape or the base state of your model.

Deformed shape

A deformed shape plot displays the shape of your model according to the values of a nodal variable such as displacement.

Contours

For an output database, a contour plot displays the values of an analysis variable such as stress or strain at a specified step and frame of your analysis. For a model in the current model database, a contour plot displays the value of a load, a predefined field, or an interaction at a selected step of your model. The Visualization module represents the values as customized colored lines, colored bands, or colored faces on your model.

Symbols

For an output database, a symbol plot displays the magnitude and direction of a particular vector or tensor variable at a specified step and frame of your analysis. For a model in the current model database, a symbol plot displays the magnitude and direction of a load, a predefined field, or an interaction at a specified step of your model. The Visualization module represents the values as symbols (for example, arrows) at locations on your model.

Material orientations

A material orientation plot displays the material directions of elements in your model at a specified step and frame of your analysis. The Visualization module represents the material directions as material orientation triads at the element integration points.

X–Y data

An *X–Y* plot is a two-dimensional graph of one variable versus another.

Time history animation

Time history animation displays a series of plots in rapid succession, giving a movie-like effect. The individual plots vary according to actual result values over time.

 Scale factor animation

Scale factor animation displays a series of plots in rapid succession, giving a movie-like effect. The individual plots vary in the scale factor applied to a particular deformation.

 Harmonic animation

Harmonic animation displays a series of plots in rapid succession, giving a movie-like effect. The individual plots vary according to the angle applied to the complex number results being displayed.

Additional capabilities include:

Visualizing diagnostic information

Diagnostic information helps you determine the causes of nonconvergence in a model. You can view information for each stage of the analysis and use Abaqus/CAE to highlight problematic areas on the model in the viewport.

Understanding probing

Probing displays model data and analysis results as you move the cursor around a model or a model plot; probing an *X*–*Y* plot displays the coordinates of graph points. You can write this information to a file.

Results plotting along a path

A path is a line you define by specifying a series of points through your model. You can view results along the path in the form of an *X*–*Y* plot.

Stress linearization

Stress linearization is the separation of stresses through a section into constant membrane and linear bending stresses. You specify the section as a path through your model, and the Visualization module displays the linearized stresses in the form of an *X*–*Y* plot.

Cutting through your model

View cuts allow you to slice through a model so that you can visualize the interior or selected sections of the model. You can define planar, cylindrical, or spherical view cuts. In addition, you can define a view cut along a constant contour variable value.

X–Y and field output reporting

An *X*–*Y* report is a tabular listing of *X*- and *Y*-data values; a field output report is a tabular listing of field output values.

Visualizing the plies in a composite layup

A ply stack plot is a graphical representation of the plies in a composite layup. The image shows the plies in the layup along with details of each ply, such as its fiber orientation, thickness, and the reference plane. You can also create a ply stack plot in the Property module while you are creating a composite layup.

Plot customization

The Visualization module provides numerous options that you can use to customize your plots.

Entering and exiting the Visualization module

You can enter the Visualization module at any time during an Abaqus/CAE session by clicking **Visualization** in the **Module** list located in the context bar. The **Result**, **Plot**, **Animate**, **Report**, **Options**, and **Tools** menus appear on the main menu bar; and the title bar of the current viewport displays the name of the current output database, if one exists.

You can also enter the Visualization module by opening an existing output database. To open an output database, select **File->Open** from the main menu bar (for more information, see *Opening a model database or an output database*) or click **Results** in the **Job Manager** when results are available for a selected job. When you use one of these methods to enter the Visualization module, Abaqus/CAE displays a plot of the model from the output database in the current viewport.

To exit the Visualization module, select any other module from the **Module** list, or end the session by selecting **File->Exit** from the main menu bar. When you end the session, Abaqus/CAE closes all files and windows. Abaqus saves your plot options only for the duration of the session.

Understanding plot states and plot customization

This section describes how to customize the appearance of a plot by selecting plot customization options.

In this section:

- *What is a plot state?*
- *Activating plot states*
- *Customizing your plots*
- *Customizing multiple viewports*

What is a plot state?

The Visualization module offers several distinct types of plots for viewing your model and results. These plot types are:

- *Undeformed shape*
- *Deformed shape*
- *Contour*
- *Symbol*
- *Material orientation*
- *History or X–Y data*
- *Time history animation*
- *Scale factor animation*
- *Harmonic animation*

Each of these plots corresponds to a *plot state*. Plot states are important because some of the customization options provided by the Visualization module pertain only to a particular plot state.

Additional information

- *Activating plot states*
- *Customizing your plots*

Activating plot states

A plot state combines all of the active customization options to produce a plot in the viewport. Some options are common to all plot types, some are applied only when you choose to superimpose the deformed and undeformed model shapes, and some are specific to the current plot type. You enter a particular plot state by producing a plot of the corresponding type. For example, if you produce an undeformed plot, the current viewport will then be in the undeformed plot state. The plot state of a viewport persists and Abaqus/CAE updates it with any changes you make to the customization options until you produce a plot in some other state in that viewport. If you create multiple viewports, each viewport can contain a different plot state. In addition, you can choose to allow multiple plot states in a single viewport by plotting both the undeformed and deformed shape for a single plot type or by displaying multiple plot types in the viewport.

Additional information

• *Customizing your plots*

Customizing your plots

The Visualization module provides numerous customization options, which are available through the **Viewport**, **Options**, and **View** menus of the main menu bar. These options fall into three categories:

Plot state–dependent options

Plot type options affect only a particular plot state. These are separate options affecting contour, symbol, and material orientation plots; *X–Y* curves; *X–Y* graphs; time history animations; scale factor animations; and harmonic animations.

Plot state–independent options

Plot state–independent options are those that affect all plots collectively. These are common options governing the viewpoint, graphics, individual item coloring, display body appearance, and such general characteristics as plot legends, model labels, and the appearance of text blocks giving the model's title and state.

Superimpose options

Superimpose options are a special set of plot state–independent options that affect only the undeformed plot state when you choose to superimpose it on a deformed, contour, symbol, or material orientation plot. These options allow you to control many common customization options to distinguish the undeformed plot from the deformed plot when both shapes are displayed.

Plot state–dependent options affect such plot attributes as the contour intervals, limits, and colors (for example, color spectrums for contour plots or axis colors for material orientation plots). You control these attributes separately for each plot state using the options associated with that state. To choose the contour type, for example, you must use the **Contour** plot options. To do so, you can select **Options->Contour** from the main menu bar. Alternatively, you can use the **Contour Options** tool  from the toolbox. The **Options** tools provide quick access to the plot state–dependent and plot state–independent customization options.

Plot state–dependent options affect only plots in the associated state. If you select axis colors from the material orientation plot options dialog box, those colors will affect only material orientation plots. If there is a material orientation plot in the current viewport, you will see the effect of your changes when you click **Apply** or **OK** in the material orientation plot options dialog box. However, if the current viewport does not contain a material orientation plot, you will not see the effect of your changes until you produce one.

Plot state–independent options affect plots across all plot states. For example, if you select **Viewport->Viewport Annotation Options** from the main menu bar to suppress the appearance of the view triad, the view triad will be suppressed for all plots. Settings in the **Common Plot Options** dialog box are also plot state–independent; when you change the render style in this dialog box, the new render style is used for all plots.

Superimpose options affect the undeformed plot when you superimpose an undeformed plot on a deformed plot in one of the plot states. For example, you can independently set the render style, edge display, and fill color; and you can apply an offset between the undeformed and deformed shape symbol plots when both are displayed.

Select **File->Save Options** from the main menu bar to save your plot state–dependent, plot state–independent, and superimpose customization options. Saving your customization options allows you to apply them to subsequent Abaqus/CAE sessions. For more information, see *Saving your display options settings*. For more information on the plot customization options available in the Visualization module, see *Customizing plot display*.

Customizing multiple viewports

When you create a new viewport, it initially inherits the customization options of the current viewport. For example, if you *establish the **Filled** render style* for plots in the current viewport and then create a new viewport, subsequent plots in the new viewport will appear in the filled render style. New viewports inherit the plot state of the current viewport—until you change customization options, plot states, or output databases, new viewports appear identical to the viewport that was active when you created them.

After a new viewport has been established, the plot state and any *subsequent* customizations are independent of other viewports by default. Multiple viewports can each be in a separate plot state; if you use multiple viewports, you must first designate a particular viewport as current to change its display. Customization selections you apply affect only the current viewport. When you designate a viewport as current, the options dialog boxes are refreshed to show the state of options associated with that viewport. For more information on working with viewports, see *Working with viewports*.

You can also link multiple viewports in your session to manipulate multiple objects simultaneously and to display the same plot state and the same plot options in different viewports. For more information, see *Linking viewports for view manipulation*.

Additional information

• *Activating plot states*

Understanding toolsets in the Visualization module

Toolsets in the Visualization module provide additional control over data display.
Unless otherwise stated, the toolsets described in this section are for postprocessing of model and results data from output databases only; only selected toolsets are for use with model data from the current model database.

The following toolsets are available in the Visualization module:

- The Color Code toolset allows you to customize the edge and fill color of individual elements. For more information, see *Coloring nodes or elements in the Visualization module*.
- The Coordinate System toolset allows you to create local coordinate systems for use in postprocessing. For more information, see *Creating coordinate systems during postprocessing*.
- The Create Set toolset allows you to create node and element sets during postprocessing. For more information, see *Creating node and element sets during postprocessing*.
- The Display Group toolset allows you to selectively plot one or more items from a model or from an output database. For more information, see *Using display groups to display subsets of your model*.
- The Field Output toolset allows you to perform operations on the field output available in an output database. For more information, see *Creating and saving new field output*.
- The Free Body toolset allows you to create and delete free body cuts, display or hide them in the viewport, and customize several aspects of their appearance. For more information, see *The Free Body toolset*.
- The Job Diagnostics toolset allows you to access the diagnostic information written to the output database during an Abaqus/Standard analysis job. For more information, see *Viewing diagnostic output*.
- The Path toolset allows you to specify a path through your model along which you can obtain and view *X–Y* data. For more information, see *Viewing results along a path*.
- The Query toolset allows you to obtain information about your model, both for data from the current model database or for data from an output database. For more information, see *Querying the model in the Visualization module*.
- The Stream toolset allows you to display streamlines to investigate velocity or vorticity in a fluid flow analysis. For more information, see *The Stream toolset*.
- The View Cut toolset allows you to create cuts through a model so that you can visualize the interior or selected sections of the model. This functionality is available for model data from the current model database or from an output database. For more information, see *Cutting through a model*.
- The XY Data toolset allows you to create and operate on *X–Y* data objects. For more information, see *X–Y plotting*.

Understanding Visualization module performance

In general, the speed of postprocessing and graphical results display in the Visualization module is more than satisfactory for most models. However, it is often necessary to balance high performance levels with detailed results plotting. Depending on your postprocessing requirements, you may wish to modify the default display options at the expense of performance. Many options are available that can affect the speed of graphics display.

To maximize performance in the Visualization module, we recommend the following:

- Cache results in memory during postprocessing to speed up the generation of images on the screen. See *Understanding results caching*.
- Use the texture-mapped contour method whenever possible. Likewise, avoid using display options that are not supported by the texture-mapped method: line-type contours, contour edges, CAXA or SAXA elements, or shrinking elements about their centroid. If such display options are used, Abaqus/CAE will override the user setting for texture-mapped contours and use the slower tessellated method instead. See *Understanding how contours are rendered*.
- Be selective about the model labels and symbols that you choose to display. The more model entities that are drawn, the longer the screen refresh will take. This applies to element edges as well. See *Controlling the display of model entities*.
- Use a high results averaging threshold. The more contiguous the results are, the faster the contour display will be. See *Understanding result value averaging*.
- Use the status field output variable rather than creating display groups based on result values to achieve high-performance time history animation. Abaqus/CAE recomputes result-based display groups as each result frame is displayed, so using this type of display group degrades animation performance. The status field output variable allows you to remove elements that meet a result-based failure criteria from your model plots. See *Selecting the status field output variable*.
- Do not use a remote display. This configuration of Abaqus/CAE is not supported; its use is at the sole discretion of the user. Performance optimization can never be achieved using remote display.

In some cases performance may not be optimal for element-based results plotting on very large models because of physical memory limits on your machine. Increasing the physical memory or exiting other applications that are consuming memory can help to restore optimal performance.

Viewing diagnostic output

Abaqus/CAE provides a visual diagnostics tool to help you understand the convergence behavior of your job. You can use diagnostic output to assess the quality of analysis results or to locate the source of convergence problems in a model.

This chapter explains how you locate and use diagnostic output within Abaqus/CAE.

In this section:

- *Understanding job diagnostics*
- *Generating diagnostic information*
- *Interpreting diagnostic information*
- *Accessing diagnostic information*

Understanding job diagnostics

Abaqus writes diagnostic information to the output database, along with any other output that you request, as it attempts to analyze your model.
The diagnostic information in the output database is a subset of the diagnostic information that is written to the message and status files. You can use the **Job Diagnostics** dialog box to access the diagnostic information written to the output database during an Abaqus/Standard or Abaqus/Explicit analysis job.

For an Abaqus/Standard analysis, diagnostic information is available for the job and for each step, increment, attempt, and iteration. *Figure 1* shows contact diagnostics for an Abaqus/Standard analysis iteration. You can choose the type of contact information that you want to view, and you can select a column to sort the table data.

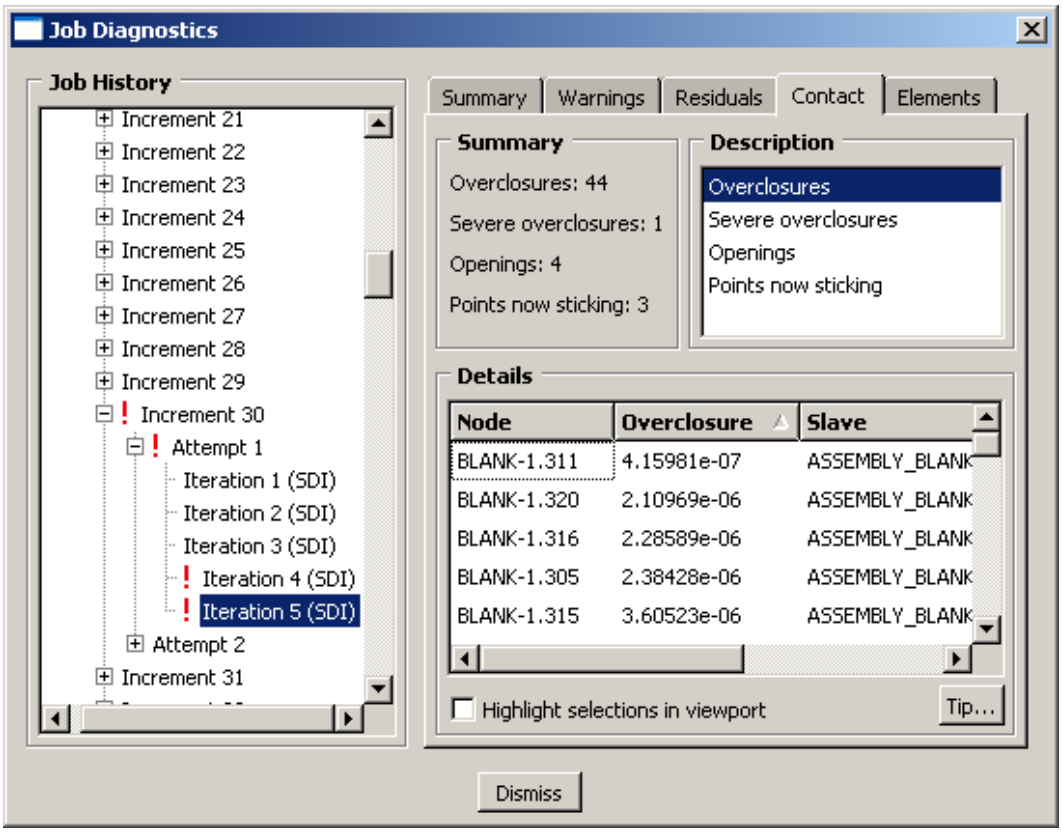

Figure 1: The Job Diagnostics dialog box.

For an Abaqus/Explicit analysis, diagnostic information is available for the job and for each step. Because of the large number of increments in a typical Abaqus/Explicit analysis, diagnostic information is recorded for summary (heartbeat) increments and for any other increments in which diagnostic information is generated. The interval between summary increments depends on the CPU time and the amount of output specified in the analysis. The diagnostic data are written to the status file and to the output database.

You can use the **Job Diagnostics** dialog box to determine when an analysis ended and whether any warnings were issued. If warnings were issued during the job, you can view the warnings and assess whether your results may have been affected. The **Job Diagnostics** dialog box also provides more detailed information to explain the meanings of or possible causes for most warnings and errors and, if the warnings are associated with nodes or elements, to help you locate them on the model in the viewport.

You can view diagnostic information during an analysis or after it ends. However, the **Job Diagnostics** dialog box does not update automatically. If you view diagnostic information while an analysis is running, you must close and then reopen the output database as the analysis progresses to display any new diagnostic information.

Generating diagnostic information

Abaqus generates diagnostic information during an analysis job; Abaqus/CAE reads the diagnostic information that is stored in the output database. Thus, you can use the **Job Diagnostics** dialog box to view convergence information only for procedures that generate information in the output database. Job diagnostics are stored in the output database for the following Abaqus/Standard procedures:

- **Coupled temp-displacement**
- **Geostatic**
- **Soils**
- **Static, General**
- **Static, Linear perturbation**
- **Static, Riks**
- **Visco**

Diagnostic information for other Abaqus/Standard analysis procedures is located in the message file and cannot be viewed in Abaqus/CAE.

Diagnostic information is available in Abaqus/CAE for all Abaqus/Explicit analysis procedures. An anneal procedure does not generate any diagnostic data, so no diagnostics are displayed for an anneal step.

Detailed diagnostic information is saved to the output database by default for the supported analysis procedures in both Abaqus/Standard and Abaqus/Explicit. If you do not want to include diagnostic information, use the **Keywords Editor** to edit the input file to include the following line in the model data:

```
*OUTPUT, DIAGNOSTICS=NO
```

You can also use the **Keywords Editor** to change the default diagnostic output parameters for Abaqus/Explicit by including one or more lines for the keyword **DIAGNOSTICS* and specifying the desired parameter values.

For more information on using the **Keywords Editor**, see *Adding unsupported keywords to your Abaqus/CAE model*.

Interpreting diagnostic information

This section describes the individual pages in the **Job Diagnostics** dialog box (the available pages depend on the analysis type and results).

In a typical Abaqus/Standard analysis a load is applied to the model in increments, and Abaqus attempts to calculate the model's response to each incremental load. Abaqus further reduces the response calculations by performing iterations to approach the result for an increment. If the iterations are not approaching a solution (converging), Abaqus stops and attempts to solve again, this time with a smaller load increment. If Abaqus makes too many attempts without a solution, the analysis is ended. For more information about load increments, see *Analysis Solution and Control*.

In an Abaqus/Explicit analysis, incrementation is based on a large number of small time increments. The time incrementation is made according to an estimated stable time increment size based on the size of the elements in the model. Abaqus/Explicit uses a central-difference time integration rule to integrate the equations of motion, so there is no need for multiple attempts and iterations in each increment.

Viewing the diagnostic information can help you determine the causes of convergence problems so that you can make the necessary corrections in the model. Diagnostic information also indicates potential problems and areas for improvement even when a converged solution is reached. With proper interpretation of the available diagnostic information, you can improve a model to achieve the results that match your analysis intent.

In this section:

- *Diagnostics summary*
- *Incrementation*
- *Warnings and errors*
- *Residuals*
- *Contact*
- *Elements*
- *Other*

Diagnostics summary

The **Summary** page in the **Job Diagnostics** dialog box is always available. The summary includes attributes of the item that is currently highlighted in the **Job History** tree as well as an indication of the diagnostic information available in the other pages of the dialog box. The information that appears for each job, step, increment, attempt, and iteration for an Abaqus/Standard analysis or for each job, step, and increment for an Abaqus/Explicit analysis varies as follows, becoming more specific as you move from the job to an iteration.

Job

When you first open the **Job Diagnostics** dialog box, the job item is highlighted in the **Job History** tree and the **Summary** page is visible. The job name and status and the analysis code and release are displayed. For an Abaqus/Explicit job the Abaqus/Explicit precision (single or double) and the number of domains for parallel job execution are displayed. If there are warnings or errors, the total number of each is also displayed.

Step

The summary for each step displays the step name, step number, analysis procedure, and number of warnings (if any) in the step. Depending on the procedure additional information may also be displayed as part of the step summary. For example, the summary of a general nonlinear step will also include the step time that has been completed, the number of increments that were completed, the time incrementation method (automatic or fixed) that was used, whether nonlinear geometry was accounted for during the step, and the extrapolation type used for a previous state at the start of each increment. See *The Step module* for more information.

Increment

The summary for each increment displays the increment number and the number of warnings (if any) in the increment. For an Abaqus/Standard analysis the number of attempts is also displayed. The increment summary also indicates the convergence status; if the increment converged, the increment size and the completed step time are displayed.

Attempt

The summary for each attempt in an Abaqus/Standard analysis displays the attempt number, attempt size, number of warnings (if any), and number of iterations. Severe discontinuity iterations and equilibrium iterations are listed separately, along with the total number of iterations. If Abaqus is unable to find a solution, it makes a cutback in the increment size and begins a new attempt; if Abaqus makes a cutback, the attempt summary indicates the reason for the cutback. There are no attempts in an Abaqus/Explicit analysis.

Iteration

The iteration summary in an Abaqus/Standard analysis displays the convergence status. If the iteration did not converge, the summary indicates the other pages (**Warnings**, **Residuals**, **Contact**, and **Elements**) that provide detailed information about the convergence criteria that were not satisfied. There are no iterations in an Abaqus/Explicit analysis.

Additional information

- *Viewing diagnostic output*
- *Interpreting diagnostic information*
- *About Convergence and Time Integration Criteria*

Incrementation

The **Incrementation** page in the **Job Diagnostics** dialog box displays the incrementation control settings and the resulting incrementation used by Abaqus during the analysis. The **Incrementation** page is available only if you highlight a step in the **Job History** tree.

The **Status** table contents depend on whether you are viewing diagnostic information for an Abaqus/Standard or Abaqus/Explicit analysis step. For an Abaqus/Standard step the table displays each increment along with the number of attempts, the number of severe discontinuity and equilibrium iterations, the total number of iterations, the step time, and the increment size. For an Abaqus/Explicit step the table displays all summary increments and any additional increments for which diagnostic information was recorded. The critical element, the stable time increment for that element, the elapsed step time, the total time, and the kinetic energy are also listed for each increment. For more information on incrementation diagnostics in Abaqus/Explicit, see *Explicit Dynamic Analysis*.

If you select a column of data and click **Plot selected column**, Abaqus/CAE creates an *X*–*Y* plot using the increment number (first column) for the *X*-axis and the selected column for the *Y*-axis.

Note:

You cannot plot the critical element numbers.

Additional information

- *Viewing diagnostic output*
- *Using the step editor*

Warnings and errors

The **Warnings** and **Errors** pages in the **Job Diagnostics** dialog box both display detailed information about undesirable conditions that were encountered during an analysis. Warnings include information about conditions that may lead to questionable analysis results. Errors include information about conditions that caused Abaqus to terminate the analysis prematurely.

The contents of the **Warnings** page depend on the item that is highlighted in the **Job History** tree; if the job is highlighted, the **Warnings** page displays all warnings saved to the output database for the entire job. If you highlight a step, increment, attempt, or iteration in the **Job History** tree, Abaqus/CAE displays information about only those warnings associated with the highlighted item. The **Errors** page is available only when the job item is highlighted; it displays information about all errors saved to the output database for the entire job.

Note:

Only a subset of the warnings and errors written to the message and status files by Abaqus/Standard and Abaqus/Explicit are saved to the output database for access through the **Job Diagnostics** dialog box.

Each **Warnings** or **Errors** page includes a **Summary** table that provides a concise description of all the problems associated with the item that you highlighted in the **Job History** tree. If there is more than one type of problem, you can filter the list of problems based on a common problem **Category**.

The **Details** region of the **Warnings** and **Errors** pages displays more information corresponding to the item that is highlighted in the **Summary** table. Depending on the type of warning or error that you selected, Abaqus/CAE displays either a statement or a table providing detailed information about the problem. If the **Details** region displays tabular information including nodes and elements, you can toggle **Highlight selections in viewport** and select items to view them in the current viewport.

Figure 1 shows the **Warnings** page for a Abaqus/Standard analysis step; the first warning occurs on the step, and the remaining warnings indicate the increment numbers where they occur. In this case the **Details** section includes the coupling release variation for a numerical singularity.

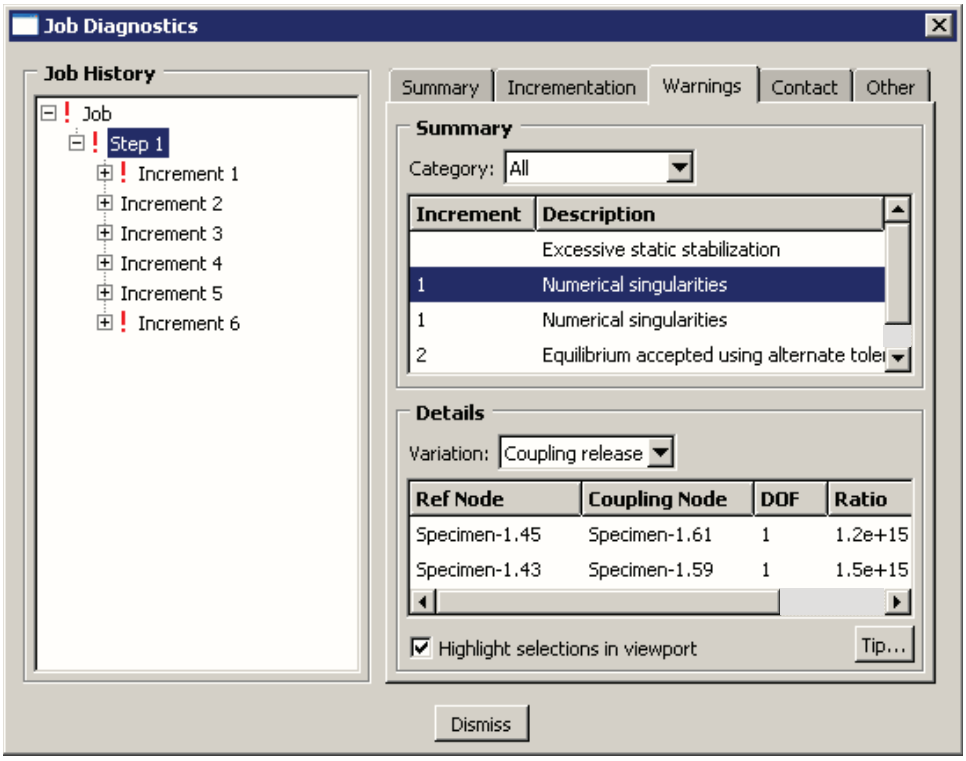

Figure 1: The Warnings page.

Additional information

- *Viewing diagnostic output*
- *Explicit Dynamic Analysis*
- *About Convergence and Time Integration Criteria*
- *Overconstraint Checks*
- *Common Difficulties Associated with Contact Modeling in Abaqus/Standard*

Residuals

The **Residuals** page in the **Job Diagnostics** dialog box displays information about the quantities that Abaqus/Standard uses to determine whether an iteration has produced an equilibrium solution.

Residuals represent the difference between the internal and external forces acting on a model. If the residuals are small, Abaqus accepts the iteration as converged. The tolerances used to determine whether a solution is converged are very important. The tolerances must be small enough to provide an accurate solution but large enough to achieve the solution within a reasonable number of iterations. Before accepting an iteration as converged, Abaqus further requires that corrections to the primary solution variables and constraint equation compatibility errors must also be small.

When the equilibrium iterations do not converge, the node where the maximum residual occurs during the final iterations is usually the best place to begin searching for the problem. There are many conditions that may prevent the equilibrium iterations from converging; diagnosing the source of the problem requires a certain amount of experience.

Residual information, including the maximum residual value in each iteration, is summarized in tabular form for each attempt that contains residual diagnostics. Your selections in the **Equations** and **Variables** fields control the data in the table. You can plot columns from the table by selecting **Plot selected column**. When you have located a problematic iteration, select it in the **Job History** tree. Then you can select items from the **Residuals** page for the iteration and click **Highlight selections in viewport** to view the regions in the current viewport.

Additional information

- *General solution controls*
- *Direct Linear Equation Solver*
- *Solving Nonlinear Problems*
- *About Convergence and Time Integration Criteria*

Contact

The **Contact** page in the **Job Diagnostics** dialog box displays information about regions of the model where changes in the contact status prevent Abaqus from accepting the solution for an Abaqus/Standard step. The **Contact** page can also indicate diagnostics such as initial contact overclosures and adjustments for an Abaqus/Explicit step.

Abaqus/Standard contact information is available for any iterations that are followed by `(SDI)` (Severe Discontinuity Iteration) in the **Job History** tree. Contact information may also be available for other iterations where contact impacts the analysis, such as when stick-slip friction behavior is present. Use the contact information to locate regions in your model where Abaqus could not establish the correct conditions. You may need to edit the contact controls to resolve a contact problem. For more information, see *Customizing contact controls*.

Contact information, including the total number of problems in each iteration, is summarized in tabular form for each attempt that contains contact diagnostics. Your selection in the **Description** field controls the data in the table, and you can plot columns from the table by selecting **Plot selected column**. When you have located a problematic iteration, select it in the **Job History** tree. Then you can select items from the **Contact** page for the iteration and click **Highlight selections in viewport** to view the regions in the current viewport. Click the column headings to sort the information in the **Details** field for an iteration.

For an Abaqus/Explicit step the contact summary may include diagnostics such as the number of initial overclosures, unresolved initial overclosures, and initial contact adjustments. Your selection in the **Description** field controls the data in the table. For example, if you select initial overclosures or unresolved initial overclosures, the table lists the overclosed nodes and elements, the element face that the nodes penetrated, and the overclosure amount. You can select items from the **Details** field and click **Highlight selections in viewport** to view the contact nodes and elements in the current viewport.

Additional information

- *Customizing contact controls*
- *Viewing diagnostic output*
- *About Convergence and Time Integration Criteria*
- *Contact Diagnostics in an Abaqus/Standard Analysis*
- *Common Difficulties Associated with Contact Modeling in Abaqus/Standard*

Elements

The **Elements** page in the **Job Diagnostics** dialog box displays information about regions of the model where problems with the element and material point calculations may be preventing Abaqus from finding a converged solution for an Abaqus/Standard step. Abaqus/Explicit displays information for the critical elements—the elements with the lowest stable time limits.

Note:

Only a subset of the element and material point diagnostics written to the message and status files by Abaqus/Standard and Abaqus/Explicit are accessible through the **Job Diagnostics** dialog box.

Select **Highlight selections in viewport** to locate elements in the current viewport. Your selections in the **Element Diagnostics** and **Details** fields determine the elements that Abaqus/CAE will highlight.

Additional information

- *Viewing diagnostic output*
- *About Convergence and Time Integration Criteria*
- *Common Difficulties Associated with Contact Modeling in Abaqus/Standard*

Other

The **Other** page in the **Job Diagnostics** dialog box appears only when you select a **Step** from the **Job History** tree for an Abaqus/Standard analysis. It displays information about the matrix solver used for the analysis and the characteristic element length in the mesh. Depending on the procedure type, other pertinent information such as the mass of the model and the center of mass are also provided. This reference information can help you determine the possible cause or extent of a problem. For example, if the total mass or center of mass are not correct, there is a problem with the material definition, sections, or section assignments in the Property module.

- *Viewing diagnostic output*
- *About Convergence and Time Integration Criteria*
- *Common Difficulties Associated with Contact Modeling in Abaqus/Standard*

Accessing diagnostic information

You can use the **Job Diagnostics** dialog box to access diagnostic information that Abaqus writes to the output database during an analysis job.

1. From the main menu bar in the Visualization module, select **Tools->Job Diagnostics**.

   The **Job Diagnostics** dialog box appears.

2. Click the "+" symbols in the **Job History** tree to expand the tree to see the steps, increments, attempts, and iterations in the job history.
3. Click an item in the **Job History** tree to highlight it.

   Abaqus/CAE displays additional tabs on the right side of the dialog box containing diagnostic information associated with the selected item.

4. Click the tabs on the right side of the dialog box. Abaqus/CAE displays various types of diagnostic information corresponding to the item that is selected in the tree. The following sections describe the information available in each tabbed page:

   - *Diagnostics summary*
   - *Warnings and errors*
   - *Residuals*
   - *Contact*
   - *Elements*
   - *Other*

5. Click **Dismiss** to close the **Job Diagnostics** dialog box.

Selecting model data and analysis results to plot

Abaqus/CAE obtains model data from the current model database and model data and analysis results from the output database. Results need not be available to produce an undeformed plot; in this case output database information from a **datacheck** run is sufficient.

This chapter explains how to select model data and analysis results for display.

In this section:

- *Selecting results from an output database*
- *Selecting results from the current model database*
- *Selecting the results step and frame*
- *Customizing the display of steps and frames in the results*
- *Selecting the field output to display*
- *Selecting result options*
- *Creating and saving new field output*
- *Creating coordinate systems during postprocessing*
- *Creating node and element sets during postprocessing*

Selecting results from an output database

Abaqus/CAE reads analysis results from the output database.
Output database results consist of those you have saved during the analysis as field and history output variables. If, for example, you have written data to the field output portion of the output database after every 10 increments, you can now select results at 10 increment intervals only. These increment intervals are called frames.

In addition to the analysis results you have saved, you can operate on output database field output to create new results. You can display the values of both output database field output variables and field output variables that you have created in the form of a deformed, contour, symbol, or *X–Y* plot; as *X–Y* data obtained along a path through your model; by probing any model or *X–Y* plot; or in a tabular report. Furthermore, you can display a subset of your model based on field output values, and you can color code a portion of your model according to these values.

You can display output database history output values in the form of an *X–Y* plot.

Use the **Result** menu from the main menu bar to access the options affecting results; the following menu items are available:

- **Step/Frame**: Control the step and frame at which Abaqus/CAE obtains results.
- **Active Steps/Frames**: Control the subset of steps and frames that Abaqus/CAE displays when stepping through results frame by frame, in animations, and in *X–Y* plots.
- **Section Points**: Control which section points provide results for integration point variables.
- **Field Output**: The **Field Output** dialog box contains the following tabs:
  - **Primary Variable**: Control the variable and, if applicable, the invariant or component for which Abaqus/CAE displays results.
  - **Deformed Variable**: Control the variable Abaqus/CAE uses to display the deformed model shape.
  - **Symbol Variable**: Control the vector or tensor variable and optionally the component Abaqus/CAE uses for symbol plots.
  - **Status Variable**: Control the removal of elements that meet the specified result-based failure criteria from model plots.
- **History Output**: Select history output for *X–Y* plotting.
- **Options**: The **Result Options** dialog box contains the following tabs:
  - **Computation**: Display field output or discontinuities, control the averaging of element-based field output results, and control the computation of results at region boundaries.
  - **Transformation**: Apply coordinate system transformations to field output results.
  - **Complex Form**: Control the numeric form in which Abaqus/CAE displays complex number results.
  - **Caching**: Control whether analysis results are cached in memory during postprocessing and how often the output database should be checked for updated results.

Additional information

- *Opening a model database or an output database*
- *Selecting the results step and frame*
- *Customizing the display of steps and frames in the results*
- *Selecting the field output to display*
- *Selecting result options*
- *Creating and saving new field output*

Selecting results from the current model database

Abaqus/CAE can read selected data from any of the models in the current model database.
When you select a model in the Visualization module, Abaqus/CAE makes a subset of the loads, predefined fields, boundary conditions, and interactions specified in that model available for selection as field output variables. Once selected, you can plot contours or symbols for the selected item in a particular step of your analysis. Abaqus/CAE creates a single dummy frame for each step in the model database.

Only a subset of the loads, predefined fields, boundary conditions, and interactions you can define in a model are available for visualization; and the attributes in this section can be displayed when their propagation status is **Created in this step**, **Propagated from a previous step**, or **Modified in this step**. The following attributes can be displayed in contour plots or symbol plots in the Visualization module:

Supported loads

Unless stated otherwise, the loads below are supported for display for all distributions except user-defined distributions. Abaqus/CAE does not consider any amplitude data associated with the load definition when you display it in the Visualization module. Abaqus/CAE displays **(L)** before the name of each load that is available for display in the current step.

- Concentrated force
- Moment
- Concentrated charge
- Concentrated heat flux
- Surface charge
- Concentrated concentration flux
- Surface heat flux (for all distributions except total flux)
- Surface concentration flux
- Pressure load (for all distributions except total force)

If you defined a load using a user-specified coordinate system, the modified orientation is reflected in the Visualization module as well. Abaqus/CAE also customizes the display of any load that is defined using an expression field as its custom distribution; display of loads with mapped fields is not supported.

Predefined fields

Abaqus/CAE displays **(P)** before the name of each predefined field that is available for display in the current step.

- Temperature (all distributions except **From results or output database file** and only the **Constant through section** variation.)
- Velocity (translational velocity components only)

If you defined a predefined field using an expression field or a mapped field, the custom distribution is reflected in the Visualization module as well.

Boundary conditions

Abaqus/CAE displays **(B)** before the name of each boundary condition that is available for display in the current step. For boundary conditions that include degrees of freedom, such as displacement/rotation, you can select the

individual degree of freedom you want to display after selecting the boundary condition. The individual components available for display are indicated below in parentheses where applicable.

You can display data for any boundary condition with parameters that support distributions:

- Displacement/rotation (translational and rotational displacements)
- Velocity/angular velocity (translational and angular velocity)
- Acceleration/angular acceleration (translational and angular acceleration)
- Fluid inlet/outlet
- Fluid wall
- Temperature
- Pore pressure
- Electric potential
- Normalized concentration
- Acoustic pressure
- Connector material flow

Interactions

Abaqus/CAE displays **(I)** before the name of each interaction that is available for display in the current step. Surface film condition (film coefficient and sink temperature) is the only supported interaction.

Additional information

- *Opening a model database or an output database*
- *Selecting the results step and frame*
- *Customizing the display of steps and frames in the results*
- *Selecting the field output to display*
- *Selecting result options*
- *Creating and saving new field output*

Selecting the results step and frame

You can control the step and frame at which Abaqus/CAE obtains model data and results from an output database.

You can select a specific step and frame using the **Step/Frame** dialog box, or you can step through frames using controls available in the context bar. If viewport linking is activated, you can link frame display across viewports. For more information, see *Linking viewports*.

Note: If you are displaying model data from the current model database in the Visualization module, you can select a specific step using the **Step/Frame** dialog box, but the frame controls are disabled. Model database data does not include individual frames.

In this section:

- *Selecting a specific results step and frame*
- *Stepping through frames*

Selecting a specific results step and frame

You can select a specific step and frame at which Abaqus obtains model data and results from an output database, and you can select a specific step at which Abaqus obtains model data from a model in the current model database.

In an output database, available steps and frames consist of those for which analysis results have been saved; in a model database, all steps are available for data display. To view field output variables that you have created during the Abaqus/CAE session, if any, you must select **Result->Step/Frame->Session Step**. To view parametric shape variations defined in your analysis, if any, you must select **Result->Step/Frame->Step 0**.

It is possible to open an output database for an analysis that is still in progress. As the analysis moves toward completion, the lists of completed steps and frames are updated every time you close and then reopen the **Step/Frame** dialog box.

For information on stepping through results frames, see *Stepping through frames*.

1. Locate the **Step/Frame** options.

   From the main menu bar, select **Result->Step/Frame**. The **Step/Frame** dialog box appears.

   The **Step** portion of the dialog lists the available steps, and the **Frame** portion of the dialog lists the available frames for the current *output database* if an output database is selected.

   Note:

   You can also access these options by clicking  in the **Field Output** dialog box.

2. From the **Step** list, click the step to display.

   The selected step is highlighted, and Abaqus/CAE refreshes the **Frame** list to show only frames available for the selected step.

3. From the **Frame** list, click the frame to display. Select **Frame 0** to display the base state of the current step; for example, to contour initial stresses.

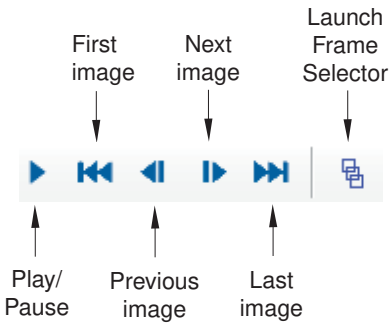
   The selected frame is highlighted.

4. The model plot in the current viewport changes to show your model at the step and frame you have selected. If active, the text in the state block changes to identify the selected step and frame. For more information on the state block, see *Customizing the state block*.

   Abaqus refreshes the ***Field Output*** dialog box to list variables available for the selected frame. (You can access the **Field Output** dialog box by clicking the **Field Output** button on the bottom of the **Step/Frame** dialog box.) Abaqus also refreshes all dialog boxes in which the current step and frame are identified.

   Your changes are saved for the duration of the session.

Additional information



- *Selecting model data and analysis results to plot*
- *Customizing the display of steps and frames in the results*
- *Creating field output by operating on fields*

Stepping through frames

You can use the **ODB Frame** control buttons available in the context bar to step through results frames. Any frames for which analysis results have been saved and that are set to active are available. For information on selecting a specific results frame, see *Selecting a specific results step and frame*. For information on activating results steps and frames, see *Activating and deactivating steps and frames*.

Stepping through frame data is available for output databases only.

1. Locate the **ODB Frame** buttons. These buttons appear on the right side of the context bar when you display an undeformed, deformed, contour, or symbol plot.

2. Click one of the following frame buttons:
   - **First** to display results from the first active frame of the current step. This button has no effect if you are already displaying results from the first frame of the step.
   - **Previous** to display results from the previous active frame. If you are currently displaying results from the first frame of a step, Abaqus/CAE will display results from the last active frame of the previous step. This button has no effect if you are already displaying results from the first frame of the first step.
   - **Next** to display results from the next frame. If you are currently displaying results from the last active frame of a step, Abaqus/CAE will display results from the first frame of the next step. This button has no effect if you are already displaying results from the last frame of the last step.
   - **Last** to display results from the last frame of the current step. This button has no effect if you are already displaying results from the last frame of the step.
   - **Frame Selector** to launch the Frame Selector dialog box, which enables you to navigate directly to a particular frame by entering its frame number or by dragging a slider to the frame you want to display. For more information, see *Navigating to a specific frame in the animation*.

   The model plot in the current viewport changes to show your model at the step and frame you have selected. If active, the text in the *state block* changes to identify the selected step and frame. Abaqus refreshes the **Step/Frame** dialog box, highlighting the selected step and frame and the **Field Output** dialog box, listing variables available for the frame you have selected. Abaqus also refreshes all dialog boxes in which the current step and frame are identified.
3. Continue clicking frame buttons to step through available frames.

Additional information

- *Selecting model data and analysis results to plot*
- *Customizing the display of steps and frames in the results*
- *Customizing the state block*

Customizing the display of steps and frames in the results

You can customize your display of an output database's steps and frames by activating only a subset of these steps and frames or by changing the duration or arc length of one or more steps.
Abaqus/CAE displays only active steps and frames when you examine output data by stepping through data frame by frame, when you animate the data, and when you generate *X–Y* history data from field data.

In this section:

- *Activating and deactivating steps and frames*
- *Changing the period of a step*

Activating and deactivating steps and frames

You can customize the display of analysis results by activating a subset of the steps and frames in the output database. Abaqus/CAE displays only active steps and frames when you examine analysis results by stepping through frames, animating the data, or creating *X–Y* history data from field data. The subset of active steps and frames persists throughout your session and applies to every display of a model database's results.

You can activate and deactivate steps or frames either from the Results Tree or from the **Active Steps/Frames** dialog box. Both tools also enable you to expand and collapse steps by clicking on the "plus" and "minus" signs to the left of each step name. Expanding a step reveals its frames, enabling you to activate some of the frames rather than the entire step.

The Results Tree and **Active Steps/Frames** dialog box also provide visual cues to indicate the active status of steps or frames in the output database. The Results Tree flags inactive frames with a red "X" that appears to the left of the frame shortcut; frames not displayed in this manner are currently active. In the **Active Steps/Frames** dialog box, step and frame status is indicated by check marks that appear in the area between the plus/minus sign and the step's name. A green check mark display for a step means that all of its frames are active; a green check mark for an individual frame means that the frame is active; a dark grey check mark on a light grey background means that some of the step's frames are active; and when no check mark appears, the step is completely inactive. This visual cue can help you assess a step's active status when the step container is collapsed. *Figure 1* shows the **Active Steps/Frames** dialog box for an output database with two steps completely active, one step partially active, and two steps inactive.

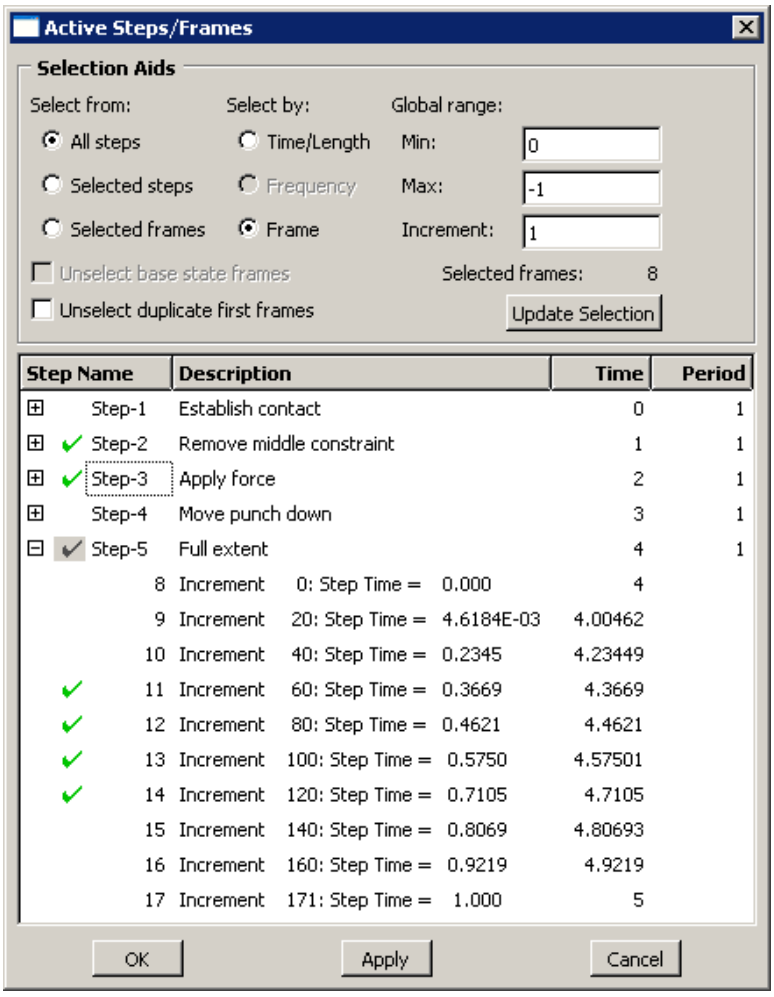


Figure 1: Active Steps/Frames dialog box.

Each row in the **Active Steps/Frames** dialog box also provides the following information about the step:

- The **Step Name** and **Description** columns reflect the values that were defined for this step when the model was created.
- The value in the **Time** column either provides the step's starting time or describes the nature of the step. For a time-based step, this column displays the starting time for the step. If the step is not time-based, this column describes whether the step is a Modal, Frequency, or Arc (Riks analysis) step.
- The value in the **Period** column also depends on the step type. For a time-based step, the period is the step's total duration. For a Riks analysis step, the period is the step's total arc length. Modal and frequency steps have a dash (−) displayed in this column to indicate that a period is not applicable for this step.

  You can modify the period value for time-based and Riks analysis steps, provided the period does not equal 0. See *Changing the period of a step*, for more information.

The **Active Steps/Frames** dialog box provides two methods of activating steps and frames: you can use the filtering tools in the **Selection Aids** portion of the dialog box to activate a set of steps or frames, and you can activate individual step and frame rows by clicking their rows in the lower portion of the dialog box. Activating steps or frames using the selection aids clears the subset of steps and frames that you currently have active. If you plan to select steps and frames manually, do so after you choose a subset using the selection aids.

Selection Aids

The **Selection Aids** filtering options enable you to choose a subset of steps and frames according to several selection criteria.

- The **Select from** options define the candidate set of steps and frames for your search. You can search across all steps in the output database, or search only within the subset of steps or frames that are currently selected in the lower portion of the **Active Steps/Frames** dialog box.
- The **Select by** options specify the variable for which you want to search for matching steps and frames. You can search for any steps or frames that occurred within a particular range of time. For frequency extraction steps, you can search for any steps or frames during which the model exhibited a particular frequency. Alternatively, you can search for frames by their frame number.
- The **Global range** fields enable you to specify the upper and lower bounds for your search and to define the increment between matching steps or frames. For example, if you want to activate all even-numbered frames between a lower bound of frame 0 and an upper bound of frame 20, enter 2 as the increment.
- You can also deactivate base state frames in the output database by selecting **Unselect base state frames**. This option is available only when the output database contains linear perturbation steps.
- Some steps may have initial frames that duplicate the final frame of the previous step. Unselecting these duplicate first frames can make your data analysis smoother and more realistic. Choose **Unselect duplicate first frames** to unselect all duplicate first frames throughout all steps in the database.

Selecting steps and frames manually

You can activate and deactivate individual steps and frames by clicking rows in the lower portion of the **Active Steps/Frames** dialog box. Clicking a single step activates or deactivates all of its frames, while clicking a frame activates or deactivates that frame only. If you click and drag across several steps or frames, Abaqus/CAE inverts the activation status of all selected steps of frames you select.

Tip: You can also activate or deactivate steps and frames from the Results Tree. Highlight the steps or frames that you want to toggle, click mouse button 3, then select **Activate all** or **Deactivate all** to change the active status of all frames within the selected steps or select **Activate** or **Deactivate** to change the active status of the selected frames.

The Results Tree indicates inactive frames with a red “X” that appears to the left of the frame shortcut. User-defined session steps, which cannot be deactivated, are indicated with a red exclamation point; these steps are not displayed in the **Active Steps/Frames** dialog box.

Manually activating and deactivating steps and frames in the dialog box can supplement and refine the choices you make by using the selection aids. In addition, clicking mouse button 3 in the lower portion of the dialog box provides access to the following manual selection shortcuts:

- **Expand All** expands all of the steps containers, selected and unselected, to reveal the frames of every step in the output database.
- **Collapse All** collapses all of the selected and unselected step containers in the output database.
- **Select All** selects every frame of every step in the output database.
- **Deselect All** deselects every frame of every step in the output database.
- **Reset Selection** reverts the active steps and frames to the subset that was active when you last clicked **Apply**.
- **Reset Periods** reverts the period values to the settings that were active when you last clicked **Apply**.

1. Locate the **Active Steps/Frames** dialog box.

   From the main menu bar, select **Result->Active Steps/Frames**. The **Active Steps/Frames** dialog box appears.

   The lower portion of the dialog box shows the steps and, for expanded steps, the frames in the output database. The first time you examine an output database’s steps and frames during a session, all of the steps and frames are active.

2. From the **Selection Aids** portion of the dialog box, choose the data set, variable, and global range values for your search.
3. Click **Update Selection**.

   Abaqus/CAE updates the subset of active steps and frames.

4. Activate or deactivate steps manually in the lower portion of the dialog box. You can toggle the activate status of a single step or frame by clicking the appropriate row, or you can toggle the activation status of multiple rows by clicking and dragging several rows.
5. Click **Apply**.

   Abaqus/CAE updates all viewports that display this output database with the newly selected subset of active steps and frames.

Additional information

• *Selecting the results step and frame*
• *Changing the period of a step*
• *Reading X–Y data from output database field output*
• *Animating plots*

Changing the period of a step

The meaning of a step's period value depends on whether the step is a Riks analysis step or a time-based step. For Riks analysis steps, the period specifies the total arc length for the step. For time-based steps, the period specifies the step's total duration, so changing this value affects how long this step is displayed and changes the starting times for all subsequent steps. Changing the time period of a single step also changes the duration of the entire animation or frame-by-frame display, affects the auto-computed start and end time of time-based animations, and affects the way the animation of this model synchronizes with other models. You might want to adjust the time period if you want to synchronize events in different models that occur at different times in the common time line.

Changes to the period values last for the duration of your session. Abaqus/CAE does not save these changes to the output database.

You cannot edit the period value of a Riks analysis or time-based step if the value equals 0. In addition, modal and frequency extraction steps do not have period values; Abaqus/CAE displays an uneditable dash (−) in the **Period** column for steps of these types.

Tip: If you want to revert the period values to the output database's settings, click mouse button 3 in the lower portion of the window and select **Reset Periods**.

1. Locate the **Active Steps/Frames** dialog box.

   From the main menu bar, select **Result->Active Steps/Frames**. The **Active Steps/Frames** dialog box appears.

   The lower portion of the dialog box shows the steps and, for expanded steps, the frames in the output database. The first time you examine an output database's steps and frames during a session, all of the steps and frames are active.

2. From the lower portion of this dialog box, click the value in **Period** column for a step, then enter a new value in the field. Repeat this change for every step period that you want to customize.
3. Click **Apply**.

   Abaqus/CAE updates all viewports that display this output database with the revised period and time values.

- *Animating plots*

Selecting the field output to display

This section explains how to select field output variables to display.

To learn how to select output database history output to produce an *X–Y* plot, see *Reading X–Y data from output database history output*. To learn how to select output database field output to produce an *X–Y* plot, see *Reading X–Y data from output database field output*.

In this section:

- *Selecting field output variables*
- *Using the field output toolbar*
- *Selecting the primary field output variable*
- *Selecting the deformed field output variable*
- *Selecting the symbol field output variable*
- *Selecting the status field output variable*
- *Selecting the stream field output variable*
- *Selecting complex results*
- *Selecting section point data*
- *Selecting contact output*

Selecting field output variables

Contour plots, model probing, view cuts based on an isosurface, and *X–Y* plots of results along a model path all show the values of a particular field output variable at a specified step and frame of your analysis.
Similarly, when you form a display group or specify color coding based on results, or when you display a load or predefined field from data in the current model database, these results pertain to a particular field output variable. The variable whose values are shown is called the *primary field output variable*.

Deformed plots show the shape of your model based on the values of a nodal variable (such as displacement) at a specified step and frame of your analysis. The variable whose values are shown is called the *deformed field output variable*.

Symbol plots show the magnitude and directions of a particular vector or tensor variable at a specified step and frame of the analysis. A symbol plot can also the magnitude and direction of a selected load or predefined field in a model from the current model database. The variable whose values are shown is called the *symbol field output variable*.

You can specify result-based criteria for element failure for a selected field output variable and remove elements that meet the failure criteria from model plots. The variable for which you define the failure criteria is called the *status field output variable*.

You can specify velocity or vorticity data for stream display. The variable for which you display these data is called the *stream field output variable*.

You can choose to display contour and symbol plots on either the undeformed or deformed model shape. When you use the deformed model shape, the contours or symbols represent the values of the primary field output variable or symbol field output variable, respectively, while the shape of the underlying model is determined by the values of the deformed field output variable.

1. Locate the **Field Output** options.

   From the main menu bar, select**Result->Field Output**. The **Field Output** dialog box appears.

   Tip: You can also access these options by clicking the **Field Output** button in any dialog box in which it appears or by clicking  in the **Field Output** toolbar.

2. Select the primary, deformed, symbol, and status field output variables that you want as described in the following sections:

   - *Selecting the primary field output variable*
   - *Selecting the deformed field output variable*
   - *Selecting the symbol field output variable*
   - *Selecting the status field output variable*
   - *Selecting the stream field output variable*
   - *Selecting complex results*
   - *Selecting section point data*
   - *Selecting contact output*

   The model plot in the current viewport changes to show the variables you have selected. If active, the text in the legend and state block changes to identify the variables associated with the plot. For more

information on the legend and state block, see *Customizing the legend*, and *Customizing the state block*. In addition, Abaqus refreshes all dialog boxes in which the currently selected variables are identified.

Additional information

- *Selecting model data and analysis results to plot*
- *Using the field output toolbar*
- *Creating or editing a view cut*

Using the field output toolbar

You can use the **Field Output** toolbar to access the basic functionality of the **Field Output** dialog box. From the toolbar, you can

- choose the type of field output variables to manipulate (***Primary***, ***Deformed***, or ***Symbol***);
- choose the variable name from a list of the available field output variables;
- choose the refinement level, such as invariants and components for the selected primary variable, if available; and
- choose whether the viewport plot state should be synchronized with the toolbar selections.

The **Status** and **Stream** variable types are the only field output that you cannot select from the toolbar. The **Status** and **Stream** variable types are available in the **Field Output** dialog box; the status variable allows you to specify criteria that Abaqus/CAE uses to remove failed elements from the model display, and the stream variable determines the field output displayed in streamlines for an analysis of fluid flow data. To open the **Field Output** dialog box, click , located on the left side of the **Field Output** toolbar.

Figure 1: The Field Output toolbar.

As you make selections from the toolbar, Abaqus/CAE updates the current viewport to display the output; the viewport plot state is also updated if a change in plot state is needed and if the plot state synchronization toggle () is enabled. For example, selecting **Primary** as the variable type changes the plot state to display contours on the deformed model if the viewport does not already contain a contour plot. If you disable synchronization, Abaqus/CAE still displays your newly selected field output variable in the current viewport but does not change the plot state.

Additional information

- *Selecting model data and analysis results to plot*
- *Selecting field output variables*

Selecting the primary field output variable

You can select the variable to display for *contour plots*, *model probing*, view cuts based on an isosurface, and for which to *obtain results along a model path*; this variable is called the primary field output variable. Abaqus/CAE also uses the primary field output variable to *form display groups*, to *apply color coding* based on results, and for display of loads, predefined fields, or interactions from a model in the current model database.

When an output database is selected, Abaqus/CAE lists for your selection all variables available at the current *step and frame* of your *output database* by default. An asterisk to the left of the description indicates that the variable includes complex number results.

When a model in the current model database is selected, Abaqus/CAE lists for your selection all loads, predefined fields, boundary conditions, and interactions available in the current step of your model by default. All of these selectable items are preceded by a letter in parentheses to distinguish them by category: **(L)** for loads, **(P)** for predefined fields, **(B)** for boundary conditions, and **(I)** for interactions. Only the real part of a complex load or predefined field is available for display.

Use the **Primary Variable** options in the **Field Output** dialog box to choose the variable and, if applicable, the invariant or component that you want. For information on individual output variable identifiers, see *Output Variables*.

1. Locate the options that control the primary field output variable.

   From the main menu bar, select**Result->Field Output**. Click the **Primary Variable** tab in the dialog box that appears.

   The **Primary Variable** options appear.

   Tip: You can also access these options by clicking the **Field Output** button in any dialog box in which it appears.

   To see the complete descriptions of the variables listed, increase the width of the dialog box by dragging one corner.

2. To control which variables appear in the **Name** and **Description** list:
   a. Toggle **List only variables with results** to display a list that is limited by the storage location of the variables. Limiting the list helps you select variables by presenting, for example, only integration point quantities.

      When **List only variables with results** is on, filter options become available in the pull-down menu.

   b. Click the **List only variables with results** arrow to reveal the filter options.
   c. Click the text stating the location of the variables you want to include in the **Name** and **Description** list.

      The text appears in the **List only variables with results** box, and the **Name** and **Description** list is refreshed to include only variables having that location.

3. From the **Name** and **Description** list, click the name of the analysis variable that you want. An asterisk to the left of the description in the list indicates that the variable includes complex number results.

   The selected variable is highlighted. If applicable, the **Component** and **Invariant** lists on the bottom of the dialog box are refreshed to display available components or invariants, respectively.

4. If items are listed in the **Component** or **Invariant** list, click the component or invariant that you want.

   The selected component or invariant is highlighted.

   Note: For S and E field output, there are two invariants, **Max. Principal (abs)** and **Max. In-Plane Principal (abs)**, which are available only in the Visualization module. **Max. Principal**

(abs) is the largest principal value when the absolute value of all principal values are compared. **Max. In-Plane Principal (abs)** is the largest principal value when the absolute value of all in-plane principal values are compared. The out-of-plane principal value is not considered when the **Max. In-Plane Principal (abs)** value is computed.

5. When active, a contour plot in the current viewport changes to show values for the analysis variable you have specified. If active, the text in the legend and state block changes to identify the variable associated with the plot. For more information on the legend and state block, see *Customizing the legend*, and *Customizing the state block*. In addition, Abaqus refreshes all dialog boxes in which the current primary variable is identified.

   Your changes are saved for the duration of the session.

Additional information

• *Selecting model data and analysis results to plot*

Selecting the deformed field output variable

You can display the deformed model by producing a deformed plot or by selecting the deformed model as the underlying shape of a contour or symbol plot. The shape of your deformed model is based on the values of the particular deformed field output variable that you select. An asterisk to the left of the description in the **Output Variable** list indicates that the variable includes complex number results. For information on individual output variable identifiers, see *Output Variables*.

1. Locate the options that control the deformed field output variable.

   From the main menu bar, select **Result->Field Output**. Click the **Deformed Variable** tab in the dialog box that appears.

   The **Deformed Variable** options become available.

   Tip: You can also access these options by clicking the **Field Output** button in any dialog box in which it appears.

   Abaqus/CAE lists by name and description all variables available at the current *step and frame* of your *output database* that can be used for a deformed plot (nodal vector quantities). To see the complete descriptions of the variables listed, increase the width of the dialog box by dragging one corner.

2. From the **Name** and **Description** list, click the deformed field variable that you want. An asterisk to the left of the description in the list indicates that the variable includes complex number results.

   The selected variable is highlighted.

3. The deformed model shape in the current viewport changes to reflect the values of the deformed field output variable you have specified. If active, the text in the state block changes to identify the variable associated with the plot. For more information on the state block, see *Customizing the state block*.

   Your changes are saved for the duration of the session.

Additional information

- *Selecting model data and analysis results to plot*

Selecting the symbol field output variable

You can select the vector or tensor variable component and optionally select a component to display for a symbol plot; this variable is called the symbol field output variable.

When an output database is selected, Abaqus/CAE lists for your selection all vector and tensor variables available at the current *step and frame* of your *output database* by default; resultant values are displayed in vector variable symbol plots, and all principal components are displayed in tensor variable symbol plots. An asterisk to the left of the description indicates that the variable includes complex number results.

When a model from the current model database is selected, Abaqus/CAE lists for your selection all loads, predefined fields, boundary conditions, and interactions available at the current step of your model by default. All of these selectable items are preceded by a letter in parentheses to distinguish them by category: **(L)** for loads, **(P)** for predefined fields, **(B)** for boundary conditions, and **(I)** for interactions.

Use the **Symbol Variable** options in the **Field Output** dialog box to choose the variable and the specific components that you want. For information on individual output variable identifiers, see *Output Variables*.

When you display a vector variable in a symbol plot, you can choose from the following options:

- Display arrows that represent resultant values of the variable. For example, a symbol plot of total displacement appears on the left side of *Figure 1*.
- Display arrows that represent specific component values of the variable. For example, a symbol plot of displacement in the 1-direction appears on the right side of *Figure 1*.

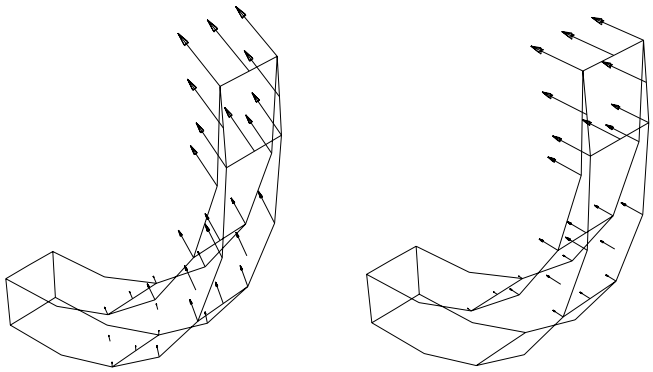

Figure 1: Symbol plots showing total displacement (left) and displacement in the 1-direction (right).

Likewise, when you display a tensor variable in a symbol plot, you can choose from the following options:

- Display arrows that represent each of the principal components of the variable. For example, a symbol plot of maximum, intermediate (mid), and minimum principal stress appears on the left side of *Figure 2*.
- Display arrows that represent a specific principal component of the variable. For example, a symbol plot of only maximum principal stress appears on the right side of *Figure 2*.

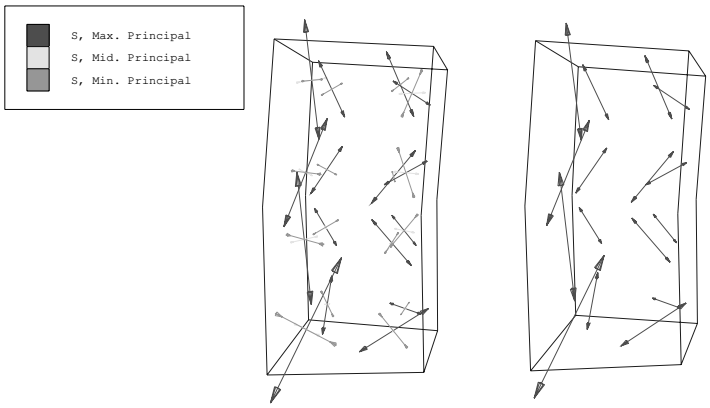

Figure 2: Symbol plot showing all three principal components (left), and symbol plot showing only maximum principal stress (right).

- Display arrows that represent each of the direct components of the variable. For example, a symbol plot of all direct components appears on the left side of *Figure 3*.
- Display arrows that represent a specific direct component of the variable. For example, a symbol plot of only S22 appears on the right side of *Figure 3*.

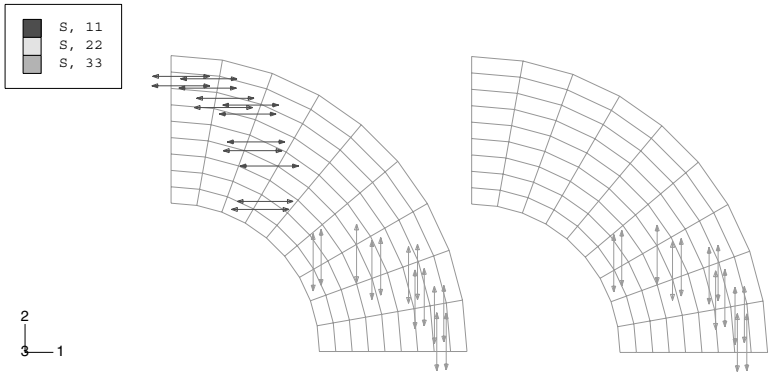

Figure 3: Symbol plot showing all direct components (left), and symbol plot showing only S22 (right).

1. Locate the options that control the symbol field output variable.

   From the main menu bar, select**Result->Field Output**. Click the **Symbol Variable** tab in the dialog box that appears.

   The **Symbol Variable** options appear.

   Tip: You can also access these options by clicking the **Field Output** button in any dialog box in which it appears.

   To see the complete descriptions of the variables listed, increase the width of the dialog box by dragging one corner.

2. To control which variables appear in the **Name** and **Description** list:

   a. Toggle **List only variables with results** to display a list that is limited by the storage location of the variables. Limiting the list helps you select variables by presenting, for example, only integration point quantities.

When **List only variables with results** is on, filter options become available in the pull-down menu.

b. Click the **List only variables with results** arrow to reveal the filter options.

c. Click the text stating the location of the variables you want to include in the **Name** and **Description** list.

The text appears in the **List only variables with results** box, and the **Name** and **Description** list is refreshed to include only variables having that location.

3. From the **Name** and **Description** list, click the name of the analysis variable that you want. An asterisk to the left of the description in the list indicates that the variable includes complex number results.

The selected variable is highlighted. The **Vector Quantity**, **Tensor Quantity**, and **Component** lists on the bottom of the dialog box are refreshed to display available vector quantities, tensor quantities, and components, respectively.

4. If you are creating a vector variable symbol plot, select the components to plot.

- Select **Resultant** to display arrows that represent the resultant of the variable.
- Select **Selected Component** and the component that you want to display arrows that represent a particular component of the variable.

5. If you are creating a tensor variable symbol plot, select the component to plot.

- Select **All Principal Components** to display arrows that represent all available principal components.
- Select **Selected Principal Component** and the component that you want to display only arrows that represent a particular principal component.
- Select **All Direct Components** to display arrows that represent all three direct components.
- Select **Selected Direct Component** and the component that you want to display only arrows that represent a particular direct component.

Note: For S and E field output, there are two invariants, **Max. Principal (abs)** and **Max. In-Plane Principal (abs)**, which are available only in the Visualization module. **Max. Principal (abs)** is the largest principal value when the absolute value of all principal values are compared. **Max. In-Plane Principal (abs)** is the largest principal value when the absolute value of all in-plane principal values are compared. The out-of-plane principal value is not considered when the **Max. In-Plane Principal (abs)** value is computed.

6. Click **Apply** to implement your changes.

The symbol plot in the current viewport changes to show values for the analysis variable you have specified. If active, the text in the legend and state block changes to identify the variable associated with the plot. For more information on the legend and state block, see *Customizing the legend*, and *Customizing the state block*.

Your changes are saved for the duration of the session.

Additional information

• *Selecting model data and analysis results to plot*

Selecting the status field output variable

You can specify result-based criteria for element failure for a selected field output variable; this variable is called the status field output variable. When you enable the use of the status field output variable, elements that meet the specified criteria are considered failed and they are removed from model plots. Use the **Status Variable** options in the **Field Output** dialog box to enable the use of the status variable; to select the variable and, if applicable, an invariant or components; and to specify the result-based criteria for failure. If desired, you can apply the status field output variable to undeformed shape plots. By default, failed elements are not removed when the model is displayed in an undeformed state.

By default, the status field output variable is not enabled unless the output variable STATUS appears in the output database. In this case the use of the status field output variable is enabled by default, the output variable STATUS is selected, and the failure criteria is set to remove elements with values less than or equal to 0.5 (the status of an element is 1.0 if the element is active, 0.0 if the element is not). Elements with a value of 0.0 are not displayed in the model plot in the current viewport.

When selecting a status field output variable, Abaqus/CAE lists for your selection all of the variables (except surface-based field output variables) available at the current *step and frame* of your *output database*. An asterisk to the left of the description indicates that the variable includes complex number results. For information on individual output variable identifiers, see *Output Variables*.

1. Locate the options that control the status field output variable.
   a. From the main menu bar, select**Result**->**Field Output**. Click the **Status Variable** tab in the dialog box that appears.
   b. Toggle **Use status variable** to disable or enable use of the status variable.

      When **Use status variable** is on, the status variable is enabled and the **Status Variable** options become available.

      Tip: You can also access these options by clicking the **Field Output** button in any dialog box in which it appears.

   To see the complete descriptions of the variables listed, increase the width of the dialog box by dragging one corner.
2. Toggle on **Apply to undeformed state** to apply the status field output variable to undeformed shape plots. If your model contains no deformations, you must toggle on this setting to apply the status field output variable.
3. To control which variables appear in the **Name** and **Description** list:
   a. Toggle **List only variables with results** to display a list that is limited by the storage location of the variables. Limiting the list helps you select variables by presenting, for example, only integration point quantities.

      When **List only variables with results** is on, filter options become available in the pull-down menu.
   b. Click the **List only variables with results** arrow to reveal the filter options.
   c. Click the text stating the location of the variables you want to include in the **Name** and **Description** list.

      The text appears in the **List only variables with results** box, and the **Name** and **Description** list is refreshed to include only variables having that location.
4. From the **Name** and **Description** list, click the name of the analysis variable that you want. An asterisk to the left of the description in the list indicates that the variable includes complex number results.

The selected variable is highlighted. If applicable, the **Invariant** and **Component** lists on the bottom of the dialog box are refreshed to display available invariants or components, respectively.

5. If items are listed in the **Invariant** or **Component** list, click the invariant or component that you want.

   The selected invariant or component is highlighted.

   Note: For S and E field output, there are two invariants, **Max. Principal (abs)** and **Max. In-Plane Principal (abs)**, which are available only in the Visualization module. **Max. Principal (abs)** is the largest principal value when the absolute value of all principal values are compared. **Max. In-Plane Principal (abs)** is the largest principal value when the absolute value of all in-plane principal values are compared. The out-of-plane principal value is not considered when the **Max. In-Plane Principal (abs)** value is computed.

6. Choose from the filtering methods in the **Remove elements** field to specify the failure criteria. If any result value of an element meets the specified criteria, that element is considered failed and it is removed from model plots. Element output quantities are compared against the specified criteria; there is no extrapolation or averaging performed on the element data. If a nodal quantity is selected and a value for a given node meets the specified criteria, all elements connected to the failed node are removed.

   - Select  and enter a value in the **Max** field to remove elements with values less than or equal to the specified value.
   - Select  and enter a value in the **Min** field to remove elements with values greater than or equal to the specified value.
   - Select  (inside) and enter values for the upper and lower bounds of the range in the **Min** and **Max** fields to remove elements with values between and including the specified values.
   - Select  (outside) and enter values for the upper and lower bounds of the range in the **Min** and **Max** fields to remove elements with values outside the specified range.

7. Click **Apply** to implement your changes.

   The model plot in the current viewport changes to remove elements with values of the selected status field output variable that meet the specified criteria. If active, the text in the legend and state block changes to identify the variable associated with the plot. For more information on the legend and state block, see *Customizing the legend*, and *Customizing the state block*.

   Your changes are saved for the duration of the session.

Additional information

- *Selecting model data and analysis results to plot*

Selecting the stream field output variable

You can specify the variable for which stream data are computed; this variable is called the stream field output variable. For most analyses velocity (**V**) can be used for the stream data. Only node-centered vector results can be associated with streamline traces.

When selecting a stream field output variable, Abaqus/CAE lists all of the vector variables stored at nodal locations and available at the current *step and frame* of your *output database*.

1. Locate the options that control the stream field output variable.

   From the main menu bar, select **Result->Field Output**. Click the **Stream Variable** tab in the dialog box that appears.

   Tip: You can also access these options by clicking the **Field Output** button in any dialog box in which it appears.

   To see the complete descriptions of the variables listed, increase the width of the dialog box by dragging one corner.

2. From the **Name** and **Description** lists, click the name of the analysis variable that you want.

   The selected variable is highlighted.

3. Click **Apply** to implement your changes.

   Abaqus/CAE recomputes the streamlines in the current viewport based on the selected stream output variable. Your selection for stream output variable is also saved for the duration of the session.

Additional information

- *Selecting model data and analysis results to plot*

Selecting complex results

By default, Abaqus/CAE lists for your selection all variables available at the current *step and frame* of your *output database*. If the current step is a steady-state dynamic analysis, the value of an output variable such as stress (S) or displacement (U) can be a complex number with both real and imaginary components. Use the **Primary Variable**, **Deformed Variable**, **Symbol Variable**, **Status Variable**, and **Stream Variable** options in the **Field Output** dialog box to choose the complex variables that you want to display. The description of each listed variable begins with an asterisk if that variable includes complex results. For information on individual output variable identifiers, see *Output Variables*.

You can display complex results in the form of a *deformed*, *contour*, or *symbol* plot; by *model probing*; by *obtaining results along a model path*; and by forming a display group or specifying color coding based on results. In each of these cases you can choose from several *numeric forms* to display different aspects of the complex results. You can animate complex results using *harmonic animation*. During harmonic animation the real and imaginary components of each complex number are used to calculate and display the value of the result at a sequence of angles representing a half cycle (0° to 180°) or a full cycle (–180° to 180°).

Selecting section point data

If your model contains shells, beams, or composite layups, you can view data from selected section points when you are displaying a contour, symbol, or material orientation plot.

You can select section points, by category or ply, that will apply across linked viewports. The linking also applies to envelope plots. For more information, see *Linking viewports*.

You can choose either of the following selection methods:

By category

For each section of your model, you first choose the active location of a section point (bottom, top, or both). You then choose from a list of available section points for this category. For example, you can choose to display data from the midpoint of each section. The available section points are related to the section points that you requested when you created the field output request in the Step module. You can also display a plot of the section point containing the critical value (maximum or minimum) of the field output variable across all of the section points. For more information, see *Selecting section point data by category*.

By ply

For a model containing a composite layup, you first choose a ply, and you then choose a location from which to display the field output variable. You can specify one of the following as the section point location in the selected ply: the bottommost section point, the middle or only section point, the topmost section point, or both the topmost and bottommost section points. For more information, see *Selecting section point data by ply*.

In this section:

- *Selecting section point data by category*
- *Selecting section point data by ply*

Selecting section point data by category

When you are displaying a contour plot, you can use the **Section Points** dialog box to control the section points from which Abaqus obtains integration point results and material orientations by selecting a category and the section points that represent the bottom and top locations.

Reinforcement (rebar) layers in membrane, shell, and surface elements are treated as section points for output purposes; each reinforcement layer has a unique name. For example, you can request results from the section points at the top surfaces of certain shells in the model, from the middle section points of certain beams in the model, or from a named reinforcement layer in certain membrane elements in the model.

Contour plots displaying output at two section points vary in appearance depending on the type of shell. In a conventional shell the two contours appear as a double-sided shell with different contours on each side, while in a continuum shell (or a composite solid) the two contours appear as distinct two-dimensional contour fronts at each section point location. Axisymmetric shells, which are composed of line elements swept to form a three-dimensional surface, exhibit neither behavior because they are not considered three-dimensional shells; instead, these shells display output at a single section point only.

In many cases the location of a section point is described in terms of its position relative to the midpoint of the cross-section. For two-dimensional beams this relative position is reported as a fraction of the distance between the midpoint of the cross-section and the top or bottom surface of the section. For shells this relative position is reported as a fraction of the distance between the midpoint of the cross-section and the SPOS or SNEG surface of the section. Reinforcement layers are indicated by their unique name.

For beams with three-dimensional sections, the relative position of a section point can be reported as a fraction of the distance between the midpoint of the cross-section and

- the top or bottom of the section (along the local 2-axis of the section) or
- the left or right side of the section (along the local 1-axis of the section).

For circular beams the section point locations are defined as a relative position with respect to the section radius and an angle rotated from the positive 1-axis about the midpoint of the cross-section.

For more information about where section points are located in different section types, see the following:

- *Beam Elements*
- *Shell Elements*

For more information about reinforcement layers, see *Defining Reinforcement*.

Abaqus/CAE provides the following methods for choosing the section points to display:

- Display a category of elements and a location. Examples of element categories include element types and materials. The location can be the top or bottom surface or both.
- Display the section point containing the critical value (absolute maximum, maximum, or minimum). Abaqus/CAE searches for the critical value across all of the section points in each element. The resulting plot is called an envelope plot.

Additional information

• *Selecting model data and analysis results to plot*

Select the section point using categories and a location

1. Display a contour plot of the desired field output variable. For more information, see *Producing a contour plot*.
2. Locate the **Section Points** dialog box.

From the main menu bar, select **Result->Section Points**.

The **Section Points** dialog box appears.

3. From the **Selection method** field, select **Categories**.

   The elements within each category share common section properties, such as the following:

   - The section type associated with the elements in this category.
   - The material name or composite specification included in the section definition.
   - The number of section points through the section.
   - The cross-section geometry (beams only).

4. From the **Active locations** field, select **Bottom** or **Top** to activate only the **Bottom Location** or **Top Location** section point. For contour plots of integration point variables on three-dimensional shells or composite solids, select **Top and bottom** to display output simultaneously at both section points. Only contour plots of this type can display output for both section points simultaneously; in all other contexts, Abaqus/CAE displays output only at the **Bottom Location** section point when you select **Top and bottom**.

   Abaqus/CAE displays output only at active locations. The **Bottom Location** and **Top Location** fields display the two section points at which you can display output for the selected category. By default, these fields display the SNEG and SPOS section points, respectively.

5. In the **Category** table, select the element category or categories for which you want to change the output location and select the location. If you selected **Top and bottom** from the **Active locations** field, select both locations.

   The **Available Section Points in Cross-Section** field in the bottom half of the dialog box lists the section points from which output was saved for the category and location you have selected. If you have selected more than one category, only those locations that are common to all of the selected categories appear in the list.

6. In the **Available Section Points in Cross-Section** field, select the section point location to display.
7. Click **Apply** to view your settings.

   The model plot in the current viewport changes to display values from the specified section points. The plot legend, if active, changes to identify the specified section points. For information about the plot legend, see *Customizing the legend*.

   Results for subsequent *contour*, *symbol*, and *material orientation* plots; *tabular reports*; model probing; and *X–Y data objects along a path* will be obtained from the section points you have specified.

8. Click **OK** to select the section points and to exit the dialog box.

Select the section point containing the critical value

1. Display a contour plot of the desired field output variable. For more information, see *Producing a contour plot*.
2. Locate the **Section Points** dialog box.

   From the main menu bar, select **Result->Section Points**.

   The **Section Points** dialog box appears.

3. From the **Selection method** radio buttons, select **Categories**.
4. From the **Active locations** radio buttons, select **Envelope**.
5. From the **Criteria** field of the dialog box, select the criterion (absolute maximum, maximum, or minimum) that will determine the section point containing the critical value.

6. From the **Position** field, select the algorithm that Abaqus/CAE will use to determine the section point containing the critical value.
   - If you choose **Integration point**, Abaqus/CAE compares the value at all of the integration points of each section.
   - If you choose **Centroid**, Abaqus/CAE compares the value averaged at the centroid of each section.
   - If you choose **Element nodal**, Abaqus/CAE compares the value extrapolated to the nodes of each section.

7. Click **Apply** to view your settings.

   The model plot in the current viewport displays the critical section point and its value for each element in the mesh. For information about the plot legend, see *Customizing the legend*.

8. If you are displaying a composite layup, you can determine how Abaqus/CAE displays the critical section point by selecting ply options for the contour plot.
   a. From the main menu, select **Options->Contour**.
   b. From the **Contour Plot Options** dialog box that appears, click the **Other** tab.
   c. From the options at the bottom of the tabbed page, do the following:
      - Toggle on **Show labels of plies that match criteria** to see labels for the critical plies in the contour plot.
      - Toggle on **Color by plies that match criteria** to change the value that is being contoured from the field output variable to a ply name. The contour plot updates to show the critical plies in the model. The legend updates to show the names of the plies that are being displayed.

9. Click **OK** to retain your settings and to exit the dialog box.

Selecting section point data by ply

You can use the **Section Points** dialog box to control the section points from which Abaqus obtains integration point results and material orientations by selecting a ply and the location from within the ply at which Abaqus/CAE reads the results.

Contour plots displaying output at both the top and bottom of the selected ply vary in appearance depending on the type of composite layup. In a conventional shell composite layup the two contours appear as a double-sided shell with different contours on each side. In a continuum shell composite layup or a solid composite layup the two contours appear as distinct two-dimensional contour fronts at each section point location.

1. Display a contour plot of the desired field output variable. For more information, see *Producing a contour plot*.
2. Locate the **Section Points** dialog box.

   From the main menu bar, select **Result->Section Points**.

   The **Section Points** dialog box appears.
3. From the **Selection method** radio buttons, select **Plies**.
4. To limit the list for easier selection, type a filter pattern into the **Name filter** field, and press the **[Enter]** key to apply the filter.

   If viewport linking is activated, you can toggle on **Show common list between linked viewports** to display only the plies that are common to all linked viewports.
5. From the list of plies in the layup, select the desired ply.
6. From the **Ply result location** radio buttons, do one of the following:
   - Select **Bottommost** to select the bottommost section point in the selected ply.
   - Select **Middle/Single section point** to select the middle section point or the only section point in the selected ply. The middle section point is the middle of the available locations in the section, not the middle of the total locations. For example, if results are available at TOP and BOTTOM only, the number of available locations is two and the “middle” will correspond to the TOP location.
   - Select **Topmost** to select the topmost section point in the selected ply.
   - Select **Topmost and bottommost** to select both the topmost and bottommost section points in the selected ply.
7. Click **Apply** to view your settings.

   The model plot in the current viewport changes to display values from the specified ply at the specified location. The plot legend, if active, changes to identify the plies. For information about the plot legend, see *Customizing the legend*.
8. Click **OK** to retain your settings and to exit the dialog box.

Additional information

- *Selecting model data and analysis results to plot*
- *Linking viewports*

Selecting contact output

Contact output data for nonkinematic scalar output variables such as CPRESS, COPEN, CSLIP, CSHEAR1, and CSHEAR2 are consolidated from all continuum element–based surfaces into a single data set.
Data for overlapping surfaces are combined. If contact output is requested for membrane or shell elements, the data for the SPOS and SNEG surfaces are contained in separate data sets. When contact surfaces are double-sided or node-based, separate contact output data sets are created for each contact surface pair.

The method that Abaqus/CAE uses to combine overlapping facet data in the consolidated data set depends on the output variable:

- For the variables CPRESS, CSHEAR, and CSLIP, Abaqus/CAE uses the largest value, positive or negative, in the model for the selected variable.
- For the variable COPEN, Abaqus/CAE uses the minimum value for contact opening, which can reflect the smallest opening in the model or, if there are overclosures, the greatest overclosure value.
- For the vector variables CNORMF and CSHEARF, Abaqus/CAE evaluates the sum of all vector values for the individual surface pairs and stores the resultant vector in the consolidated data set.
- For the variable CSTATUS, Abaqus/CAE assigns one of four contact statuses to individual nodes on the main and secondary surfaces.

  Abaqus/CAE uses the following settings in the consolidated data set:

  - **Sticking** if any of the overlapping regions are in contact and sticking,
  - **Slipping** if any of the overlapping regions are in contact and slipping,
  - **Bonded** if any of the overlapping regions are in contact and bonded, and
  - **Not in contact** if the regions are not in contact.

The variable names that appear in Abaqus/CAE for each data set indicate the regions to which the contact output applies. For example, a CPRESS data set for an individual contact surface pair (for a double-sided or node-based contact surface) is named `CPRESS SECONDARY NAME/MAIN NAME`; the data sets for contact on the SPOS or SNEG side of a membrane or shell surface are named `CPRESS SPOS` and `CPRESS SNEG`, respectively; and all other surface variable output is named `CPRESS`.

Contact output data for any individual contact surface pair, without summed contributions from other contact pairs, are accessible using the **Create Field Output** dialog box or the Abaqus Scripting Interface to the output database; these data sets have names of the form `CPRESS SECONDARY NAME/MAIN NAME`.

Because CPRESS, CSHEAR1, and CSHEAR2 are associated with particular surfaces defined in the model, the surfaces must be included in the current display group when these output variable results are probed. These variables can be probed only at the nodes.

• *Accessing an Output Database*

Selecting result options

Abaqus/CAE offers several methods for you to display field output results stored in the output database. Some of these methods require that field output data originally saved to the output database at element centroid or integration point locations be calculated at nodal locations. Such calculations apply to line- and banded-type contour plots, probing at nodal locations, forming a display group or color coding based on result values, and extracting element-based *X*–*Y* data along a path. You can control some of the options related to these computations, such as how element-based results are averaged.

In addition, you can choose to apply coordinate system transformations to your field output results; you can choose from several display forms for complex results: the magnitude, phase angle, real component, imaginary component, or value at a specified angle; and you can choose whether or not to cache results in memory to improve performance.

Select **Result->Options** to locate the options that control the result calculations, result transformations, display of complex results, and result caching. This section discusses the result computations and the options that affect these computations.

In this section:

- *Understanding how results are computed*
- *Understanding result value averaging*
- *Understanding complex results*
- *Understanding results caching*
- *Displaying field output values or discontinuities*
- *Controlling result averaging*
- *Controlling computations at region boundaries*
- *Transforming results into a new coordinate system*
- *Controlling the form of complex results*
- *Controlling results caching*

Understanding how results are computed

The computations necessary to display results stored in the output database depend on whether the results are for a node-based quantity, such as displacement or velocity, or for an element-based quantity, such as stress or strain.

How node-based field output results are computed

Node-based field output variables are written to the output database at each node, along with any nodal transformations applied during model creation. For the display of nodal field output variables, Abaqus/CAE reads the required values from the output database for each node included in the plot. By default, these values are displayed in the global coordinate system; you can choose to apply the nodal transformations to the results or to apply a user-specified coordinate system transformation. The final values are then used to produce contours, nodal probe values, display groups or color coding based on results, or *X*–*Y* data along a path.

How element-based field output results are computed

Element-based field output variables are written to the output database at the integration points, the element centroid, or the element nodes, depending on the variable. For the display of element-based field output variables, Abaqus/CAE reads values from the output database for all elements connected to all nodes included in the plot. Computations are then applied to these values to produce contours, nodal probe results, display groups or color coding based on results, or *X*–*Y* data along a path.

For results saved to the output database at the integration points or at the element centroid, the first computation applied is extrapolation. (Results saved at the element nodes do not require extrapolation.) For contour plots only, you can choose quilt-type extrapolation, in which case the remaining computations discussed below do not apply. To learn more about quilt-type extrapolation, see *Understanding how contour values are computed*. For all other methods of results display, Abaqus/CAE extrapolates results to the nodes using weighting appropriate for the element type and shape.

Extrapolated values are generally not as accurate as the values calculated at the integration points. Therefore, adequately detailed meshing is recommended around nodes where accurate nodal values of such element results are needed. You should be particularly careful interpreting output variables extrapolated to the nodes for second-order elements with midside nodes outside the quarter-point region, such as when one edge is collapsed in two dimensions or one face is collapsed in three dimensions.

Extrapolation of element tensor quantities is performed on the individual tensor components in the local material coordinate system. Nodes common to two or more elements receive extrapolated values from all contributing elements. Depending on the characteristics of your model, these contributions may originate from more than one *result region*. If all contributions at a node originate from a single result region, the values are combined as necessary in further computations. If contributions are received from more than one result region, you can choose to respect the region boundary and keep the contributions separate in further computations or to ignore the region boundary and combine the values. The default result regions in an output database duplicate the regions that were used to assign section properties to the model prior to analysis. Alternatively, you can select element sets or display groups to use as result regions. For more information, see *Controlling computations at region boundaries*.

If invariants or components are requested, you can specify whether Abaqus/CAE should use the extrapolated data from each element or the combined data from all contributing elements to compute the invariants. By default, invariants are computed before the extrapolated results are combined (averaged). Contour plots of invariants or components may be affected by the order in which Abaqus performs the computations. For example, values for the von Mises stress may exceed the yield stress of inelastic materials; in addition, the invariant results may not take into account situations where the material orientations vary within a finite element in a non-isoparametric fashion. If invariants are computed after averaging, Abaqus determines the orientations at a node by averaging the contributing element orientations; component values will be affected if the orientations differ between contributing elements.

If you select element sets to define the result regions and invariants will be computed after averaging, the element sets that you select must contain compatible elements. Compatible elements

- share the same basic element type (continuum, shell, beam, etc.),
- use interpolation functions of the same order (first-order elements versus second-order elements), and
- have the same integration scheme (reduced integration, full integration, etc.).

Finally, computations depend on whether you choose to display the field output values or discontinuities; discontinuities are the differences in field output values between adjacent elements.

- **Field Output**: For the display of field output values, the calculated invariants or components at nodes common to two or more elements are averaged conditionally, depending on the compatibility of contributing *result regions* and on options you select. For more information, see *Understanding result value averaging*.
- **Discontinuities**: For the display of discontinuities, the calculated invariants or components at nodes common to two or more elements are compared to determine the greatest difference, depending on the compatibility of contributing result regions and on options you select. Nodes associated with only one element and nodes receiving equivalent values from all contributing elements will show a value of zero in a plot of discontinuities.

For more information, see *Displaying field output values or discontinuities*.

How result transformations are computed

Both node- and element-based results can be transformed into a user-specified coordinate system, and angular transformations can be applied to coordinate- and distance-based nodal vector results; see *Transforming results into a new coordinate system*, for information on applying a transformation to your results.

Element-based results for three-dimensional continuum elements and all node-based results are transformed into the specified coordinate system based on the locations of the results. The 1-, 2-, and 3-directions for the transformed results correspond to the *X*-, *Y*-, and *Z*-directions of a rectangular coordinate system; the *R*-, θ-, and *Z*-directions of a cylindrical coordinate system; and the *R*-, θ-, and ϕ-directions of a spherical coordinate system.

Element-based results for two-dimensional continuum elements, shell elements, and membrane elements are transformed by rotating the results about the element normal at the element result location. The 2-direction for the transformed results is determined by the projection of the rectangular *Y*-direction or the cylindrical or spherical θ-direction onto the element plane. If the *Y*- or θ-direction of the user-defined coordinate system forms an angle less than 30° with the element normal, the next axis that follows the *Y*- or θ-axis in a cyclic permutation of the axes is projected on the element plane instead to form the local material 2-direction, and a warning message is displayed. This method of results transformation is different from the method used by Abaqus/Standard and Abaqus/Explicit to compute local orientations (see *Orientations*).

Element-based results for beam and truss elements cannot be transformed; they are always displayed in the local element orientation system. In addition, element results for rebar and for CAXA, SAX, or SAXA elements are not transformed.

When you transform results to a user-specified coordinate system, you can control the following additional aspects of the coordinate system transformation:

- You can include or exclude the effects of the current deformation in the transformation calculations. Deformation effects are not scaled; Abaqus/CAE performs these calculations using a deformation scale factor of 1.0. Including deformation effects in a transformation can change the orientation of node-based coordinate systems, the projection of coordinate systems on shell and membrane elements, and the orientation of location-dependent cylindrical and location-dependent spherical coordinate systems.
- You can adjust the results to account for the rigid body transformation of the coordinate system. You can adjust the display of primary variable results or results from both the primary and deformed variables.

Rigid body transformation helps you to understand relative displacements when large rigid body displacements are present. Rigid body transformation applies a transformation to the model to negate the displacement and rotation of a user-specified coordinate system that follows nodes (see *Creating coordinate systems during postprocessing*, for more information) as these nodes deform from frame to frame. The rigid body transformation is determined as the translation and rotation necessary to transform the nodes of the specified coordinate system from their current locations back to their original locations.

You can apply angular transformations for coordinate- and distance-based nodal vector results. The angular transformation computes components in terms of R, θ, and Z for cylindrical coordinate systems and in terms of R, θ, and ϕ for spherical coordinate systems.

You can apply layup orientation transformations for results that include output from the field output variable SORIENT and include composite sections. The tensor and vector fields will be transformed into the layup orientation defined in the composite section definition.

Understanding result value averaging

Result value averaging is applicable to the display of element-based field output variables, such as stress or strain, using any of the following methods:

- line- or banded-type contours,
- probing at nodal locations,
- forming a display group or color coding based on result values,
- extracting *X*–*Y* data from fields,
- extracting *X*–*Y* data along a path, or
- generating reports for field data.

The display of node-based field output variables (such as displacement), quilt contour plots, and plots of discontinuities does not involve value averaging.

Extrapolated output database values at nodes common to two or more elements are averaged conditionally. You can use the following options to control the extent to which Abaqus/CAE averages the values at the nodes:

- Select *result regions* and choose whether averaging takes place across region boundaries.
- Choose whether shell and membrane feature edges are treated as region boundaries for averaging.
- Include or exclude contributions from elements that are not displayed.
- Choose whether invariants are computed and components are extracted before or after averaging.
- Select a threshold value to control averaging based on the difference between the contributing element values (this option is available only if you choose to calculate invariants before averaging).

Abaqus/CAE averages values at nodes common to two or more elements when the contributing elements lie in the same result region. The default result regions are the same regions defined when you assign sections to your model; you can also define custom result regions using saved element sets or display groups. You can choose whether or not Abaqus/CAE averages values at nodes common to two or more result regions. You can suppress averaging across regions (use the region boundaries) to emphasize any discontinuities at region boundaries, or you can request averaging across regions (ignore region boundaries) to produce a more continuous effect. For example, *Figure 1* shows a contour plot using region boundaries on the left and averaging across region boundaries on the right.

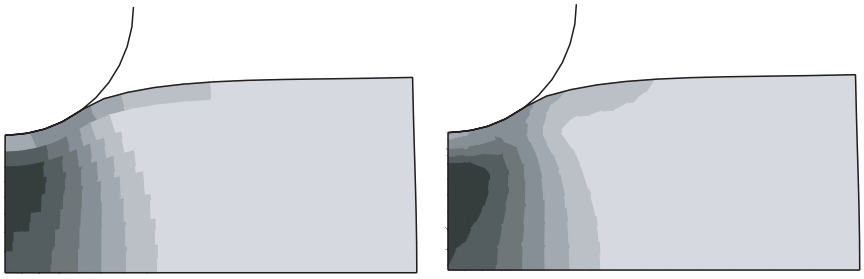

Figure 1: Contour plots using region boundaries and averaging across region boundaries.

If you choose to average across regions, the extent to which values are averaged is controlled by the threshold that you specify as follows:

$$\text{relative nodal variation} = \frac{(\text{maximum at node} - \text{minimum at node})}{(\text{maximum over active regions} - \text{minimum over active regions})}$$

If the relative nodal variation for each node included in the plot is less than your averaging threshold, values of contributing elements are averaged at that node. If the relative nodal variation exceeds your setting, the values are not averaged. When you decide to average across regions, the averaging threshold is considered in relation to the variation of values across the whole model unless you limit averaging to the displayed elements. Setting a high averaging threshold would allow you to smooth out all but the most extreme discontinuities relative to results across your model or all displayed results.

If you choose not to average across regions, the extent to which values are averaged at nodes within each region is controlled by the averaging threshold that you specify as follows:

$$\textbf{relative nodal variation} = \frac{\textbf{(maximum at node} - \textbf{minimum at node)}}{\textbf{(maximum within region} - \textbf{minimum within region)}}$$

If the relative nodal variation for each node included in the plot is less than your averaging threshold, values of contributing elements are averaged at that node. If the relative nodal variation exceeds your setting, the values are not averaged. When you suppress averaging across regions, the averaging threshold is considered in relation to the variation of values within each region rather than across the whole model or all displayed results.

The lower the averaging threshold you apply, the more the displayed values depict the individual element results. Conversely, a higher averaging threshold produces a smoother effect with fewer noticeable discontinuities from element to element.

When using threshold-based averaging in conjunction with the extraction of *X–Y* data from element-based fields, you might want to adjust the threshold value. The element region used when extracting *X–Y* data is reduced to include only the elements that are attached to the specified nodes.

If you choose to compute invariants and extract components after averaging,

- Abaqus/CAE does not apply the averaging threshold;
- tensors are transformed to an average orientation at each node prior to averaging; and
- result regions, if used, must contain compatible elements.

For more information, see *Understanding how results are computed*.

Select **Result->Options** to locate the options that affect averaging. *Controlling result averaging*, and *Controlling computations at region boundaries*, provide details on using the averaging options.

Understanding complex results

If the current step is a steady-state dynamic analysis, the value of an output variable such as stress (S) or displacement (U) can be a complex number with both real and imaginary components. Complex number results are saved during the analysis as pairs of real and imaginary data.

When you use Abaqus/CAE to display complex results, you can choose any of the following forms to view the analysis data:

- **Magnitude** displays the combined magnitude of both the real and imaginary portions of the result value.
- **Phase angle** displays the angle between the positive horizontal axis and the plotted point (*real, imaginary*). This selection is valid only for scalars or for vector and tensor components.
- **Real** displays only the real component. This option is the default setting.
- **Imaginary** displays only the coefficient of the imaginary component of the complex result.
- **Value at angle** displays the combined value of the real and imaginary portion of the result at an angle that you specify. When the angle is 0°, the real part of the result is displayed; when the angle is −90°, the imaginary part of the result is displayed.
- **Envelope: Min** displays the minimum of the combined value of the real and imaginary portion of the result by varying the angle from 0° to 360°.
- **Envelope: Max** displays the maximum of the combined value of the real and imaginary portion of the result by varying the angle from 0° to 360°.
- **Envelope: Max absolute** displays the maximum absolute of the combined value of the real and imaginary portion of the result by varying the angle from 0° to 360°.

The **Magnitude** is calculated after any invariants, such that the magnitude value is the square root of the sum of the squares of the real and imaginary invariant components. Similarly, the other complex forms are also calculated after invariants. **Value at angle** and the complex envelope values are exceptions; they are calculated prior to invariants to preserve the proper physical meaning.

You can also choose to animate complex results using harmonic animation. This technique animates complex field output by displaying the **Value at angle** through a sequence of angles. Abaqus/CAE generates angles ranging from 0° to 180° or from −180° to 180°, according to your specification, and displays the value of the complex results at each angle.

The magnitude and phase angle are related to the real and imaginary components with the usual expressions. For example, the real and imaginary displacement components, U_r and U_i, are related to the magnitude, $\overline{U}$, and phase angle, ϕ, as follows:

$$U_r = \overline{U} cos\phi$$

and

$$U_i = \overline{U} sin\phi.$$

The complex results represent a time-domain variation of the form:

$$\begin{aligned} U(t) &= U_r cos\Omega t - U_i sin\Omega t, \\ &= \overline{U} cos\left(\Omega t + \phi\right), \end{aligned}$$

where Ω is the excitation frequency. This time variation is shown when you request a harmonic animation. The value of the result at a selected angle, θ, is obtained by using $\theta = \Omega t$ so that

$$\begin{aligned} U(\theta) &= U_r cos\theta - U_i sin\theta, \\ &= \overline{U} cos\left(\theta + \phi\right). \end{aligned}$$

The magnitude, $\overline{U}$, for a given variable is displayed when $\theta = -\phi$. Stepping θ from −180° to 180° corresponds to one full animation cycle.

Understanding results caching

A cache is a portion of system memory. You can choose to store analysis results in a cache during postprocessing to speed up the generation of images on the screen. When results are cached, Abaqus/CAE can plot results without recomputing values for display or accessing the output database file as often. This can greatly improve performance. However, caching results will increase memory usage. If you find that Abaqus/CAE is consuming a lot of memory on your workstation and consequently hindering the performance of your system, you can disable the results caching options to erase the memory associated with results caches. Clearing this memory can increase overall performance; however, the display of results will be slower. Switching to a new output variable or output database will automatically clear the current results cache. For more information, see *Controlling results caching*.

Abaqus/CAE can display data from an output database while an analysis job is still running and while the database continues to be updated. After most Visualization module operations and during animations, Abaqus/CAE monitors the output database for updated results and updates the current viewport accordingly. If you are displaying data from a remote output database, the performance of Abaqus/CAE may be degraded if the time taken to monitor the database over the network is significant. To increase the performance, you can reduce the frequency with which Abaqus/CAE monitors the output database for updates, or you can disable the monitoring. For more information, see *Accessing an output database on a remote computer*.

Additional information

- *Controlling results caching*

Displaying field output values or discontinuities

For element-based field output variables, such as stress or strain, you can choose to display the field output values themselves or the *differences* in field output values between adjacent elements. This choice is applicable to line- and banded-type contours, probing at nodal locations, forming display groups and color coding based on result values, or extracting *X–Y* data along a path.

The default is to display **Field output** values. If you choose to display **Discontinuities**, the **Averaging** threshold is not applicable.

Figure 1 displays a contour plot of field output values on the left and a contour plot of discontinuities on the right.

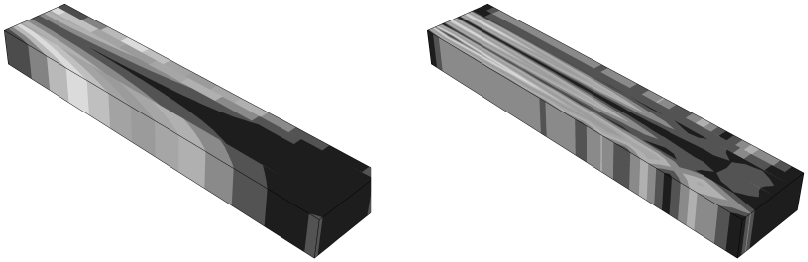

Figure 1: Contour plots showing field output values and discontinuities in values.

1. Locate the **Quantity to Plot** options.

   From the main menu bar, select **Result->Options**; then click the **Computation** tab in the dialog box that appears. The **Quantity to Plot** options are at the top of the page.
2. Click **Field output** or **Discontinuities** to choose the quantity that you want to plot.
3. Abaqus displays results in the current viewport according to your specifications.

   By default, your changes are saved for the duration of the session and will affect all subsequent display of results. If you want to retain your changes for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

Additional information

- *Understanding how results are computed*

Controlling result averaging

You can control the averaging of element-based field output results, such as stress or strain. Averaging is applicable to creating line- and banded-type contours, probing nodal locations, forming display groups and color coding based on result values, or extracting *X–Y* data along a path.

Element values are first extrapolated to the nodes. Nodes common to two or more elements will receive multiple contributions. To control the averaging of multiple contributions, you can:

- Enable or suppress averaging.
- Define result regions and choose whether averaging will cross them.
- Include or exclude shell and membrane feature edges as additional region boundaries for averaging.
- Suppress averaging of elements that are not displayed.
- Choose whether Abaqus/CAE computes invariants before or after averaging.
- Set the averaging threshold.

The averaging threshold governs the extent of averaging; it is available when Abaqus/CAE computes invariants or extracts components before averaging. If the relative difference between contributions at a node is greater than the threshold percentage you set, Abaqus/CAE will not average the contributing values and your results will appear discontinuous at that node. Use a higher percentage to produce a smoother, more continuous effect.

For information on averaging across regions, see *Controlling computations at region boundaries*.

1. Locate the **Averaging** options.

   From the main menu bar, select **Result->Options**; then click the **Computation** tab in the dialog box that appears. The **Averaging** options appear.

2. To control whether Abaqus/CAE averages output from multiple elements at shared nodes, toggle **Average element output at nodes**.

   Suppress averaging to identify discontinuities in the field output or to establish contour limits based on the extrapolated, unaveraged results.

3. Toggle off **Use region boundaries** to ignore region boundaries and average results across the entire model.

4. If region boundaries are used, specify the result regions to set the boundaries. For more information, see *Controlling computations at region boundaries*.

   Tip: To view the current result regions, color code an undeformed or deformed plot using the **Averaging regions** method of attribute selection. (For more information, see *Coloring all geometry in the Visualization module*.)

5. If region boundaries are used, by default Abaqus/CAE includes shell and membrane feature edges as additional region boundaries. To change the minimum angle used to create feature edges, click  and change the **Feature Angle** setting in the **ODB Display Options** dialog box. Feature edges correspond to the undeformed model and are not recalculated for model deformation. (For more information, see *Defining model feature edges*.)

   To average the results across feature edges, toggle off **Include shell/membrane feature edge boundaries**.

6. To control whether Abaqus/CAE averages nodal results based on all contributing elements or based only on the elements in the current display group, toggle **Average only displayed elements**.

7. Choose whether Abaqus will compute invariants (scalars) and extract components before or after averaging results over the specified regions.

   By default, Abaqus computes the scalars before averaging; if you choose to compute the results after averaging, Abaqus averages all results and their orientations to maintain a valid basis for computing the invariants.

   Tip: To view the nodal-averaged orientations in a contour plot, you can display their labels using the **Contour Plot Options** dialog box. For more information, see *Displaying nodal-averaged orientations*.

8. If you compute scalars before averaging, you can set the **Averaging Threshold (%)** to control the averaging between neighboring elements. A value of 0 suppresses all averaging; a value of 100 averages all results.
9. Click **Apply** to implement your changes.

   Abaqus averages result values for the display in the current viewport according to your specifications. The contour legend, if active, changes to state the averaging threshold that you have specified. For more information on the contour legend, see *Customizing the legend*.

   By default, your changes are saved for the duration of the session and will affect all subsequent display of results. If you want to retain your changes for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

Additional information

- *Understanding result value averaging*

Controlling computations at region boundaries

The default result regions in an output database duplicate the regions that were used to assign section properties to the model prior to analysis. Alternatively, you can select element sets or display groups to use as result regions. You can control computations at nodes common to two or more result regions. Choose to ignore region boundaries to computationally combine results for a smoother, more continuous effect. Choose not to ignore region boundaries to visually emphasize model discontinuities. See *Figure 1* for an example of contour plots with and without averaging across regions; averaging across regions occurs when you choose to ignore region boundaries.

1. Locate the **Region Boundaries** options.

   From the main menu bar, select **Result->Options**; then click the **Computation** tab in the dialog box that appears. The **Region Boundaries** options appear within the **Averaging** controls.

2. To govern computations at nodes common to two or more result regions, toggle **Use region boundaries**.

   To use region boundaries means *not* to combine values from neighboring result regions when computing nodal averages or when computing discontinuities.

3. Choose one of the following options to define the result regions:

   Tip: To view the current result regions, color code an undeformed or deformed plot using the **Averaging regions** method of attribute selection. (For more information, see *Coloring all geometry in the Visualization module*.)

   ### ODB regions

   By default, the result regions are the same as the section assignment regions saved in the output database (`.odb`) file. For more information, see *Assigning sections, orientations, normals, and tangents to a part*.

   ### Element sets

   Specify the results regions by selecting element sets.

   ### Display groups

   Specify the result regions by selecting display groups.

   Note:

   If the desired display groups do not exist, select **Tools->Display Group->Create** to create them (for more information, see *Creating or editing a display group*).

   The region boundaries are defined using the display groups as they are defined at the time of selection. If you subsequently modify or delete display groups, the region boundaries do not change unless you redefine them.

4. If you chose the **Element sets** or **Display groups** method to set the region boundaries, complete the following:

   a. Click .

   Abaqus/CAE opens the **Specify Averaging Regions** dialog box.

   b. From the list on the left side of the dialog box, click the desired regions to highlight them in the list. Use **[Shift] + Click** and **[Ctrl] + Click** to select multiple items.

c. Click the right-facing arrow button in the center of the dialog box to copy the highlighted items to the **Selection** column. To move the entire list, click the double right arrow button.

d. To remove region selections, highlight them in the **Selection** column and use the left-facing arrow button.

Any elements that are not included in the region boundary selections will be colored using the "no results" color (for more information, see *Coloring elements with no results*). Selections that overlap will be combined.

5. By default, Abaqus/CAE uses feature edges as additional region boundaries. To change the minimum angle used to create feature edges, click  and change the **Feature Angle** setting in the **ODB Display Options** dialog box. Feature edges correspond to the undeformed model and are not recalculated for model deformation. (For more information, see *Defining model feature edges*.)

To average results across feature edges, toggle off **Include shell/membrane feature edge boundaries**.

6. Click **Apply** to implement your changes.

Abaqus computes result values for the display in the current viewport according to your specifications.

By default, your changes are saved for the duration of the session and will affect all subsequent display of results. If you want to retain your changes for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

Additional information

- *Understanding how results are computed*

Transforming results into a new coordinate system

By default, Abaqus/CAE displays element-based field output results in the coordinate systems defined during preprocessing and node-based field output results in the global coordinate system.
If you defined nodal transformations during preprocessing, you can choose to apply these transformations to node-based results. Alternatively, you can choose to transform both element- and node-based results into a user-specified coordinate system or to apply an angular transformation to coordinate- and distance-based nodal vector results.

For vector quantities such as displacement, velocity, and acceleration, which are derived from nodal coordinates, Abaqus/CAE transforms the results to the requested coordinate system using the final quantity (saved vector) instead of the original coordinates. For example, the cylindrical displacement component is computed by projecting the displacement vector along the current r- or θ- direction. By comparison, taking the differential between the transformed nodal coordinates would yield a different result.

When you transform results into a local coordinate system, Abaqus/CAE rotates the global rectangular coordinate system as needed to align with the local system at the point of interest. The transformed results are reported in the rotated global rectangular coordinates.

For transformations to user-specified coordinate systems, Abaqus/CAE includes the effects of the current deformation by default when deformation effects are available. You can exclude these effects if you want transformation calculations to consider only the undeformed state. Deformation effects are not scaled; Abaqus/CAE performs these calculations using a deformation scale factor of 1.0. Including deformation effects in a transformation can change the orientation of node-based coordinate systems, the projection of coordinate systems on shell and membrane elements, and the orientation of location-dependent cylindrical and location-dependent spherical coordinate systems. For more information, see *Transformation of results*.

When you select a user-specified coordinate system for a transformation, you can also adjust the display of primary variable results or results from both the primary and deformed variables to account for the rigid body transformation of the coordinate system. Displaying deformations that account for rigid body transformations enables you to visualize the relative displacements of the model with respect to a moving, user-defined coordinate system. For more information about selecting results variables, see *Selecting the primary field output variable*, and *Selecting the deformed field output variable*.

You can apply angular transformations for coordinate- and distance-based nodal vector results. The angular transformation computes components in terms of R, θ, and Z for cylindrical coordinate systems and in terms of R, θ, and ϕ for spherical coordinate systems.

You can apply layup orientation transformations for results that include output from the field output variable SORIENT and include composite sections. SORIENT will be included as long as element material orientations were requested, which is the default. The tensor and vector fields will be transformed into the layup orientation defined in the composite section definition.

1. Locate the **Transform Type** options.

   From the main menu bar, select **Result->Options**; then click the **Transformation** tab in the dialog box that appears. The **Transform Type** options appear.

2. Select the transform type to use for your results.

   - Select **Default** to use the default coordinate systems defined for your model. Node-based results are displayed in the global system. Element-based results are displayed in the local orientations defined for the model; if none has been defined, the global system is used. A projection of the global system or local orientation is used for two-dimensional continuum elements, shell elements, and membrane elements.
   - Select **Nodal** to consider local directions that are defined at the nodes. Element-based results are displayed in the default coordinate system (as described above). Nodal transformations defined for the model are applied to node-based results; if none is defined, the global system is used.

- Select **User-specified** to transform the results for the entire model into a specified coordinate system.

  To limit the list for easier selection, type a filter pattern into the **Name filter** field, and press the **[Enter]** key to apply the filter.

  Select the transformation to apply from the list of coordinate systems that appears, or click  and select the coordinate system from the viewport. Coordinate systems defined either during model generation or during postprocessing are available. Systems designated with an asterisk are saved to the current output database.
- Select **Angular** to transform results for coordinate- and distance-based nodal vector results in terms of R, θ, and Z or R, θ, and ϕ. Select the transformation to apply from the list of cylindrical and spherical coordinate systems that appears, or click  and select the coordinate system from the viewport. Coordinate systems defined either during model generation or during postprocessing are available. Systems designated with an asterisk are saved to the current output database.
- Select **Layup orientation** to transform tensor and vector fields into the layup orientation defined in the composite section definition.

3. If you selected a user-specified coordinate system, you can also include the effects of deformation in the transformation to that coordinate system.

   Toggle on **Include effects of deformation (when available)** to include the effects of deformation, or toggle off this option to exclude the effects of deformation and to consider only the undeformed state in the transformation.

4. If you selected a user-specified coordinate system, you can also apply rigid body transformations to the presentation of primary and deformed variables.

   From the **Rigid Body Transformations** options, do one of the following:

   - Toggle on **Primary variable** to apply rigid body transformations to the primary variable results.
   - Toggle on **Primary variable** and **Deformed variable** to apply rigid body transformations to the results for both variables.

5. Abaqus displays results in the current viewport in the specified coordinate system or systems. Angular components are given in radians. Angular transformation component results are denoted using (AT: *CSYS-name*), and rigid body transformation component results are denoted using (RT: *CSYS-name*) to differentiate them from the results obtained using the default transformation type.

   By default, your changes are saved for the duration of the session and will affect all subsequent display of results. If you want to retain your changes for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

Controlling the form of complex results

If the current step is a steady-state dynamic analysis, the value of an output variable such as stress (S) or displacement (U) can be a complex number with both real and imaginary components. You can control the form of complex numbers when displaying plots of a model or recording probed values from a model in Abaqus/CAE.

You can choose to view the magnitude, phase angle, real component, imaginary component, value at a selected angle, or complex envelope values of your analysis results. The selected form is applied to all complex results, except harmonic animations, in the current session of Abaqus/CAE until you make a new selection. Harmonic animations, by definition, always use the "value at angle" form regardless of the current numeric form.

1. Locate the **Numeric Form** options.

   From the main menu bar, select **Result->Options**; then click the **Complex Form** tab in the dialog box that appears. The **Numeric Form** options appear.

2. Select the form to use for complex numbers:

   - **Magnitude** to display the combined magnitude of both the real and imaginary portions of the result value.
   - **Phase angle** to display the angle between the positive horizontal axis and the plotted point (*real, imaginary*) that represents the complex number in rectangular coordinates. This selection is valid only for scalars or for vector and tensor components.
   - **Real** to display only the real component of the complex result value. This option is the default setting.
   - **Imaginary** to display only the coefficient of the imaginary component of the complex result value.
   - **Value at angle** to display the combined value of the real and imaginary portion of the result at an angle that you specify. When the angle is 0°, the real part of the result is displayed; when the angle is −90°, the imaginary part of the result is displayed.
   - **Envelope: Min** to display the minimum of the combined value of the real and imaginary portion of the result by varying the angle from 0° to 360°.
   - **Envelope: Max** to display the maximum of the combined value of the real and imaginary portion of the result by varying the angle from 0° to 360°.
   - **Envelope: Max absolute** to display the maximum absolute of the combined value of the real and imaginary portion of the result by varying the angle from 0° to 360°.

3. Abaqus updates the display in the current viewport according to your specifications. By default, your changes are saved for the duration of the session and will affect all subsequent display of results. If you want to retain your changes for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

Additional information

- *Selecting complex results*

Controlling results caching

You can choose to store analysis results in a cache during postprocessing to speed up the generation of images on the screen. However, caching results will consume system memory and may decrease overall performance. Switching to a new output variable or output database will automatically clear the current results cache.

To increase performance, you can reduce the frequency with which Abaqus/CAE monitors the output database for updates, or you can disable the monitoring altogether. If you are displaying data from a remote output database, the performance of Abaqus/CAE may be degraded if the time taken to monitor the database over the network is significant. For more information, see *Accessing an output database on a remote computer*.

1. Locate the **Results Caching** options.

   From the main menu bar, select **Result->Options**; then click the **Caching** tab in the dialog box that appears.

2. Use the **Caching Options** field to speed up the generation of images on the screen.
   a. Toggle on **Cache deformed variable results** to store the deformed variable results for the current output database in memory.
   b. Toggle on **Cache primary variable results** to store the primary variable results for the current output database in memory.
   c. Toggle on **Cache cut fields** to store the values used for displaying cut models in memory.

3. Use the **ODB Access Options** field to increase performance when accessing an output database.
   a. Toggle off **Check for ODB file updates** to stop Abaqus/CAE from monitoring the output database for updates.
   b. Enter the minimum time interval in seconds between checks of the output database for updates. A larger number will reduce the frequency with which Abaqus/CAE checks the output database for updates.

4. By default, your changes are saved for the duration of the session and will affect all subsequent display of results. If you want to retain your changes for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

Additional information

- *Understanding results caching*

Creating and saving new field output

The field and history output initially available in the output database are limited to those variables you have saved during the analysis. You can augment these analysis results by operating on field output to create new results.

Once created, you can save the new field output to the output database. You must open an output database file with write privileges if you want to save field output from the session to the file.

The following methods can be used to create and save new field output:

- Select **Tools->Field Output->Create From Fields** from the main menu bar or use the **Create Field Output From Fields** tool in the toolbox to create new field output variables by *operating on individual existing field output variables*.
- Select **Tools->Field Output->Create From Frames** from the main menu bar or use the **Create Field Output From Frames** tool in the toolbox to create new field output by *combining results from several output database frames*.
- Select **Tools->Field Output->Save Fields** from the main menu bar to save new field output.

For information on selecting and plotting output database field output, see *Selecting field output variables*.

In this section:

- *Building valid field output expressions*
- *Using operations on field output*
- *Combining results from several frames*
- *Creating field output by operating on fields*
- *Creating field output by operating on frames*
- *Saving field output created during the session*

Building valid field output expressions

To define a new field output variable by operating on individual existing field output variables, you *build an arithmetic expression* in the expression text field of the **Create Field Output** dialog box.

An expression is composed of one or more existing field output variable tags and, optionally, one or more operators, transformations, and scalars. See *Using operations on field output*, for information on supported operators. Expressions are evaluated as Python input; entries containing syntax errors will generate non-specific Python exceptions.

The **Create Field Output** dialog box lists field output by the variable name and by a unique "tag" created by Abaqus/CAE. The tag for a given field output variable is composed of the step and frame numbers prepended to the output variable name; for example, `s1f1_RF` is the reaction force at Step 1, Frame 1. This tag enables you to combine output from different steps and frames in one expression.

Field output variables can consist of different types of data that may not be compatible. The **Create Field Output** dialog box lists the type of each field output variable as one of three general types: scalar, vector, and tensor. The tensor types are further subdivided into five subtypes that describe the dimensionality of the tensor and the components available. The following rules apply:

- Only like data object types and subtypes can appear in an expression.
- Operations on complex data use only the real component.
- The multiplication and division operations are not supported between two vector objects or between two tensor objects.
- Operations on tensors are performed on the tensor component data that Abaqus/CAE reads from the output database. Subsequently, the display of the resulting field output variable may give unexpected values for extrapolated components or for computed invariants. For example, if the components of a stress tensor are negative, applying the absolute value operation to the stress tensor will produce positive values for the stress components, but the values of pressure—an invariant computed after the absolute value operation has been applied—may be negative. Similarly, applying the sine operation to a stress tensor will produce component values within the range {−1, 1}, but the extrapolation used to compute contour values of such components may produce values beyond this range.
- Operations on fields associated with different regions are not supported.

The following examples demonstrate valid field output expressions:

Example 1

To create a field output variable by finding the difference in the stress fields for two increments, type:

```
s1f2_S - s1f1_S
```

in the expression text field of the **Create Field Output** dialog box.

`s1f2_S` and `s1f1_S` are field output variables representing stress at two different increments of a particular step. The result of this equation is a field output variable representing the difference in the stress fields for the two increments.

Example 2

To create a field output variable by expressing pressure in decibels as a function of acoustic pressure, type:

```
20.0 * log10(s1f1_POR/Pref)
```

in the expression text field of the **Create Field Output** dialog box.

`Pref` is the reference pressure. The result of this equation is a field output variable representing pressure in decibels as a function of the analysis variable POR.

Example 3

To create a field output variable by transforming a tensor result to a user-specified coordinate system:

1. Select **Transformation** from the **Function** list on the right side of the **Create Field Output** dialog box.
2. Select a tensor result from the list of field output variables; for example, `s1f10_S`.
3. Select a coordinate system transformation to apply; for example, a fixed coordinate system named `CSYS-1`.

   The expression `s1f10_S.getTransformedField(datumCsys=o_CSYS_1)` appears in the expression text field.

The result of this equation is a field output variable representing the transformation of the stress tensor `s1f10_S` to the `CSYS-1` coordinate system.

Additional information

- *Creating field output by operating on fields*
- *Creating coordinate systems during postprocessing*
- *Understanding how results are computed*

Using operations on field output

This section lists the operations that you can perform on individual field output variables using the **Create Field Output** dialog box and the arguments accepted by each operation.
Arguments to trigonometric functions are assumed to be in radians.

The following keys are used to classify function arguments:

Text keys for operations on field output:

A	The argument can be a field output variable, a floating point number, or an integer.
F	The argument must be a floating point number.
FO	The argument must be a field output variable.

Operations on field output:

+	Perform addition.
–	Perform subtraction or unary negation.
*****	Perform multiplication.
/	Perform division.
abs(A)	Take the absolute value.
acos(A)	Take the arccosine.
asin(A)	Take the arcsine.
atan(A)	Take the arctangent.
cos(A)	Take the cosine.
degreeToRadian(A)	Convert degrees to radians.
exp(A)	Take the natural exponential.
exp10(A)	Take the base 10 exponential.
log(A)	Take the natural logarithm.
log10(A)	Take the base 10 logarithm.
power(FO,F)	Raise a field output object to a power.
radianToDegree(A)	Convert radians to degrees.
sin(A)	Take the sine.
sqrt(A)	Take the square root.
tan(A)	Take the tangent.

Additional information

- *Building valid field output expressions*
- *Creating field output by operating on fields*

Combining results from several frames

To define new field output by combining results from several output database frames, you use the ***Create Field Output From Frames*** dialog box.

You can select from the following operations involving frames:

- Sum values over all frames
- Find the minimum value over all frames
- Find the maximum value over all frames

The **Create Field Output From Frames** dialog box initially contains no output. You select the output database frames to consider; all the results available for these frames can then be combined, or you can select individual field output variables to combine. If you choose to sum the values over the selected frames, Abaqus/CAE will create new field output variables representing the linear combinations of the selected results. Alternatively, you can choose to have Abaqus/CAE determine the minimum or maximum values of the selected results in the range of selected frames. Abaqus does not perform consistency checks on the physical validity of frame operations; for example, the linear superposition of two frames containing the results from load cases with different boundary conditions is allowed even though the combined results may not be physically meaningful.

Operations on tensors are performed in the local coordinate system, if it is available; otherwise, the global system is used. Abaqus/CAE assumes that the local coordinate systems are consistent for nonunary operations involving tensors.

Figure 1 shows an example of creating field output by combining the results from several load cases (see *Load cases* for more information on load cases). A new "load case" is created by summing the results from the selected load cases; you can assign a name to the new load case, as shown in the figure.

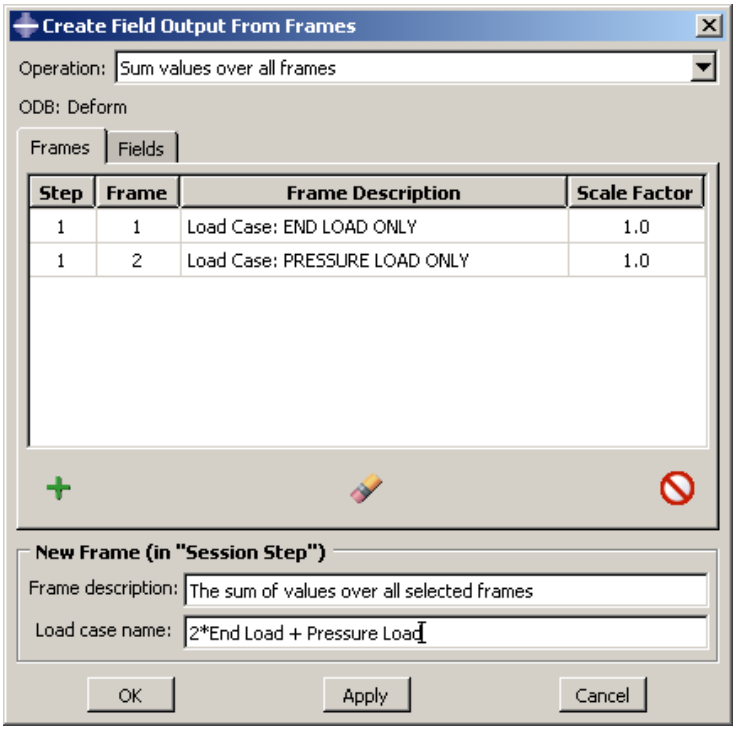

Figure 1: Creating field output by combining the results from several load cases.

Additional information

• *Creating field output by operating on frames*

Creating field output by operating on fields

You can create field output by computing new results using the field output available in the output database. For example, you might create new field output variables to show the differences in the stress fields between two increments. For detailed examples, see *Building valid field output expressions*.

You create new field output variables from fields by operating on analysis results found in the output database. You can display field output variables that you have created in the same ways as output database field output variables: in the form of a deformed, contour, or symbol plot; by probing any model or *X*–*Y* plot; as *X*–*Y* data obtained along a path through your model; or in a tabular report. Field output variables that you have created are saved in the session step until you end the session or close the output database from which the field output originates. You can also save the field output to the output database, in which case you must open the output database with write privileges.

Note: Field output created using complex results will contain only the real portion of the data. You cannot create field output that includes the imaginary part of complex results.

If you create field output that extracts an invariant scalar component of a tensor variable, such as the tensor variable's Mises stress or one of its principal stresses, contour plots of the resulting field output may be different than the original contour plots of the invariant. This difference occurs because these contours are calculated differently. Abaqus/CAE calculates the original invariant by first extrapolating the tensor to the nodes, calculating the invariant values, and averaging the values at the nodes. For the field output, Abaqus/CAE extrapolates the invariant values to the element nodes and averages them, which can result in a different contour plot.

Note: Some field output variables like PEEQ and PEMAG always have positive values at the integration points. For these variables extrapolation of the results from integration points to element nodes can result in negative values at some nodes. To avoid these negative value results, Abaqus/CAE clamps the element nodal values of such fields internally at 0.0 and resets negative values to 0.0. If you operate on these field output variables to create new field output, Abaqus/CAE does not clamp the values at 0.0 for the new resulting field output and the contour plot may show some negative values.

1. Locate the options for creating field output from fields.

   From the main menu bar, select **Tools->Field Output->Create From Fields**.

   The **Create Field Output** dialog box appears.

   Tip: You can also specify field output by using the  tool in the toolbox.

2. The default name for the new field output variable appears in the **Name** text field. To provide a more meaningful name, replace this default with the name of your choice (including blank spaces if you wish).
3. Build your expression in the expression text field using a combination of the following procedures:
   a. Select a function from the menu on the right side of the **Create Field Output** dialog box.

      - Select **Operators** to apply a built-in arithmetic operator to the selected field output.
      - Select **Transformation** to apply a coordinate system transformation to the selected field output.
      - Select **Scalar** to extract a scalar component from the selected field output.

      The list below the menu changes to reflect your selection.

   b. Select field output variables from the list on the left side of the **Create Field Output** dialog box. You can select field output for any step and frame in the analysis.

Tip: Place your cursor over the vertical lines separating each column in the output variable table, and enlarge the column widths to see the complete text.

The field output variable appears in the expression text field.

c. Select operators, transformations, or scalars from the list on the right side of the **Create Field Output** dialog box.

The selected function appears in the expression text field.

Note:

If you select a dynamic coordinate system (a system that follows nodes in your model) from the list of transformations, `deformationField=` appears in the expression text field inside the transform function. You must select a deformation field output variable that Abaqus/CAE will use to compute the position of the coordinate system.

d. Use standard mouse and keyboard editing techniques in the expression text field to position the cursor and configure your expression.

e. Adjust *the syntax of your expression* if necessary: parentheses may be needed.

f. If you make a mistake and wish to start over, click **Clear Expression**.

For more information, see *Building valid field output expressions*.

4. Click **OK** to create your new field output variable and to dismiss the dialog box.

Abaqus creates a new field output variable that is contained in Frame 0 of the session step by default and available from the **Field Output** dialog box. Current results plots, if any, are not affected.

Additional information

Creating field output by operating on frames

You can create field output by combining the results from several frames available in the output database. For example, you might create new field output to show the combined response to several load cases. For a detailed example, see *Combining results from several frames*.

You can sum field output over specified frames, and you can find the minimum or maximum values over specified frames. You can display field output that you have created in the same ways as output database field output variables: in the form of a deformed, contour, or symbol plot; by probing any model or *X–Y* plot; as *X–Y* data obtained along a path through your model; or in a tabular report. Field output that you have created is saved in the session step until you end the session or close the output database from which the field output originates. You can also save the field output to the output database, in which case you must open the output database with write privileges.

Note:

Field output created using complex results will contain only the real portion of the data. You cannot create field output that includes the imaginary part of complex results.

1. Locate the options for creating field output from frames.

   From the main menu bar, select **Tools->Field Output->Create From Frames**.

   The **Create Field Output From Frames** dialog box appears.

    **Tip:** You can also create field output from frames by using the  tool in the toolbox.

   By default, the **Frames** and **Fields** pages in this dialog box are empty.

2. Select the operation you wish to perform from the list in the **Operation** field.

3. Click  to select the frames that will be included in the operation.

   The **Add Frames** dialog box appears.

4. Select the analysis step from the list in the **Step** field.

   A list of the available frames for that step appears.

5. Select the individual frames you would like to include in the operation (see *Selecting multiple items from lists and tables*, for more information), or click **Select All** to include all the available frames.

6. Click **OK** or **Apply** in the **Add Frames** dialog box.

   The frames you selected appear in the **Frames** field of the **Create Field Output From Frames** dialog box. You can use the  button (**Remove Selected**) and  button (**Remove All**) at the bottom of the **Frames** field to modify your frame selections as needed. You can also continue to add frames from the **Add Frames** dialog box.

7. If you have chosen the sum operation, a **Scale Factor** column also appears in the **Frames** field of the **Create Field Output from Frames** dialog box. The default scale factor for every frame is 1.0. You can modify the scale factor for a selected frame by clicking in the **Scale Factor** column and entering a new scale factor value.

8. Click the **Fields** tab in the **Create Field Output From Frames** dialog box to select the field output that will be included in the operation.

   The field output variables available for the selected frames are shown, along with information on the output variable type (tensor, vector, or scalar). If you have chosen the minimum or maximum operation, the invariant/component information for tensor and vector variables and the option to select the output

position are also available. By default, all the available output variables have a check mark in the **Select** column.

a. Click in the **Select** column to unselect the output variables you do not wish to include in the operation.

b. If you have chosen the minimum or maximum operation, you can click in the **Invariant/Component** column and select the invariant or component that you wish to use to determine the minimum or maximum field results from the list that appears at the right. For example, if you select the Mises invariant for a stress variable, Abaqus/CAE creates a new stress field output variable in which the stress tensor at each point is obtained from the frame at which the maximum Mises value occurs (within the list of frames selected in Step 5).

c. If you have chosen the minimum or maximum operation, you can click in the **Position** column and select the output position at which to store the new field output. For example, if you want to create new field output from stress at integration points by finding the maximum values, you can choose to store the field output at **Element Nodal** positions, ensuring that contour plots display the expected results.

d. Use the **Select All**, **Unselect All**, and **Default** buttons to modify your field output selections as needed.

9. You can accept the default frame description provided by Abaqus/CAE, or you can supply your own in the **Frame description** field.

10. By default, Abaqus/CAE does not provide a load case name for the new field output; if your new field output represents an additional load case in your analysis, you can supply a name in the **Load case name** field. This name will be used only for organizational purposes.

11. Click **OK** in the **Create Field Output From Frames** dialog box to create your new field output and to dismiss the dialog box.

Abaqus operates on the selected field output over the selected frames to create new field output that is contained in a new session frame of the session step and available from the **Field Output** dialog box. The descriptions of the new variables indicate the operation by which they were derived. Current results plots, if any, are not affected.

When you choose the minimum or maximum operation, Abaqus also creates a field output variable for each result indicating the frames from which each minimum or maximum value was obtained. (The frames are identified by their index in the list of selected frames.) This variable, named *outputVariable*_Index, is available from the same frame of the session step as the actual results of the minimum or maximum operation and can be queried or plotted in the same way as other field output variables.

Tip: *outputVariable*_Index works better with Element Nodal, Nodal, or Centroid position since, plotting *outputVariable*_Index created at the integration point position is subjected to extrapolation and averaging, which may result in incorrect plots. To know more, please refer to: *Understanding how results are computed*

Additional information

- *Selecting a specific results step and frame*
- *Creating and saving new field output*
- *Saving field output created during the session*

Saving field output created during the session

You can save field output that you created during the session to the output database.
You must open an output database file with write privileges if you want to save field output from the session to the file. If you create new field output by operating on analysis results found in the output database, you can save the field output to an existing step in the output database or you can create a new step.

1. Locate the options for saving field output.

   From the main menu bar, select **Tools->Field Output->Save Fields**.

   The **Save Sessions Field Output Variables** dialog box appears. The field output that you created during the session is displayed in the table.
2. In the **Target step** field, select the step in which you want to save the field output.
3. In the **Target frame** field, select the frame in which you want to save the field output.
4. Select the field output from the table that you want to save to the output database.
5. If you want to create a new step in the output database file, click **Create Step**.
6. In the **Create Odb Step** dialog box that appears, do the following:
   a. Enter a name and description for the new step.
   b. In the **Domain** field, select one of the following options to specify the domain of the step:
      - **TIME**, and enter time period
      - **FREQUENCY**
      - **ARC_LENGTH**
      - **MODAL**
   c. Click **OK** to create the step.
7. Click **OK** to save the fields.

- *Creating field output by operating on frames*

Creating coordinate systems during postprocessing

You can create local (or "session") coordinate systems in the Visualization module for postprocessing purposes: field output results can be transformed to a specified user-defined coordinate system.
These user-defined coordinate systems can be fixed in space or move with specified nodes as the model deforms. Session coordinate systems persist for the duration of your session only and are available only for a single output database; however, you can save session coordinate systems to their associated output database file for use in subsequent Abaqus sessions.

You can rename or delete session coordinate systems from the **Coordinate System Manager** or the **Session Coordinate Systems** container in the Results Tree for the current output database. You can also display, highlight, and hide individual coordinate systems by using their shortcuts from the Results Tree or by adding them to display groups. See *Managing display groups*, for more information about adding both session-based and output database–based coordinate systems to display groups.

For information on controlling the display of all coordinate systems during postprocessing, see *Controlling the display of model entities*. For information on controlling the display of individual coordinate systems during postprocessing, see *Managing display groups*. For information on results transformation, see *Transforming results into a new coordinate system* and *Creating field output by operating on fields*.

In this section:

- *Methods for creating a coordinate system*
- *Creating a fixed coordinate system*
- *Creating a coordinate system following three nodes*
- *Creating a coordinate system following three nodes on a circle*
- *Creating a coordinate system following a single node*
- *Saving a coordinate system to an output database file*

Methods for creating a coordinate system

Select **Tools->Coordinate System->Create** from the main menu bar in the Visualization module to define a local coordinate system.
You choose the type of coordinate system and follow the prompts in the prompt area to define the coordinate system axes. The following types of coordinate systems are available:

- **Fixed system**
- **System following 3 nodes**
- **System following 3 nodes on a circle**
- **System following a single node**

You can use the **Session Coordinate Systems** container in the Results Tree or the **Coordinate System Manager** to rename or delete user-defined coordinate systems and to save the coordinate systems to an output database file for use in later Abaqus/CAE sessions.

Creating a fixed coordinate system

You define a fixed coordinate system by specifying the origin and two points. The line from the origin to point 1 is the *X*-axis (for a rectangular coordinate system) or the *R*-axis (for a cylindrical or spherical coordinate system); the plane containing the origin, point 1, and point 2 is the *X*–*Y* plane (for a rectangular coordinate system) or the *R*–θ plane (for a cylindrical or spherical coordinate system). The coordinate system remains fixed in space regardless of the motion of the model.

You can either select individual nodes in the viewport or enter the *X*-, *Y*-, and *Z*-coordinates of the points in the prompt area. When you select nodes in the viewport, the nodal coordinates of the current plot state are used to orient the coordinate system; that is, the true coordinates of the node on the undeformed or deformed shape are used (any deformation scale factor applied to the deformed shape is ignored).

1. From the main menu bar, select **Tools->Coordinate System->Create**.

   The **Create Coordinate System** dialog box appears.

   Tip: You can also create a coordinate system by using the tool in the toolbox or the **Session Coordinate Systems** container in the Results Tree for the current output database.

2. In the **Create Coordinate System** dialog box:
   a. Accept the default name for the coordinate system, or enter the name of your choice in the text field.
   b. Toggle on **Fixed system** to specify the motion of the coordinate system.
   c. Select one of the following as the coordinate system type:
      - **Rectangular**: The *X*-, *Y*-, and *Z*-axes are interpreted as the 1-, 2-, and 3-axes, respectively.
      - **Cylindrical**: The *R*-, θ-, and *Z*-axes are interpreted as the 1-, 2-, and 3-axes, respectively.
      - **Spherical**: The *R*-, θ-, and ϕ-axes are interpreted as the 1-, 2-, and 3-axes, respectively.
   d. Click **Continue**.

   Abaqus/CAE displays prompts in the prompt area to help you define the coordinate system axes.
3. Select a node in the viewport to be the origin; or enter the *X*-, *Y*-, and *Z*-coordinates of the origin in the prompt area.
4. Select a node in the viewport to lie on the *X*-axis (for a rectangular coordinate system) or the *R*-axis (for a cylindrical or spherical coordinate system); or enter the *X*-, *Y*-, and *Z*-coordinates of the point in the prompt area.
5. Select a node in the viewport to lie in the *X*–*Y* plane (for a rectangular coordinate system) or the *R*–θ plane (for a cylindrical or spherical coordinate system); or enter the *X*-, *Y*-, and *Z*-coordinates of the point in the prompt area.

   The coordinate system appears in the viewport, in the list in the **Coordinate System Manager**, and under the **Session Coordinate Systems** container in the Results Tree for the current output database. Abaqus saves user-defined coordinate systems only until the output database is closed unless you save them to the output database file. You cannot edit a coordinate system once it has been created; you can rename or delete coordinate systems that have not been saved to the output database.

Additional information

- *Saving a coordinate system to an output database file*
- *Controlling the display of model entities*

Creating a coordinate system following three nodes

You can define a coordinate system that is attached to nodes on your model by specifying three nodes. The line from node 1 (the origin) to node 2 is the *X*-axis (for a rectangular coordinate system) or the *R*-axis (for a cylindrical or spherical coordinate system); the plane containing the three nodes is the *X*–*Y* plane (for a rectangular coordinate system) or the *R*–θ plane (for a cylindrical or spherical coordinate system). The motion of the coordinate system is defined by the translational motion of the three nodes.

The visual display of coordinate systems that follow nodes on your model is updated to reflect any deformation scale factors applied; however, result transformations based on these coordinate systems use the actual, not the scaled, deformations.

1. From the main menu bar, select **Tools->Coordinate System->Create**.

   The **Create Coordinate System** dialog box appears.

   Tip: You can also create a coordinate system by using the  tool in the toolbox or the **Session Coordinate Systems** container in the Results Tree for the current output database.

2. In the **Create Coordinate System** dialog box:
   a. Accept the default name for the coordinate system, or enter the name of your choice in the text field.
   b. Toggle on **System following 3 nodes** to specify the motion of the coordinate system.
   c. Select one of the following as the coordinate system type:
      - **Rectangular**: The *X*-, *Y*-, and *Z*-axes are interpreted as the 1-, 2-, and 3-axes, respectively.
      - **Cylindrical**: The *R*-, θ-, and *Z*-axes are interpreted as the 1-, 2-, and 3-axes, respectively.
      - **Spherical**: The *R*-, θ-, and ϕ-axes are interpreted as the 1-, 2-, and 3-axes, respectively.

   d. Click **Continue**.

   Abaqus/CAE displays prompts in the prompt area to help you define the coordinate system axes.
3. Select a node in the viewport to be the origin.
4. Select a node in the viewport to lie on the *X*-axis (for a rectangular coordinate system) or the *R*-axis (for a cylindrical or spherical coordinate system).
5. Select a node in the viewport to lie in the *X*–*Y* plane (for a rectangular coordinate system) or the *R*–θ plane (for a cylindrical or spherical coordinate system).

   The coordinate system appears in the viewport, in the list in the **Coordinate System Manager**, and under the **Session Coordinate Systems** container in the Results Tree for the current output database. Abaqus saves user-defined coordinate systems only until the output database is closed unless you save them to the output database file. You cannot edit a coordinate system once it has been created; you can rename or delete coordinate systems that have not been saved to the output database.

Additional information

- *Saving a coordinate system to an output database file*
- *Controlling the display of model entities*

Creating a coordinate system following three nodes on a circle

You can select three nodes that lie on a circular arc to define a coordinate system that is attached to your model. This method is useful when the model does not contain any nodes along the axis of a hollow cylinder or at the center of a hollow sphere, but you would like to define a coordinate system at those locations. The center of the circle defined by the three nodes is the origin of the coordinate system. The line from the origin to node 1 defines the *X*-axis (for a rectangular coordinate system) or the *R*-axis (for a cylindrical or spherical coordinate system); thus, the order in which you select the nodes determines the direction of increasing θ. Three colinear nodes are not valid. The normal to the circle is parallel to the *Z*-axis (for a rectangular or cylindrical coordinate system) or the ϕ-axis (for a spherical coordinate system). The motion of the coordinate system is defined by the translational motion of the three nodes.

The visual display of coordinate systems that follow nodes on your model is updated to reflect any deformation scale factors applied; however, result transformations based on these coordinate systems use the actual, not the scaled, deformations.

1. From the main menu bar, select **Tools->Coordinate System->Create**.

   The **Create Coordinate System** dialog box appears.

   Tip: You can also create a coordinate system by using the  tool in the toolbox or the **Session Coordinate Systems** container in the Results Tree for the current output database.

2. In the **Create Coordinate System** dialog box:
   a. Accept the default name for the coordinate system, or enter the name of your choice in the text field.
   b. Toggle on **System following 3 nodes on a circle** to specify the motion of the coordinate system.
   c. Select one of the following as the coordinate system type:
      - **Rectangular**: The *X*-, *Y*-, and *Z*-axes are interpreted as the 1-, 2-, and 3-axes, respectively.
      - **Cylindrical**: The *R*-, θ-, and *Z*-axes are interpreted as the 1-, 2-, and 3-axes, respectively.
      - **Spherical**: The *R*-, θ-, and ϕ-axes are interpreted as the 1-, 2-, and 3-axes, respectively.

   d. Click **Continue**.

   Abaqus/CAE displays prompts in the prompt area to help you define the coordinate system axes.

3. Select three nodes in the viewport that lie on a circular arc.

   The coordinate system appears in the viewport, in the list in the **Coordinate System Manager**, and under the **Session Coordinate Systems** container in the Results Tree for the current output database. Abaqus saves user-defined coordinate systems only until the output database is closed unless you save them to the output database file. You cannot edit a coordinate system once it has been created; you can rename or delete coordinate systems that have not been saved to the output database.

Additional information

- *Saving a coordinate system to an output database file*
- *Controlling the display of model entities*

Creating a coordinate system following a single node

You can define a coordinate system that is attached to a single node on your model. The specified node is the origin of the coordinate system. The degrees of freedom present at the node (translational and rotational) determine the orientation of the coordinate system axes at each step and frame of the analysis. If the node has only translational degrees of freedom, the coordinate system will always be parallel to the global system.

The visual display of coordinate systems that follow nodes on your model is updated to reflect any deformation scale factors applied; however, result transformations based on these coordinate systems use the actual, not the scaled, deformations.

1. From the main menu bar, select **Tools->Coordinate System->Create**.

   The **Create Coordinate System** dialog box appears.

   Tip: You can also create a coordinate system by using the  tool in the toolbox or the **Session Coordinate Systems** container in the Results Tree for the current output database.

2. In the **Create Coordinate System** dialog box:
   a. Accept the default name for the coordinate system, or enter the name of your choice in the text field.
   b. Toggle on **System following a single node** to specify the motion of the coordinate system.
   c. Select one of the following as the coordinate system type:
      - **Rectangular**: The *X*-, *Y*-, and *Z*-axes are interpreted as the 1-, 2-, and 3-axes, respectively.
      - **Cylindrical**: The *R*-, θ-, and *Z*-axes are interpreted as the 1-, 2-, and 3-axes, respectively.
      - **Spherical**: The *R*-, θ-, and ϕ-axes are interpreted as the 1-, 2-, and 3-axes, respectively.

   d. Click **Continue**.

   Abaqus/CAE displays prompts in the prompt area to help you define the coordinate system axes.

3. Select the node in the viewport.

   The coordinate system appears in the viewport, in the list in the **Coordinate System Manager**, and under the **Session Coordinate Systems** container in the Results Tree for the current output database. Abaqus saves user-defined coordinate systems only until the output database is closed unless you save them to the output database file. You cannot edit a coordinate system once it has been created; you can rename or delete coordinate systems that have not been saved to the output database.

Additional information

- *Saving a coordinate system to an output database file*
- *Controlling the display of model entities*

Saving a coordinate system to an output database file

Coordinate systems defined during postprocessing are available by default only until the associated output database file is closed. You must save these coordinate systems to the output database file if you want them to be available in future Abaqus/CAE sessions. Local coordinate systems defined during the analysis are written automatically to the output database. You can only append data to the output database; you cannot modify the contents of the file in any other way (i.e., once a coordinate system has been saved to the output database, it cannot be modified, renamed, or deleted).

Note:

By default, Abaqus/CAE opens output database files as read-only. You must choose to open an output database file with write privileges if you want to save any data, such as coordinate systems, to it (see *Opening a model database or an output database*, for more information).

1. From the main menu bar, select **Tools->Coordinate System->Manager**.

   The **Coordinate System Manager** appears. By default, **Current session** is toggled on and the coordinate systems that have been defined for the current output database during the current session are listed.

2. Select the user-defined coordinate systems that you wish to save, and click **Move to ODB** from the buttons on the right side of the dialog box.

   If the current output database file was opened with write permissions, the selected coordinate systems are moved from the current session list to the current output database list. To see the list of coordinate systems that have been saved to the current output database file, toggle on **Current ODB**.

Creating node and element sets during postprocessing

You can create node and element sets in the Visualization module.
Select **Tools->Create Set** from the main menu bar. You can create and save sets only when the output database (`.odb`) file is opened with write privileges.

In addition, the following rules apply:

- You can create sets only on the rootAssembly instance; however, the instance cannot be named `ASSEMBLY`.
- You cannot edit or delete the sets created in the output database.

1. From the main menu bar in the Visualization module, select **Tools->Create Set**.
2. In the **Create Set** dialog box that appears, do the following:
   a. Enter a name for the set.
   b. Select **Node** or **Element** as the set type.
   c. Click **Continue**.
   d. Select nodes or elements from the viewport. You can select the nodes and elements individually, by angle, or by feature edge. You can also select elements by topology.
   e. Click **Done**.

   The newly created set appears in the Results Tree.

- *Opening a model database or an output database*
- *Using the angle and feature edge method to select multiple objects*
- *Using the topology method to select multiple elements*

Plotting the undeformed and deformed shapes

This section explains undeformed and deformed shape plotting and superimposed plots.

Immediately upon opening an output database, Abaqus/CAE displays the undeformed shape of your model. For general analysis steps an undeformed plot displays the shape of your model without any deformation. For linear perturbation steps an undeformed plot displays the base state of your model. The deformed plot shows the shape of your model according to the values of a nodal variable such as displacement. The undeformed and deformed shapes are also used to display each of the other plot states available in Abaqus/CAE. You can view contours, symbols, or material orientations on either the undeformed or the deformed shape or superimpose them to view the differences in the shapes.

In this section:

- *Understanding undeformed shape plotting*
- *Understanding deformed shape plotting*
- *Using common plot options*
- *Producing an undeformed shape plot*
- *Producing a deformed shape plot*
- *Superimposing deformed and undeformed model plots*

Understanding undeformed shape plotting

Abaqus/CAE obtains the information needed to produce an undeformed plot from the output database. Immediately upon opening an output database, Abaqus/CAE displays the undeformed plot state of your model.

You can use the plot state-independent options to customize your plot. Select **Options->Common** in the main menu bar to choose the plot state-independent customization options.

By default, Abaqus/CAE displays your undeformed model at the last frame of the last step available in the output database. If your model varies between steps, perhaps because of the addition or removal of contact surfaces or the application of loads or boundary conditions, you may want to view your undeformed model at steps other than the default. You can choose the step at which to view your undeformed model by selecting **Result->Step/Frame** from the main menu bar. For more information, see *Selecting the results step and frame*.

You can also use Abaqus/CAE to combine your undeformed and deformed model shapes into a single plot. For more information, see *Superimposing deformed and undeformed model plots*. Combining the shapes provides a context for evaluating the deformations.

Additional information

- *Producing an undeformed shape plot*

Understanding deformed shape plotting

A deformed plot shows the shape of your model according to the values of a nodal variable such as displacement. You can choose the nodal variable (called the deformed field output variable) for which Abaqus/CAE displays results, and you can choose the step and frame of these results.

If you do not choose a deformed field output variable, Abaqus/CAE attempts to select a default. Most procedures in Abaqus/Standard and Abaqus/Explicit write displacement to the output database by default; in these cases Abaqus/CAE selects displacement as the nodal vector quantity to use for the default deformed variable. Some procedures—for example, heat transfer—do not write displacement to the output database by default; therefore, Abaqus/CAE does not select a default deformed variable. Abaqus/CAE cannot display a deformed plot if the output database does not contain any variables that can be used to compute a deformed shape.

After obtaining the information needed to produce a deformed plot from the output database, Abaqus/CAE computes the shape of your deformed model by adjusting the coordinates of each node according to:

- The deformed field output variable (see *Selecting the deformed field output variable*).
- The analysis step and frame (see *Selecting a specific results step and frame*).
- Uniform or nonuniform deformation scale factors (see *Scaling deformations*).
- Any user-defined rigid body transformation applied to the deformed field output variable (see *Transforming results into a new coordinate system*).

Like the undeformed plot shape, you can use the plot state–independent options to customize your deformed shape plot. Select **Options->Common** in the main menu bar to choose the plot state–independent customization options.

You can also use Abaqus/CAE to combine your undeformed and deformed model shapes into a single plot. Combining the shapes provides a context for evaluating the deformations. If you choose to superimpose your undeformed and deformed model shapes, you can use the **Superimpose** plot options to control the display of the undeformed shape separately from the deformed shape.

Tip: Use the **Allow Multiple Plot States**  tool to display both model shapes if you want to display one or both shapes without contours, symbols, or material orientations. You can also use this tool to select any combination of plot states from the tools in the Visualization module toolbox (see *Displaying multiple plot states*, for more information).

Using common plot options

You can use the common plot options to customize the appearance of undeformed and deformed plots.

The common options are also used in conjunction with the other plot state–independent options in the **View** menu and the dependent and independent customization options for contour, symbol, and material orientation plots. Select **Options->Common** from the main menu bar or use the  tool in the toolbox to access the **Common Plot Options** dialog box. Click the following tabs to customize the appearance of plots in the current viewport:

- **Basic**: Choose render style, edge visibility, and deformation scale factor (deformed plot only).
- **Color & Style**: Control model edge color and style, model face color, edge style, and edge thickness.
- **Labels**: Control element, face, and node labels and node symbols; and control probe annotation labels.
- **Normals**: Control element and surface normals.
- **Other**: The **Other** page contains the following tabs:
  - **Scaling**: Control model scaling and shrinking.
  - **Translucency**: Control shaded and filled render style translucency.

If you choose to superimpose the undeformed and deformed model shapes, the common options control the display of the deformed shape and the superimpose plot options control the display of the undeformed shape (for more information, see *Superimposing deformed and undeformed model plots*). Plot state–dependent options may override some common options; for example, the color options for contour plots will always override the common color options.

To learn how to customize the render style and other display characteristics of your plots, see *Customizing plot display*.

Producing an undeformed shape plot

For general analysis steps an undeformed plot displays the shape of your model without any deformation. For linear perturbation steps an undeformed plot displays the base state of your model. Since analysis results are not needed; an output database resulting from a **datacheck** run is sufficient to produce an undeformed shape plot. Model and analysis characteristics such as surface definitions can cause the appearance of your undeformed model to vary from step to step; you can select the step and frame at which to display your undeformed plot. For more information, see *Selecting the results step and frame*.

By default, when you *open an output database*, Abaqus/CAE displays the undeformed plot state for the last step and frame of the analysis. The plot is produced using the default display options for the current session (for information on saving display options, see *Saving your display options settings*). To produce an undeformed shape plot for an output database that is already open, select **Plot->Undeformed Shape** from the main menu bar or use the  tool in the toolbox.

1. Use the **File** menu to *open the output database* containing your model data.
2. Use the **Result** menu to select the *results step* to display.
3. Select the plot state–independent *customization options* that you want.

Abaqus automatically refreshes your undeformed plot each time you click **Apply** in the results or plot state–independent dialog boxes.

Producing a deformed shape plot

A deformed plot displays the shape of your model at a specified step and frame of the analysis results, according to the values of the deformed field variable. For more information on selecting a step and frame, see *Selecting a specific results step and frame*. For more information on selecting a deformed field variable, see *Selecting the deformed field output variable*. To learn how to display the minimum and maximum values associated with your deformed plot, see *Customizing the legend*.

1. Use the **File** menu to *open the output database* containing your analysis results.
2. Use the **Result** menu to select the following:
   a. The step and frame at which Abaqus obtains values.
   b. The deformed field variable for which Abaqus obtains values. The variables that have been saved during the analysis are available.
   c. The numeric form in which Abaqus displays complex number results.
3. Select the plot state–independent *customization options* that you want.
4. From the main menu bar, select **Plot->Deformed Shape** to display the deformed plot.

Tip: You can also produce a deformed shape plot using the  tool in the toolbox.

The current viewport displays a customized deformed plot of the specified deformation field variable at the specified step and frame of the output database. The state block, if active, changes to show the name of the variable displayed.

Abaqus automatically refreshes your deformed plot each time you click **Apply** in the results or plot state–independent dialog boxes.

Additional information

- *Producing an undeformed shape plot*
- *Using common plot options*

Superimposing deformed and undeformed model plots

You can combine the deformed and undeformed model shapes in a single plot. Combining the shapes provides a context for displaying and interpreting the contours, symbols, or material orientations. An example of superimposed model shapes is shown in *Figure 1*.

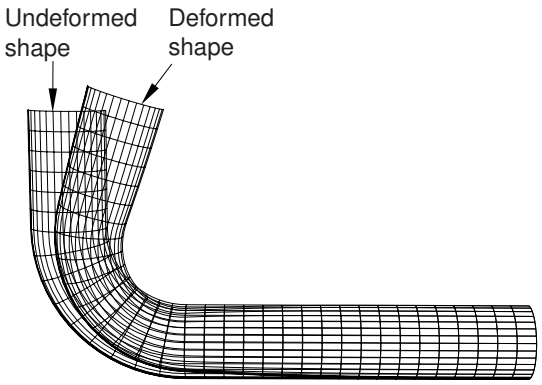

Figure 1: Deformed shape superimposed on the undeformed shape.

To produce a superimposed plot, select **Plot->*Contours, Symbols, or Material Orientations*->On Both Shapes** from the main menu bar or use the , , and tools in the toolbox. To superimpose the undeformed and deformed shapes without contours, symbols, or material orientations or to display any combination of plot types for the same results, use the tool and select all of the desired plot types from the toolbox (for more information, see *Displaying multiple plot states*).

1. From the main menu bar, select **Options->Superimpose** to customize the appearance of the undeformed shape.

   Tip: You can also customize the undeformed plot shape using the tool in the toolbox.

2. Click the following tabs to modify the options:

   - **Basic**: Choose render style and edge visibility.
   - **Color & Style**: Control model edge color and style, model face color, edge style, and edge thickness.
   - **Labels**: Control element, face, and node labels and node symbols.
   - **Normals**: Control element and surface normals.
   - **Other**: The **Other** page contains the following tabs:
     - **Scaling**: Control model scaling and shrinking.
     - **Translucency**: Control shaded and filled render style translucency.
     - **Offset**: Control the offset between the undeformed and deformed shapes.

     For more detailed information on customizing the display characteristics of your plots, see *Customizing plot display*.

   Abaqus/CAE uses the superimpose plot options in place of the common plot options to display the undeformed plot in the viewport.

3. To customize the similar options for the deformed shape, select **Options->Common** or use the  tool in the toolbox.
4. If contours, symbols, or material orientations are active, use the associated plot state–dependent options to customize the display of both the undeformed and the deformed plot.
5. Click **Apply** in each options dialog box to implement your changes in the viewport.

Your superimposed plot options changes are saved for the duration of the session and will affect the undeformed shape in all subsequent plots where both model shapes are displayed.

Contouring analysis results

This section explains contour plotting.

A contour plot displays the values of an analysis variable at a specified step and frame. In addition, a contour plot can be used to show the value of attributes such as loads or predefined fields at a specified step of a model in the current model database. Abaqus/CAE represents the values as customized colored lines, colored bands, colored faces, colored isosurfaces, or tick marks on your model.

In this section:

- *Understanding contour plotting*
- *Using contour plot options*
- *Producing a contour plot*
- *Producing a contour plot of linear beam section stresses*
- *Customizing a contour plot*

Understanding contour plotting

This section discusses the computation and rendering of contour values and the computation of contour limits.

In this section:

- *About contour plotting*
- *Understanding how contour values are computed*
- *Understanding how contours are rendered*
- *Understanding contour limits*

About contour plotting

A contour plot displays results that are stored in the output database or displays model attributes from a model in the current model database.
Each contour plot displays the following values: for an output database, contour plots display the value of a particular field output variable in a specified step and frame of the analysis; for a model in the current model database, contour plots display the value of a selected attribute such as a load in a specified step in your analysis. These values are shown as colored lines, colored bands, or quilt-type colored faces on the surface of your model, or they are shown as isosurfaces that extend line contours into the model, depending on the customization options you select. A contour plot cannot be produced if no elements are visible in the current viewport.

Line, banded, quilt-type, and isosurface contours are shown in *Figure 1*.

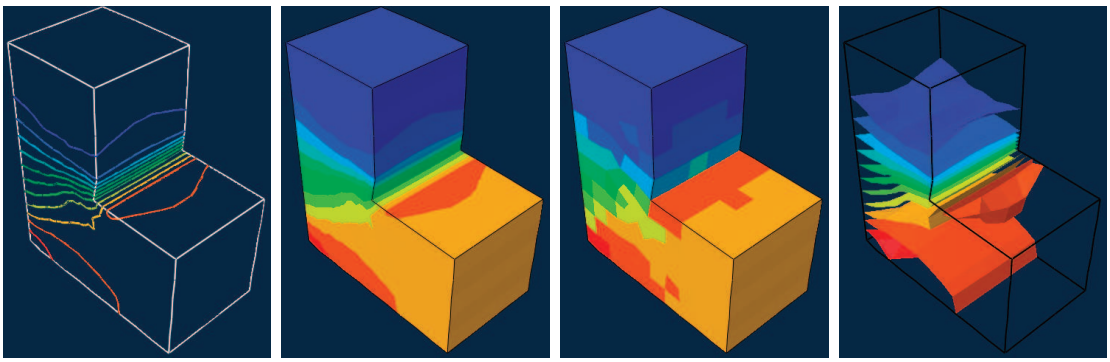

Figure 1: From left to right: contours shown as colored lines, colored bands, colored faces, and colored isosurfaces.

As with other elements, contour lines for line-shaped elements (beams, one-dimensional elements, gasket link elements, and three-dimensional line gasket elements, as well as two-dimensional contact surfaces) are plotted along the elements by default. Line-type contour plots are not recommended for line-shaped elements. Tick mark contour plotting provides an alternative means of visualizing contours on beams and other line-shaped elements. The contour is displayed as a curve plotted between two sets of lines normal to the elements, as shown in *Figure 2*. The contour level is indicated by “tick marks” on these normal lines.

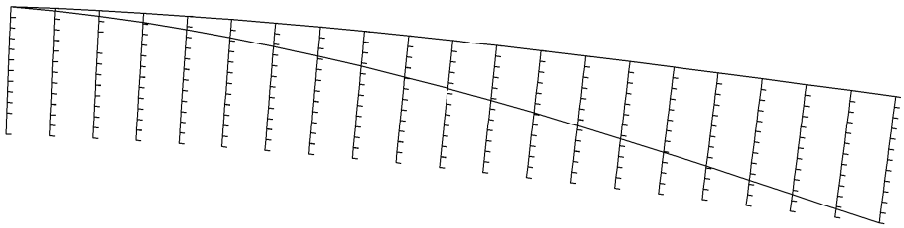

Figure 2: Tick mark contour plot.

The key to interpreting a contour plot is the plot legend. The legend indicates the correspondence between contour values and contour colors.

By default, Abaqus/CAE evenly divides the difference between the minimum and maximum values in the legend into 12 intervals. You can change the number of intervals if necessary. A color is associated with each interval. For a line-type or isosurface-type contour plot each colored line or surface corresponds to a set of locations in the model for

which the field output variable has the value shown in the legend. For a banded contour plot each colored contour band corresponds to a range of values within the bounds indicated by the legend. For a quilt contour plot each colored element face corresponds to a single value within the bounds indicated by the legend for that color. For a tick mark contour plot each colored tick mark corresponds to a single value indicated by the legend.

Abaqus/CAE follows a different convention for contour plots of contact status (CSTATUS). This variable describes whether individual nodes on the main and secondary surfaces are in contact and, if so, whether the surfaces are sticking or slipping at that point. Because three settings are available to describe the contact status at each node—sticking, slipping, or open—Abaqus/CAE displays contact status data using three contour intervals and renders the contour plot by coloring the region around a node according to its contact status.

The components of connector vector output are resolved with respect to different coordinate systems depending on whether the output requested is field output or history output. See *Displaying connectors and connector output in the Visualization module* for how to interpret the vector component values in field plots.

To learn how to produce a contour plot, see *Producing a contour plot*.

Understanding how contour values are computed

The computations necessary to produce a contour plot from results stored in the output database depend on whether the contour plot displays values for a node-based quantity, such as displacement or velocity, or for an element-based quantity, such as stress or strain. This section applies to contour plots of output database data only.

How node-based field output variable contour values are computed

For contour plots of node-based field output variables, contour values are obtained directly from the quantities on the output database. These values are then used without further computation to produce colored lines or colored bands on the surface of your model.

How element-based field output variable contour values are computed

For contour plots of element-based field output variables, Abaqus/CAE applies computations to the output database results to form the contour values. The computations vary according to the following criteria:

- the quantity you choose to plot (field output or discontinuities),
- the averaging options you select,
- the *result regions* you select,
- the compatibility of elements included in the plot, and
- the type of contour plot you request (line, banded, or quilt).

Select **Result->Field Output** from the main menu bar to choose the field output variable. To learn more about this topic, see *Selecting the field output to display*.

Select **Result->Options** from the main menu bar to choose the quantity to plot, the averaging options, the result regions, and to control the handling of incompatible elements during the computation of element-based contour values. To learn more about these topics, see *Selecting result options*.

Select **Options->Contour->Basic** from the main menu bar to choose the type of contour plot that you want. *Choosing line-, banded-, quilt-, or isosurface-type contours*, contains detailed instructions on choosing the contour type.

The type of contour plot that you request governs the extrapolation applied to the results read from the output database. For line-, banded-, and isosurface-type contours of element-based variable values, Abaqus/CAE extrapolates results to the nodes. By default, the results are conditionally averaged after Abaqus/CAE performs any necessary transformations and computes any requested scalar components or invariants; if desired, you can compute invariants after the results are averaged. For quilt-type contours of element-based variable values, Abaqus/CAE extrapolates results to the element faces on the surface of your model and then takes a weighted sum to produce a single value per face. Since quilt contour values are computed for each element face individually with no averaging across element boundaries, a quilt contour plot is an effective means of displaying results on an element-by-element basis. You can choose quilt-type contours only for element-based field output variables.

Understanding how contours are rendered

Contour values are drawn on element faces using one of two methods: texture mapping or tessellation. Texture mapping is a high-performance rendering method that essentially lays an image of the contour values (the texture) over an image of the model, similar to the process of wrapping a present. Tessellation is a method of transforming arbitrary contour values into repeating patterns of distinct shapes, such as triangles or simple polygons; the shape values are computed face by face and can take a long time for large models. Texture mapping is the default and preferred method and will maximize the performance of Abaqus/CAE. Although certain graphics adapters do not support texture mapping properly, Abaqus/CAE can emulate texture mapping in software. However, line-type and isosurface contours, the display of contour edges, shrinking elements about their centroid, and contours on CAXA or SAXA elements are supported only by the tessellation method.

The differences between contour plots generated with texture mapping or tessellation are minimal; you may see slight differences in the appearance of contour bands on quadrilateral element faces. Texture mapping can sometimes introduce precision issues; for example, if the contour value is exactly on a limit, the color may appear as just above or below the value.

Note:

If you display tessellated contours under intense lighting, the colors in the contours might not match the colors displayed in the legend because the light can fade some colors on the surface facets. For more information, see *Controlling model lighting*.

For detailed information on choosing the contour method, see *Choosing the contour method*.

Understanding contour limits

The minimum and maximum values shown in a contour plot can be computed by Abaqus/CAE, or you can specify them.
You can decide to specify one or both limits; for example, to eliminate extremes or to examine variations within a fixed set of bounds.

Contours are shown on visible surfaces of your model only; however, depending on the type of contour plot and the result options that you select, Abaqus/CAE might computer contour values based on all elements in the current display group or on all elements in the model. (For more information, see *Selecting result options*.) The reported minimum and maximum values might, therefore, occur at interior elements. You can display contours on the interior of your model by using display groups to show only the interior elements in the plot or by shrinking all elements about their centroids so that interior elements are visible between the bodies of exterior elements.

Abaqus/CAE computes the minimum and maximum values differently, according to the type of field output variable shown (nodal or element), the type of contour plot (quilt versus line or banded), and options you select. For contour plots of nodal field output variables, the limits are the maximum and minimum nodal values. For quilt-type contour plots, the limits are the maximum and minimum element face values. For line-, banded-, or isosurface-type contours of element field output variables, Abaqus/CAE determines the minimum and maximum by the extrapolated, averaged values as defined by the current averaging criteria. For element field output variables, the contour maximum and minimum values can be given at element faces, integration points, and element centroids as well as at nodes.

When Abaqus/CAE computes the minimum and maximum over values averaged at the nodes, the limits are based on the values used to create the plot. In this case, the legend bounds may vary as you vary the averaging criteria. To learn how to control the averaging criteria, see *Controlling result averaging*.

You can also control which contour limits are used for each frame of a contour plot animation: the limits computed for the first and last frame, the limits computed for the current frame, the recomputed limits for each individual frame, or the limits computed for all frames in the animation. Computing limits based on all frames in the animation requires one full pass through the animation sequence to establish the contour limits used for subsequent passes through the animation.

For detailed information on controlling contour limits, see *Setting contour limits*. To learn how to display the minimum and maximum values associated with your contour plot, see *Customizing the legend*.

Using contour plot options

You can use the contour plot options to customize the appearance of contour plots.

Select **Options->Contour** from the main menu bar or click  in the toolbox to access the **Contour Plot Options** dialog box. Click the following tabs to customize the appearance of contour plots in the current viewport:

- **Basic**: Choose the contour type (including whether to show tick marks for line elements), contour intervals, and contour method.
- **Color & Style**: The **Color & Style** page contains the following tabs:
  - **Model Edges**: Control the color of model edges.
  - **Spectrum**: Choose contour colors, and control the order of the values displayed in the legend.
  - **Line**: For line-type contours control the style and thickness of each line.
  - **Banded / Isosurface**: For banded- or isosurface-type contours control the color, style, and thickness of contour edges.
- **Limits**: Control the computation of contour limits and the display of annotations for the maximum and minimum contour values.
- **Other**: Control tick mark plot display options, the display of nodal averaged vector or tensor orientations, and the display of section point or envelope plots.

Other options such as the render style, edge visibility, deformation scale factor, and translucency are located in the ***Common Plot Options*** dialog box. If you choose to plot contours on both the undeformed and the deformed shape, you can use the ***Superimpose Plot Options*** to customize the appearance of the undeformed shape. See *Superimposing deformed and undeformed model plots*, for more information about superimpose plots. To learn how to customize the render style and underlying model of your contour plot, see *Customizing plot display*. For information on the computation of result values, see *Understanding how results are computed*.

Additional information

- *Customizing a contour plot*

Producing a contour plot

A contour plot can display either the values of an analysis variable at a specified step and frame of an output database or the values of selected attributes at a specified step of a model in the current model database. Abaqus/CAE represents the values as customized colored lines, colored bands, colored faces, or colored isosurfaces on your model or as colored tick marks on lines drawn normal to your model. For more information on selecting an analysis variable, see *Selecting the primary field output variable*. For more information on selecting a specific step and frame, see *Selecting a specific results step and frame*. To learn how to display the minimum and maximum values associated with your contour plot, see *Customizing the legend*.

If your model includes beam elements, some additional steps can be required for proper contour display. See *Producing a contour plot of linear beam section stresses*.

If you are plotting data from a model database, specify only the primary field variable.

1. Use the **File** menu to *open the model database or output database* containing your model data or analysis results.
2. If you are plotting data from a model database, switch to the Visualization module, expand the **Model Database** container of the Results Tree, and select the model you want to use.
3. Use the **Result** menu to select the following:
   a. The *step and frame* to display (or just the step, if a model database is selected).
   b. The *primary field* output variable to display.
   c. The *deformed field* output variable to display (for contours on the deformed shape only).
   d. The *quantity to plot* and *averaging* options (for output databases only).
4. Select the plot state–independent and contour plot *customization options* that you want.
5. If your chosen field output variable includes complex numbers, select the ***Complex Form*** tab in the **Result Options** dialog box to control the numeric form to display. Complex form options apply only to output databases.
6. From the main menu bar, select **Plot->Contours** and choose whether to plot the contours on the undeformed shape, the deformed shape, or both.

   Tip: You can also produce a contour plot using the deformed , undeformed , or superimposed  contour tools in the toolbox.

   The current viewport displays a customized contour plot of the specified field output variable at the specified step and frame of the current output database or at the specified step of the selected model in the current model database.

   Abaqus automatically refreshes your contour plot each time you click **Apply** in the step and frame selector, field output options, plot state–independent options, superimpose plot options (if applicable), or contour plot options dialog boxes.

Additional information

- *Using contour plot options*
- *Selecting model data and analysis results to plot*

Producing a contour plot of linear beam section stresses

If your model includes beam geometry and beam rendering is enabled for your session, you can display field output results along the beam cross-sections as contours. For nodal quantities and element integration point quantities, Abaqus/CAE displays contours that are constant through the thickness of the beam cross-section. For the element-based data, the contour reflects the currently selected section point.

You can also create a contour plot that shows a more realistic stress distribution through the beam based on section force and section moment data, which Abaqus/CAE calculates using linear elastic solid mechanics theory. *Figure 1* shows an example of beam stresses through an I-beam.

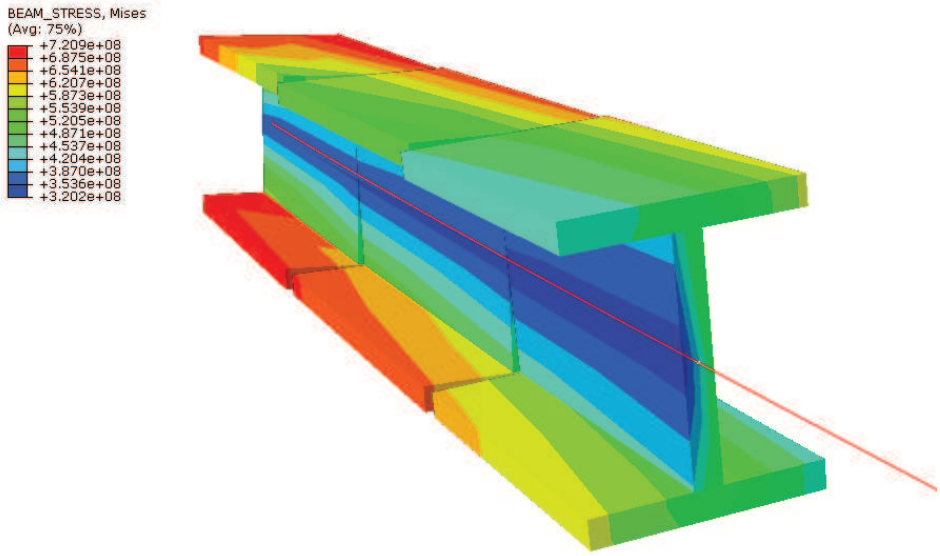

Figure 1: Linear beam section stresses displayed for an I-beam cross-section.

Beam stress contour plots are available only when the selected step and frame include data from the integrated output quantities SF (section force) and SM (section moment). Furthermore, these plots are available only for a subset of profiles in Abaqus/CAE:

- Thin-walled box profiles
- Thin-walled pipe profiles
- Circular profiles
- Rectangular profiles
- I-shaped profiles
- L-shaped profiles
- T-shaped profiles

BEAM_STRESS output is not available for random response and response spectrum procedures.

Abaqus/CAE does not include beam element normals for eigenfrequency extraction in its calculations for beam cross section rendering, so you cannot visualize the torsional and out-of-plane modes for the beam elements in these plots. However, the torsional modes are calculated for the beam elements because the beam elements have torsional stiffness; this information is available in the data (`.dat`) file.

1. Use the **File** menu to *open the output database* containing your analysis results.

2. Use the **Result** menu to select the following:
   a. The *step and frame* to display.
   b. The *primary field* output variable to display.
   c. The *deformed field* output variable to display (for contours on the deformed shape only).
   d. The *quantity to plot* and *averaging* options.
3. Select the plot state–independent and contour plot *customization options* that you want.
4. From the **Output Variable** options, select **BEAM_STRESS**.
5. Choose the invariant or component for which you want to display contour data:
   - Select **Mises** from the **Invariant** options to display von Mises stress.
   - Select **S11** from the **Component** options to display axial stress along the beam.
   - Select **S12** from the **Component** options to display shear stress along the local beam section 2-axis caused by shear force and torsion.
   - Select **S13** from the **Component** options to display shear stress along the local beam section 1-axis caused by shear force and torsion.
6. From the main menu bar, select **Plot->Contours** and choose whether to plot the contours on the undeformed shape, the deformed shape, or both.

   Tip: You can also produce a contour plot using the deformed , undeformed , or superimposed contour tools in the toolbox.

   The current viewport displays a customized contour plot of the specified field output variable at the specified step and frame of the current output database.

   Abaqus automatically refreshes your contour plot each time you click **Apply** in the step and frame selector, field output options, plot state–independent options, superimpose plot options (if applicable), or contour plot options dialog boxes.

Customizing a contour plot

This section describes how to customize a contour plot. Abaqus/CAE offers numerous options for you to control the contour type, limits, intervals, and colors.

To learn how to customize the render style, translucency, or model edge characteristics of your contour plot, see *Customizing plot display*. For information on adding nodal-averaged orientations to your contour plot, see *Displaying nodal-averaged orientations*. For information on customizing an envelope plot, see *Selecting section point data by category*. For information on the computation of result values, see *Understanding how results are computed*.

In this section:

- *Choosing line-, banded-, quilt-, or isosurface-type contours*
- *Stylizing line-type contours*
- *Customizing banded- and isosurface-type contours*
- *Contouring line-shaped elements with tick mark contour plots*
- *Customizing tick mark contour plots*
- *Choosing the contour method*
- *Setting contour limits*
- *Annotating the minimum and maximum contour values*
- *Controlling how Abaqus/CAE computes contour limits*
- *Customizing contour colors*
- *Creating a new color spectrum*
- *Customizing contour intervals*

Choosing line-, banded-, quilt-, or isosurface-type contours

You can choose **Line**-, **Banded**-, or **Isosurface**-type contours to display the values of nodal (such as displacement) or element (such as stress) field output variables. Line-type contours represent values as customized colored lines on the surface of your model. Banded contours represent values as color-filled bands. Isosurface contours extend line-type contours through the model. Line, banded, and isosurface contours of element-based variable values are computed by extrapolating results to the nodes and conditionally *averaging*. Averaging depends on the characteristics of your model and on options you select. Line-type contours are not recommended for line-shaped elements, such as beams.

You can choose **Quilt**-type contours only for element field output variables. Variable values are extrapolated to element faces on the surface of your model, with no averaging between elements. Quilt contours are useful for evaluating results on an element-by-element basis. Only one color per element is plotted for axisymmetric elements with asymmetric deformation (CAXA or SAXA).

Banded-type contours are the default. You must choose line-, banded-, or isosurface-type contours to produce a plot of:

- Nodal-based field output values.
- Element-based field output values averaged across elements.
- Element-based results discontinuities rather than field output values.

Figure 1 shows the appearance of line-, banded-, quilt-, and isosurface-type contour plots.

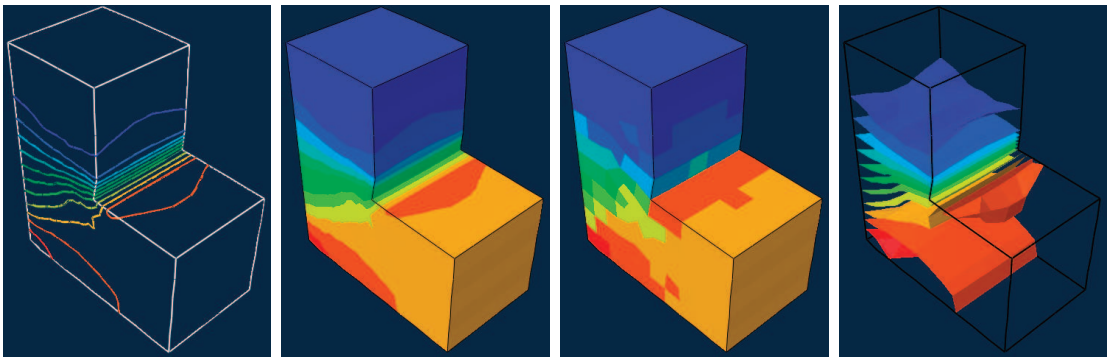

Figure 1: From left to right: line-, banded-, quilt-, and isosurface-type contours.

1. Locate the **Contour Type** options.

   Select **Options->Contour** from the main menu bar or click  in the toolbox; then click the **Basic** tab in the dialog box that appears. The **Contour Type** options are in the upper left corner of the page.
2. Click **Line**, **Banded**, **Quilt**, or **Isosurface** to choose the contour type you want.
3. Click **Apply** to implement your changes.

   The contour plot in the current viewport changes to display the contour type you have specified.

   By default, your changes are saved for the duration of the session and will affect all subsequent contour plots. If you want to retain your changes for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

Additional information

- *Understanding how contour values are computed*
- *Stylizing line-type contours*
- *Customizing banded- and isosurface-type contours*

Stylizing line-type contours

Abaqus/CAE displays line-type contours as customized colored lines on the surface of your model. You can stylize individual contour lines to make them easy to distinguish.

This option is particularly useful when colors are not available; for example, for black and white hard-copy plotting. *Figure 1* shows a contour plot with customized contour lines.

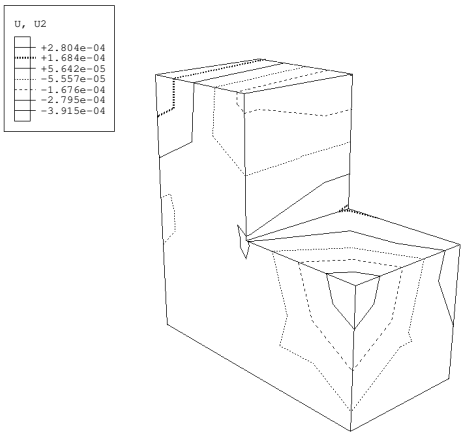

Figure 1: Line-type contour plot with customized contour lines.

You customize the colored lines one color *(interval)* at a time, referring to each interval by its position in the contour legend. Interval number 1 is the first colored line starting from the bottom of the contour plot legend. For information on the contour legend, see *Customizing the legend*.

1. Locate the **Line** options.

   Select **Options->Contour** from the main menu bar or click  in the toolbox. Click the **Color & Style** tab in the dialog box that appears; then click the **Line** tab. The **Line** options appear.

2. To choose the interval you want to customize, click the **Interval** arrows until the desired interval number appears in the **Interval** box.

   Note:

   The **Style** and **Thickness** buttons change to show the current style and thickness of this interval, respectively. The numbers above and below the **Interval** box change to correspond to the adjacent interval numbers. The area above and below the **Style** and **Thickness** buttons changes to show the style and thickness, respectively, of these adjacent intervals.

3. Choose the style of the interval line:
   a. Click the **Style** button to reveal the style choices.
   b. Click the style you want.

      The specified style appears on the **Style** button.

4. Choose the thickness of the interval line:
   a. Click the **Thickness** button to reveal the thickness choices.
   b. Click the thickness you want.

      The specified thickness appears on the **Thickness** button.

5. Repeat Steps 2 through 4 to customize additional intervals.

6. Click **Apply** to implement your changes.

   The contour lines of the line-type contour plot in the current viewport change to reflect your style and thickness specifications. The contour legend, if active, will also change to show your selections. For more information on the contour legend, see *Customizing the legend*. In addition, tick mark axes, if present, will change to show your selections. For more information on tick mark contours, see *Contouring line-shaped elements with tick mark contour plots*.

   By default, your changes are saved for the duration of the session and will affect all subsequent contour plots. If you want to retain your changes for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

Additional information

- *Understanding contour plotting*
- *Customizing a contour plot*
- *Customizing contour intervals*

Customizing banded- and isosurface-type contours

Abaqus/CAE displays banded-type contours as colored bands on the surface of your model and displays isosurface contours by extending line-type contours through the model to create surfaces. You can display or suppress lines at the edges of each contour band or isosurface; these lines are called contour edges. Contour edges visually separate the colors used to represent contour values in a banded-type contour plot; for isosurfaces, where the separation is often more distinct, the display of contour edges is more decorative. You can further customize the color, style, and thickness of contour edges. For example, in *Figure 1* the contour plot on the left has contour edges suppressed, while the plot on the right has contour edges displayed.

Note:

Contour edges are not applicable to *continuous interval* contour plots.

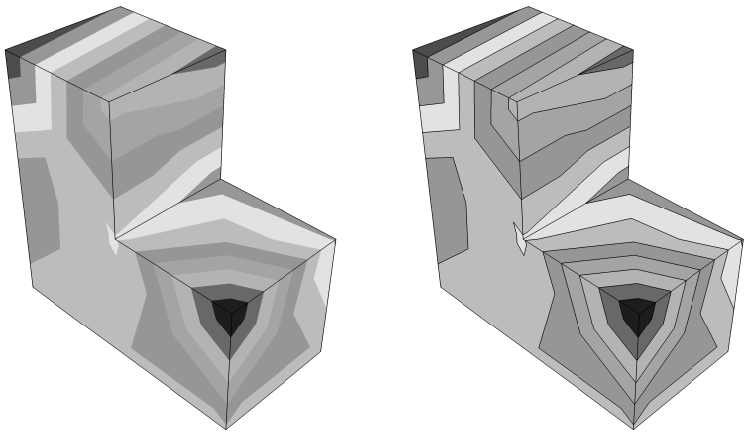

Figure 1: Banded-type contour plots with contour edges suppressed and displayed.

1. Locate the **Banded / Isosurface** options.

   Select **Options->Contour** from the main menu bar or click in the toolbox. Click the **Color & Style** tab in the dialog box that appears; then click the **Banded / Isosurface** tab. The **Banded / Isosurface** options appear.

2. Toggle **Show contour edges** to display or suppress contour edges.

   When **Show contour edges** is on, the contour edge options become available.

3. Choose the color of the contour edges:

   a. Click the color sample .

      Abaqus/CAE displays the **Select Color** dialog box.

   b. Use one of the methods in the **Select Color** dialog box to select a new color. For more information, see *Customizing colors*.

   c. Click **OK** to close the **Select Color** dialog box.

      The color sample changes to the selected color. The new color does not appear in the viewport until you click **OK** or **Apply** in the **Contour Plot Options** dialog box.

4. Choose the style of the contour edges:

   a. Click the **Style** button to reveal the contour edge style options.

   b. Click the edge style you want.

The specified edge style appears on the **Style** button.

5. Choose the thickness of the contour edges:
   a. Click the **Thickness** button to reveal the contour edge thickness options.
   b. Click the edge thickness you want.

      The specified edge thickness appears on the **Thickness** button.

6. Click **Apply** to implement your changes.

   The contour edges of the banded contour plot in the current viewport change to reflect your specifications.

   By default, your changes are saved for the duration of the session and will affect all subsequent contour plots. If you want to retain your changes for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

Additional information

- *Choosing line-, banded-, quilt-, or isosurface-type contours*
- *Customizing contour intervals*
- *Understanding contour plotting*

Contouring line-shaped elements with tick mark contour plots

Contour lines drawn on line-shaped elements are difficult to visualize clearly. To see the contours of line-shaped elements (beams, one-dimensional elements, gasket link elements, three-dimensional line gasket elements, and two-dimensional contact surfaces) better, you can choose to display the contour lines using tick mark contour plots.

A tick mark contour plot shows the contour curve drawn between sets of lines that are normal to the actual elements. The contour level is indicated by "tick marks" on these normal lines. Abaqus displays the contour curve only when it falls within the limits you have specified. For more information on limiting the range of the plot, see *Setting contour limits*.

Figure 1 shows the appearance of a tick mark contour plot.

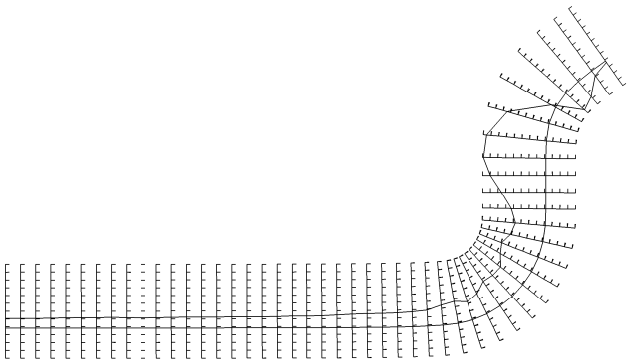

Figure 1: Tick mark contour plot.

The normal lines, or tick mark axes, are drawn at nodes. At part boundaries, two tick mark axes are drawn. Within a part, if the angle between two adjacent line elements is less than the specified feature angle, a single tick mark axis is drawn in the direction of the average normal of elements sharing the node. Otherwise, a tick mark axis is drawn normal to each element sharing the node. When averaging normals, only displayed elements of the same type are considered in the calculation.

1. Locate the **Contour Type** options.

   Select **Options->Contour** from the main menu bar or click in the toolbox; then click the **Basic** tab in the dialog box that appears. The **Contour Type** options are in the upper left corner of the page.

2. Toggle **Show tick marks for line elements**.
3. Click **Apply** to implement your changes.

   The contour plot in the current viewport changes to display tick mark plots for the line elements in the model.

   By default, your changes are saved for the duration of the session and will affect all subsequent contour plots. If you want to retain your changes for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

Additional information

- *Understanding contour plotting*
- *Customizing tick mark contour plots*

Customizing tick mark contour plots

When you choose to show tick marks for line-shaped elements in your model, Abaqus/CAE indicates the contour levels as tick marks on lines (axes) drawn normal to the elements and displays the contour curve between the axes. You can specify the length of the tick mark axes, the color of the contour curve, the contour value (tick mark) that will intersect the element, and the normal direction in which the axes will be drawn on beam elements. In addition, for line-type contour plots, style selections you apply to individual contour lines will appear on the tick mark axes. For more information, see *Stylizing line-type contours*.

1. Locate the **Tick Marks** options.

   Select **Options->Contour** from the main menu bar or click  in the toolbox. Click the **Other** tab in the dialog box that appears; then click the **Tick Marks** tab. The **Tick Marks** options appear.

2. To choose the normal direction in which the tick mark axes will be drawn on beam elements, toggle the **N1** or **N2** button in the **Orientation** field.

   Note:

   This option will be ignored when tick mark contour plots are displayed on line elements other than beams. In this case, the tick mark axes are drawn in the element normal direction.

3. Choose the length of the tick mark axes:
   a. Click the **Axis length** button to reveal the length choices: **Short**, **Medium**, or **Long**.
   b. Click the length you want.

      The specified length appears on the **Axis length** button.

4. Choose the contour value that will intersect the element:
   a. Enter the desired base contour value in the **Base Value** field.

      The value specified will be checked to determine whether it falls within the contour range. If it is above the maximum contour value, the maximum contour value will be used as the base value; if it is below the minimum contour value, the minimum contour value will be used as the base value. By default, zero is used as the base value.

5. Choose the color of the tick mark curve:
   a. Click the color sample .

      Abaqus/CAE displays the **Select Color** dialog box.
   b. Use one of the methods in the **Select Color** dialog box to select a new color. For more information, see *Customizing colors*.
   c. Click **OK** to close the **Select Color** dialog box.

      The color sample changes to the selected color. The new color does not appear in the viewport until you click **OK** or **Apply** in the **Contour Plot Options** dialog box.

6. Click **Apply** to implement your changes.

   The contour lines of the tick mark contour plot in the current viewport change to reflect your specifications.

By default, your changes are saved for the duration of the session and will affect all subsequent contour plots. If you want to retain your changes for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

Additional information

- *Understanding contour plotting*
- *Customizing a contour plot*

Choosing the contour method

Contour values are drawn on element faces using either the texture mapping or tessellation method. Texture mapping is the default and preferred method and will maximize the performance of Abaqus/CAE. Although certain graphics adapters do not support texture mapping properly, Abaqus/CAE can emulate texture mapping in software. However, certain display options are supported only by the tessellation method; in such cases Abaqus/CAE will override the user setting for texture-mapped contours automatically.

1. Locate the **Contour Method** options.

   Select **Options**->**Contour** from the main menu bar or click  in the toolbox; then click the **Basic** tab in the dialog box that appears. The **Contour Method** options are at the bottom of the page.

2. Choose one of the following rendering methods:

   - **Texture-mapped**. This option uses high-performance graphics rendering capabilities to draw contour values on each element face. If the graphics parameters for your system have been configured to disable texture mapping (see *Tuning graphics cards*), Abaqus/CAE will emulate texture mapping in software.
   - **Tessellated**. This option uses the process of tessellation to draw contour values on each element face.

3. Click **Apply** to implement your changes.

   The contour plot in the current viewport changes to use the contour method you have specified.

   By default, your changes are saved for the duration of the session and will affect all subsequent contour plots. If you want to retain your changes for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

Additional information

- *Understanding how contours are rendered*
- *Customizing a contour plot*

Setting contour limits

By default, Abaqus/CAE automatically computes the limits of the values shown in your contour plot. You can control the minimum and maximum values Abaqus/CAE displays; for example, to eliminate extremes or to examine variations within a fixed set of bounds.

Contour limits, once set, remain in effect for the duration of the session. To learn how to display the minimum and maximum values associated with your contour plot, see *Customizing the legend*.

You can override the contour limits if you use custom contour interval values; see *Customizing contour intervals* for more information. When you use a custom contour interval, Abaqus/CAE uses the maximum and minimum interval values that you specify in the **Edit Intervals** dialog box as the contour limits for the contour plot.

If you specify the contour limits and subsequently modify the limits, the smaller the number of contour intervals increases the likelihood that your limit modifications will result in changes to the contour plot.

1. Locate the **Contour Limits** options.

   Select **Options->Contour** from the main menu bar or click  in the toolbox; then click the **Limits** tab in the dialog box that appears. The contour **Limits** options become available.

2. In the area labeled **Max**, choose one of the following options:

   - Select **Auto-compute** to request that Abaqus compute the maximum contour value.
   - Select **Specify** to specify the maximum value yourself; then enter the maximum value of your choice in the **Specify** text field.

3. In the area labeled **Min**, choose one of the following options:

   - Select **Auto-compute** to request that Abaqus compute the minimum contour value.
   - Select **Specify** to specify the minimum value yourself; then enter the minimum value of your choice in the **Specify** text field.

4. Click **Apply** to implement your changes.

   In the contour plot in the current viewport, Abaqus displays contour values within the limits you have specified. The contour legend, if active, changes to show the limits you have specified. If you have specified a maximum value that is less than the actual maximum or if you have specified a minimum value that is greater than the actual minimum, Abaqus displays the actual maximum or minimum value (respectively) in the legend. For more information on the contour legend, see *Customizing the legend*. To learn how to control the color of values that exceed your limits, see *Customizing contour colors*.

   By default, your changes are saved for the duration of the session and will affect all subsequent contour plots. If you want to retain your changes for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

Additional information

- *Understanding contour limits*
- *Annotating the minimum and maximum contour values*
- *Controlling how Abaqus/CAE computes contour limits*

Annotating the minimum and maximum contour values

By default, Abaqus/CAE indicates the general locations of the minimum and maximum contour values through changes in the contour color. The actual locations may be in any part of the model displayed using the extremes of the selected color spectrum. You can toggle on **Show location** to annotate the nodal location of the minimum and/or maximum contour values. The annotations are of the form `Min: value` and `Max: value`, respectively, with a line pointing to the node, face (for quilt plots), or element centroid where the minimum and maximum occur.

Displaying the minimum or maximum value annotations activates the contour legend and the **Show min/max values** option (for more information, see *Customizing the legend*). The annotations are created automatically—you cannot edit them using the **Annotation Manager**. The annotation font and color match those of the legend text, and the node symbols are determined by the node symbol settings in the **Common Plot Options** dialog box. If you display the minimum and maximum contour values and a view cut is activated, the locations of the minimum and maximum values are updated relative to the viewport display. The contour legend is also updated to reflect the new bounds.

Note:

The minimum and maximum locations are not shown in an overlay plot.

1. Locate the **Show location** checkboxes.

   Select **Options->Contour** from the main menu bar or click  in the toolbox; then click the ***Limits tab*** in the dialog box that appears.

2. Toggle on **Show location** in the **Min** and **Max** areas, respectively, to annotate each location on the model.
3. Click **Apply** to implement your changes in the viewport.

   Abaqus/CAE activates the contour legend, including the **Show min/max values** option. The legend displays both the minimum and maximum values, regardless of whether you annotate one or both of them on the model.

4. If desired, use the **Viewport Annotation Options** to customize the annotation font and color (controlled by the legend text options), to hide the minimum and maximum values in the legend, or to hide the entire legend. Use the symbol and size options on the **Labels** tabbed page of the **Common Plot Options** dialog box to edit the displayed node symbols.

   By default, your changes are saved for the duration of the session and will affect all subsequent contour plots. If you want to retain your changes for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

Additional information

- *Understanding contour plotting*
- *Customizing a contour plot*
- *Customizing model labels*
- *Customizing the legend*

Controlling how Abaqus/CAE computes contour limits

By default, Abaqus/CAE automatically computes the minimum and maximum values shown in your contour plot. Automatic computation does not apply if you have *set limits* for both the minimum and maximum contour values.

For contour plots of nodal field output variables, the limits are the minimum and maximum nodal values. For *quilt-type contour* plots, the limits are the minimum and maximum element face values.

For *line-, banded-, or isosurface-type contours* of element field output variables, the limits are based on the values from individual elements extrapolated to and averaged at the nodes. The range may vary due to changes in the results averaging options. To learn how to control the averaging options, see *Controlling result averaging*.

For animations of contour plots, you can control which contour limits are used in each frame of the animation. You can choose to always use the auto-computed limits from the first and last frame, to always use the auto-computed limits from the current frame, or to recompute the limits for each frame.

1. Locate the **Auto-Computed Limits** options.

   Select **Options->Contour** from the main menu bar or click  in the toolbox; then click the **Limits** tab in the dialog box that appears. The **Auto-Computed Limits** options are in the lower half of the page.

2. Choose one of the following options for animation contour limits:

   - Select **Use first and last frame limits** to use the auto-computed contour limits from the first and last frame for each frame of the animation.
   - Select **Use current frame limits** to use the auto-computed contour limits from the current frame for each frame of the animation.
   - Select **Recompute limits for each frame** to recompute the contour limits for each frame of the animation based on the result values for the frame.
   - Select **Use limits from all frames** to recompute the auto-computed contour limits from all frames of the animation.

3. Click **Apply** to implement your changes.

   Contour limits for each frame of animations generated for the contour plot in the current viewport will be determined based on the option you selected. The *contour legend*, if active, changes to show the limits Abaqus computes.

   By default, your changes are saved for the duration of the session and will affect all subsequent contour plots. If you want to retain your changes for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

Additional information

- *Understanding contour limits*
- *Setting contour limits*
- *Choosing line-, banded-, quilt-, or isosurface-type contours*

Customizing contour colors

By default, Abaqus/CAE represents contour values using the **Rainbow** color spectrum from red (for the maximum value) to blue (for the minimum value). You can select alternative color spectrums or create new color spectrums to use.
See *Creating a new color spectrum* for more information about creating a new color spectrum.

If your results include cyclic data in which positive and negative extreme values are equivalent, select the **Wraparound** color spectrum. This spectrum, with green at both extremes, correctly displays results such as the phase angle of a complex number, where 180° and −180° are the same.

By default, the contour plot legend displays values in descending order with the maximum value at the top. You can choose to reverse the order and display the values in ascending order with the minimum value at the top.

For non-tick mark contour plots you can also choose the colors Abaqus uses to represent values that exceed the limits you have specified for the plot, if any. By default, Abaqus displays such values in shades of gray. (For tick mark contour plots Abaqus displays the contour curve itself only within the limits you have specified.) You can choose to hide these values that are exceeding the limits specified for the plot from the contour legend. For more information on limiting the range of the plot, see *Setting contour limits*.

1. Locate the **Spectrum** options.

   Select **Options->Contour** from the main menu bar or click  in the toolbox. Click the **Color & Style** tab in the dialog box that appears; then click the **Spectrum** tab. The **Spectrum** options appear.

2. To choose the color of values within the limits of the plot, either select a spectrum name or click  to create and use a new color spectrum. See *Creating a new color spectrum* for information about creating a new color spectrum.

   Tip: Alternatively, you can choose or create a contour spectrum from the Results Tree. Click the **Spectrums** container to create a new spectrum, or click the name of any spectrum in the Results Tree to display the model using that spectrum.

3. To display the values in the contour plot legend in ascending order with the minimum value at the top, toggle on **Reverse contour legend range**.
4. To hide the values in the contour plot legend that exceed the specified limits, toggle on **Use specified limits for contour legend**.
5. To control the color of values that exceed the limits of the plot, do one of the following:

   - Click **Specify**; then click the **Greater than max** or **Less than min** color sample  to open the **Select Color** dialog box. Select a new color, and click **OK** to close the **Select Color** dialog box and update the color sample. (For more information, see *Customizing colors*.)

     Or,

   - Click **Use spectrum min/max** to accept the minimum and maximum contour spectrum colors for such values.

6. Click **Apply** to implement your changes.

   Contours in the current viewport change to the colors you have specified. The correspondence between contour colors and contour values appears in the contour legend, if active. For more information on the contour legend, see *Customizing the legend*.

By default, your changes are saved for the duration of the session and will affect all subsequent contour plots. If you want to retain your changes for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

Additional information

- *Understanding contour plotting*
- *Customizing a contour plot*
- *Creating a new color spectrum*
- *Coloring elements with no results*

Creating a new color spectrum

Abaqus/CAE provides seven predefined color spectrums that you can use to customize the colors in a contour plot. If you prefer a different set of colors or a different arrangement, you can create a new color spectrum and apply its colors to the contour plot.

Creating and editing a color spectrum are similar processes. When you create a new color spectrum, Abaqus/CAE populates the **Create Spectrum** dialog box with the contents of the last color spectrum that you either modified or applied to the contour plot. If you had not yet modified a spectrum or created a contour plot in your session, Abaqus/CAE populates a new color spectrum with the colors in the predefined **Rainbow** color spectrum. You can then edit this new color spectrum by adding, modifying, moving, and deleting colors to achieve the content and arrangement that you want.

A spectrum must contain at least two colors and can contain as many colors as you want to include. In many situations the number of colors in your selected color spectrum will not match the number of contour intervals, so Abaqus/CAE cannot perform a one-to-one assignment of colors to contour intervals. In this case Abaqus/CAE performs one of the following actions:

- If your spectrum has more colors than the current number of contour intervals, Abaqus/CAE samples colors from the spectrum to create the contour plot. For example, when a spectrum contains 24 colors and only 12 intervals are selected, the contour plot will display every other color in the spectrum.
- If your spectrum has fewer colors than the current number of contour intervals, Abaqus/CAE interpolates between spectrum colors to determine additional colors to use for the contour intervals. All user-defined color spectrums follow an HSV interpolation scheme, while the **Red to blue** predefined spectrum follows an RGB interpolation scheme. This difference means that the **Red to blue** predefined spectrum and a user-defined spectrum could contain the same two colors, red and blue, but behave differently because their interpolation schemes would create different intermediate interval values. In general, HSV interpolation conforms more closely to human intuition than RGB interpolation does.

Color spectrums are session-specific definitions; therefore, they are available for use in any viewport during your session but are not saved to the output database (`.odb`). You can edit the colors and arrangement of any color spectrum, and you can rename, copy, or delete any user-created color spectrum. Abaqus/CAE does not allow you to rename or delete the seven predefined color spectrums. Abaqus/CAE provides access to color spectrums both from the main menu bar and from the Results Tree.

1. Locate the **Create Spectrum** dialog box.

   From the main menu bar, select **Tools**->**Spectrum**->**Create**.

   The **Create Spectrum** dialog box appears.
2. Specify the **Name** for this new color spectrum.
3. To insert a new color into the color spectrum:

   1. Highlight the color in the color spectrum that you want to precede or follow the color that you add.
   2. Click **Insert Before** or **Insert After** to add a new color in the indicated location.

      The **Select Color** dialog box opens.
   3. Choose a color, and click **OK** to close the **Select Color** dialog box.

   Abaqus/CAE adds the new color in the selected location.
4. To change one of the colors in the color spectrum, double-click the color and select a new color from the **Select Color** dialog box that appears.
5. To move a color within the color spectrum, highlight the color and click either **Move Up** or **Move Down** to move the color one step in the selected direction.
6. To delete a color from the spectrum, highlight the color and click **Delete**.

7. Continue adding, changing, moving, and deleting colors until the color spectrum contains the colors you want in the desired order.
8. Click **OK**.

   Abaqus/CAE adds the new color spectrum, making it available for use in customizing contour plots.

- *Customizing contour colors*
- *Coloring elements with no results*

Customizing contour intervals

Abaqus/CAE evenly divides the range between the minimum and maximum contour values into intervals. You can customize the number of intervals and whether the intervals are represented by discrete or continuous colors.

By default, there are 12 discretely colored intervals. *Figure 1* shows a banded-type contour plot with nine uniform contour intervals on the left and with continuous contours on the right.

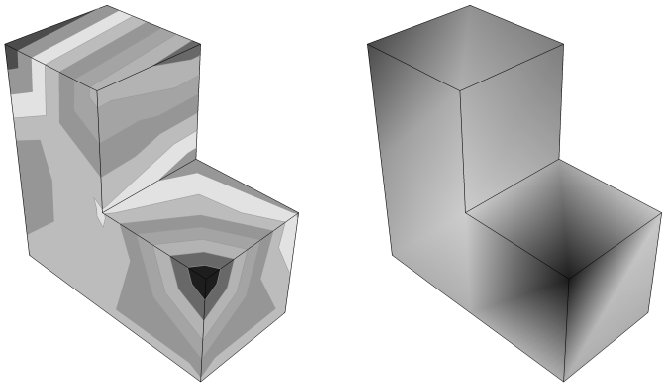

Figure 1: Contour plots showing uniform and continuous contour intervals.

When you represent contour plots using discrete intervals, you can also control the type of progression between interval values. If you choose a uniform interval type, Abaqus/CAE creates a uniform, arithmetic progression between the interval values; if you choose a logarithmic interval type, Abaqus/CAE creates a logarithmic progression between interval values. In addition, you can create a new set of contour intervals with a custom progression that includes any values that you want to include. You can also provide just a few interval values and interpolate additional intervals between the values you define. The interval values you provide must appear in descending order from top to bottom in the **Edit Intervals** dialog box.

If you select a custom interval, Abaqus/CAE overrides the contour limits specified in the **Limits** area of the **Contour Plot Options** dialog box and uses the maximum and minimum interval values as the custom contour limits. See *Setting contour limits*, for more information.

If you select custom contour intervals and subsequently modify the intervals, the smaller the number of contour intervals increases the likelihood that your interval modifications will result in changes to the contour plot.

The contour legend, if active, will include two more intervals than the number you choose. Abaqus/CAE adds intervals at the top and bottom of the legend to indicate any values that exceed the contour plot limits. For more information on the contour legend, see *Customizing the legend*.

This section describes how to customize the contour intervals and how to edit the contour intervals that you use.

1. Locate the **Contour Intervals** options.

   From the main menu bar, select **Options->Contour**; then click the **Basic** tab in the dialog box that appears. The **Contour Intervals** options are on the left side of the page.

2. Choose **Continuous** or **Discrete** to request continuous or discrete contour intervals, respectively.

   Continuous intervals are available only for *banded-type contours*. Abaqus represents your contour values in a smooth, non-delineated color spectrum.

   When you choose **Discrete** intervals, the **Contour Interval** slider becomes available.

3. For **Discrete** intervals, perform the following tasks:

   1. Choose the number of intervals by dragging the **Contour Intervals** slider to the number of intervals (between 2 and 24) that you want.

2. Choose one of the following selections from the **Interval type** list:
   - Select **Uniform** to use an arithmetic progression of values in the contour plot.
   - Select **Log** to use a logarithmic progression of values in the contour plot.
   - Select **User-defined** to use a customized set of values in the contour plot.

3. To customize interval values for the **User-defined** interval type, click .

   The **Edit Intervals** dialog box appears with a default set of contour intervals that you can modify in any of the following ways:
   - Edit any interval value by clicking its row and entering a new value. You must provide interval values in descending order from top to bottom in the dialog box.
   - Click **Insert Before** or **Insert After** to insert another interval before or after the selected interval. New intervals are added without values, so you must supply interval values either by entering them directly in the appropriate row or by interpolating their values.
   - Click **Delete** to remove the selected intervals from the set.
   - Click **Interpolate** to calculate interpolated interval values for all blank intervals in the set. Abaqus/CAE interpolates values using an arithmetic progression.
   - Click **Clear Values** to clear the values for the selected intervals.

   When you have completed your set of contour intervals, click **OK** to close the **Edit Intervals** dialog box.

4. Click **Apply** to implement your changes in the viewport.

   The contours and, if active, the *contour legend* in the current viewport change to reflect the interval options you have selected.

   By default, your changes are saved for the duration of the session and will affect all subsequent contour plots. If you want to retain your changes for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

Plotting analysis results as symbols

A symbol plot shows the magnitude and direction of a particular vector or tensor variable at a specified step and frame of the analysis. In addition, a symbol plot can be used to show the magnitude and direction of attributes such as loads or predefined fields at a specified step of a model in the current model database.
Abaqus/CAE represents the values as symbols (for example, arrows) at locations on your model. This section explains symbol plotting.

In this section:

- *Understanding symbol plotting*
- *Using symbol plot options*
- *Producing a results symbol plot*
- *Producing a symbol plot of free body nodal forces*
- *Customizing symbol plot appearance*

Understanding symbol plotting

Symbol plots allow you to visualize the magnitude and direction of vector and tensor variable results. In addition, a symbol plot can be used to show the magnitude and direction of attributes such as loads or predefined fields at a specified step of a model in the current model database.

Each vector and tensor result value appears as an arrow drawn at the location in the model where the result was obtained or the attribute is located; arrows representing nodal quantities appear at nodes, and arrows representing integration point quantities appear at integration points. (You cannot create a symbol plot of element quantities stored at nodes.)

For example, a symbol plot of the principal stress tensor is shown in *Figure 1*.

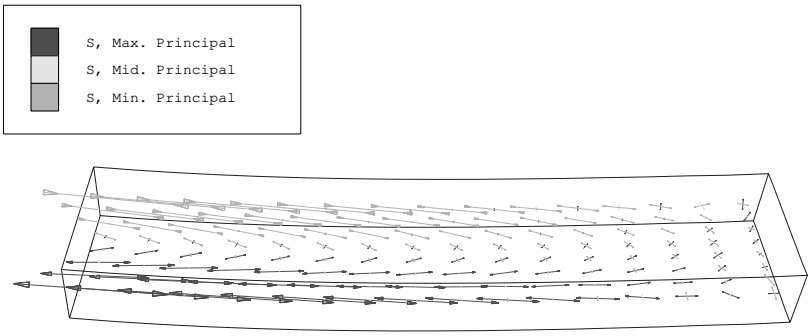

Figure 1: Symbol plot of principal stress.

Symbol plotting behavior changes slightly when you cut through a model using view cuts. If you display a view cut to investigate a symbol plot of a nodal output variable, Abaqus/CAE interpolates values from the nodes closest to the view cut surface and draws these interpolated vector arrows on the view cut surface. Abaqus/CAE performs this interpolation only for nodal output variables and does not perform any interpolation on the cutting surface when you display the portions of the model below the cut or above the cut. For more information on view cut functionality, see *Understanding view cuts*.

The relative sizes of the arrows indicate the magnitude of the result values. The directions of the arrows indicate the global directions of the results. In tensor plots arrows with arrowheads pointing in toward the arrow shaft represent compressive values; arrows with arrowheads pointing out from the arrow shaft represent tensile values.

The symbol plot legend shows you how each arrow color corresponds to a specific range of values. To learn how to display the minimum and maximum values associated with your symbol plot, see *Customizing the legend*.

By default, Abaqus/CAE plots all of a variable's result values in a symbol plot. The maximum value appears as the largest arrow in the plot, and all other arrows are scaled in proportion to that arrow size. However, you can use the **Symbol Plot Options** dialog box to limit the range of values that appear in a plot.

- When you specify a particular maximum value, only arrows representing absolute values less than or equal to that maximum value appear in the plot.

  The largest arrow in the plot will represent the largest absolute result value that is less than or equal to the limit you specify. All other arrows in the plot will be scaled in proportion to that arrow size.
- When you specify a particular minimum value, only arrows representing absolute values greater than that minimum value appear in the plot.

The components of connector vector output are resolved with respect to different coordinate systems depending on whether the output requested is field output or history output. See *Displaying connectors and connector output in the Visualization module* for how to interpret the vector component values in field plots.

Additional information

- *Setting vector and tensor limits*

Using symbol plot options

You can use the symbol plot options to customize the appearance of symbol plots.
For data from an output database, use the ***Symbol Variable*** options in the **Field Output** dialog box to select the vector or tensor quantity and optionally the component to plot.

Note: If you selected a model from the current model databases, symbol plots display the primary variable, not the symbol variable. Changing the symbol variable has no effect unless you plot data from an output database.

Select **Options->Symbol** from the main menu bar or click  in the toolbox to access the **Symbol Plot Options** dialog box. Click the following tabs to customize the appearance of symbol plots in the current viewport:

- **Color & Style**: The **Color & Style** page contains the following tabs:
  - **Vector**: Choose to customize the appearance of arrows that represent resultant values or selected component values of a vector variable.
  - **Tensor**: Choose to customize the appearance of arrows that represent all principal components, all direct components, or selected components of a tensor variable. Tensor arrows can be displayed at the element integration points, centroids, or nodes. If arrows are displayed at the nodes, the scalars are always computed after averaging.
- **Limits**: The **Limits** page contains the following tabs:
  - **Vector**: Choose either to specify the minimum and maximum vector values or to have Abaqus/CAE automatically compute these values.
  - **Tensor**: Choose either to specify the minimum and maximum tensor values or to have Abaqus/CAE automatically compute these values.
- **Labels**: The **Labels** page contains the following tabs:
  - **Vector**: Choose to display numerical labels for the vector values and to customize the color, font, type size, number format, and number of decimal places used for the vector values.
  - **Tensor**: Choose to display numerical labels for the tensor values and to customize the color, font, type size, number format, and number of decimal places used for the tensor values.

Other options such as the render style, edge visibility, deformation scale factor, and translucency are located in the ***Common Plot Options*** dialog box. If you choose to plot symbols on both the undeformed and the deformed shape, you can use the ***Superimpose Plot Options*** to customize the appearance of the undeformed shape. To learn how to customize the render style and other display characteristics of your symbol plot, see *Customizing plot display*. For more information on tensor and field output variables, see *Selecting field output variables*. For more information on selecting the results step, see *Selecting a specific results step and frame*.

Additional information

• *Customizing symbol plot appearance*

Producing a results symbol plot

A symbol plot shows either the magnitude and direction of a vector or tensor variable at a specified step and frame of an output database or the magnitude and direction of model attributes at a specified step of a model in the current model database. Abaqus/CAE represents the values as symbols (for example, arrows) at locations on your model. For more information on tensor and field output variables, see *Selecting field output variables*. For more information on selecting the results step, see *Selecting a specific results step and frame*. To learn how to display the minimum and maximum values associated with your symbol plot, see *Customizing the legend*.

1. *Open the model database or the output database* containing your model data or analysis results.
2. If you are plotting data from a model database, switch to the Visualization module, expand the **Model Database** container of the Results Tree, and select the model you want to use.
3. Select the results *step and frame* to display (or just the step, if the current model database is selected).
4. For output databases, select the *symbol field output variable* to display. For model databases, select the *primary field output variable* as the variable to display.

   The symbol plot state is activated.
5. Select the plot state–independent and symbol plot *customization* options you want.
6. If your chosen field output includes complex numbers, select the ***Complex Form*** tab in the **Result Options** dialog box to control the numeric form to display. This option applies only to plots for output databases.
7. For plots of output database data, select **Plot->Symbols** from the main menu bar to modify whether to plot the symbols on the deformed model shape, the undeformed shape, or both.

   Tip: You can also produce a symbol plot using the deformed , undeformed , or superimposed  symbol tools in the toolbox.

   The current viewport changes to display a customized symbol plot of the specified field output variable at the specified step and frame of the current output database.

   Abaqus automatically refreshes your symbol plot each time you click **Apply** in the step and frame selector dialog box, plot state–independent options, superimpose plot options (if applicable), or symbol plot options dialog boxes.

Additional information

- *Using symbol plot options*

Producing a symbol plot of free body nodal forces

You can create a symbol plot that shows the summation of free body nodal forces at individual nodes in your model. The symbol field output variable FREEBODY is the sum of the individual NFORC*n* components at a node, but with the vector's direction reversed. The FREEBODY output variable also takes into account the displayed elements by default; in contrast, contour plots of NFORC1 consider the whole model.

The FREEBODY symbol plot is a representation of the unbalanced forces acting on the object that is represented by the current display group. This sensitivity to current display group is not exhibited in any other context, such as contour plots.

1. *Open the output database* containing your analysis results with NFORC data included.
2. Select the results *step and frame* to display.
3. If desired, focus in on a subset of your model *using a display group*.
4. Select **FREEBODY** as the *symbol field output variable* to display.

   The symbol plot state is activated.
5. Select the plot state–independent and symbol plot *customization* options you want.
6. From the main menu bar, select **Plot->Symbols** to modify whether to plot the symbols on the deformed model shape, the undeformed shape, or both.

   Tip: You can also produce a symbol plot using the deformed , undeformed , or superimposed  symbol tools in the toolbox.

   The current viewport changes to display a customized symbol plot of free body nodal forces at the specified step and frame of the current output database for the current display group.

   Abaqus automatically refreshes your symbol plot each time you click **Apply** in the step and frame selector dialog box, plot state–independent options, superimpose plot options (if applicable), or symbol plot options dialog boxes.

Additional information

- *Selecting the symbol field output variable*

- *Resultant forces and moments on free body cuts in Abaqus/CAE*

Customizing symbol plot appearance

This section explains how to customize the style of symbol plot vector and tensor arrows, how to choose the quantity to display, and how to control the minimum and maximum values shown in the plot.

To learn how to customize the render style and the underlying model attributes of your symbol plot, see *Customizing plot display*.

In this section:

- *Customizing symbol plot arrows*
- *Setting vector and tensor limits*
- *Customizing vector and tensor labels*

Customizing symbol plot arrows

You can customize the arrow color, maximum arrow length, arrow shaft thickness, and arrowhead appearance for symbol plot vector and tensor arrows. When you customize arrow color for nodal vector symbols, you can select a single color for all arrows in the plot or display arrows with different colors depending on their length. You can use either the size of the model or the size of the screen as the basis for calculations of maximum arrow length.

For tensor symbol plots of element output variables, arrows are typically displayed with three different colors.

1. Locate the vector or tensor **Color & Style** options.

   Select **Options->Symbol** from the main menu bar or click  in the toolbox; then click the **Color & Style** tab in the dialog box that appears.

   - Click the **Vector** tab if you are creating a vector symbol plot.
   - Click the **Tensor** tab if you are creating a tensor symbol plot.

   The options for the symbol type of your choice appear.

2. To display all arrows in the plot with a single color, select **Uniform**, then do one of the following:

   - For a vector plot, click the **Uniform Color** sample , and select the color in which you want the variable or variable component arrows to appear. (For more information, see *Customizing colors*.)
   - For plotting all principal components in a tensor plot, click the color samples labeled **Maximum principal**, **Mid principal**, and **Minimum principal**; and select the colors in which you want each arrow type to appear.
   - For plotting all direct components in a tensor plot, click the color samples labeled **11**, **22**, and **33**; and select the colors in which you want each arrow type to appear.
   - For plotting only one principal or direct component, click the color sample labeled **Color**, and select the color in which you want the component arrows to appear.

3. To display all arrows in the plot using colors that correspond to their length, select **Spectrum**. You can choose one of the predefined color spectrums from the **Spectrum Name** list or define a new spectrum; for more information on selecting and defining a color spectrum, see *Customizing contour colors*, and *Creating a new color spectrum*. You can also drag the **Number of intervals** slider to change the number of intervals available for coloring the various arrows in the symbol plot; for more information about contour interval selection, see *Customizing contour intervals*.
4. Drag the **Size** slider to change the arrow length. The arrow size ranges from 0 to 30; the default arrow size is 6.

   Your selection determines the size of the arrow representing the largest vector or tensor value in the plot. All other vector and tensor arrows in the plot will be scaled to that size.

   Note:

   Abaqus/CAE maintains one size setting for both vectors and tensors; you cannot change the size of one independently of the other.

5. From the **Basis** options, select **Screen size** or **Model size** as the basis for calculations of maximum arrow length. If you select **Screen size**, Abaqus/CAE resizes the arrows as you change the size of the viewport; and if you select **Model size**, Abaqus/CAE resizes the arrows as you zoom in and out.
6. Click the arrow next to the **Thickness** field, and select the arrow shaft thickness of your choice.
7. Click the arrow next to the **Arrowhead** field, and select the arrowhead design of your choice.

8. If you are creating a tensor plot, customize the locations of the tensor arrows so that they are displayed at the **Integration point**, the **Centroid**, or the **Nodal** values for your model.

   Note:

   If you choose the **Nodal** option for tensor variables, the results averaging option **Compute scalars before averaging** is not valid; the scalars are always computed after averaging.

9. If desired, you can display a smaller subset of the arrows in a symbol plot to clarify the presentation of a plot with many arrows. Drag the **Symbol density** slider to a value between **High** and **Low**.
10. Click **Apply** to implement your changes.

    The symbol plot vector or tensor arrows in the current viewport change to reflect your settings.

    By default, your changes are saved for the duration of the session and will affect all subsequent symbol plots. If you want to retain your changes for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

Additional information

- *Customizing colors*
- *Customizing symbol plot appearance*

Setting vector and tensor limits

By default, Abaqus/CAE includes all of a variable's result values in a symbol plot. However, you can use the **Symbol Plot Options** dialog box to limit the range of values that appear in the plot.

When you specify a particular maximum value, only arrows representing values less than or equal to that maximum value appear in the plot. When you specify a particular minimum value, only arrows representing values greater than that minimum value appear in the plot. Changing the maximum or minimum value is also reflected in the symbol plot legend.

To learn how to display the minimum and maximum values associated with your symbol plot, see *Customizing the legend*.

1. Locate the **Limits** options.

   Select **Options**->**Symbol** from the main menu bar or click  in the toolbox; then click the **Limits** tab in the dialog box that appears. Click either the **Vector** tab or the **Tensor** tab; the symbol plot **Limits** options for the variable type of your choice become available.

2. In the area labeled **Max** in the top half of the page, choose one of the following options:

   - Select **Auto-compute** to use the largest result value as the maximum value.
   - Select **Specify** to specify the maximum value yourself; then enter the maximum value of your choice in the **Specify** text field.

3. In the area labeled **Min** in the bottom half of the page, choose one of the following options:

   - Select **Auto-compute** to use the smallest result value as the minimum value.
   - Select **Specify** to specify the minimum value yourself; then enter the minimum value of your choice in the **Specify** text field.

4. Click **Apply** to implement your changes.

   The symbol plot in the current viewport changes to display arrows only for variable values that fall within the limits you have specified.

   By default, your changes to symbol plot options are saved for the duration of the session and will affect all subsequent symbol plots in the current viewport and in any new viewports created from the current viewport. If you want to retain your changes for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

Additional information

- *Understanding symbol plotting*

Customizing vector and tensor labels

You can display a label next to each vector or tensor arrow in a symbol plot that expresses its value in numerical form. You can also customize these labels by changing their color, font, type size, number format, and number of decimal places.

1. Locate the **Labels** options.

   Select **Options->Symbol** from the main menu bar or click  in the toolbox; then click the **Labels** tab in the dialog box that appears. Click either the **Vector** tab or the **Tensor** tab; the symbol plot **Labels** options for the variable type of your choice become available.

2. Toggle on **Display value next to vector symbol** to show vector labels for the selected type of vector.
3. Select the color of the vector labels for the selected type of vector.

   a. Click the **Text color** color sample .

   Abaqus/CAE displays the **Select Color** dialog box.

   b. Use one of the methods in the **Select Color** dialog box to select a new color. For more information, see *Customizing colors*.

   c. Click **OK** to close the **Select Color** dialog box.

4. Select the font of the vector labels for the selected type of vector.

   a. Click **Set Font**.

   Abaqus/CAE displays the **Select Font** dialog box.

   b. Use one of the methods in the **Select Font** dialog box to select a new font, size, and style. For more information, see *Customizing fonts*.

   c. Click **OK** to close the **Select Font** dialog box.

5. To change the format of the vector labels for the selected vector type, click the **Number Format** arrow and select one of the following formats:

   - Select **Scientific** to display legend values in scientific notation, which expresses legend values as a decimal value between 1 and 10 multiplied by a power of 10. When you select this format for the number `501,000`, the value appears in the legend as `5.01e5`.
   - Select **Fixed** to display legend values without using exponent values. When you select this format, the number `501,000` is displayed in the legend as `501000.00`.
   - Select **Engineering** to select engineering notation, which expresses values in a similar format to scientific notation but allows exponent values that are multiples of three only. When you select this format, the number `501,000` is displayed in the legend as `501E3`.

6. Click the **Decimal places** arrows to specify the desired number of decimal places in each label.
7. Click **Apply** to implement your changes.

   The symbol plot in the current viewport changes to display labels with your selected formatting.

   By default, your changes to symbol plot options are saved for the duration of the session and will affect all subsequent symbol plots in the current viewport and in any new viewports created from the current viewport. If you want to retain your changes for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

• *Understanding symbol plotting*

Plotting material orientations

A material orientation plot shows the material directions of elements in the model at the element integration points.

The material orientations are plotted at a specified step and frame of the analysis and at a specified section point for shell elements. Material orientation plots can also be created to show the material directions of reinforcements (rebar orientation) in membrane, shell, and surface elements. Abaqus/CAE represents the material orientations as triads. This section explains material orientation plotting.

In this section:

- *Understanding material orientation plotting*
- *Using material orientation plot options*
- *Producing a material orientation plot*
- *Customizing material orientation plot triads*

Understanding material orientation plotting

Material orientation plots allow you to visualize the material directions of the elements in your model.

Abaqus/CAE draws a triad at the element integration points to indicate the material orientation. For example, a material orientation plot is shown in *Figure 1*.

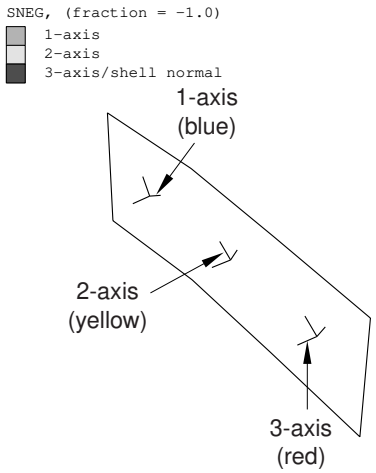

Figure 1: Material orientation plot.

Material orientations are available only for those elements for which field output is requested at the selected section points. Valid elements include all shell elements, as well as solid elements for which you have defined a local orientation. The material orientations are displayed at the current step and frame of the analysis and at the current section point selection for shell elements. If display is enabled for both the top and bottom section point locations, Abaqus/CAE displays material orientations for the bottom location only. For small-strain shell elements the material orientations do not rotate with the deformation of the model (see *About Shell Elements*, for more information). Material orientation plots can also be created for reinforcement layers in membrane, shell, and surface elements.

Additional information

• *Selecting section point data by category*

Using material orientation plot options

You can use the material orientation plot options to customize the appearance of material orientation triads.

Select **Options->Material Orientation** from the main menu bar or click  in the toolbox to access the **Material Orientation Plot Options** dialog box. Use the options in the dialog box to control the visibility, color, length, thickness, and arrow appearance of the material orientation triad axes.

Other options such as the render style, edge visibility, deformation scale factor, and translucency are located in the ***Common Plot Options*** dialog box. If you choose to plot material orientations on both the undeformed and the deformed shape, you can use the ***Superimpose Plot Options*** to customize the appearance of the undeformed shape. For more information on customizing a superimposed plot, see *Superimposing deformed and undeformed model plots*. To learn how to customize the render style and other display characteristics of your material orientation plot, see *Customizing plot display*. For more information on selecting the results step, see *Selecting a specific results step and frame*. For more information on selecting section point locations, see *Selecting section point data by category*.

Additional information

- *Customizing material orientation plot triads*

Producing a material orientation plot

A material orientation plot shows the material directions of the elements in a model at a specified step and frame and a specified section point. Abaqus/CAE represents the material orientations as triads at the element integration points. For more information on selecting the results step, see *Selecting a specific results step and frame*. For more information on selecting section point locations, see *Selecting section point data by category*.

1. *Open the output database* containing your analysis results.
2. Select the results *step and frame* to display.
3. Select the *section point* to display.
4. Select the plot state–independent and material orientation plot *customization* options you want.
5. From the main menu bar, select **Plot->Material Orientations** and choose whether to plot the material orientations on the undeformed shape, the deformed shape, or both.

   Tip: You can also produce a material orientation plot using the deformed , undeformed , or superimposed  material orientation tools in the toolbox.

   The current viewport changes to display a customized material orientation plot.

   Abaqus automatically refreshes your material orientation plot each time you click **Apply** in the step and frame selector, section point selector, plot state–independent options, superimpose plot options (if applicable), or material orientation plot options dialog boxes.

Additional information

- *Using material orientation plot options*

Customizing material orientation plot triads

This section explains how to customize the style of material orientation plot triads.

To learn how to customize the render style and the underlying model attributes of your material orientation plot, see *Customizing plot display*.

You can customize the color, length, thickness, and arrowhead appearance of the material orientation plot triad axes. You can also suppress the appearance of one or more of the triad axes; and for results with composite sections, you can display results using either the material orientation of the entire layup or one of its individual plies.

1. Select **Options->Material Orientation** from the main menu bar or click  in the toolbox.

   The triad options appear.
2. Toggle on the buttons to the left of each of the axes to display or suppress them.
3. Click on the color samples to select the color or colors of your choice for the visible triad axes in the plot.
4. Drag the **Size** slider to increase or decrease the length of the axes in the material orientation triads in your plot. Axis length ranges from 0 to 30; the default length is 6.

   Note:

   You can specify an axis length value larger than 30 by using the Abaqus Scripting Interface. See *Using the Python interpreter*.
5. From the **Basis** options, select **Screen size** or **Model size** as the basis for calculations of axis length in material orientation triads. If you select **Screen size**, Abaqus/CAE resizes the triads as you change the size of the viewport; and if you select **Model size**, Abaqus/CAE resizes the triads as you zoom in and out.
6. Click the arrow next to the **Thickness** field, and select the axis thickness of your choice.
7. Click the arrow next to the **Arrowhead** field, and select the arrowhead design of your choice.
8. If desired, you can display a smaller subset of the material orientation triads to clarify the presentation of a plot with many triads. Drag the **Symbol density** slider to a value between **High** and **Low**.
9. Material orientation based on the SORIENT output variable is plotted when **Section / Layup** is selected. If your results include field output from the SORIENT output variable and output from elements with composite sections, specify the material orientation you want to use. Select **Material / Ply** to display each ply with its own material orientation, or select **Section / Layup** to display the entire composite layup using the orientation specified in the composite layup definition.
10. Click **Apply** to implement your changes.

    The material orientation plot triads in the current viewport change to reflect your settings.

    By default, your changes are saved for the duration of the session and will affect all subsequent material orientation plots. If you want to retain your changes for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

X–Y plotting

This chapter explains the concept of *X–Y* plotting and gives details of how to create *X–Y* data objects and how to produce and customize an *X–Y* plot.

In this section:

- *Understanding X–Y plotting*
- *Specifying and saving X–Y data objects*
- *Producing an X–Y plot*
- *Operating on saved X–Y data objects*
- *Customizing X–Y plot axes*
- *Customizing X–Y curve appearance*
- *Customizing X–Y plot appearance*
- *Customizing the X–Y plot title*
- *Customizing the appearance of the X–Y plot legend*
- *Customizing border and fill colors for an X–Y plot*

Understanding X–Y plotting

An *X–Y* data object is a two-dimensional array of data that Abaqus/CAE stores in two columns. You can display *X–Y* data as a graph in an *X–Y* plot or as a table in an *X–Y* report. In addition, you can probe an *X–Y* plot to display the *X*- and *Y*-coordinates of graph points. This section discusses *X–Y* data objects and the various methods you can use to create them. For more information on *X–Y* reports, see *Generating tabular data reports*; for information on probing *X–Y* plots, see *Probing the model*.

In this section:

- *What is an X–Y data object, and what is an X–Y plot?*
- *Understanding how to specify an X–Y data object*
- *Understanding "Temp" and other X–Y data object names*
- *Understanding quantity types*

What is an X–Y data object, and what is an X–Y plot?

An *X*–*Y* data object is a collection of ordered pairs that Abaqus/CAE stores in two columns—an *X*-column and a *Y*-column. The *X*–*Y* data can originate from an output database or an ASCII file, or you can enter the data using the keyboard. In addition, you can derive *X*–*Y* data by combining existing *X*–*Y* data objects. For example, you might combine an *X*–*Y* data object containing stress values versus time with a second *X*–*Y* data object containing strain values versus time to produce an *X*–*Y* data object containing stress versus strain at equivalent times. You can save *X*–*Y* data objects; and you can edit, copy, rename, and delete them.

By default, the *X*–*Y* data objects you save are retained for the duration of the session only. If you want to make *X*–*Y* data objects available for subsequent sessions, you can save them to an XML file, to the model database, or to an output database using the **File->Save Session Objects** option; or you can copy them to an output database file using the **Copy to ODB** button in the **XY Data Manager**.

Abaqus/CAE can display *X*–*Y* data in the form of an *X*–*Y* plot. An *X*–*Y* plot is a two-dimensional graph of one variable versus another. Examples of *X*–*Y* plots include temperature versus time, load versus displacement, and stress versus strain. You can display multiple *X*–*Y* data objects in one *X*–*Y* plot, and you can use the customization options to control the appearance of each data object and the overall appearance of the components of an *X*–*Y* plot. These components include the axes; the legend, which is a key that associates each *X*–*Y* curve in the plot with the *X*–*Y* data object it represents; and the *X*–*Y* curves. *Figure 1* shows an *X*–*Y* plot displaying three *X*–*Y* data objects.

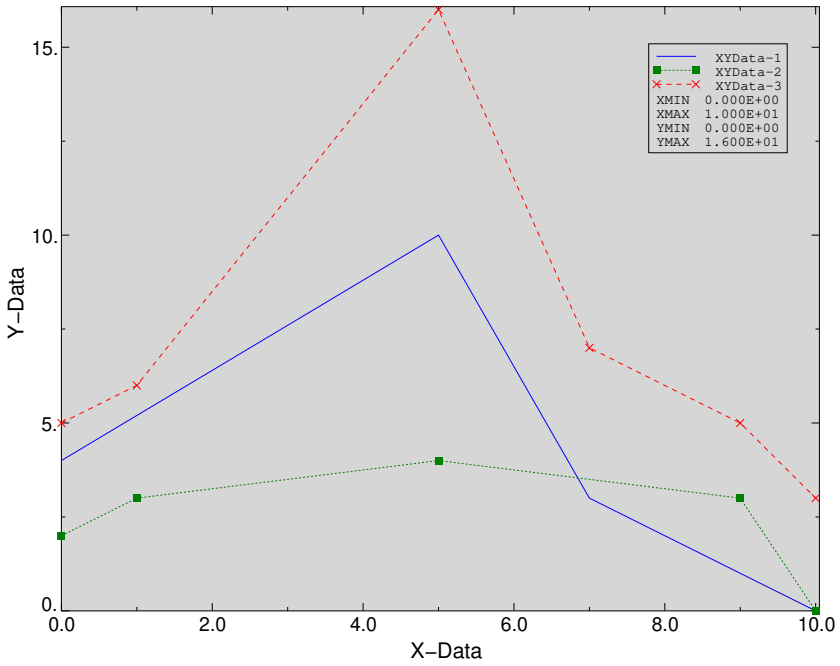

Figure 1: X–Y plot displaying three objects of data.

- *Copying a session X–Y data object to an output database file*

Understanding how to specify an X–Y data object

To specify an *X–Y* data object, you first choose the source of the data and then provide any necessary details. Possible sources are:

ODB history output

Select this method to specify an *X–Y* data object by reading history output results from an output database. You can specify which variables to read from the output database, from which steps of the analysis to read, and the frequency at which to read the data; for example, you can read every third data point. You can also specify a numeric form for any complex-valued output data. For more information, see *Reading X–Y data from output database history output*.

ODB field output

Select this method to specify an *X–Y* data object by reading field output results from an output database. You can specify which variables to read from the output database and for which elements or nodes to read the data. Abaqus/CAE extracts results from the currently active steps and frames; see *Activating and deactivating steps and frames*, for more information. You can also specify a numeric form for any complex-valued output data. For more information, see *Reading X–Y data from output database field output*.

Thickness

Select this method to specify an *X–Y* data object by reading field output results from elements through the thickness of a shell region of your model. Abaqus/CAE extracts results from the current step and frame. You can specify which variables to read from the output database and for which elements to read the data. For more information, see *Reading X–Y data through the thickness of a shell*.

Free body

Select this method to specify an *X–Y* data object by reading field output results from all active free bodies in your session. Abaqus/CAE extracts results from the current step and frame and displays results for the nodal force (NFORC) output variable. For more information, see *Reading X–Y data from all active free body cuts*.

Operate on X–Y data

Select this method to derive a new *X–Y* data object by manipulating previously saved *X–Y* data objects. You specify the new *X–Y* data object by applying functions and mathematical operations to existing data. An example of a function is **Combine**. If you **Combine** an *X–Y* data object containing stress versus time with an *X–Y* data object containing strain versus time, you produce an *X–Y* data object containing stress versus strain at equivalent times. For more information, see *Operating on saved X–Y data objects*.

ASCII file

Select this method to read *X*- and *Y*-values from an existing text file. The file can contain more than two columns of data, separated by commas, spaces, or tabs; and you can specify which columns correspond to the *X*- and *Y*-axis data. In addition, you can specify the frequency at which the data should be read from the file; for example, every third row. For more information, see *Reading X–Y data from an ASCII file*.

Keyboard

Select this method to manually type *X*- and *Y*-values into a simple table editor. Within this method, Abaqus supports several special editing techniques, as well as an option to read data from a file. For more information on this topic, see *Entering X–Y data from the keyboard*.

Path

Select this method to specify an *X–Y* data object by reading field output results at locations along a path through your model. Abaqus obtains results from an output database. You can specify the points, elements, or edges that make up the path and the step, frame, and variable for which to obtain results. For more information, see *Viewing results along a path*.

In addition, you can create an *X–Y* data object while using the table editor to create a material in the Property module. For more information, see *Entering tabular data*.

Once you have specified your *X–Y* data object, you can save it or you can display it in the form of an *X–Y* plot. Saving the *X–Y* data object allows you to subsequently plot, edit, rename, delete, or operate on it; it also allows you to copy the *X–Y* data object to an output database file for use in later Abaqus sessions. For *X–Y* data originating from sources other than output database history output, you must save your data to later produce an *X–Y* plot containing multiple data objects. Saved *X–Y* data objects are retained only for the duration of the session. For the *X–Y* data object to be persistent across sessions, you must copy it to an output database file.

If you have copied an *X–Y* data object to your output database file during an earlier session, you can access that object when you open the file in the current session. You can display the *X–Y* data object in the form of an *X–Y* plot, just as you can any other specified objects. To edit, rename, delete, or operate on a data object that was created in a previous session, you must load it to the current session.

Understanding “Temp” and other X–Y data object names

By default, when you save or plot an *X–Y* data object, Abaqus/CAE names it for you. This name is an important means of identifying and referring to the *X–Y* data object.

X–Y data object names appear in the following instances:

- When you plot *X–Y* data, the *X–Y* plot legend identifies by name all *X–Y* data objects appearing in the plot.
- When you select **Tools->XY Data** from the main menu bar, the **Manager**, **Edit**, **Copy**, **Rename**, **Delete**, and **Plot** tools list all *X–Y* data objects created during the session by name.
- When you *customize the appearance of the curve* representing an *X–Y* data object, you first select the *X–Y* data object by name from those listed in the **XY Curve Options** dialog box.

In most cases Abaqus/CAE is able to provide a meaningful default name for your *X–Y* data object. As you save your *X–Y* data object, Abaqus/CAE shows you the default name and gives you an opportunity to override this default with the name of your choice. Once saved, you can provide a new name for your *X–Y* data object at any time by renaming it. For information on renaming, see *Managing objects using manager dialog boxes*.

There are three basic forms of *X–Y* data object names, as follows:

Temp-*n*

If you produce an *X–Y* plot by clicking **Plot** from any of the following dialog boxes:

- **XY Data from ASCII File**
- **XY Data from Keyboard**
- **XY Data from Path**
- **Plot Expression** from the **Operate on XY Data** dialog box

Abaqus/CAE names your *X–Y* data according to the pattern **Temp-1**, **Temp-2**, etc. This name indicates that the plot represents the data configured in the dialog box, which is considered temporary data whether or not you have clicked **Save As** to save it.

Conversely, if **Temp-***n* appears in your plot legend, you are plotting temporary data. You cannot edit, copy, rename, delete, operate on, or produce a report of temporary data. To accomplish any of these tasks, you must first save your data. You can select curve style preferences for temporary data, but the curve styles will revert to the defaults if you replot the data without having saved it. To learn how to save your data, see *Saving an X–Y data object*.

XYData-*n*

If you create a new *X–Y* data object using the **Save As** button provided in the **XY Data from ASCII File** or **XY Data from Keyboard** dialog boxes, Abaqus/CAE suggests a default name for your *X–Y* data according to the pattern **XYData-1**, **XYData-2**, etc. To establish a more meaningful name, you can use the **Save XY Data As** dialog box to overwrite this default with the name of your choice.

To locate the **XY Data from ASCII File** or **XY Data from Keyboard** dialog boxes, select **Tools->XY Data->Create** from the main menu bar; then click the choice of interest in the dialog box that appears, and click **Continue**.

Meaningful names

You can establish a meaningful name (a name of your choice) for your *X–Y* data object either by specifying a name as you save your data or by subsequently renaming it. As you save your data, Abaqus/CAE displays the

default name in the **Save XY Data As** dialog box; you can overwrite this default. Abaqus/CAE generates meaningful default names for *X–Y* data created from the **History Output** or **XY Data from ODB Field Output** dialog boxes.

Understanding quantity types

A quantity type is a category that describes the data in one of the columns of an *X–Y* data object. Abaqus/CAE includes over eighty predefined quantity types that describe the output of every variable in Abaqus, including commonly used types like temperature, time, stress, and strain. The quantity types associated with each column appear in *X–Y* reports and as the default axis labels in an *X–Y* plot of that data object.

When you create an *X–Y* data object from field output data or history output data, Abaqus/CAE automatically uses the quantity types specified in the output database. When you create an *X–Y* data object by loading data from an ASCII file or by entering data directly from the keyboard, you can specify quantity types for each column as you create the object. In either case, you can change the quantity types associated with either column by editing the data object in the **Edit XY Data** dialog box.

Specifying and saving X–Y data objects

This section explains the various methods of specifying and saving *X–Y* data objects. *X–Y* data objects can originate from analysis results, an external file, keyboard entry, or operations on previously saved *X–Y* data objects.

For information on specifying *X–Y* data objects by obtaining field output results along a path through your model, see *Viewing results along a path*; for information on specifying *X–Y* data objects by operating on existing *X–Y* data, see *Operating on saved X–Y data objects*.

In this section:

- *Reading X–Y data from output database history output*
- *Reading X–Y data from output database field output*
- *Reading X–Y data through the thickness of a shell*
- *Reading X–Y data from all active free body cuts*
- *Reading X–Y data from an ASCII file*
- *Entering X–Y data from the keyboard*
- *Saving an X–Y data object*
- *Copying a session X–Y data object to an output database file*
- *Loading an X–Y data object to the current session*
- *Editing individual data points in an X–Y data object*

Reading X–Y data from output database history output

You can read *X*–*Y* data from history output in the output database. Available data consist of history output that were saved during the analysis.

From this output, you can select the following:

- a variable at a location—for example, U1 (displacement in the *X*-direction) at node 1;
- the step or steps of interest;
- a pattern of frames within those steps—for example, every 10th frame; and
- the time basis.

Abaqus/CAE then reads *X*–*Y* data pairs from the output database at the frames you specify. If you select multiple variables, Abaqus/CAE reads the data pairs and creates a separate *X*–*Y* data object for each variable by default. When you save history output variables, you can choose to operate on the data first; Abaqus/CAE saves the results of the operation as a new *X*–*Y* data object.

For time-based analyses, *X*-values are taken as total time from the start of the analysis or, in the case of a restarted analysis, as total time from the start of the last continuation of the analysis. Alternatively, you can use the step time as the time basis. *Y*-values are taken as the value at that time of the variable at the location you specify.

History output from an Abaqus/Standard analysis is available after 10 increments are written to the output database; history output from an Abaqus/Explicit analysis is available after 100 increments are written to the output database or after an Abaqus/Explicit heartbeat is triggered based on CPU time, whichever occurs first.

1. Locate the **History Output** options.

   Select **Tools->XY Data->Create** from the main menu bar, then choose **ODB history output**.

   Tip: You can also specify history output by selecting **Result->History Output** from the main menu bar.

   The **History Output** dialog box appears.

   Note:

   The **History Output** dialog box lists all history output saved during the analysis, giving the variable name and the location at which it was saved. If this list is empty, history output is not available.

2. Click the **Variables** tab, if it is not already selected. Select one or more variables that you want to read. Variables are listed alphabetically along with their locations. The default is to read the first entry in the list. For more information on selecting multiple items in dialog boxes, see *Selecting multiple items from lists and tables*.

   If your output database contains many history output variables, you can use the filter to reduce the number of output variable names displayed. Click next to the **Name filter** field to see examples of valid filtering syntax.

   The specified variable and location are highlighted.

3. If viewport linking is activated, you can toggle on **Show common list between linked viewports** to display only the variables that are common to all linked viewports.

4. Click **Steps/Frames** to change the steps, frames, or time basis from which Abaqus/CAE reads *X*–*Y* data. For more information, see *Activating and deactivating steps and frames*.

5. If the data include complex numbers, you can select the displayed form using the **Result Options** dialog box. For more information on complex number forms in Abaqus/CAE, see *Controlling the form of complex results*.
6. To evaluate and display the data, click **Plot**.

   An *X–Y* plot appears in the current viewport. The plot represents the data you have configured in the dialog box, which Abaqus considers temporary data whether or not you have clicked **Save As** to save it.
7. To save the data you have configured, click **Save As**. Any complex data are saved as the current complex form, not as complete complex numbers.

   Note:

   To plot saved *X–Y* data, select **Tools->XY Data->Plot** from the main menu bar and choose the *X–Y* data from the pull-right menu.

   In the **Save XY Data As** dialog box that appears, you can perform any of a number of mathematical, trigonometric, logarithmic, exponential, or other operations on the data before saving (see *Saving an X–Y data object*, for more information).
8. When you have finished, click **Dismiss** to close the **History Output** dialog box.

Additional information

- *Understanding "Temp" and other X–Y data object names*
- *Controlling the form of complex results*
- *Linking viewports*

Reading X–Y data from output database field output

You can read *X–Y* data from field output in the output database.

Available data consist of field output that were saved during the analysis. From this output, you can select the following:

- a variable at an output position—for example, S11 (stress in the 11-direction) at integration points; and
- a single location or a set of locations (elements or nodes).

Abaqus/CAE then reads *X–Y* data pairs from the output database at the currently active steps and frames. If you select multiple variables or multiple locations, Abaqus/CAE reads the data pairs and creates a separate *X–Y* data object for each variable/location pair. For all time-based analyses, *X*-values are taken as total time from the start of the analysis. *Y*-values are taken as the corresponding values of the variable at the specified location.

Element-based field data extracted at nodes are controlled by the current settings for result averaging. However, if you requested the unique nodal position, then result averaging is always 100% to obtain unique values at the nodes. For more information, see *Understanding result value averaging*.

When reading the *X–Y* data for element-based field output at any output position, Abaqus/CAE reads the field values from the specified position if the same position is available in the output database.

1. Locate the **XY Data from ODB Field Output** options.

   Select **Tools->XY Data->Create** from the main menu bar, then choose **ODB field output**.

   The **XY Data from ODB Field Output** dialog box appears.

   Note: The **XY Data from ODB Field Output** dialog box lists all field output saved during the analysis (except quaternion variables). If this list is empty, field output is not available.

2. Click the **Position** arrow to reveal possible positions at which to list variables for your selection; then choose the desired position.

   The list of variables is refreshed to show only those that can be read at the selected position.

3. Select the field output variables to be read using either the check box next to each variable in the list or the **Edit** text field at the bottom of the page.

   ### To use the check box method:

   1. To select a variable and all of its components, click that variable's check box.
   2. To choose among the individual components of a variable, click the arrow next to that variable's check box to list its components; then click individual component check boxes to select them.

   ### To use the edit method:

   In the **Edit** text field, enter the names of the variables and components to be read. To be valid, a variable must be available on the output database for the current position.

4. Click the **Elements/Nodes** tab.

   The **Elements/Nodes** options appear.

5. From the **Item** list at the upper left of the dialog box, select either **Elements** or **Nodes**.

   Abaqus refreshes the **Selection Method** list at the bottom of the dialog box and the item list at the right.

6. Select the specific elements or nodes for which to read output data.

   - To specify elements or nodes by picking them directly from the viewport:

     1. Choose **Pick from viewport** from the **Selection Method** list.

        Abaqus/CAE enters the pick mode. **Select *items* for the display group** (where *items* are elements or nodes) appears in the prompt area.

     2. Select one or more items from the viewport (for more information, see *Selecting objects within the viewport*"). The items are highlighted in the viewport.

        Note:

        If you click **Done** in the prompt area, Abaqus/CAE exits the pick mode and your selections disappear; you must choose a **Selection Method** from the list.

   - To specify elements or nodes by number:

     1. Choose **Element labels** or **Node labels** from the **Selection Method** list.

        The **Part instance** and **Labels** fields appear.

     2. Select the name of the part instance for which you are obtaining results from the list in the **Part instance** field. Type into the **Labels** field a list of element or node numbers separated by commas or a range of numbers such as 1:4.

     3. Verify your selection by clicking **Highlight Items in Viewport**.

   - To specify elements or nodes by set name:

     1. Choose **Element sets** or **Node sets** from the **Selection Method** list.

        Abaqus refreshes the item list at the right. If this list is empty, there are no items that meet your selection criteria.

        Note:

        This list does not include the internal sets generated by Abaqus/CAE.

     2. Select one or more set names from the item list. (For more information, see *Selecting multiple items from lists and tables*.) If your model contains many sets, you can use the filter to reduce the number of set names displayed. Click  next to the **Filter** field to see examples of valid filtering syntax.

     3. Verify your selection by toggling **Highlight items in viewport**.

   - To specify elements or nodes belonging to internal sets (sets created by Abaqus/CAE):

     1. Choose **Internal sets** from the **Selection Method** list.

        Abaqus refreshes the item list at the right. If this list is empty, there are no items that meet your selection criteria.

     2. Select one or more set names from the item list. (For more information, see *Selecting multiple items from lists and tables*.) If your model contains many internal sets, you can use the filter to reduce the number of set names displayed. Click  next to the **Filter** field to see examples of valid filtering syntax.

     3. Verify your selection by toggling **Highlight items in viewport**.

The following table summarizes the restrictions that exist on the availability of element or node data for the output position specified on the **Variables** page:

Output position	Available for
Integration point	Elements
Centroid	Elements
Element nodal	Elements or nodes
Unique nodal	Nodes

7. Click **Active Steps/Frames** to change the steps or frames from which Abaqus/CAE reads *X–Y* data. For more information, see *Activating and deactivating steps and frames*.
8. If the data include complex numbers, you can select the displayed form using the **Result Options** dialog box. For more information on complex number forms in Abaqus/CAE, see *Controlling the form of complex results*.
9. To evaluate and display the data, click **Plot**.

   An *X–Y* plot appears in the current viewport. The plot represents the data you have configured in the dialog box, which Abaqus considers temporary data whether or not you have clicked **Save** to save it.
10. To save the data you have configured, click **Save**. Any complex data are saved as the current complex form, not as complete complex numbers.

    Note:

    To plot your saved *X–Y* data, select **Tools->XY Data->Plot** from the main menu bar and choose the *X–Y* data from the pull-right menu.
11. When you have finished, click **Dismiss** to close the dialog box.

Additional information

- *Saving an X–Y data object*
- *Understanding "Temp" and other X–Y data object names*
- *Controlling the form of complex results*

Reading X–Y data through the thickness of a shell

You can read *X–Y* data from field output data that are stored in the elements through the thickness of a shell or composite solid region of your model. Available data consist of field output that were saved during the analysis. From this output, you can select the following:

- a variable at an output position—for example, S11 (stress in the 11-direction) at integration points; and
- a single element or a set of elements.

Abaqus/CAE then reads *X–Y* data pairs from the output database at the current step and frame. If you select multiple variables or multiple locations, Abaqus/CAE reads the data pairs and creates a separate *X–Y* data object for each variable/location pair. *Y*-values are taken as the thickness through the model. *X*-values are taken as the corresponding values of the variable at the specified location.

1. Locate the **Thickness** options.

   Select **Tools->XY Data->Create** from the main menu bar, then choose **Thickness**.

   The **XY Data from Shell Thickness** dialog box appears.

   Note:

   The **XY Data from Shell Thickness** dialog box lists all field output saved during the analysis (except quaternion variables). If this list is empty, field output is not available.

2. Click the **Position** arrow to reveal possible positions at which to list variables for your selection; then choose the desired position.

   The list of variables is refreshed to show only those that can be read at the selected position.

3. Select the field output variables to be read using either the check box next to each variable in the list or the **Edit** text field at the bottom of the page.

   ### To use the check box method:

   1. To select a variable and all of its components, click that variable's check box.
   2. To choose among the individual components of a variable, click the arrow next to that variable's check box to list its components; then click individual component check boxes to select them.

   ### To use the edit method:

   In the **Edit** text field, enter the names of the variables and components to be read. To be valid, a variable must be available in the output database for the current position.

4. Click the **Elements** tab.

   The **Elements** options appear.

5. Select the specific elements for which to read output data.

   - To specify elements by picking them directly from the viewport:

     1. Choose **Pick from viewport** from the **Selection Method** list.

        Abaqus/CAE enters the pick mode. **Select elements for the display group** appears in the prompt area.

2. Select one or more elements from the viewport (for more information see *Selecting objects within the viewport*"). The elements are highlighted in the viewport.

   Note:

   If you click **Done** in the prompt area, Abaqus/CAE exits the pick mode and your selections disappear; you must choose a **Selection Method** from the list.

- To specify elements by number:

  1. Choose **Element labels** from the **Selection Method** list.

     The **Part instance** and **Element Labels** fields appear.

  2. Select the name of the part instance for which you are obtaining results from the list in the **Part instance** field. Type into the **Element Labels** field a list of element numbers separated by commas or a range of numbers such as 1:4.
  3. Verify your selection by clicking **Highlight Items in Viewport**.

- To specify elements by set name:

  1. Choose **Element sets** from the **Selection Method** list.

     Abaqus refreshes the item list at the right. If this list is empty, there are no items that meet your selection criteria.

     Note:

     This list does not include the internal sets generated by Abaqus/CAE.

  2. Select one or more set names from the item list. (For more information, see *Selecting multiple items from lists and tables*.) If your model contains many sets, you can use the filter to reduce the number of set names displayed. Click  next to the **Filter** field to see examples of valid filtering syntax.
  3. Verify your selection by toggling **Highlight items in viewport**.

- To specify elements belonging to internal sets (sets created by Abaqus/CAE):

  1. Choose **Internal sets** from the **Selection Method** list.

     Abaqus refreshes the item list at the right. If this list is empty, there are no items that meet your selection criteria.

  2. Select one or more set names from the item list. (For more information, see *Selecting multiple items from lists and tables*.) If your model contains many internal sets, you can use the filter to reduce the number of set names displayed. Click the **Tip** button next to the **Filter** field to see examples of valid filtering syntax.
  3. Verify your selection by toggling **Highlight items in viewport**.

6. If the data include complex numbers, you can select the displayed form using the **Result Options** dialog box. For more information on complex number forms in Abaqus/CAE, see *Controlling the form of complex results*.
7. To evaluate and display the data, click **Plot**.

An *X–Y* plot appears in the current viewport. The plot represents the data you have configured in the dialog box, which Abaqus considers temporary data whether or not you have clicked **Save** to save it.

8. To save the data you have configured, click **Save**. Any complex data are saved as the current complex form, not as complete complex numbers.

   Note:

   To plot your saved *X–Y* data, select **Tools->XY Data->Plot** from the main menu bar and choose the *X–Y* data from the pull-right menu.

9. When you have finished, click **Dismiss** to close the dialog box.

Additional information

- *Saving an X–Y data object*
- *Understanding "Temp" and other X–Y data object names*
- *Composite layups*

Reading X–Y data from all active free body cuts

You can read *X–Y* data from all the active free body cuts defined in your session. The data available for selection include the following:

- data from forces, moments, and heat flow rate; and
- if you select forces or moments, the resultant magnitude and the individual components in the 1-, 2-, and 3-directions; and
- if you select heat flow rate (valid only for free body cuts based on view cuts), the resultant magnitude.

Abaqus/CAE then computes *X–Y* data pairs by performing free body calculations at all pertinent time frames and creates *X–Y* data objects showing force, moment, or heat flow rate data against time. A separate *X–Y* data object is created for every force or moment and component combination you select; if you toggle on both the force and moment options and all four component options, Abaqus/CAE creates eight *X–Y* data objects for each active free body cut in your session. You can activate and deactivate free body cuts in the **Free Body Cut Manager**; for more information, see *Displaying, hiding, and highlighting free body cuts*.

1. Locate the **Free body** options.

   Select **Tools->XY Data->Create** from the main menu bar, and choose **Free body**.

   The **XY Data from Free Body** dialog box appears.
2. Click **Active Steps/Frames** to change the steps or frames from which Abaqus/CAE reads *X–Y* data. For more information, see *Activating and deactivating steps and frames*.
3. From the **Entity** options, toggle on **Force**, **Moment**, **Heat Flow Rate**, or all of these options to display *X–Y* data for the selected entity or entities. The **Heat Flow Rate** option is valid only for free body cuts based on view cuts.
4. From the **Force/Moment Components** options, toggle on the vector components that you want to include in the *X–Y* data set for forces and moments. Options include the resultant magnitude and the individual component values in each direction. For heat flow rate, only the resultant magnitude is included.
5. To evaluate and display the data, click **Plot**.

   An *X–Y* plot of the data you have configured in the dialog box appears in the current viewport.
6. To save the data you have configured as one or more *X–Y* data objects, click **Save**. *X–Y* data objects are saved only for the current session.

   Note:

   To plot your saved *X–Y* data, select **Tools->XY Data->Plot** from the main menu bar, and select the *X–Y* data from the menu.
7. When you have finished, click **Dismiss** to close the dialog box.

Additional information

- *Saving an X–Y data object*
- *Understanding "Temp" and other X–Y data object names*
- *Displaying, hiding, and highlighting free body cuts*

Reading X–Y data from an ASCII file

You can read *X*–*Y* data from an ASCII text file that contains columns of numerical data separated by commas, tabs, or spaces.
The file can contain more than two columns of data; you can specify which columns (fields) correspond to the *X*- and *Y*-axis data. You can also specify which rows of data to read from the file.

1. Locate the **XY Data from ASCII File** options:

   From the main menu bar, select**Tools->XY Data->Create**. Click **ASCII file** in the dialog box that appears; then click **Continue**.

   Tip: You can also specify *X*–*Y* data by clicking **Create** in the **XY Data Manager** or by using the  tool in the toolbox.

   The **XY Data from ASCII File** dialog box appears.

2. Enter the name of your ASCII file in one of the following ways:

   - Type the name into the **File** window at the top of the dialog box, or
   - Click **Select** to filter and browse existing file names.

     The **ASCII File Selection** dialog box appears.

     Filter and browse existing files. When you locate the file you want, click the name to select it; then click **OK**.

3. Specify which columns of the file to read. Columns can be separated by spaces, tabs, or commas. Multiple consecutive spaces, tabs, and/or commas are interpreted as a single field delimiter.
   a. To specify the column within the file to read as *X*-values, enter an integer in the **Read X values from field** box. The default is field 1, the first column.
   b. To specify the column within the file to read as *Y*-values, enter an integer in the **Read Y values from field** box. The default is field 2, the second column.

4. To assign quantity types to the values in the *X*- or *Y*-columns, expand the **Quantity Types** list for the **X** or **Y** column and select quantity types from the lists that appear.

5. Specify which rows of the file to read; the default is all rows.

   - Click **Read all** to read every row of the file, or
   - Click **Skip**; then enter the number of file rows to skip in the **rows between reads** box. A value of 0 means read all rows; a value of 1 means read every other row. Reading always begins with the first row.

6. To evaluate and display the data, click **Plot**.

   An *X*–*Y* plot appears in the current viewport. The plot represents the data you have configured in the dialog box, which Abaqus considers temporary data whether or not you have clicked **Save As** to save it.

7. To save the data you have configured, click **Save As**.

   Note: *X*–*Y* data objects have a precision of six significant digits; therefore, only six significant digits are retained when you save an *X*–*Y* data object.

   To plot your saved *X*–*Y* data object, select **Tools->XY Data->Plot** from the main menu bar and choose the *X*–*Y* data object from the pull-right menu.

8. When you have finished, click **Dismiss** to close the dialog box.

Additional information

- *Saving an X–Y data object*
- *Understanding "Temp" and other X–Y data object names*
- *Understanding quantity types*

Entering X–Y data from the keyboard

You can specify *X*–*Y* data directly from the keyboard.
To do so, you type *X*- and *Y*-values into a simple table editor.

1. Locate the **XY Data from Keyboard** options:

   From the main menu bar, select**Tools->XY Data->Create**. Click **Keyboard** in the dialog box that appears; then click **Continue**.

   Tip: You can also specify *X*–*Y* data by clicking **Create** in the **XY Data Manager** or by using the  tool in the toolbox.

   The **XY Data from Keyboard** dialog box appears.

2. Use standard keyboard and mouse editing techniques to insert, modify, or delete *X*- and *Y*-values in the **XY Data from Keyboard** table. For special table editing options or to read data from an ASCII file, press mouse button 3. (For more information, see *Entering tabular data*.)
3. To assign quantity types to the values in the *X*- or *Y*-columns, expand the **Quantity Types** list for the **X** or **Y** column and select quantity types from the lists that appear.
4. To evaluate and display the data, click **Plot**.

   An *X*–*Y* plot appears in the current viewport. The plot represents the data you have configured in the dialog box, which Abaqus considers temporary data whether or not you have clicked **Save As** to save it.

5. To save the data you have configured, click **Save As**.

   Note: *X*–*Y* data objects have a precision of six significant digits; therefore, only six significant digits are retained when you save an *X*–*Y* data object.

   To plot your saved *X*–*Y* data object, select **Tools->XY Data->Plot** from the main menu bar and choose the *X*–*Y* data object from the pull-right menu.

6. When you have finished, click **Cancel** to close the dialog box.

Additional information

- *Saving an X–Y data object*
- *Understanding "Temp" and other X–Y data object names*
- *Understanding quantity types*

Saving an X–Y data object

Abaqus/CAE provides several dialog boxes to help you specify *X–Y* data.

Each of these dialog boxes contains a **Save As** button, which you can use to save the *X–Y* data object you create. You must save your *X–Y* data to do any of the following:

- Produce an *X–Y* plot containing multiple *X–Y* data objects from any source other than history output.
- Edit, copy, rename, delete, or operate on your *X–Y* data. For history output, you can operate on the data during the save procedure or after it has been saved.
- Establish persistent curve style preferences for your *X–Y* data.
- Produce a report of your *X–Y* data.
- Copy your *X–Y* data to an output database file.

Abaqus/CAE also saves the quantity types specified for each column in your *X–Y* data object, as long as the quantity types you select are among the preset quantity types available in the **XY Data from ASCII File**, **XY Data from Keyboard**, and **Edit XY Data** dialog boxes. If you derive a different quantity type by operating on *X–Y* data objects, Abaqus/CAE will not record the nonstandard quantity type in the saved *X–Y* data object.

Saved data persist only for the duration of the session. To save your *X–Y* data object beyond the duration of the session, you must save the data to a file. You can either copy your *X–Y* data object to an output database (binary) file or write it to a report (ASCII) file. For information on copying *X–Y* data to an output database file, see *Copying a session X–Y data object to an output database file*. For information on writing *X–Y* data to a report file, see *Generating tabular data reports*.

1. Specify your *X–Y* data.
   a. From the main menu bar, select **Tools->XY Data->Create**.

      The **Create XY Data** dialog box appears.

      Tip: You can also specify *X–Y* data by clicking **Create** in the **Data Manager** or by using the  tool in the toolbox.

   b. *Choose the source* of your data from the list, and click **Continue**.

      Abaqus displays the appropriate dialog box.

   c. Enter the necessary data or information in the dialog box.
2. Save your data for the current Abaqus session.
   a. Click **Save As** or **Save** (as available).

      If you are saving field data, do one of the following:

      - To save the data set without changing it, leave the default choice of **as is** in the **Save Operation** list.
      - You can choose to perform any of the *mathematical, trigonometric, logarithmic, exponential, or other operations* available in the **Save Operation** list. The selected operation will be performed on the data before the data set is saved.

      Note: After you perform operations on the data set, the *x*-axis and *y*-axis labels are redefined automatically based on the resulting dimensional changes. You can retain the default labels or customize them by selecting the desired quantity types from the **Quantity Types** menu in the **Edit XY Data** dialog box.

b. Accept the default name, or enter the data object name of your choice in the text field.

Note: If you save data from the **XY Data from ODB Field Output** dialog box, you must accept the default names. If you selected multiple history output variables in the **History Output** dialog box, each *X–Y* data set will be saved with the default name, which is a shortened form of the history output name.

c. If you are saving history data, do one of the following:

- To save the data set without changing it, leave the default choice of **as is** in the **Save Operation** list.
- If you selected a single history output variable, you can choose to perform any of the *mathematical, trigonometric, logarithmic, exponential, or other operations* available in the **Save Operation** list. The selected operation will be performed on the data before it is saved.
- If you selected two history output variables, you can choose to perform any of the *dual-operand operations* available in the **Save Operation** list:
  - *append((XY,XY))*
  - *avg((XY,XY))*
  - *combine((XY,XY))*
  - *maxEnvelope((XY,XY))*
  - *minEnvelope((XY,XY))*
  - *power((XY,XY))*
  - *rng((XY,XY))* (range)
  - *srss((XY,XY))* (square root of the sum of the squares)
  - *sum((XY,XY))*
- If you selected three or more history output variables, you can choose to perform any of the *multi-operand operations* available in the **Save Operation** list:
  - *append((XY,XY,...))*
  - *avg((XY,XY,...))*
  - *maxEnvelope((XY,XY,...))*
  - *minEnvelope((XY,XY,...))*
  - *rng((XY,XY,...))*
  - *srss((XY,XY,...))*
  - *sum((XY,XY,...))*
  - *vectorMagnitude((XY,XY,XY))*

d. If available, toggle on **Plot curves on OK** to plot the *X–Y* data sets when you click **OK**.

e. If available, toggle on **Swap variables** to swap the order of operations.

f. If available, toggle on **Apply to linked viewports** to save the *X–Y* data across all linked viewports.

The viewport number is appended to the *X–Y* data set name; for example, *XyData-1*`_VP1`, *XyData-1*`_VP2`, etc.

g. Click **OK** to close the dialog box.

3. Click **Dismiss** or **Cancel** (as available) to close the output dialog box.

Additional information

- *Understanding how to specify an X–Y data object*
- *Copying a session X–Y data object to an output database file*
- *Loading an X–Y data object to the current session*
- *Using X–Y data operations*
- *Linking viewports*

Copying a session X–Y data object to an output database file

You must save an *X–Y* data object to be able to manipulate the data within a session; however, saved data persist only for the duration of the session in which they were created. You must copy saved data to a file if you want it to be available in another session.
You can either copy your data to an output database file or write it to a report file. (For information on writing *X–Y* data to a report file, see *Generating tabular data reports*.) The output database file is binary, so it is efficient to save large amounts of data to this file for future use. You can only append data to the output database; you cannot modify the contents of the file in any other way. It is easy to read data into Abaqus/CAE from an output database file during a later session. You can copy your data to any output database file for which you have write privileges, including any currently open output database files.

Note: By default, Abaqus/CAE opens output database files as read-only. You must choose to open an output database file with write privileges if you want to copy any X–Y data objects to it (see *Opening a model database or an output database* for more information).

1. From the main menu bar, select **Tools->XY Data->Manager**.

   The **XY Data Manager** appears.

   Tip: You can also access the **XY Data Manager** from the  tool in the toolbox.

2. From the list of *previously saved* *X–Y* data objects, select the *X–Y* data object that you wish to copy, and click **Copy to ODB**.

   The **Copy Session XYData to ODB** dialog box appears.

3. Enter the file name of your choice in the appropriate text field, or click **Select** to choose from an existing file name.
4. Accept the default name for the *X–Y* data object, or enter a name of your choice in the text field; then click **OK**.

Additional information

- *Understanding how to specify an X–Y data object*
- *Saving an X–Y data object*
- *Loading an X–Y data object to the current session*

Loading an X–Y data object to the current session

When you create an *X–Y* data object, you must save it to be able to manipulate the data within a session. You can then copy the *X–Y* data object to an output database file so that you can access it from a later session. The **XY Data Manager** lists the *X–Y* data objects that are available from two sources: the current session or the current output database file. If you have created an *X–Y* data object in a previous session and copied it to an output database file, you must load the *X–Y* data object to the current session to manipulate it.

1. From the main menu bar, select **Tools->XY Data->Manager**.

   The **XY Data Manager** appears.

    **Tip:** You can also access the **XY Data Manager** from the  tool in the toolbox.

2. Toggle on **Current ODB:** ***odb_name*** as the **Data Source** to see a list of the *X–Y* data objects associated with the currently open output database file.
3. Select an *X–Y* data object to load.
4. Click **Load to Session**.
5. Toggle on **Current session** as the **Data Source**.

   The loaded *X–Y* data object will be listed as available; you can now edit, copy, rename, or delete this *X–Y* data object.

Additional information

- *Understanding how to specify an X–Y data object*
- *Saving an X–Y data object*
- *Copying a session X–Y data object to an output database file*

Editing individual data points in an X–Y data object

You can edit individual records in any *X–Y* data object in your session, including temporary data objects. Abaqus/CAE presents the data in tabular format in the **Edit XY Data** dialog box.

1. Locate the **Edit XY Data** options:

   From the main menu bar, select **Tools**->**XY Data**->**Edit**->***XY Data Object***, where ***XY Data Object*** is a saved *X–Y* data object in your session. The **Edit XY Data** dialog box appears with the *X–Y* data presented in tabular format.
2. To edit any of the data points, click in the appropriate cell and change the value.
3. To assign quantity types to the values in the *X*- or *Y*-columns, expand the **Quantity Types** list for the **X** or **Y** column and select quantity types from the lists that appear.
4. To save the data you have configured, click **Save**.

Producing an X–Y plot

To produce an *X–Y* plot, you first specify an *X–Y* data object. You can then choose to simply plot the specified *X–Y* data object or to save the data object and plot it later.

If viewport linking is activated, you can link plot display across viewports.

History and field data objects can include complex numbers; you can control the displayed form of complex numbers using the **Result Options** dialog box. An abbreviation of the complex form is appended to the *Y*-axis title when you plot the variable and becomes part of the saved variable name. For example, if `S-Mises` is the selected field output variable and `Magnitude` is the complex form, the *Y*-axis title is `S-Mises CPX: Mg`. For more information on complex number forms in Abaqus/CAE, see *Controlling the form of complex results*.

Use one of the following methods to produce an *X–Y* plot:

To produce an X–Y plot of history data from an output database:

Select **Tools->XY Data->Create** from the main menu bar to launch the **Create XY Data** dialog box; then choose **ODB history output**. Click **Continue**. From the dialog box that appears, select one or more variables to plot and the step or steps of interest; then click **Plot**.

Tip: To launch the **Create XY Data** dialog box from the Results Tree, click mouse button 3 on the **XYData** container and select **Create** from the list that appears.

You can also specify history output by selecting **Result->History Output** from the main menu bar.

To produce an X–Y plot of field data from an output database:

Select **Tools->XY Data->Create** from the main menu bar; then choose **ODB field output**. Click **Continue**. From the dialog box that appears, select one or more variables to plot, the location or locations from which to read the data, and the step or steps of interest; then click **Plot**.

To produce an X–Y plot of output database results along a path through your model:

To specify a path through your model, select **Tools->Path->Create** from the main menu bar; then configure the dialog boxes that appear. For more information, see *Creating a path through your model*.

After you have created the path, select **Tools->XY Data->Create** from the main menu bar. Choose **Path** as the source of the *X–Y* data object, then click **Continue**. Configure the dialog box that appears, then click **Plot**. For more information, see *Obtaining X–Y data along a path*.

To produce an X–Y plot of new data, not from an output database:

Select **Tools->XY Data->Create** from the main menu bar. Choose either **Operate on XY data**, **ASCII file**, or **Keyboard** as the source of the *X–Y* data object; then click **Continue**. In the dialog box that appears, enter your *X–Y* data object; then click **Plot** (or **Plot Expression** in the **Operate on XY Data** dialog box).

To produce an X–Y plot of one or more saved X–Y data objects:

- To display a single *X–Y* data object, select **Tools->XY Data->Plot** from the main menu bar; and select the *X–Y* data object from the pull-right menu.
- To display multiple *X–Y* data objects on a single *X–Y* plot, select **Tools->XY Data->Manager** from the main menu bar. Select the *X–Y* data objects from the dialog box that appears; then click **Plot**.

You can also perform either of these actions from the Results Tree. To display a single *X–Y* data object using the Results Tree, expand the **XYData** container, click mouse button 3 on the *X–Y* data object you want to plot, and select **Plot** from the list that appears. To display multiple *X–Y* data objects using the Results Tree, highlight multiple *X–Y* objects under the **XYData** container, click mouse button 3 on one of the highlighted objects, and select **Plot** from the list that appears.

Understanding how to operate on saved X–Y data objects

You can derive new *X–Y* data by operating on *previously saved* *X–Y* data objects. You define your new data by building a mathematical expression. The expression can include the names of previously saved *X–Y* data objects, built-in functions, and mathematical operators. An example of an expression might be: `currentMax("XYData-1")+2.5`. Abaqus/CAE evaluates the expression to derive the new *X–Y* data.

To build your expression, you use the ***Operate on XY Data*** dialog box. This dialog box lists the data object names and operators available for your expression. You can click to select listed data objects and operators; type values in using the keyboard; and use standard mouse and keyboard editing techniques such as backspace, copy, and paste to configure your expression. The expression can contain any syntactically valid series of supported operations. The following syntax rules apply:

- Multiple arguments to a function must be separated by commas.
- Data object names must be surrounded by quotation marks.
- Parentheses must be used to group function arguments.

Parentheses can also be used to control mathematical evaluation or for visual clarity. Abaqus/CAE notifies you if your expression contains invalid syntax or cannot be evaluated for mathematical reasons; for example, if evaluation would require dividing by zero.

Tip: When you select multiple variables in the **History Output** dialog box and click **Save As**, you can choose to apply one of the more common operators to the *X–Y* data before saving it.

By default, Abaqus/CAE performs checks to validate the mathematical expressions you create. If your expression includes a large number of *X–Y* data points, this validation can be time consuming. You can toggle on **Skip checks** to skip this set of checking procedures.

Additional information

- *Understanding X–Y data interpolation and extrapolation*
- *Operating on saved X–Y data objects*
- *Using X–Y data operations*

Understanding X–Y data interpolation and extrapolation

Abaqus/CAE performs *X–Y* data interpolation and extrapolation as necessary when you combine multiple *X–Y* data objects. You can combine multiple *X–Y* data objects by using *X–Y* data operations or by requesting that multiple data objects appear in a single table within an *X–Y report*.

A complete list of *X–Y* data operations appears in *Using X–Y data operations*. Several of the *X–Y* data operations that accept two or more *previously saved*X–Y data objects as input arguments require that the data objects have matching *X*-coordinate values. Examples of such operations are the **combine** and **sum** functions.

Similarly, matching *X–Y* values are required for data objects appearing in the same *X–Y* report table. For information on combining *X–Y* data objects into a single report table, see *Controlling report layout, width, format, and coordinate system*.

If the *X*-coordinate values to be combined do not match, Abaqus/CAE computes additional data points to allow the objects to be aligned. For each unmatched *X*-coordinate value, Abaqus/CAE constructs a data pair by creating a matching *X*-coordinate value and computing a *Y*-coordinate value as follows:

- If the missing *X*-coordinate lies within the minimum and maximum available *X*-coordinates for the data object, a new *Y*-coordinate value is computed by linear interpolation.
- If the missing *X*-coordinate lies beyond the minimum or maximum available *X*-coordinates for the data object, a new *Y*-coordinate value is computed by assuming the *Y*-coordinate value remains constant beyond these extreme points.

These additional data points exist only to carry out the operation and are not saved as part of the input argument data objects.

Additional information

- *Using X–Y data operations*
- *Generating tabular data reports*

Operating on saved X–Y data objects

To define a new *X–Y* data object by operating on *previously saved X–Y* data objects, select **Tools->XY Data->Create** from the main menu bar; then choose **Operate on XY data** from the dialog box that appears.

1. Locate the **Operate on XY Data** dialog box.

   From the main menu bar, select **Tools->XY Data->Create**. Click **Operate on XY data** in the dialog box that appears; then click **Continue**. The **Operate on XY Data** dialog box appears.

2. Build your expression:

   a. Click on data object names and built-in functions in the dialog box to select them. Click **Add to Expression** near the bottom of the dialog box to add data objects to the expression; the built-in functions appear in the expression automatically when you select them.

      Use drag-select for multiple contiguous data object name selection.

      Commas are inserted automatically between the data object names.

   b. Use standard mouse and keyboard editing techniques to position the cursor and configure your expression.

   c. Adjust the syntax of your expression if necessary: data object names must be surrounded by quotation marks, commas must separate function arguments, and parentheses may be needed.

3. To save your new *X–Y* data object, click **Save As**.

   The **Save XY Data As** dialog box appears. Provide a name for your data; then click **OK**.

4. To plot the expression you have configured, click **Plot Expression**.

   An *X–Y* plot appears in the current viewport. The plot represents the expression in the dialog box, which Abaqus considers temporary data, whether or not you have saved your new *X–Y* data object.

5. To plot your new, saved *X–Y* data object, select **Tools->XY Data->Plot** from the main menu bar and select the *X–Y* data object from the pull-right menu.

6. To clear (erase) the expression, click **Clear Expression**.

7. When you are done, click **Cancel** to close the dialog box.

Using X–Y data operations

You can derive new *X–Y* data by operating on *previously saved**X–Y* data objects. This overview lists the operations you can perform on *X–Y* data. You can also operate on history data during the save procedure. For more information, see *Saving an X–Y data object*.

The following keys are used to classify function arguments:

Text keys for X–Y operations:

A	The argument can be an *X–Y* data object, a floating point number, or an integer.
X	The argument must be an *X–Y* data object.
I	The argument must be an integer.
F	The argument must be a floating point number.

The following list indicates the section where you can find more information for each *X–Y* data operation.

Mathematical operations:

+	*Using addition on X–Y data objects*
–	*Using negation or subtraction on X–Y data objects*
*****	*Using multiplication on X–Y data objects*
/	*Using division on X–Y data objects*
1/A	*Using division on X–Y data objects*
abs(A)	*Taking the absolute value of an X–Y data object*
avg(X,X,...)	*Finding the average of two or more X–Y data objects*
currentAvg(X)	*Finding the current average of an X–Y data object*
differentiate(X)	*Differentiating an X–Y data object*
fit(X)	*Performing curve fitting on an X–Y data object*
integrate(X)	*Integrating an X–Y data object*
interpolate(X)	*Interpolating an X–Y data object*
linearize(X,CONSTANT)	*Linearizing an X–Y data object*
linearize(X,LINEAR)	*Linearizing an X–Y data object*
normalize(X)	*Normalizing an X–Y data object*
sqrt(A)	*Taking the square root of an X–Y data object*
srss(X,X,...)	*Taking the square root of the sum of the squares of two or more X–Y data objects*
sum(A,A,...)	*Summing two or more X–Y data objects*
vectorMagnitude(X,X,X)	*Calculating vector magnitudes*

Trigonometric operations:

For more information, see *Applying trigonometric functions to an X–Y data object*.

cos(A)	Take the cosine of an *X–Y* data object.
acos(A)	Take the arccosine of an *X–Y* data object.
cosh(A)	Take the hyperbolic cosine of an *X–Y* data object.

sin(A)	Take the sine of an *X–Y* data object.
asin(A)	Take the arcsine of an *X–Y* data object.
sinh(A)	Take the hyperbolic sine of an *X–Y* data object.
tan(A)	Take the tangent of an *X–Y* data object.
atan(A)	Take the arctangent of an *X–Y* data object.
tanh(A)	Take the hyperbolic tangent of an *X–Y* data object.

Logarithmic and exponential operations:

exp(A)	*Taking the exponential of an X–Y data object*
log(A)	*Applying logarithmic functions to an X–Y data object*
log10(A)	*Applying logarithmic functions to an X–Y data object*
power(A,A)	*Raising an X–Y data object to a power*

Filtering and smoothing operations:

butterworthFilter(X,F)	*Applying Butterworth filtering to an X–Y data object*
chebyshev1Filter(X,F,F)	*Applying Chebyshev Type I or Type II filtering to an X–Y data object*
chebyshev2Filter(X,F,F)	*Applying Chebyshev Type I or Type II filtering to an X–Y data object*
decimateFilter(X,I)	*Reducing the sample size of an X–Y data object*
saeGeneralFilter(X,F)	*Applying SAE filtering to an X–Y data object*
sae60Filter(X,F)	*Applying SAE filtering to an X–Y data object*
sae100Filter(X,F)	*Applying SAE filtering to an X–Y data object*
sae180Filter(X,F)	*Applying SAE filtering to an X–Y data object*
sae600Filter(X,F)	*Applying SAE filtering to an X–Y data object*
sae1000Filter(X,F)	*Applying SAE filtering to an X–Y data object*
sineButterworthFilter(X,F)	*Applying sine-Butterworth filtering to an X–Y data object*
smooth(X,I)	*Smoothing an X–Y data object*
smooth2(X,F)	*Smoothing an X–Y data object*

Range and magnitude related operations:

currentMax(X)	*Finding the current maximum of an X–Y data object*
currentMin(X)	*Finding the current minimum of an X–Y data object*
currentRng(X)	*Finding the current range of an X–Y data object*
maxEnvelope(A,A,...)	*Finding the current maximum of two or more X–Y data objects*
minEnvelope(A,A,...)	*Finding the current minimum of two or more X–Y data objects*
rng(A,A,...)	*Finding the current range of two or more X–Y data objects*

Other operations:

append(X,X,...)	*Appending two or more X–Y data objects*
combine(X,X)	*Combining two X–Y data objects*

degreeToRadian(A)	*Converting the angular units used for X–Y data objects*
radianToDegree(A)	*Converting the angular units used for X–Y data objects*
swap(X)	*Swapping the order of an X–Y data object*
truncate(X,F)	*Truncating data from the ends of an X–Y data object*

Additional information

- *Understanding how to operate on saved X–Y data objects*
- *Operating on saved X–Y data objects*

Using addition on X–Y data objects

You can use addition on previously saved X–Y data objects to produce a new X–Y data object.

Use the mathematical **+** symbol to operate on a *previously saved*X–Y data object (a collection of ordered pairs) to produce a new X–Y data object. The **+** operator accepts two commutative arguments and can be applied in one of two ways:

To add a scalar to an X–Y data object:

This method yields a new X–Y data object having the same X-coordinate values as the original X–Y data object. Abaqus/CAE computes the new Y-coordinates as the scalar added to each original Y-coordinate. For example, if

$$\mathbf{XYData} = [(1,1),(2,2),(3,3)],$$

then

$$(\mathbf{XYData} + 5) = [(1,6),(2,7),(3,8)].$$

To add an X–Y data object to another X–Y data object:

This method yields a new X–Y data object having as its X-coordinates all X-coordinates of the first data object and any additional X-coordinates needed for alignment of the two objects. Abaqus/CAE computes additional X–Y data pairs by *interpolation and extrapolation*. The new data object has as its Y-coordinates the Y-coordinates of the first data object added to the Y-coordinates of the second data object. For example, let

$$\mathbf{XYData1} = [(1,1),(2,2),(3,3)],$$

and

$$\mathbf{XYData2} = [(4,4),(5,5)].$$

For alignment, Abaqus/CAE computes the values of the first and second data objects as:

$$\mathbf{XYData1\ extrapolated} = [(1,1),(2,2),(3,3),(4,3),(5,3)],$$

and

$$\mathbf{XYData2\ extrapolated} = [(1,4),(2,4),(3,4),(4,4),(5,5)];$$

then

$$(\mathbf{XYData1} + \mathbf{XYData2}) = [(1,5),(2,6),(3,7),(4,7),(5,8)].$$

Figure 1 illustrates the above example.

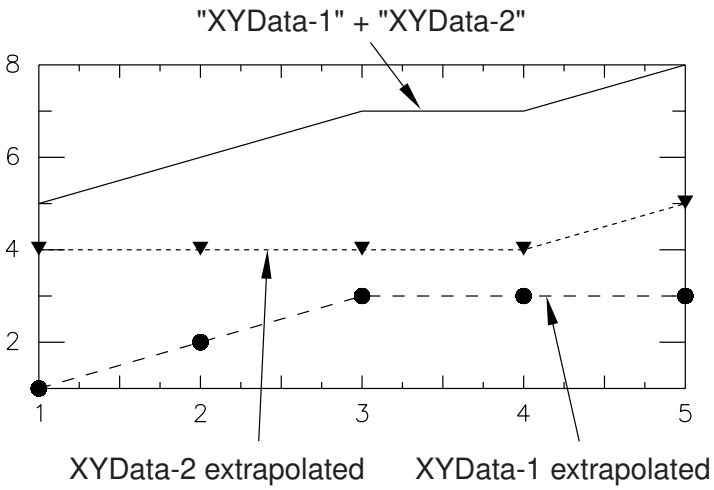

Figure 1: *X–Y* plot illustrating addition of data objects.

Note:

This application of the **+** symbol has the same behavior as the **sum** function.

1. Locate the **Operate on XY Data** dialog box.

   From the main menu bar, select **Tools->XY Data->Create**. Click **Operate on XY data** in the dialog box that appears; then click **Continue**. The **Operate on XY Data** dialog box appears.

2. From the **XY Data** choices, click the name of the *X–Y* data object on which to operate and click **Add to Expression**. You can choose from all *X–Y* data objects previously saved within this session (listed alphabetically in the **XY Data** field).

   The *X–Y* data object name appears within the expression window.

3. From the **Operators** listed, click **+**.

   The **+** symbol appears after the data object name in the expression window.

4. To specify the second argument, do one of the following:

   - Use your mouse and keyboard to enter a scalar as the second argument of the **+** operator in the expression window, or
   - From the **XY Data** choices, click the name of a data object argument for the **+** operator in the expression window and click **Add to Expression**.

5. To continue to build your expression, position the cursor in the expression window and type in or select the functions, operators, and *X–Y* data you want to include.
6. To evaluate and display your expression, click **Plot Expression**.
7. To *save* your new *X–Y* data object, click **Save As** and then provide a name in the dialog box that appears.

   Saving your data object makes it available for future operations within this session and for inclusion in *X–Y* plots containing multiple data objects.

8. When you are finished, click **Cancel** to close the dialog box.

Additional information

• *Understanding X–Y data interpolation and extrapolation*

- *Summing two or more X–Y data objects*
- *Appending two or more X–Y data objects*
- *Combining two X–Y data objects*
- *Using X–Y data operations*

Using negation or subtraction on X–Y data objects

Use the mathematical **–** symbol to perform negation or subtraction on a *previously saved*X–Y data object (a collection of ordered pairs) to produce a new X–Y data object.

To perform negation, precede a single X–Y data object with the **–** operator. Negation yields a new X–Y data object having the same X-coordinate values as the original X–Y data object. Abaqus/CAE computes the new Y-coordinates as the negative of each original Y-coordinate.

To perform subtraction, use one of three methods:

To subtract a scalar from an X–Y data object:

This method yields a new X–Y data object having the same X-coordinate values as the original X–Y data object. Abaqus/CAE computes the new Y-coordinates as the scalar subtracted from each original Y-coordinate. For example, if

$$\mathbf{XYData} = [(1,6),(2,7),(3,8)],$$

then

$$(\mathbf{XYData} - 5) = [(1,1),(2,2),(3,3)].$$

To subtract an X–Y data object from a scalar:

This method yields a new X–Y data object having the same X-coordinate values as the original X–Y data object. Abaqus/CAE computes the new Y-coordinates as each original Y-coordinate subtracted from the scalar. For example, if

$$\mathbf{XYData} = [(1,6),(2,7),(3,8)],$$

then

$$(5 - \mathbf{XYData}) = [(1,-1),(2,-2),(3,-3)].$$

To subtract one X–Y data object from another X–Y data object:

This method yields a new X–Y data object having as its X-coordinates all X-coordinates of the first data object and any additional X-coordinates needed for alignment of the two objects. Abaqus/CAE computes additional X–Y data pairs by *interpolation and extrapolation*. The new data object has as its Y-coordinates the Y-coordinates of the second data object subtracted from the Y-coordinates of the first data object. For example, let

$$\mathbf{XYData1} = [(4,4),(5,5)]$$

and

$$\mathbf{XYData2} = [(1,1),(2,2),(3,3)].$$

For alignment, Abaqus/CAE computes the values of the first and second data objects as:

$$\mathbf{XYData1\ extrapolated} = [(1,4),(2,4),(3,4),(4,4),(5,5)]$$

and

$$\mathbf{XYData2\ extrapolated} = [(1,1),(2,2),(3,3),(4,3),(5,3)];$$

then

$$(\mathbf{XYData1} - \mathbf{XYData2}) = [(1,3),(2,2),(3,1),(4,1),(5,2)].$$

Figure 1 shows an *X–Y* plot of the above example.

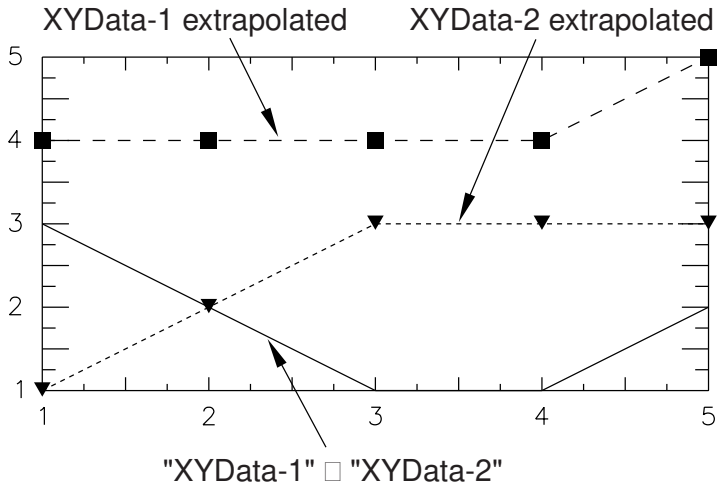

Figure 1: *X–Y* plot illustrating subtraction of data objects.

1. Locate the **Operate on XY Data** dialog box.

   From the main menu bar, select **Tools->XY Data->Create**. Click **Operate on XY data** in the dialog box that appears; then click **Continue**. The **Operate on XY Data** dialog box appears.

2. From the **Operators** listed, click **–**.

   The **–** symbol appears in the expression window.

3. Use your mouse and keyboard to position the cursor in the expression window; then specify the necessary arguments. Available *X–Y* data objects include all those previously saved within this session (listed alphabetically in the **XY Data** field).

To use negation

From the **XY Data** choices, click the name of the *X–Y* data object to negate and click **Add to Expression**.

To use subtraction

- Use your keyboard to type in a scalar argument, or
- From the **XY Data** choices, click the name of the *X–Y* data object on which to operate and click **Add to Expression**.

The arguments appear within the expression window.

4. To continue to build your expression, position the cursor in the expression window and type in or select the functions, operators, and *X–Y* data you want to include.
5. To evaluate and display your expression, click **Plot Expression**.
6. To *save* your new *X–Y* data object, click **Save As** and then provide a name in the dialog box that appears.

   Saving your data object makes it available for future operations within this session and for inclusion in *X–Y* plots containing multiple data objects.

7. When you are finished, click **Cancel** to close the dialog box.

- *Understanding X–Y data interpolation and extrapolation*
- *Using X–Y data operations*

Using multiplication on X–Y data objects

Use the mathematical * symbol to operate on a *previously saved*X–Y data object (a collection of ordered pairs) to produce a new X–Y data object. The * operator accepts two commutative arguments and can be applied in one of two ways:

To multiply a scalar and an X–Y data object:

This method yields a new X–Y data object having the same X-coordinate values as the original X–Y data object. Abaqus/CAE computes the new Y-coordinates as the scalar multiplied by each original Y-coordinate. For example, if

$$\mathbf{XYData} = [(1,1),(2,2),(3,3)],$$

then

$$(\mathbf{XYData} * 5) = [(1,5),(2,10),(3,15)].$$

To multiply an X–Y data object with another X–Y data object:

This method yields a new X–Y data object having as its X-coordinates all X-coordinates of the first data object and any additional X-coordinates needed for alignment of the two objects. Abaqus/CAE computes additional X–Y data pairs by *interpolation and extrapolation*. The new data object has as its Y-coordinates the Y-coordinates of the first data object multiplied by the Y-coordinates of the second data object. For example, let

$$\mathbf{XYData1} = [(1,1),(2,2),(3,3)]$$

and

$$\mathbf{XYData2} = [(4,4),(5,5)].$$

For alignment, Abaqus/CAE computes the values of the first and second data objects as:

$$\mathbf{XYData1\ extrapolated} = [(1,1),(2,2),(3,3),(4,3),(5,3)]$$

and

$$\mathbf{XYData2\ extrapolated} = [(1,4),(2,4),(3,4),(4,4),(5,5)];$$

then

$$(\mathbf{XYData1} * \mathbf{XYData2}) = [(1,4),(2,8),(3,12),(4,12),(5,15)].$$

Figure 1 shows an X–Y plot of the preceding example.

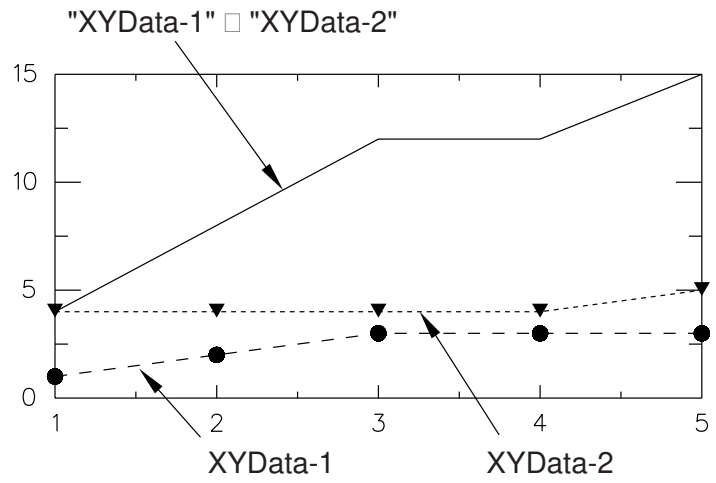

Figure 1: X–Y plot illustrating multiplication of data objects.

1. Locate the **Operate on XY Data** dialog box.

   From the main menu bar, select **Tools->XY Data->Create**. Click **Operate on XY data** in the dialog box that appears; then click **Continue**. The **Operate on XY Data** dialog box appears.

2. From the **XY Data** choices, click the name of the *X–Y* data object on which to operate and click **Add to Expression**. You can choose from all *X–Y* data objects previously saved within this session (listed alphabetically in the **XY Data** field).

   The *X–Y* data object name appears within the expression window.

3. From the **Operators** listed, click *****.

   The * symbol appears after the data object name in the expression window.

4. To specify the second argument, do one of the following:

   - Use your mouse and keyboard to enter a scalar as the second argument of the ***** operator in the expression window, or
   - From the **XY Data** choices, click the name of a data object argument for the * operator in the expression window and click **Add to Expression**.

5. To continue to build your expression, position the cursor in the expression window and type in or select the functions, operators, and *X–Y* data you want to include.
6. To evaluate and display your expression, click **Plot Expression**.
7. To *save* your new *X–Y* data object, click **Save As** and then provide a name in the dialog box that appears.

   Saving your data object makes it available for future operations within this session and for inclusion in *X–Y* plots containing multiple data objects.

8. When you are finished, click **Cancel** to close the dialog box.

Using division on X–Y data objects

Use the mathematical **/** symbol to operate on a *previously saved*X–Y data object (a collection of ordered pairs) to produce a new *X–Y* data object. The **/** operator accepts two non-commutative arguments and can be applied in one of three ways:

To divide a scalar by an X–Y data object:

This method yields a new *X–Y* data object having the same *X*-coordinate values as the original *X–Y* data object. Abaqus/CAE computes the new *Y*-coordinates as the scalar divided by each original *Y*-coordinate. For example, if

$$\mathbf{XYData} = [(1, 2), (2, 10), (3, 20)],$$

then

$$(2 \,/\, \mathbf{XYData}) = [(1, 1), (2, .2), (3, .1)].$$

Note:

As a convenience, the **Operate on XY Data** dialog box offers an inverse function, **1/A**.

To divide an X–Y data object by a scalar:

This method yields a new *X–Y* data object having the same *X*-coordinate values as the original *X–Y* data object. Abaqus/CAE computes the new *Y*-coordinates as each original *Y*-coordinate divided by the scalar. For example, if

$$\mathbf{XYData} = [(1, 2), (2, 10), (3, 20)],$$

then

$$(\mathbf{XYData} \,/\, 2) = [(1, 1), (2, 5), (3, 10)].$$

To divide one X–Y data object by another X–Y data object:

This method yields a new *X–Y* data object having as its *X*-coordinates all *X*-coordinates of the first data object and any additional *X*-coordinates needed for alignment of the two objects. Abaqus/CAE computes additional *X–Y* data pairs by *interpolation and extrapolation*. The new data object has as its *Y*-coordinates the *Y*-coordinates of the first data object divided by the *Y*-coordinates of the second data object. For example, let

$$\mathbf{XYData1} = [(4, 4), (5, 5)]$$

and

$$\mathbf{XYData2} = [(1, 1), (2, 2), (3, 3)].$$

For alignment, Abaqus/CAE computes the values of the first and second data objects as:

$$\mathbf{XYData1\ extrapolated} = [(1, 4), (2, 4), (3, 4), (4, 4), (5, 5)]$$

and

$$\mathbf{XYData2\ extrapolated} = [(1, 1), (2, 2), (3, 3), (4, 3), (5, 3)];$$

then

$$(\mathbf{XYData1} \,/\, \mathbf{XYData2}) = [(1, 4), (2, 2), (3, 1.33), (4, 1.33), (5, 1.66)].$$

Figure 1 shows an *X–Y* plot of the above example.

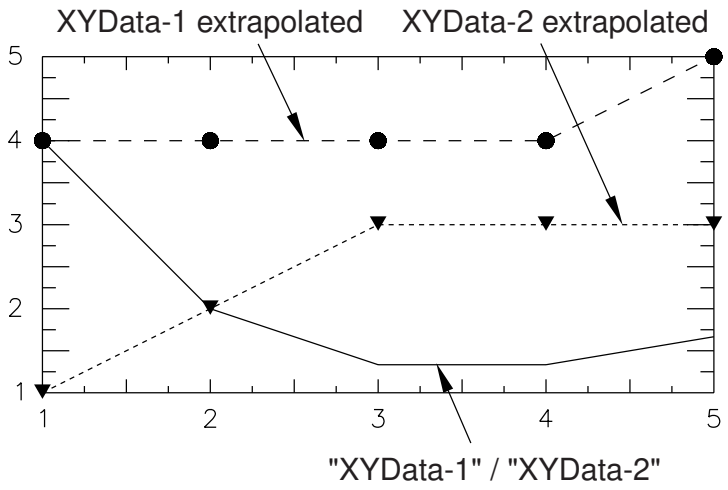

Figure 1: X–Y plot illustrating division of data objects.

1. Locate the **Operate on XY Data** dialog box.

   From the main menu bar, select **Tools->XY Data->Create**. Click **Operate on XY data** in the dialog box that appears; then click **Continue**. The **Operate on XY Data** dialog box appears.

2. From the **Operators** listed, click **/**.

   The **/** symbol appears in the expression window.

3. To specify each of the two arguments for the **/** operator, use your mouse and keyboard to position the cursor in the expression window; then do one of the following:

   - Use your keyboard to type in a scalar argument, or
   - From the **XY Data** choices, click the name of the *X–Y* data object on which to operate and click **Add to Expression**. You can choose from all *X–Y* data objects previously saved within this session (listed alphabetically in the **XY Data** field).

   The arguments appear within the expression window.

4. To continue to build your expression, position the cursor in the expression window and type in or select the functions, operators, and *X–Y* data you want to include.
5. To evaluate and display your expression, click **Plot Expression**.
6. To *save* your new *X–Y* data object, click **Save As** and then provide a name in the dialog box that appears.

   Saving your data object makes it available for future operations within this session and for inclusion in *X–Y* plots containing multiple data objects.

7. When you are finished, click **Cancel** to close the dialog box.

Additional information

- *Understanding X–Y data interpolation and extrapolation*
- *Using X–Y data operations*

Taking the absolute value of an X–Y data object

Use the **abs** function to operate on a *previously saved*X–Y data object (a collection of ordered pairs) to produce a new X–Y data object. The new X–Y data object has the same X-coordinate values as the original X–Y data object, but new Y-coordinates are computed as the absolute value of the original Y-coordinates.

Figure 1 shows an example of an X–Y plot produced using the **abs** function.

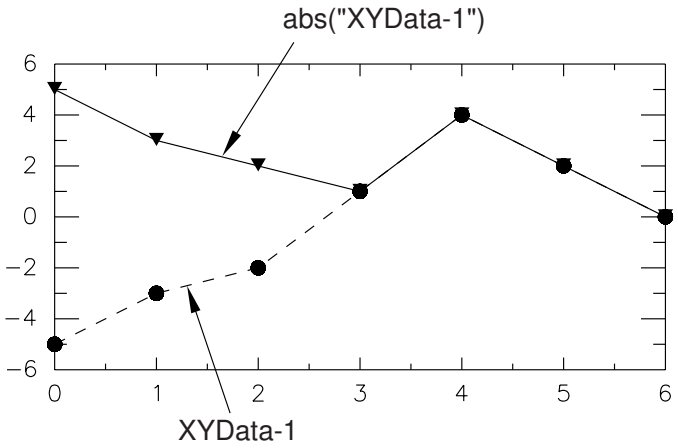

Figure 1: X–Y plot produced using the abs function.

1. Locate the **Operate on XY Data** dialog box.

   From the main menu bar, select **Tools->XY Data->Create**. Click **Operate on XY data** in the dialog box that appears; then click **Continue**. The **Operate on XY Data** dialog box appears.

2. From the **Operators** listed, click **abs(A)**.

   The **abs** function appears in the expression window.

3. From the **XY Data** choices, click the name of the X–Y data object on which to operate and click **Add to Expression**. You can choose from all X–Y data objects previously saved within this session (listed alphabetically in the **XY Data** field).

   The X–Y data object name appears within the **abs** function parentheses in the expression window.

4. To continue to build your expression, position the cursor in the expression window and type in or select the functions, operators, and X–Y data you want to include.
5. To evaluate and display your expression, click **Plot Expression**.
6. To *save* your new X–Y data object, click **Save As** and then provide a name in the dialog box that appears.

   Saving your data object makes it available for future operations within this session and for inclusion in X–Y plots containing multiple data objects.

7. When you are finished, click **Cancel** to close the dialog box.

Additional information

- *Using X–Y data operations*

Finding the average of two or more X–Y data objects

Use the **avg** function to operate on two or more *previously saved*X–Y data objects (each object is a collection of ordered pairs) to produce a new *X–Y* data object. The new *X–Y* data object has as its *X*-coordinates all *X*-coordinates of the input data objects and any additional *X*-coordinates needed for alignment of the input data objects. Abaqus/CAE computes additional *X–Y* data pairs by *interpolation and extrapolation*. Abaqus/CAE computes the new data object *Y*-coordinates as the average of all input *Y*-coordinates at the current *X*-coordinate. The arguments of this operation are commutative.

Figure 1 illustrates the type of *X–Y* plot that can be produced using the **avg** function.

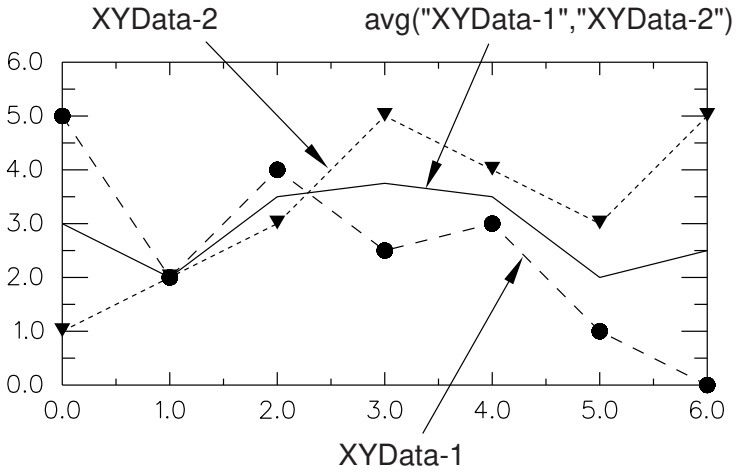

Figure 1: *X–Y* plot produced using the avg function.

For information on how to find the current average of a single *X–Y* data object, see *Finding the current average of an X–Y data object*.

1. Locate the **Operate on XY Data** dialog box.

   From the main menu bar, select **Tools->XY Data->Create**. Click **Operate on XY data** in the dialog box that appears; then click **Continue**. The **Operate on XY Data** dialog box appears.

2. From the **Operators** listed, click **avg(X,X,...)**.

   The **avg** function appears in the expression window.

3. From the **XY Data** choices, click the names of two or more *X–Y* data objects on which to operate and click **Add to Expression**. You can choose from all *X–Y* data objects previously saved within this session (listed alphabetically in the **XY Data** field).

   The *X–Y* data object names appear, separated by commas, within the **avg** function parentheses in the expression window.

4. To continue to build your expression, position the cursor in the expression window and type in or select the functions, operators, and *X–Y* data you want to include.
5. To evaluate and display your expression, click **Plot Expression**.
6. To *save* your new *X–Y* data object, click **Save As** and then provide a name in the dialog box that appears.

   Saving your data object makes it available for future operations within this session and for inclusion in *X–Y* plots containing multiple data objects.

7. When you are finished, click **Cancel** to close the dialog box.

Additional information

- *Finding the current average of an X–Y data object*
- *Using X–Y data operations*

Finding the current average of an X–Y data object

Use the **currentAvg** function to operate on a *previously saved*X–Y data object (a collection of ordered pairs) to produce a new *X–Y* data object. The new *X–Y* data object has the same *X*-coordinate values as the original *X–Y* data object, but new *Y*-coordinates are computed as the average of all *Y*-coordinates up to and including the current *X*-coordinate.

Figure 1 shows an example of an *X–Y* plot produced using the **currentAvg** function.

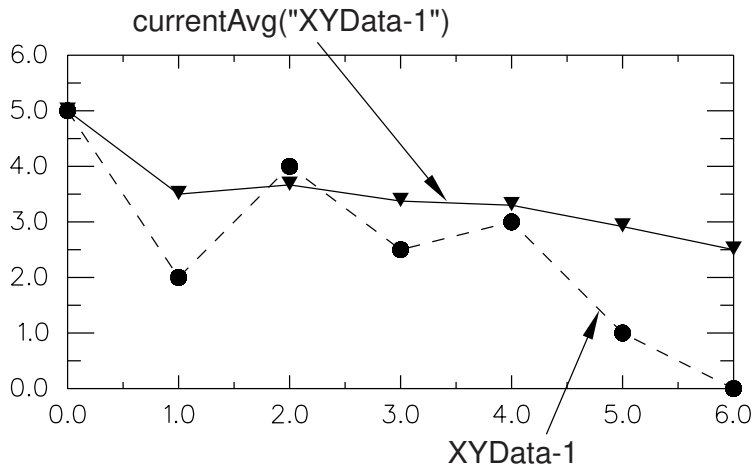

Figure 1: *X–Y* plot produced using the currentAvg function.

Note:

The last value of the new *X–Y* data object represents the overall average *Y*-coordinate of the original *X–Y* data object.

For information on how to find the current average of two or more *X–Y* data objects, see *Finding the average of two or more X–Y data objects*.

1. Locate the **Operate on XY Data** dialog box.

   From the main menu bar, select **Tools->XY Data->Create**. Click **Operate on XY data** in the dialog box that appears; then click **Continue**. The **Operate on XY Data** dialog box appears.

2. From the **Operators** listed, click **currentAvg(X)**.

   The **currentAvg** function appears in the expression window.

3. From the **XY Data** choices, click the name of the *X–Y* data object on which to operate and click **Add to Expression**. You can choose from all *X–Y* data objects previously saved within this session (listed alphabetically in the **XY Data** field).

   The *X–Y* data object name appears within the **currentAvg** function parentheses in the expression window.

4. To continue to build your expression, position the cursor in the expression window and type in or select the functions, operators, and *X–Y* data you want to include.
5. To evaluate and display your expression, click **Plot Expression**.
6. To *save* your new *X–Y* data object, click **Save As** and then provide a name in the dialog box that appears.

   Saving your data object makes it available for future operations within this session and for inclusion in *X–Y* plots containing multiple data objects.

7. When you are finished, click **Cancel** to close the dialog box.

Additional information

- *Finding the average of two or more X–Y data objects*
- *Using X–Y data operations*

Differentiating an X–Y data object

Use the **differentiate** function to operate on a *previously saved*X–Y data object (a collection of ordered pairs) to produce a new *X–Y* data object. The new *X–Y* data object has the same *X*-coordinate values as the original *X–Y* data object, but new *Y*-coordinates are computed as the numerical derivative of the original *Y*-coordinates.

Abaqus/CAE computes the derivative using three-point parabolic segments of the original *X–Y* data object. The values at the first and last points are computed as the gradient at the start and at the end of the associated parabolas, respectively. The slope at each remaining point is computed using the midpoint of the parabola defined by two neighboring points. *Figure 1* shows an example of an *X–Y* plot produced using the **differentiate** function.

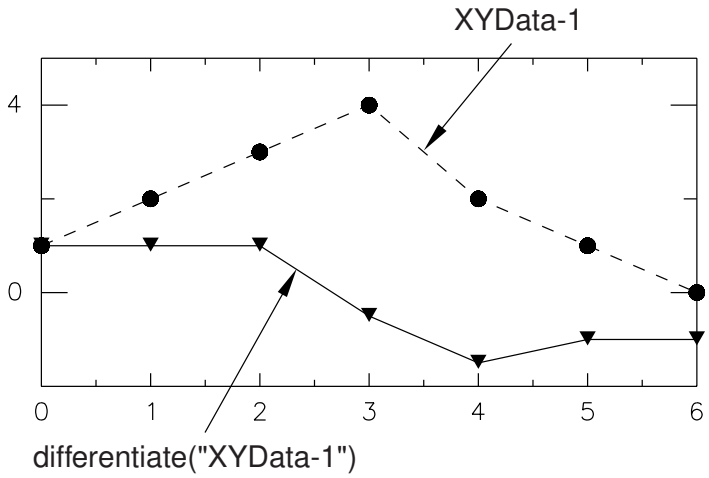

Figure 1: *X–Y* plot produced using the differentiate function.

1. Locate the **Operate on XY Data** dialog box.

   From the main menu bar, select **Tools->XY Data->Create**. Click **Operate on XY data** in the dialog box that appears; then click **Continue**. The **Operate on XY Data** dialog box appears.

2. From the **Operators** listed, click **differentiate(X)**.

   The **differentiate** function appears in the expression window.

3. From the **XY Data** choices, click the name of the *X–Y* data object on which to operate and click **Add to Expression**. You can choose from all *X–Y* data objects previously saved within this session (listed alphabetically in the **XY Data** field).

   The *X–Y* data object name appears within the **differentiate** function parentheses in the expression window.

4. To continue to build your expression, position the cursor in the expression window and type in or select the functions, operators, and *X–Y* data you want to include.
5. To evaluate and display your expression, click **Plot Expression**.
6. To *save* your new *X–Y* data object, click **Save As** and then provide a name in the dialog box that appears.

   Saving your data object makes it available for future operations within this session and for inclusion in *X–Y* plots containing multiple data objects.

7. When you are finished, click **Cancel** to close the dialog box.

Additional information

- *Integrating an X–Y data object*

- *Using X–Y data operations*

Performing curve fitting on an X–Y data object

Use the **fit** function to operate on a *previously saved*$X–Y$ data object (a collection of ordered pairs) to produce a new $X–Y$ data object. The new $X–Y$ data object contains points that are spaced at regular intervals along the curve that best fits the previously saved $X–Y$ data object. The **fit** function provides two algorithms for curve fitting: a linear least squares fit and a spline interpolation.

Figure 1 and *Figure 2* show examples of $X–Y$ plots produced using the **fit** function using each curve fitting algorithm.

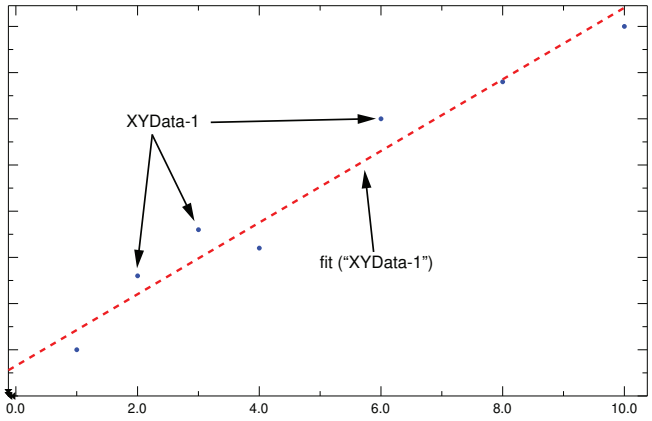

Figure 1: $X–Y$ plot produced using the fit function with the linear least squares option selected.

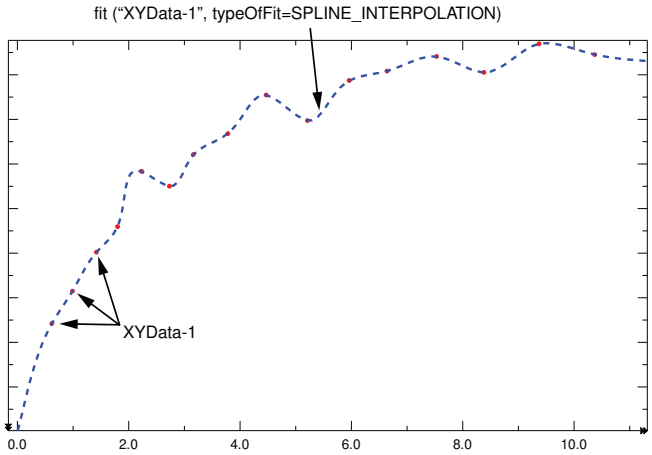

Figure 2: $X–Y$ plot produced using the fit function with the spline interpolation option selected.

1. Locate the **Operate on XY Data** dialog box.

   From the main menu bar, select **Tools->XY Data->Create**. Click **Operate on XY data** in the dialog box that appears; then click **Continue**. The **Operate on XY Data** dialog box appears.

2. From the **Operators** listed, click **fit(X)**.

   The **fit** function appears in the expression window with the linear least squares fit option selected by default.

3. From the **XY Data** choices, click the name of the $X–Y$ data object on which to operate and click **Add to Expression**. You can choose from all $X–Y$ data objects previously saved within this session (listed alphabetically in the **XY Data** field).

   The $X–Y$ data object name appears within the **fit** function parentheses in the expression window.

4. To continue to build your expression, position the cursor in the expression window and type in or select the functions, operators, and *X–Y* data you want to include. You can customize the **fit** function itself by including the following changes to its options:
   - If you want to perform a spline interpolation, set the `typeOfFit` option to `SPLINE_INTERPOLATION`.
   - If you want to specify a custom number of points to be created for the new *X–Y* data object, append `numFitPoints=`*number*. By default, Abaqus/CAE uses 2 points to define a linear least squares fit and 100 points to define a spline interpolation.
5. To evaluate and display your expression, click **Plot Expression**.
6. To *save* your new *X–Y* data object, click **Save As** and then provide a name in the dialog box that appears.

   Saving your data object makes it available for future operations within this session and for inclusion in *X–Y* plots containing multiple data objects.
7. When you are finished, click **Cancel** to close the dialog box.

Additional information

- *Integrating an X–Y data object*
- *Using X–Y data operations*

Integrating an X–Y data object

Use the **integrate** function to operate on a *previously saved*X–Y data object (a collection of ordered pairs) to produce a new *X–Y* data object. The new *X–Y* data object has the same *X*-coordinate values as the original *X–Y* data object, but new *Y*-coordinates are computed as the numerical integral (using the trapezoidal rule) of the original *Y*-coordinates.

Figure 1 shows an example of an *X–Y* plot produced using the **integrate** function.

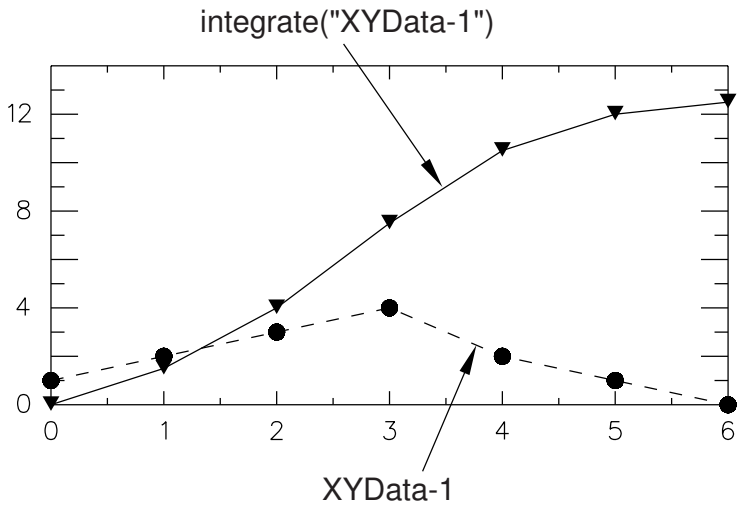

Figure 1: *X–Y* plot produced using the integrate function.

1. Locate the **Operate on XY Data** dialog box.

   From the main menu bar, select **Tools->XY Data->Create**. Click **Operate on XY data** in the dialog box that appears; then click **Continue**. The **Operate on XY Data** dialog box appears.

2. From the **Operators** listed, click **integrate(X)**.

   The **integrate** function appears in the expression window.

3. From the **XY Data** choices, click the name of the *X–Y* data object on which to operate and click **Add to Expression**. You can choose from all *X–Y* data objects previously saved within this session (listed alphabetically in the **XY Data** field).

   The *X–Y* data object name appears within the **integrate** function parentheses in the expression window.

4. To continue to build your expression, position the cursor in the expression window and type in or select the functions, operators, and *X–Y* data you want to include.
5. To evaluate and display your expression, click **Plot Expression**.
6. To *save* your new *X–Y* data object, click **Save As** and then provide a name in the dialog box that appears.

   Saving your data object makes it available for future operations within this session and for inclusion in *X–Y* plots containing multiple data objects.

7. When you are finished, click **Cancel** to close the dialog box.

Additional information

- *Differentiating an X–Y data object*
- *Using X–Y data operations*

Interpolating an X–Y data object

Use the **interpolate** function to operate on a *previously saved*X–Y data object (a collection of ordered pairs) to produce a new *X–Y* data object. Interpolating an *X–Y* data object with nonuniform data produces an *X–Y* data object with new, interpolated *Y*-coordinate values occurring at regular increments on the *X*-axis. By default, the data are interpolated at increments equal to the smallest *X*-increment in the source data.

Figure 1 shows an example of an *X–Y* plot produced using the **interpolate** function, superimposed over the raw data.

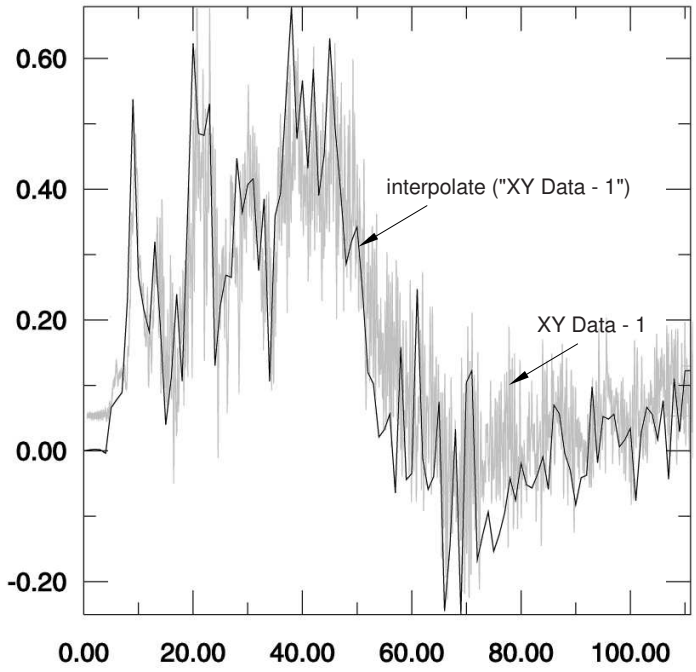

Figure 1: *X–Y* plot produced using the interpolate function.

The name of the *X–Y* data object is the only required argument for the **interpolate** function. A description of the optional arguments follows:

- The *X*-axis increment between interpolated data points (*xIncrement*). If you do not specify a value for this argument or if you specify a non-positive value, Abaqus/CAE uses the minimum *X*-increment of the raw data set.
- A symbolic constant that specifies the interpolation scheme (*interpolation*). Valid values for this argument are QUADRATIC, specifying a Lagrange second-order interpolation scheme; CUBIC_SPLINE, specifying a cubic spline interpolation scheme; and LINEAR, specifying a linear interpolation scheme. The default value is QUADRATIC.
- The slope of the raw data curve leading up to the first data point (*startslope*). This argument's default value is 0.0 (for a level slope), and it is used only when interpolation=CUBIC_SPLINE.
- The slope of the raw data curve continuing past the final data point (*endslope*). This argument's default value is 0.0 (for a level slope), and it is used only when interpolation=CUBIC_SPLINE.

1. Locate the **Operate on XY Data** dialog box.

   From the main menu bar, select **Tools->XY Data->Create**. Click **Operate on XY data** in the dialog box that appears; then click **Continue**. The **Operate on XY Data** dialog box appears.

2. From the **Operators** listed, click **interpolate(X)**.

   The **interpolate** function appears in the expression window.

3. From the **XY Data** choices, click the name of the *X–Y* data object on which to operate and click **Add to Expression**. You can choose from all *X–Y* data objects previously saved within this session (listed alphabetically in the **XY Data** field).

   The *X–Y* data object name appears within the **interpolate** function parentheses in the expression window.

4. To continue to build your expression, position the cursor in the expression window and type in or select the functions, operators, and *X–Y* data you want to include.
5. To evaluate and display your expression, click **Plot Expression**.
6. To *save* your new *X–Y* data object, click **Save As** and then provide a name in the dialog box that appears.

   Saving your data object makes it available for future operations within this session and for inclusion in *X–Y* plots containing multiple data objects.

7. When you are finished, click **Cancel** to close the dialog box.

Additional information

- *Using X–Y data operations*

Linearizing an X–Y data object

Use the **linearize** function to separate the *Y*-values of a *previously saved*X–*Y* data object (a collection of ordered pairs) into constant or linear components. The new *X*–*Y* data object produced by the **linearize** function contains exactly two points.

Figure 1 shows an example of an *X*–*Y* plot produced using the **linearize** function.

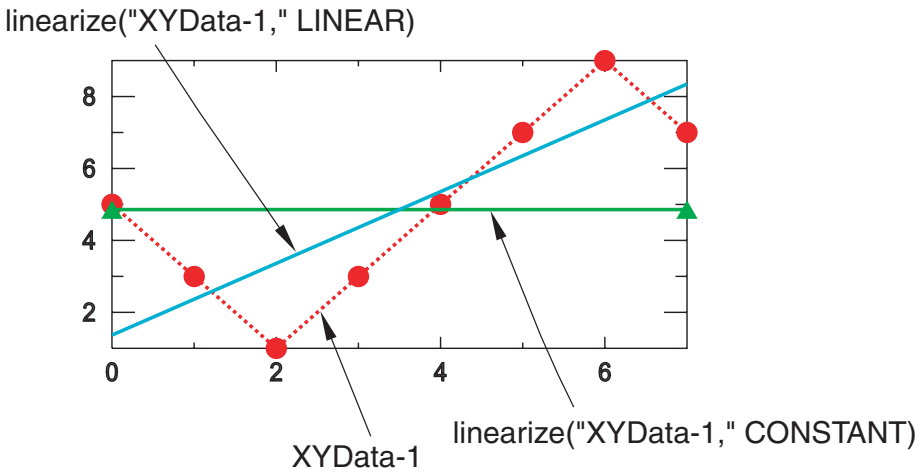

Figure 1: *X*–*Y* plot produced using both the constant and linear forms of the linearize function.

Note:

The *X*-values of the *X*–*Y* data object that you input to the **linearize** function must be equally spaced.

1. Locate the **Operate on XY Data** dialog box.

   From the main menu bar, select **Tools->XY Data->Create**. Click **Operate on XY data** in the dialog box that appears; then click **Continue**. The **Operate on XY Data** dialog box appears.

2. From the **Operators** listed, click either **linearize(X, CONSTANT)** or **linearize(X, LINEAR)** to apply linearization to create a constant Y term or to linearize the Y term, respectively.

   The **linearize** function appears in the expression window.

3. From the **XY Data** choices, click the name of the *X*–*Y* data object on which to operate and click **Add to Expression**. You can choose from all *X*–*Y* data objects previously saved within this session (listed alphabetically in the **XY Data** field).

   The *X*–*Y* data object name appears within the **linearize** function parentheses in the expression window.

4. To continue to build your expression, position the cursor in the expression window and type in or select the functions, operators, and *X*–*Y* data you want to include.
5. To evaluate and display your expression, click **Plot Expression**.
6. To *save* your new *X*–*Y* data object, click **Save As** and then provide a name in the dialog box that appears.

   Saving your data object makes it available for future operations within this session and for inclusion in *X*–*Y* plots containing multiple data objects.

7. When you are finished, click **Cancel** to close the dialog box.

Additional information

• *Using X–Y data operations*

Normalizing an X–Y data object

Use the **normalize** function to operate on a *previously saved*X–Y data object (a collection of ordered pairs) to produce a new X–Y data object. This operation is analogous to normalizing a vector. The new X–Y data object has the same X-coordinate values as the original X–Y data object. Abaqus/CAE computes the new Y-coordinates by dividing each original Y-coordinate by the root mean square (the square root of the sum of the squares) of all original Y-coordinate values.

Figure 1 illustrates the type of X–Y plot that can be produced by using the **normalize** function.

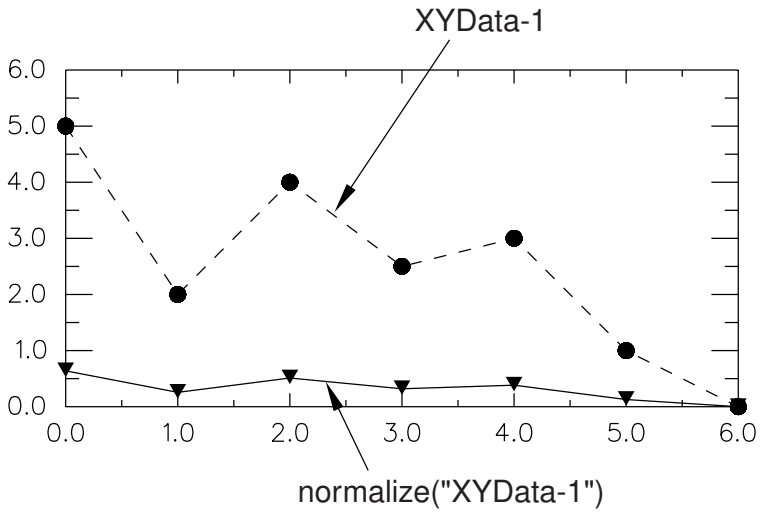

Figure 1: X–Y plot produced using the normalize function.

1. Locate the **Operate on XY Data** dialog box.

   From the main menu bar, select **Tools->XY Data->Create**. Click **Operate on XY data** in the dialog box that appears; then click **Continue**. The **Operate on XY Data** dialog box appears.

2. From the **Operators** listed, click **normalize(X)**.

   The **normalize** function appears in the expression window.

3. From the **XY Data** choices, click the name of the X–Y data object on which to operate and click **Add to Expression**. You can choose from all X–Y data objects previously saved within this session (listed alphabetically in the **XY Data** field).

   The X–Y data object name appears within the **normalize** function parentheses in the expression window.

4. To continue to build your expression, position the cursor in the expression window and type in or select the functions, operators, and X–Y data you want to include.
5. To evaluate and display your expression, click **Plot Expression**.
6. To *save* your new X–Y data object, click **Save As** and then provide a name in the dialog box that appears.

   Saving your data object makes it available for future operations within this session and for inclusion in X–Y plots containing multiple data objects.

7. When you are finished, click **Cancel** to close the dialog box.

Additional information

- *Taking the square root of the sum of the squares of two or more X–Y data objects*
- *Using X–Y data operations*

Taking the square root of an X–Y data object

Use the **sqrt** function to operate on a *previously saved*X–Y data object (a collection of ordered pairs) to produce a new X–Y data object. The new X–Y data object has the same X-coordinate values as the original X–Y data object, but new Y-coordinates are computed as the square root of the original Y-coordinates.

Figure 1 provides an example of an X–Y plot produced using the **sqrt** function.

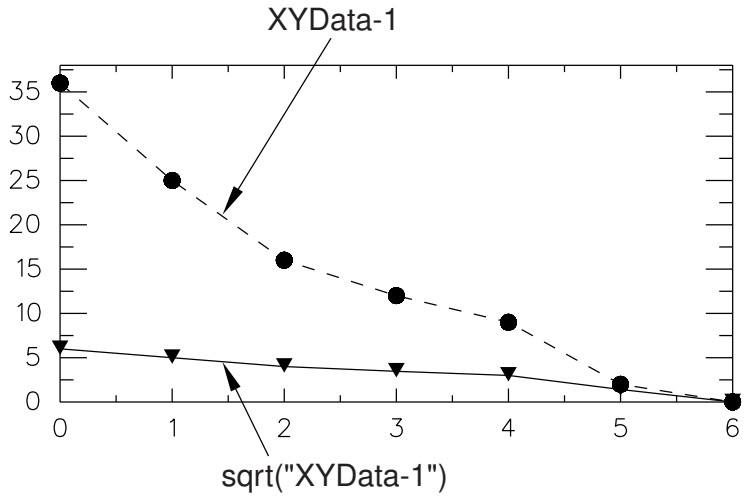

Figure 1: *X–Y* plot produced using the sqrt function.

1. Locate the **Operate on XY Data** dialog box.

   From the main menu bar, select **Tools->XY Data->Create**. Click **Operate on XY data** in the dialog box that appears; then click **Continue**. The **Operate on XY Data** dialog box appears.

2. From the **Operators** listed, click **sqrt(A)**.

   The **sqrt** function appears in the expression window.

3. From the **XY Data** choices, click the name of the X–Y data object on which to operate and click **Add to Expression**. You can choose from all X–Y data objects previously saved within this session (listed alphabetically in the **XY Data** field).

   The X–Y data object name appears within the **sqrt** function parentheses in the expression window.

4. To continue to build your expression, position the cursor in the expression window and type in or select the functions, operators, and X–Y data you want to include.
5. To evaluate and display your expression, click **Plot Expression**.
6. To *save* your new X–Y data object, click **Save As** and then provide a name in the dialog box that appears.

   Saving your data object makes it available for future operations within this session and for inclusion in X–Y plots containing multiple data objects.

7. When you are finished, click **Cancel** to close the dialog box.

Additional information

- *Taking the square root of the sum of the squares of two or more X–Y data objects*
- *Using X–Y data operations*

Taking the square root of the sum of the squares of two or more X–Y data objects

Use the **srss** function to perform a square root of the sum of the squares operation on two or more *previously saved*X–Y data objects (each object is a collection of ordered pairs) to produce a new X–Y data object. Use this function, for example, to find the total magnitude of two or more X–Y data objects at matching X-coordinates.

The new X–Y data object has as its X-coordinates all X-coordinates of the first data object and any additional X-coordinates needed for alignment of the remaining objects. Abaqus/CAE computes additional X–Y data pairs by *interpolation and extrapolation*. The new data object has as its Y-coordinates the square root of the sum of the squares of all input X–Y data object Y-coordinates at matching X-coordinates. The arguments to this function are commutative.

Figure 1 illustrates the type of X–Y plot that can be produced using the **srss** function.

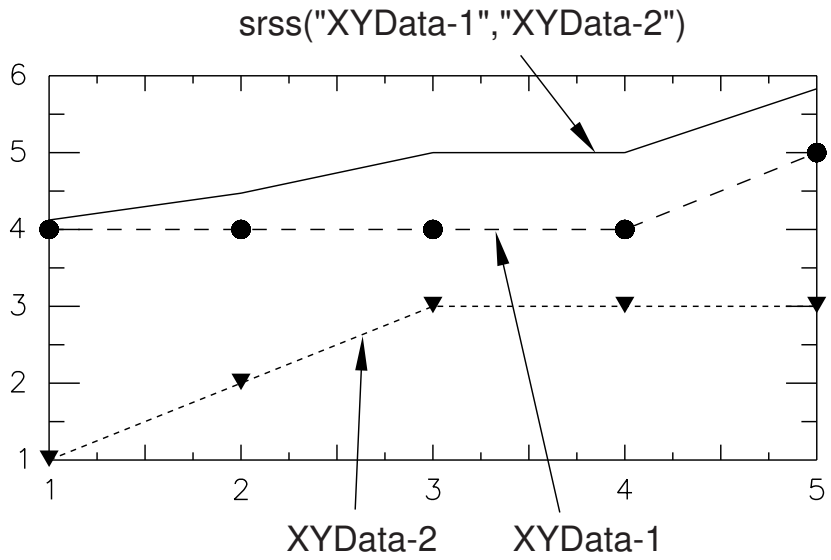

Figure 1: X–Y plot produced using the srss function.

1. Locate the **Operate on XY Data** dialog box.

   From the main menu bar, select **Tools->XY Data->Create**. Click **Operate on XY data** in the dialog box that appears; then click **Continue**. The **Operate on XY Data** dialog box appears.

2. From the **Operators** listed, click **srss(X,X,...)**.

   The **srss** function appears in the expression window.

3. From the **XY Data** choices, click the names of two or more X–Y data objects on which to operate and click **Add to Expression**. You can choose from all X–Y data objects previously saved within this session (listed alphabetically in the **XY Data** field).

   The X–Y data object names appear, separated by commas, within the **srss** function parentheses in the expression window.

4. To continue to build your expression, position the cursor in the expression window and type in or select the functions, operators, and X–Y data you want to include.
5. To evaluate and display your expression, click **Plot Expression**.
6. To *save* your new X–Y data object, click **Save As** and then provide a name in the dialog box that appears.

   Saving your data object makes it available for future operations within this session and for inclusion in X–Y plots containing multiple data objects.

7. When you are finished, click **Cancel** to close the dialog box.

Summing two or more X–Y data objects

Use the **sum** function to operate on two or more *previously saved*X–Y data objects (each object is a collection of ordered pairs) to produce a new X–Y data object. The **sum** function accepts two or more commutative arguments.

Note:

This function has the same behavior as the **+** symbol. For more information, see *Using addition on X–Y data objects*.

1. Locate the **Operate on XY Data** dialog box.

   From the main menu bar, select **Tools->XY Data->Create**. Click **Operate on XY data** in the dialog box that appears; then click **Continue**. The **Operate on XY Data** dialog box appears.
2. From the **Operators** listed, click **sum(A,A,...)**.

   The **sum** function appears in the expression window.
3. From the **XY Data** choices, click the names of two or more X–Y data objects to sum together and click **Add to Expression**. You can choose from all X–Y data objects previously saved within this session (listed alphabetically in the **XY Data** field).

   The X–Y data object names appear, separated by commas, within the **sum** function parentheses in the expression window.
4. To continue to build your expression, position the cursor in the expression window and type in or select the functions, operators, and X–Y data you want to include.
5. To evaluate and display your expression, click **Plot Expression**.
6. To *save* your new X–Y data object, click **Save As** and then provide a name in the dialog box that appears.

   Saving your data object makes it available for future operations within this session and for inclusion in X–Y plots containing multiple data objects.
7. When you are finished, click **Cancel** to close the dialog box.

Additional information

- *Using addition on X–Y data objects*
- *Appending two or more X–Y data objects*
- *Combining two X–Y data objects*
- *Using X–Y data operations*

Calculating vector magnitudes

Use the **vectorMagnitude** function to perform a square root of the sum of the squares operation on at most three *previously saved*X–Y data objects (each object is a collection of ordered pairs) to produce a new X–Y data object. This function is essentially identical to the **srss** function (see *Taking the square root of the sum of the squares of two or more X–Y data objects*) except that the operation can be performed on at most three data objects. You can use this function to plot the total magnitude of a vector by calculating the square root of the sums of the squares of the three vector components.

The new X–Y data object has as its X-coordinates all X-coordinates of the first data object and any additional X-coordinates needed for alignment of the remaining objects. Abaqus/CAE computes additional X–Y data pairs by *interpolation and extrapolation*. The new data object has as its Y-coordinates the square root of the sum of the squares of all input X–Y data object Y-coordinates at matching X-coordinates. The arguments to this function are commutative.

Figure 1 illustrates the type of X–Y plot that can be produced using the **vectorMagnitude** function.

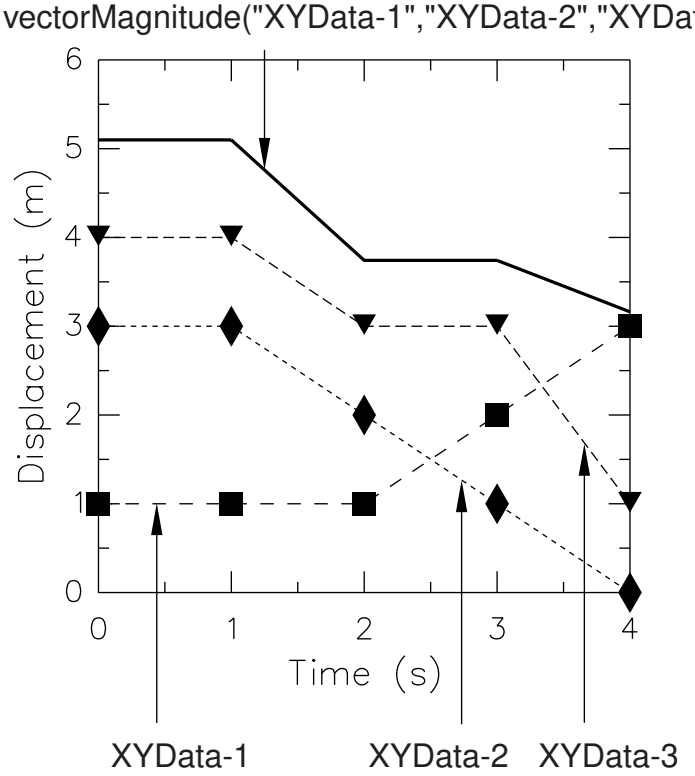

Figure 1: X–Y plot produced using the vectorMagnitude function.

1. Locate the **Operate on XY Data** dialog box.

   From the main menu bar, select **Tools->XY Data->Create**. Click **Operate on XY data** in the dialog box that appears; then click **Continue**. The **Operate on XY Data** dialog box appears.

2. From the **Operators** listed, click **vectorMagnitude(X,X,X)**.

   The **vectorMagnitude** function appears in the expression window.

3. From the **XY Data** choices, click the names of three X–Y data objects on which to operate and click **Add to Expression**. You can choose from all X–Y data objects previously saved within this session (listed alphabetically in the **XY Data** field).

   The X–Y data object names appear, separated by commas, within the **vectorMagnitude** function parentheses in the expression window.

4. To continue to build your expression, position the cursor in the expression window and type in or select the functions, operators, and *X–Y* data you want to include.
5. To evaluate and display your expression, click **Plot Expression**.
6. To *save* your new *X–Y* data object, click **Save As** and then provide a name in the dialog box that appears.

   Saving your data object makes it available for future operations within this session and for inclusion in *X–Y* plots containing multiple data objects.
7. When you are finished, click **Cancel** to close the dialog box.

Applying trigonometric functions to an X–Y data object

Use the trigonometric functions **cos**, **cosh**, **acos**, **sin**, **sinh**, **asin**, **tan**, **tanh**, and **atan** to operate on a *previously saved*X–Y data object (a collection of ordered pairs) to produce a new *X–Y* data object. The new *X–Y* data object has the same *X*-coordinate values as the original *X–Y* data object, but new *Y*-coordinates are computed as the trigonometric function value of each original *Y*-coordinate. Arguments to trigonometric functions are assumed to be in radians.

For example, if

$$\mathbf{XYData} = [(0,0),(1,1.571),(2,3.14)],$$

then

$$\mathbf{sin(XYData)} = [(0,0),(1,1),(2,0.00159)].$$

Figure 1 shows an *X–Y* plot of the above example.

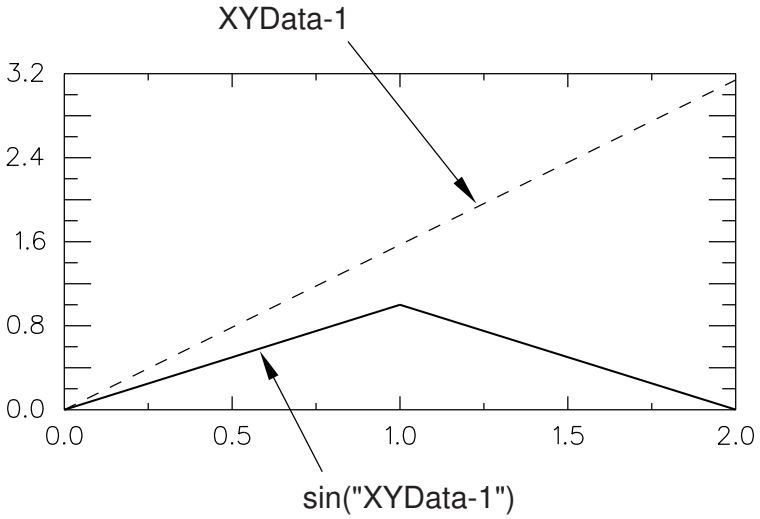

Figure 1: *X–Y* plot produced using the sin function.

1. Locate the **Operate on XY Data** dialog box.

   From the main menu bar, select **Tools->XY Data->Create**. Click **Operate on XY data** in the dialog box that appears; then click **Continue**. The **Operate on XY Data** dialog box appears.

2. From the **Operators** listed, click one of the following trigonometric functions:

sin(A)	To compute the sine of your *X–Y* data object.
sinh(A)	To compute the hyperbolic sine of your *X–Y* data object.
asin(A)	To compute the arcsine of your *X–Y* data object. Your *Y*-data values must be in the range [–1, 1].
cos(A)	To compute the cosine of your *X–Y* data object.
cosh(A)	To compute the hyperbolic cosine of your *X–Y* data object.
acos(A)	To compute the arccosine of your *X–Y* data object. Your *Y*-data values must be in the range [–1, 1].
tan(A)	To compute the tangent of your *X–Y* data object.
tanh(A)	To compute the hyperbolic tangent of your *X–Y* data object.
atan(A)	To compute the arctangent of your *X–Y* data object.

The trigonometric function you choose appears in the expression window.

3. From the **XY Data** choices, click the name of the *X–Y* data object on which to operate and click **Add to Expression**. You can choose from all *X–Y* data objects previously saved within this session (listed alphabetically in the **XY Data** field).

   The *X–Y* data object name appears within the trigonometric function parentheses in the expression window.

4. To continue to build your expression, position the cursor in the expression window and type in or select the functions, operators, and *X–Y* data you want to include.
5. To evaluate and display your expression, click **Plot Expression**.
6. To *save* your new *X–Y* data object, click **Save As** and then provide a name in the dialog box that appears.

   Saving your data object makes it available for future operations within this session and for inclusion in *X–Y* plots containing multiple data objects.

7. When you are finished, click **Cancel** to close the dialog box.

Taking the exponential of an X–Y data object

Use the **exp** function to operate on a *previously saved*X–Y data object (a collection of ordered pairs) to produce a new X–Y data object. The new X–Y data object has the same X-coordinate values as the original X–Y data object, but new Y-coordinates are computed as the exponential of the original Y-coordinates.

Figure 1 shows an example of an X–Y plot produced by using the **exp** function.

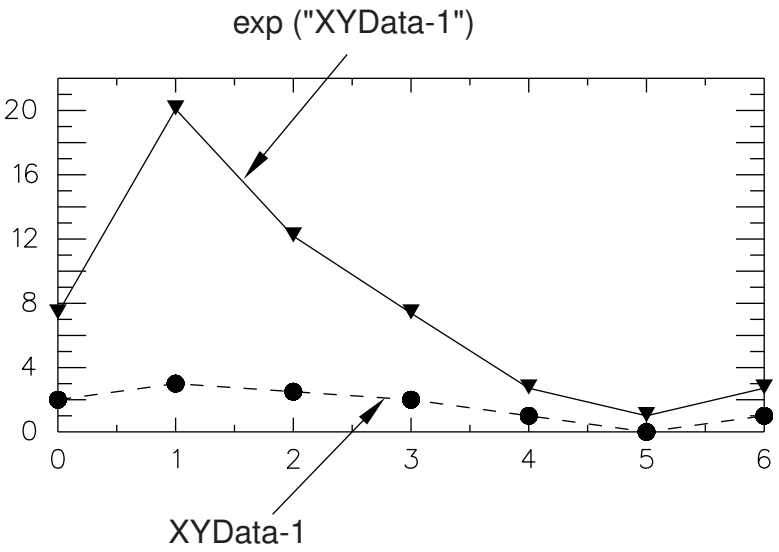

Figure 1: *X–Y* plot produced using the exp function.

1. Locate the **Operate on XY Data** dialog box.

   From the main menu bar, select **Tools->XY Data->Create**. Click **Operate on XY data** in the dialog box that appears; then click **Continue**. The **Operate on XY Data** dialog box appears.

2. From the **Operators** listed, click **exp(A)**.

   The **exp** function appears in the expression window.

3. From the **XY Data** choices, click the name of the X–Y data object on which to operate and click **Add to Expression**. You can choose from all X–Y data objects previously saved within this session (listed alphabetically in the **XY Data** field).

   The X–Y data object name appears within the **exp** function parentheses in the expression window.

4. To continue to build your expression, position the cursor in the expression window and type in or select the functions, operators, and X–Y data you want to include.
5. To evaluate and display your expression, click **Plot Expression**.
6. To *save* your new X–Y data object, click **Save As** and then provide a name in the dialog box that appears.

   Saving your data object makes it available for future operations within this session and for inclusion in X–Y plots containing multiple data objects.

7. When you are finished, click **Cancel** to close the dialog box.

- *Using X–Y data operations*

Applying logarithmic functions to an X–Y data object

Use the logarithmic functions **log** and **log10** to operate on a *previously saved*X–Y data object (a collection of ordered pairs) to produce a new X–Y data object. The new X–Y data object has the same X-coordinate values as the original X–Y data object, but new Y-coordinates are computed as the logarithmic function value of each original Y-coordinate. For example, if

$$\mathbf{XYData} = [(1,1),(2,2.71),(3,7.39)],$$

then

$$\mathbf{log(XYData)} = [(1,0),(2,1.0),(3,2.0)].$$

Figure 1 illustrates the above example.

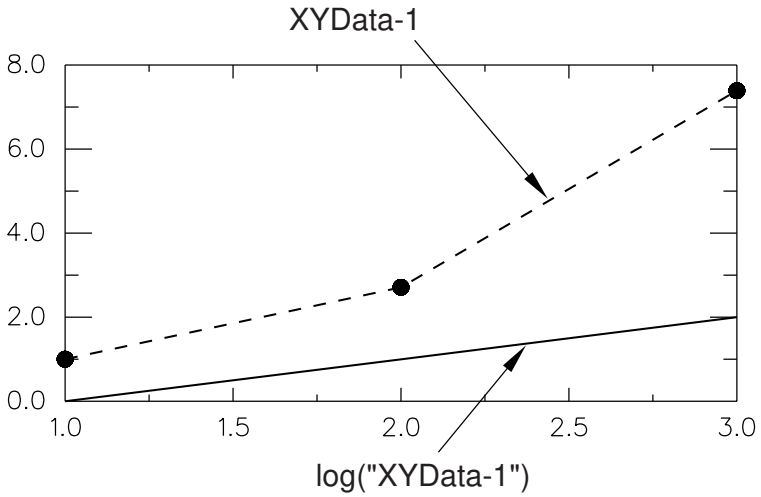

Figure 1: X–Y plot produced using the log function.

1. Locate the **Operate on XY Data** dialog box.

   From the main menu bar, select **Tools->XY Data->Create**. Click **Operate on XY data** in the dialog box that appears; then click **Continue**. The **Operate on XY Data** dialog box appears.

2. From the **Operators** listed, click either **log(A)** or **log10(A)** to apply the natural log or base 10 log function, respectively.

   The logarithmic function you choose appears in the expression window.

3. From the **XY Data** choices, click the name of the X–Y data object on which to operate and click **Add to Expression**. You can choose from all X–Y data objects previously saved within this session (listed alphabetically in the **XY Data** field).

   The X–Y data object name appears within the logarithmic function parentheses in the expression window.

4. To continue to build your expression, position the cursor in the expression window and type in or select the functions, operators, and X–Y data you want to include.
5. To evaluate and display your expression, click **Plot Expression**.
6. To *save* your new X–Y data object, click **Save As** and then provide a name in the dialog box that appears.

   Saving your data object makes it available for future operations within this session and for inclusion in X–Y plots containing multiple data objects.

7. When you are finished, click **Cancel** to close the dialog box.

Additional information

• *Using X–Y data operations*

Raising an X–Y data object to a power

Use the **power** function to operate on a *previously saved*X–Y data object (a collection of ordered pairs) to produce a new X–Y data object. The **power** function requires two arguments, at least one of which must be an X–Y data object. This function can be applied in three ways:

To raise a scalar to an X–Y data object: power(scalar, data object name).

This method yields a new X–Y data object having the same X-coordinate values as the original X–Y data object. Abaqus/CAE computes the new Y-coordinates as the scalar raised to the power of each original Y-coordinate. For example, if

$$\mathbf{XYData} = [(1,1),(2,2),(3,3)],$$

then

$$\mathbf{power}(2, \mathbf{XYData}) = [(1,2),(2,4),(3,8)].$$

To raise an X–Y data object to a scalar: power(data object name, scalar).

This method yields a new X–Y data object having the same X-coordinate values as the original X–Y data object. Abaqus/CAE computes the new Y-coordinates as each original Y-coordinate raised to the scalar. For example, if

$$\mathbf{XYData} = [(2,-2),(3,3),(4,-4)],$$

then

$$\mathbf{power}(\mathbf{XYData}, 2) = [(2,4),(3,9),(4,16)].$$

To raise an X–Y data object to another X–Y data object: power(data object name, data object name).

This method yields a new X–Y data object having as its X-coordinates all X-coordinates of the first data object and any additional X-coordinates needed for alignment of the two objects. Abaqus/CAE computes additional X–Y data pairs by *interpolation and extrapolation*. The new data object has as its Y-coordinates the Y-coordinates of the first data object raised to the Y-coordinates of the second data object. For example, let

$$\mathbf{XYData1} = [(1,1),(2,2),(4,2),(5,1)],$$

and

$$\mathbf{XYData2} = [(0,1),(3,2),(5,6)].$$

For alignment, Abaqus/CAE computes the values of the first and second data objects as:

$$\mathbf{XYData1\ extrapolated} = [(0,1),(1,1),(2,2),(3,2),(4,2),(5,1)],$$

and

$$\mathbf{XYData2\ extrapolated} = [(0,1),(1,1.33),(2,1.66),(3,2),(4,4),(5,6)];$$

then

$$\mathbf{power}(\mathbf{XYData1}, \mathbf{XYData2}) = [(0,1),(1,1),(2,3.17),(3,4),(4,16),(5,1)].$$

Figure 1 shows a plot of the above example.

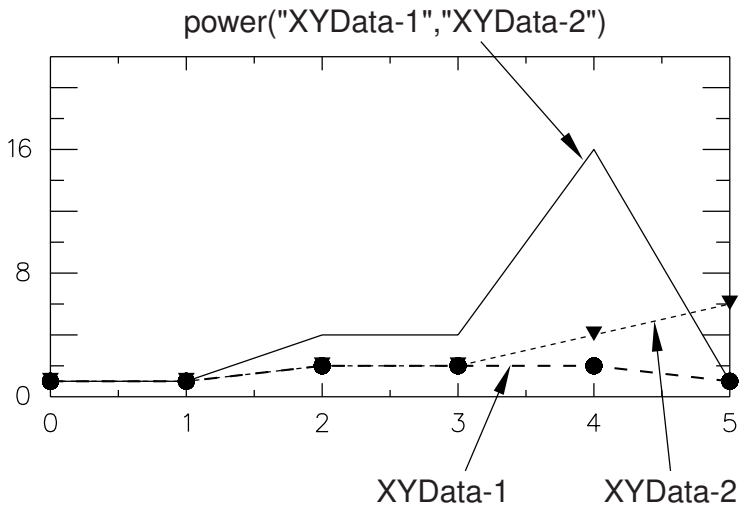

Figure 1: *X–Y* plot of one data object raised to another data object.

1. Locate the **Operate on XY Data** dialog box.

   From the main menu bar, select **Tools->XY Data->Create**. Click **Operate on XY data** in the dialog box that appears; then click **Continue**. The **Operate on XY Data** dialog box appears.

2. From the **Operators** listed, click **power(A,A)**.

   The **power** function appears in the expression window.

3. From the **XY Data** choices, click the name of the *X–Y* data object on which to operate and click **Add to Expression**. You can choose from all *X–Y* data objects previously saved within this session (listed alphabetically in the **XY Data** field).

   The *X–Y* data object name appears within the **power** function parentheses in the expression window.

4. To specify the next argument, do one of the following:

   - Use your mouse and keyboard to enter a scalar as either the first or second argument of the **power** function in the expression window, depending on the operation you want to perform, and to separate the two arguments with a comma, or
   - From the **XY Data** choices, click the name of a data object argument for the **power** function in the expression window and click **Add to Expression**.

5. To continue to build your expression, position the cursor in the expression window and type in or select the functions, operators, and *X–Y* data you want to include.
6. To evaluate and display your expression, click **Plot Expression**.
7. To *save* your new *X–Y* data object, click **Save As** and then provide a name in the dialog box that appears.

   Saving your data object makes it available for future operations within this session and for inclusion in *X–Y* plots containing multiple data objects.

8. When you are finished, click **Cancel** to close the dialog box.

Applying Butterworth filtering to an X–Y data object

Use the **butterworthFilter** function to apply a Butterworth filtering operation to a *previously saved*X–Y data object (a collection of ordered pairs) to produce a new *X–Y* data object. This filtering operation can be used, for example, to remove high-frequency noise.

The transfer function of a Butterworth filter is shown in *Filtering Output and Operating on Output in Abaqus/Explicit*.

Figure 1 illustrates the type of *X–Y* plot that can be produced using the **butterworthFilter** operation.

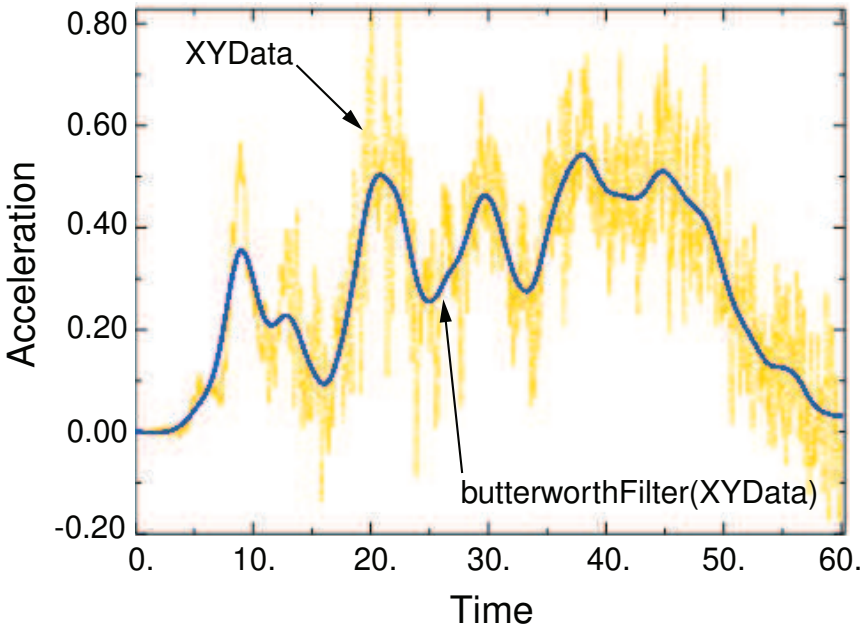

Figure 1: *X–Y* plot produced using the butterworthFilter operation.

The **butterworthFilter** function requires two arguments: the name of the *X–Y* data object (*name*) and the cutoff frequency (*cutoffFrequency*), which is the frequency above which the filter attenuates at least half of the input signal. A description of the optional arguments follows:

- The order of the filter you want to use (*filterOrder*). This argument must be a positive, even integer value; the default value is 2.
- A symbolic constant specifying the method for computation of the projection and pre-charge to be applied at the start of the data signal (*startCondition*). Valid values for this argument are ZERO, which applies a constant projection and pre-charge of zero; CONSTANT, which applies a constant projection and pre-charge equal to the first data point in the *X–Y* data object; MIRROR, which applies a projection and pre-charge equivalent to reflecting the *X–Y* data object about a vertical line passing through the first data point; REVERSE_MIRROR, which applies a projection and pre-charge equivalent to reflecting the *X–Y* data object about both a vertical line and a horizontal line passing through the first data point; and TANGENTIAL, which applies a linear projection and pre-charge that is tangential to the first two data points. The default value is CONSTANT.
- A symbolic constant specifying the method for computation of the projection and pre-charge to be applied at the end of the data signal (*endCondition*). Valid values for this argument are ZERO, which applies a constant projection and pre-charge of zero; CONSTANT, which applies a constant projection and pre-charge equal to the last data point in the *X–Y* data object; MIRROR, which applies a projection and pre-charge equivalent to reflecting the *X–Y* data object about a vertical line passing through the last data point; REVERSE_MIRROR, which applies a projection and pre-charge equivalent to reflecting the *X–Y* data object about both a vertical line and a horizontal line passing

through the last data point; and TANGENTIAL, which applies a linear projection and pre-charge that is tangential to the last two data points. The default value is CONSTANT.

- A symbolic constant that specifies the interpolation scheme (*interpolation*). Valid values for this argument are QUADRATIC, specifying a Lagrange second-order interpolation scheme; CUBIC_SPLINE, specifying a cubic spline interpolation scheme; and LINEAR, specifying a linear interpolation scheme. The default value is QUADRATIC.
- The slope of the raw data curve leading up to the first data point (*startslope*). This argument's default value is 0.0 (for a level slope), and it is used only when interpolation=CUBIC_SPLINE.
- The slope of the raw data curve continuing past the final data point (*endslope*). This argument's default value is 0.0 (for a level slope), and it is used only when interpolation=CUBIC_SPLINE.
- A Boolean specifying whether a backward pass (*backwardPass*) is to be performed on the filtered data. The default value for this argument is True. When this argument is set to False, the *endCondition* argument is ignored.

Your *X–Y* data object must have a constant time step for it to be filtered. If the time step is not constant, Abaqus/CAE computes additional points at constant intervals by *interpolation*. The constant time step for Butterworth filtering is defined by the smallest time step in the *X–Y* data object to be filtered.

1. Locate the **Operate on XY Data** dialog box.

   From the main menu bar, select **Tools->XY Data->Create**. Click **Operate on XY data** in the dialog box that appears; then click **Continue**. The **Operate on XY Data** dialog box appears.

2. From the **Operators** listed, click **butterworthFilter(X,F)**.

   The **butterworthFilter** function appears in the expression window.

3. From the **XY Data** choices, click the name of the *X–Y* data object on which to operate and click **Add to Expression**. You can choose from all *X–Y* data objects previously saved within this session (listed alphabetically in the **XY Data** field).

   The *X–Y* data object name appears within the **butterworthFilter** function parentheses in the expression window.

4. Position the cursor in the expression window before the second comma, and type in a value for the cutoff frequency.
5. To continue to build your expression, position the cursor in the expression window and type in or select the functions, operators, and *X–Y* data you want to include.
6. To evaluate and display your expression, click **Plot Expression**.
7. To *save* your new *X–Y* data object, click **Save As** and then provide a name in the dialog box that appears.

   Saving your data object makes it available for future operations within this session and for inclusion in *X–Y* plots containing multiple data objects.

8. When you are finished, click **Cancel** to close the dialog box.

Applying Chebyshev Type I or Type II filtering to an X–Y data object

Use the **chebyshev1Filter** or **chebyshev2Filter** function to apply a Chebyshev Type I or Type II filtering operation to a *previously saved*X–Y data object (a collection of ordered pairs) to produce a new *X–Y* data object. This filtering operation can be used, for example, to remove high-frequency noise.

The transfer functions of the Chebyshev filters are shown in *Filtering Output and Operating on Output in Abaqus/Explicit*.

Figure 1 illustrates the type of *X–Y* plot that can be produced using the **chebyshev1Filter** operation.

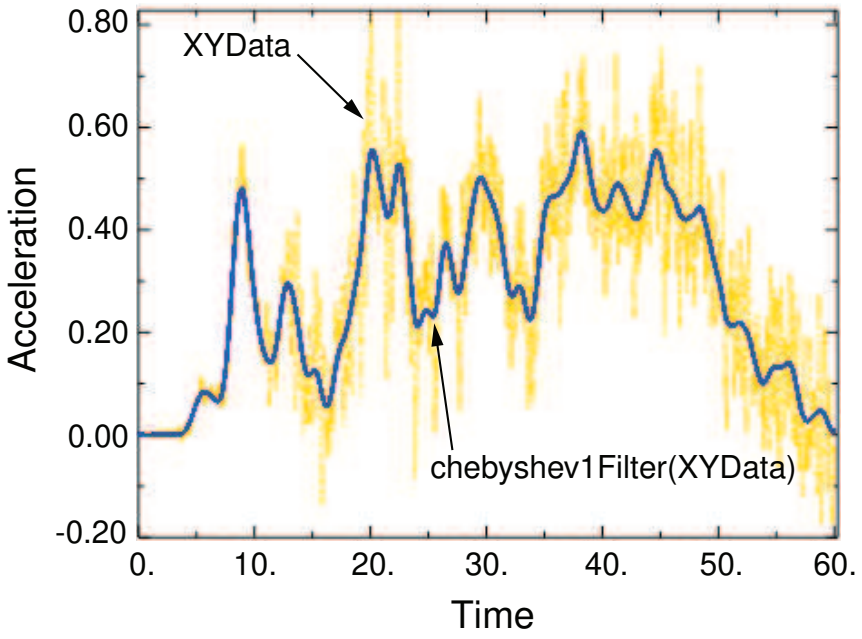

Figure 1: *X–Y* plot produced using the chebyshev1Filter operation.

The **chebyshev1Filter** and **chebyshev2Filter** functions use the same syntax and require the same set of arguments. The following arguments are required: the name of the *X–Y* data object (*name*); the cutoff frequency (*cutoffFrequency*), which is the frequency above which the filter attenuates at least half of the input signal; and the ripple factor (*rippleFactor*), which is a floating point number that indicates how much oscillation you will allow in exchange for an improved filter response. Both Chebyshev Type I and II filtering require a ripple factor greater than 0; in addition, Chebyshev Type II filtering requires the value to be less than 1. Chebyshev Type I filtering does not place any upper bound on the ripple factor value.

The two types of Chebyshev filters differ in where their response ripples occur and in their handling of the ripple factor value; see *Filtering Output and Operating on Output in Abaqus/Explicit* for a comparison of Type I and Type II Chebyshev output with typical Butterworth filter output.

A description of the optional arguments follows:

- The order of the filter you want to use (*filterOrder*). This argument must be a positive, even integer value; the default value is 2.
- A symbolic constant specifying the method for computation of the projection and pre-charge to be applied at the start of the data signal (*startCondition*). Valid values for this argument are ZERO, which applies a constant projection and pre-charge of zero; CONSTANT, which applies a constant projection and pre-charge equal to the first data point in the *X–Y* data object; MIRROR, which applies a projection and pre-charge equivalent to reflecting the *X–Y* data object about a vertical line passing through the first data point; REVERSE_MIRROR, which applies a projection

and pre-charge equivalent to reflecting the *X–Y* data object about both a vertical line and a horizontal line passing through the first data point; and TANGENTIAL, which applies a linear projection and pre-charge that is tangential to the first two data points. The default value is CONSTANT.

- A symbolic constant specifying the method for computation of the projection and pre-charge to be applied at the end of the data signal (*endCondition*). Valid values for this argument are ZERO, which applies a constant projection and pre-charge of zero; CONSTANT, which applies a constant projection and pre-charge equal to the last data point in the *X–Y* data object; MIRROR, which applies a projection and pre-charge equivalent to reflecting the *X–Y* data object about a vertical line passing through the last data point; REVERSE_MIRROR, which applies a projection and pre-charge equivalent to reflecting the *X–Y* data object about both a vertical line and a horizontal line passing through the last data point; and TANGENTIAL, which applies a linear projection and pre-charge that is tangential to the last two data points. The default value is CONSTANT.
- A symbolic constant that specifies the interpolation scheme (*interpolation*). Valid values for this argument are QUADRATIC, specifying a Lagrange second-order interpolation scheme; CUBIC_SPLINE, specifying a cubic spline interpolation scheme; and LINEAR, specifying a linear interpolation scheme. The default value is QUADRATIC.
- The slope of the raw data curve leading up to the first data point (*startslope*). This argument's default value is 0.0 (for a level slope), and it is used only when interpolation=CUBIC_SPLINE.
- The slope of the raw data curve continuing past the final data point (*endslope*). This argument's default value is 0.0 (for a level slope), and it is used only when interpolation=CUBIC_SPLINE.
- A Boolean specifying whether a backward pass (*backwardPass*) is to be performed on the filtered data. The default value for this argument is True. When this argument is set to False, the *endCondition* argument is ignored.

Your *X–Y* data object must have a constant time step for it to be filtered. If the time step is not constant, Abaqus/CAE computes additional points at constant intervals by *interpolation*. The constant time step for Chebyshev Type I or II filtering is defined by the smallest time step in the *X–Y* data object to be filtered.

1. Locate the **Operate on XY Data** dialog box.

   From the main menu bar, select **Tools->XY Data->Create**. Click **Operate on XY data** in the dialog box that appears; then click **Continue**. The **Operate on XY Data** dialog box appears.

2. From the **Operators** listed, click **chebyshev1Filter(X,F,F)** or **chebyshev2Filter(X,F,F)** for Chebyshev Type I or Type II filtering, respectively.

   The **chebyshev1Filter** or **chebyshev2Filter** function appears in the expression window.

3. From the **XY Data** choices, click the name of the *X–Y* data object on which to operate and click **Add to Expression**. You can choose from all *X–Y* data objects previously saved within this session (listed alphabetically in the **XY Data** field).

   The *X–Y* data object name appears within the **chebyshev1Filter** or **chebyshev2Filter** function parentheses in the expression window.

4. Position the cursor in the expression window before the second comma, and type in a value for the cutoff frequency.
5. Position the cursor in the expression window before the third comma, and type in a positive value for the ripple factor. For the **chebyshev2Filter** function, this value must be less than 1.
6. To continue to build your expression, position the cursor in the expression window and type in or select the functions, operators, and *X–Y* data you want to include.
7. To evaluate and display your expression, click **Plot Expression**.
8. To *save* your new *X–Y* data object, click **Save As** and then provide a name in the dialog box that appears.

   Saving your data object makes it available for future operations within this session and for inclusion in *X–Y* plots containing multiple data objects.

9. When you are finished, click **Cancel** to close the dialog box.

Additional information

Reducing the sample size of an X–Y data object

Use the **decimateFilter** function to reduce a large, *previously saved*X–Y data object (a collection of ordered pairs) to a smaller, representative sample. The **decimateFilter** function is an anti-aliasing filter that selects points at a user-defined sampling frequency to produce a new *X–Y* data object.

The **decimateFilter** function requires two arguments: the name of the *X–Y* data object (*name*) and the decimation factor (*decimationFactor*), which is the factor by which the sampling rate is to be increased. The decimation factor must be an integer value greater than 1. The function also accepts an optional argument that specifies the ratio of the new sampling rate to the cutoff frequency used by the **decimateFilter** function prior to decimation (*cutoffFactor*). The cutoff factor must be an integer value of 2 or more. The default value is 3.

1. Locate the **Operate on XY Data** dialog box.

   From the main menu bar, select **Tools->XY Data->Create**. Click **Operate on XY data** in the dialog box that appears; then click **Continue**. The **Operate on XY Data** dialog box appears.

2. From the **Operators** listed, click **decimateFilter(X,I)**.

   The **decimateFilter** function appears in the expression window.

3. From the **XY Data** choices, click the name of the *X–Y* data object on which to operate and click **Add to Expression**. You can choose from all *X–Y* data objects previously saved within this session (listed alphabetically in the **XY Data** field).

   The *X–Y* data object name appears within the **decimateFilter** function parentheses in the expression window.

4. Position the cursor in the expression window before the second comma, and type in a value for the decimation factor.
5. If desired, position the cursor in the expression window before the third comma, and type in a value for the cutoff factor.
6. To evaluate and display your expression, click **Plot Expression**.
7. To *save* your new *X–Y* data object, click **Save As** and then provide a name in the dialog box that appears.

   Saving your data object makes it available for future operations within this session and for inclusion in *X–Y* plots containing multiple data objects.

8. When you are finished, click **Cancel** to close the dialog box.

Applying SAE filtering to an X–Y data object

Use one of the SAE filtering functions to apply an SAE filtering operation to a *previously saved*X–Y data object (a collection of ordered pairs) to produce a new X–Y data object. For example, you can use these functions to remove high-frequency noise.

The SAE filtering operation performs two-pass, zero phase shift, second-order Butterworth filtering. The SAE filtering classes that are allowed in Abaqus/CAE are 60, 100, 180, 600, and 1000, as defined in SAE Standard J211 (OCT88). The Visualization module in Abaqus/CAE uses the Signal Analysis Software obtained from the National Highway Traffic Safety Administration (NHTSA). For more information, see the documentation for the Signal Analysis Software installation kit on the NHTSA website (search for NVS Software Applications on http://www.nhtsa.gov/).

Abaqus/CAE provides the following two types of SAE filtering functions:

- The general operator, **saeGeneralFilter**, uses a general filtering class and can filter data for a user-specified cutoff frequency.
- Class-specific operators filter for each of the five supported SAE filtering classes: **sae60Filter**, **sae100Filter**, **sae180Filter**, **sae600Filter**, and **sae1000Filter**. Because they use a specific filtering class, these operators do not support specification of a cutoff frequency.

Your X–Y data object must have a constant time step for it to be filtered. If the time step is not constant, Abaqus/CAE computes additional points at constant intervals by *interpolation*. The constant time step for SAE filtering is defined by the smallest time step in the X–Y data object to be filtered.

Figure 1 illustrates the type of X–Y plot that can be produced using the **saeGeneralFilter** operation.

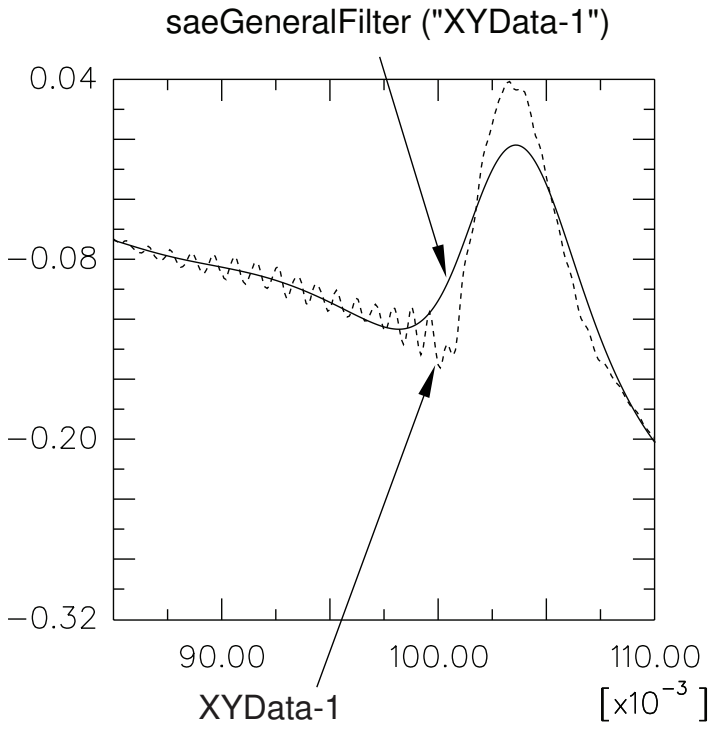

Figure 1: X–Y plot produced using the saeGeneralFilter operation.

The **saeGeneralFilter** function requires two arguments: the name of the X–Y data object (*name*) and the cutoff frequency (*cutoffFrequency*), which is the frequency above which the filter attenuates at least half of the input signal. The

class-specific filters also require two arguments: the name of the *X–Y* data object (*name*) and the time scale factor (*timeScaleFactor*), which is a multiplier for the *X*-values of the data set being filtered. For example, a value of 1 indicates a time scale of seconds, and a value of 0.001 indicates a time scale of milliseconds.

A description of the optional arguments follows:

- A symbolic constant specifying the method for computation of the projection and pre-charge to be applied at the start of the data signal (*startCondition*). Valid values for this argument are ZERO, which applies a constant projection and pre-charge of zero; CONSTANT, which applies a constant projection and pre-charge equal to the first data point in the *X–Y* data object; MIRROR, which applies a projection and pre-charge equivalent to reflecting the *X–Y* data object about a vertical line passing through the first data point; REVERSE_MIRROR, which applies a projection and pre-charge equivalent to reflecting the *X–Y* data object about both a vertical line and a horizontal line passing through the first data point; and TANGENTIAL, which applies a linear projection and pre-charge that is tangential to the first two data points. The default value is CONSTANT.
- A symbolic constant specifying the method for computation of the projection and pre-charge to be applied at the end of the data signal (*endCondition*). Valid values for this argument are ZERO, which applies a constant projection and pre-charge of zero; CONSTANT, which applies a constant projection and pre-charge equal to the last data point in the *X–Y* data object; MIRROR, which applies a projection and pre-charge equivalent to reflecting the *X–Y* data object about a vertical line passing through the last data point; REVERSE_MIRROR, which applies a projection and pre-charge equivalent to reflecting the *X–Y* data object about both a vertical line and a horizontal line passing through the last data point; and TANGENTIAL, which applies a linear projection and pre-charge that is tangential to the last two data points. The default value is CONSTANT.
- A symbolic constant that specifies the interpolation scheme (*interpolation*). Valid values for this argument are QUADRATIC, specifying a Lagrange second-order interpolation scheme; CUBIC_SPLINE, specifying a cubic spline interpolation scheme; and LINEAR, specifying a linear interpolation scheme. The default value is QUADRATIC.
- The slope of the raw data curve leading up to the first data point (*startslope*). This argument's default value is 0.0 (for a level slope), and it is used only when interpolation=CUBIC_SPLINE.
- The slope of the raw data curve continuing past the final data point (*endslope*). This argument's default value is 0.0 (for a level slope), and it is used only when interpolation=CUBIC_SPLINE.
- A Boolean specifying whether a backward pass (*backwardPass*) is to be performed on the filtered data. The default value for this argument is True. When this argument is set to False, the *endCondition* argument is ignored.

Abaqus/CAE refers to the values in the table below to determine the cutoff frequency multiplier (CM) for the class-specific SAE filter operators.

SAE class	Cutoff frequency multiplier (CM)
60	100
100	165
180	300
600	1000
1000	1650

Abaqus/CAE then calculates the cutoff frequency using the cutoff frequency multiplier and the user-specified time scale factor (TSF), as follows:

$$\text{cutoff frequency} = CM \times TSF$$

1. Locate the **Operate on XY Data** dialog box.

   From the main menu bar, select **Tools->XY Data->Create**. Click **Operate on XY data** in the dialog box that appears; then click **Continue**. The **Operate on XY Data** dialog box appears.

2. From the **Operators** listed, click **saeGeneralFilter(X,F)** for general SAE filtering or click one of the class-specific SAE filter functions.

   Your choice of filtering function appears in the expression window.

3. From the **XY Data** choices, click the name of the *X–Y* data object on which to operate and click **Add to Expression**. You can choose from all *X–Y* data objects previously saved within this session (listed alphabetically in the **XY Data** field).

   The *X–Y* data object name appears within the function parentheses in the expression window.

4. If you selected **saeGeneralFilter(X,F)**, position the cursor in the expression window and enter a value for the cutoff frequency.
5. If you selected a class-specific SAE filter, position the cursor in the expression window and enter a value for the time scale factor.
6. To continue to build your expression, position the cursor in the expression window and type in or select the functions, operators, and *X–Y* data you want to include.
7. To evaluate and display your expression, click **Plot Expression**.
8. To *save* your new *X–Y* data object, click **Save As** and then provide a name in the dialog box that appears.

   Saving your data object makes it available for future operations within this session and for inclusion in *X–Y* plots containing multiple data objects.

9. When you are finished, click **Cancel** to close the dialog box.

- *Smoothing an X–Y data object*

Applying sine-Butterworth filtering to an X–Y data object

Use the **sineButterworthFilter** function to apply a sine-Butterworth filtering operation to a *previously saved*X–Y data object (a collection of ordered pairs) to produce a new *X–Y* data object. This filtering operation can be used, for example, to remove high-frequency noise.

Abaqus/CAE uses a sine-Butterworth filter whose transfer function $|H(f)|^2$ has the following form:

For the filter to be applied to a curve, the curve must have data points at regularly spaced intervals in time. Therefore, a curve to be filtered is resampled at a given frequency (the sampling frequency). The default sampling frequency will be inadequate for curves containing data with a frequency content that is much higher than the cutoff frequency. Using a very high sampling frequency will create a curve with a very large number of data points.

The **sineButterworthFilter** requires two arguments: the name of the *X–Y* data object (*name*) and the cutoff frequency (*cutoffFrequency*), which is the frequency above which the filter attenuates at least half of the input signal. A description of the optional arguments follows:

- The order of the filter you want to use (*filterOrder*). This argument must be a positive, even integer value; the default value is 6.
- A symbolic constant specifying the method for computation of the projection and pre-charge to be applied at the start of the data signal (*startCondition*). Valid values for this argument are ZERO, which applies a constant projection and pre-charge of zero; CONSTANT, which applies a constant projection and pre-charge equal to the first data point in the *X–Y* data object; MIRROR, which applies a projection and pre-charge equivalent to reflecting the *X–Y* data object about a vertical line passing through the first data point; REVERSE_MIRROR, which applies a projection and pre-charge equivalent to reflecting the *X–Y* data object about both a vertical line and a horizontal line passing through the first data point; and TANGENTIAL, which applies a linear projection and pre-charge that is tangential to the first two data points. The default value is CONSTANT.
- A symbolic constant specifying the method for computation of the projection and pre-charge to be applied at the end of the data signal (*endCondition*). Valid values for this argument are ZERO, which applies a constant projection and pre-charge of zero; CONSTANT, which applies a constant projection and pre-charge equal to the last data point in the *X–Y* data object; MIRROR, which applies a projection and pre-charge equivalent to reflecting the *X–Y* data object about a vertical line passing through the last data point; REVERSE_MIRROR, which applies a projection and pre-charge equivalent to reflecting the *X–Y* data object about both a vertical line and a horizontal line passing through the last data point; and TANGENTIAL, which applies a linear projection and pre-charge that is tangential to the last two data points. The default value is CONSTANT.

- A symbolic constant that specifies the interpolation scheme (*interpolation*). Valid values for this argument are QUADRATIC, specifying a Lagrange second-order interpolation scheme; CUBIC_SPLINE, specifying a cubic spline interpolation scheme; and LINEAR, specifying a linear interpolation scheme. The default value is QUADRATIC.
- The slope of the raw data curve leading up to the first data point (*startslope*). This argument's default value is 0.0 (for a level slope), and it is used only when interpolation=CUBIC_SPLINE.
- The slope of the raw data curve continuing past the final data point (*endslope*). This argument's default value is 0.0 (for a level slope), and it is used only when interpolation=CUBIC_SPLINE.
- A Boolean specifying whether a backward pass (*backwardPass*) is to be performed on the filtered data. The default value for this argument is True. When this argument is set to False, the *endCondition* argument is ignored.

Your *X–Y* data object must have a constant time step for it to be filtered. If the time step is not constant, Abaqus/CAE computes additional points at constant intervals by *interpolation*. The constant time step is computed from the sampling frequency according to the following relationship:

$$\text{constant time step} = \frac{1}{2 \times \text{sampling frequency}}$$

Figure 1 illustrates the type of *X–Y* plot that can be produced using the **sineButterworthFilter** operation.

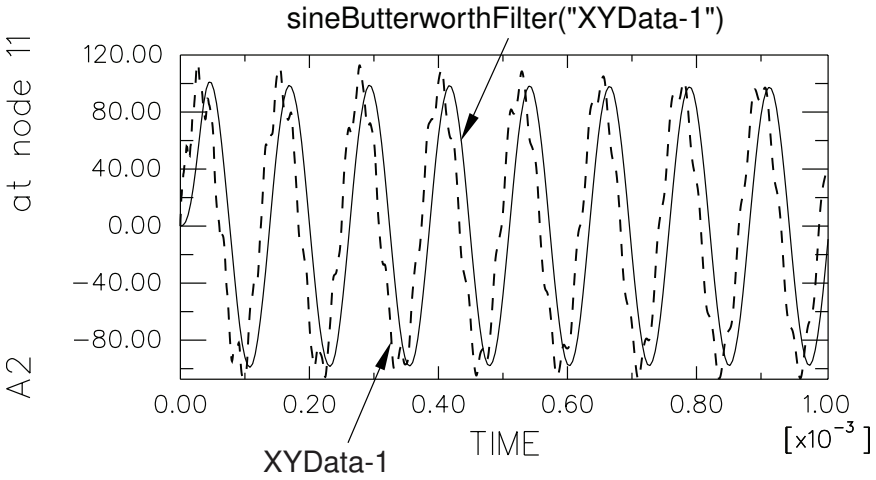

Figure 1: *X–Y* plot produced using the sineButterworthFilter operation.

1. Locate the **Operate on XY Data** dialog box.

   From the main menu bar, select **Tools->XY Data->Create**. Click **Operate on XY data** in the dialog box that appears; then click **Continue**. The **Operate on XY Data** dialog box appears.

2. From the **Operators** listed, click **sineButterworthFilter(X,F)**.

   The **sineButterworthFilter** function appears in the expression window.

3. From the **XY Data** choices, click the name of the *X–Y* data object on which to operate and click **Add to Expression**. You can choose from all *X–Y* data objects previously saved within this session (listed alphabetically in the **XY Data** field).

   The *X–Y* data object name appears within the **sineButterworthFilter** function parentheses in the expression window.

4. Position the cursor in the expression window before the second comma, and type in a value for the cutoff frequency.
5. To continue to build your expression, position the cursor in the expression window and type in or select the functions, operators, and *X–Y* data you want to include.

6. To evaluate and display your expression, click **Plot Expression**.
7. To *save* your new *X–Y* data object, click **Save As** and then provide a name in the dialog box that appears.

   Saving your data object makes it available for future operations within this session and for inclusion in *X–Y* plots containing multiple data objects.
8. When you are finished, click **Cancel** to close the dialog box.

Smoothing an X–Y data object

Use the **smooth** function or the **smooth2** function to operate on a *previously saved*X–Y data object (a collection of ordered pairs) to produce a new X–Y data object having a smoother curve. The new X–Y data object has the same X-coordinate values as the original X–Y data object. At each X-coordinate Abaqus/CAE computes the new Y-coordinate as the average of neighboring Y-coordinates of the original data object. This computation is known as a "moving average." The two functions use different algorithms to calculate this moving average value:

- The **smooth** function uses a simple moving average to calculate the new Y-coordinate values, which means that each new Y-coordinate is the unweighted mean of a number of neighboring points. You can specify the number of neighboring points to include in the average; a larger value produces a smoother curve. Abaqus/CAE interprets the value you specify as the number of points to use on either side of the current X-coordinate. The default is 2, which means Abaqus/CAE averages 5 values to compute each new Y-coordinate.
- The **smooth2** function uses an exponential moving average to calculate the new Y-coordinate values, which means that the neighboring points have an exponentially greater influence on the resulting Y-coordinate value. You can specify a smoothing factor between 0 and 1 for the curve; a smaller value produces a smoother curve. The default smoothing factor is 0.75.

Figure 1 illustrates the type of X–Y plot that can be produced using the **smooth** and **smooth2** functions.

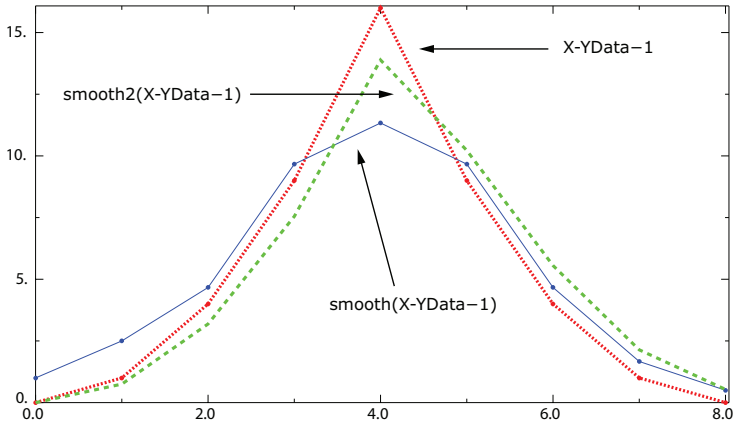

Figure 1: X–Y plots produced using the smooth and smooth2 functions.

1. Locate the **Operate on XY Data** dialog box.

   From the main menu bar, select **Tools->XY Data->Create**. Click **Operate on XY data** in the dialog box that appears; then click **Continue**. The **Operate on XY Data** dialog box appears.

2. From the **Operators** listed, click **smooth(X, I)** or **smooth2(X, F)**.

   The **smooth** or **smooth2** function appears in the expression window.

3. From the **XY Data** choices, click the name of the X–Y data object on which to operate and click **Add to Expression**. You can choose from all X–Y data objects previously saved within this session (listed alphabetically in the **XY Data** field).

   The X–Y data object name appears within the **smooth** or **smooth2** function parentheses in the expression window.

4. Position your cursor in the expression window before the second comma, and enter the following value:

- For the **smooth** function, enter an integer value for the number of points on either side of a given point to include in the average.
- For the **smooth2** function, enter a decimal value between 0 and 1 to determine the smoothing factor for the curve. A smaller value produces a smoother curve.

5. To continue to build your expression, position the cursor in the expression window and type in or select the functions, operators, and *X–Y* data you want to include.
6. To evaluate and display your expression, click **Plot Expression**.
7. To *save* your new *X–Y* data object, click **Save As** and then provide a name in the dialog box that appears.

   Saving your data object makes it available for future operations within this session and for inclusion in *X–Y* plots containing multiple data objects.
8. When you are finished, click **Cancel** to close the dialog box.

Finding the current maximum of an X–Y data object

Use the **currentMax** function to operate on a *previously saved*X–Y data object (a collection of ordered pairs) to produce a new X–Y data object. The new X–Y data object has the same X-coordinate values as the original X–Y data object, but new Y-coordinates are computed as the maximum Y-coordinate at or before the current X-coordinate.

Figure 1 provides an example of an X–Y plot produced by using the **currentMax** function.

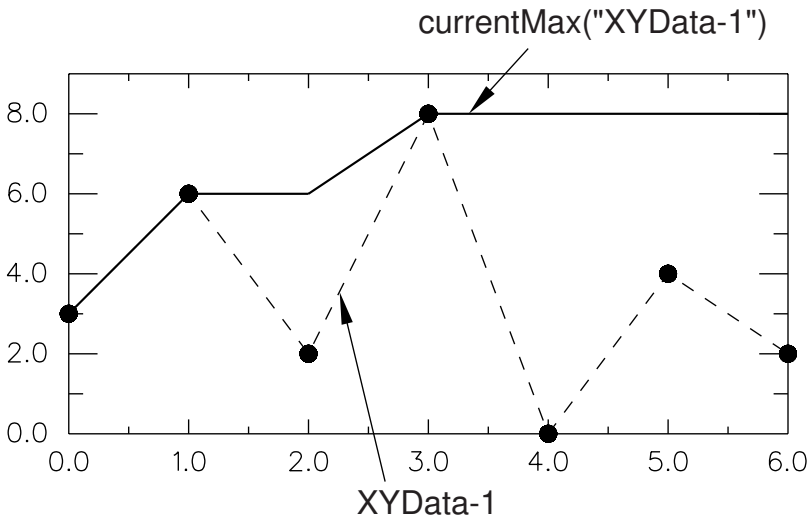

Figure 1: X–Y plot produced using the currentMax function.

Note:

The last value of the new X–Y data object represents the overall maximum Y-coordinate of the original X–Y data object.

For information on how to find the current maximum of two or more X–Y data objects, see *Finding the current maximum of two or more X–Y data objects*.

1. Locate the **Operate on XY Data** dialog box.

   From the main menu bar, select **Tools->XY Data->Create**. Click **Operate on XY data** in the dialog box that appears; then click **Continue**. The **Operate on XY Data** dialog box appears.

2. From the **Operators** listed, click **currentMax(X)**.

   The **currentMax** function appears in the expression window.

3. From the **XY Data** choices, click the name of the X–Y data object on which to operate and click **Add to Expression**. You can choose from all X–Y data objects previously saved within this session (listed alphabetically in the **XY Data** field).

   The X–Y data object name appears within the **currentMax** function parentheses in the expression window.

4. To continue to build your expression, position the cursor in the expression window and type in or select the functions, operators, and X–Y data you want to include.
5. To evaluate and display your expression, click **Plot Expression**.
6. To *save* your new X–Y data object, click **Save As** and then provide a name in the dialog box that appears.

   Saving your data object makes it available for future operations within this session and for inclusion in X–Y plots containing multiple data objects.

7. When you are finished, click **Cancel** to close the dialog box.

Finding the current minimum of an X–Y data object

Use the **currentMin** function to operate on a *previously saved*X–Y data object (a collection of ordered pairs) to produce a new X–Y data object. The new X–Y data object has the same X-coordinate values as the original X–Y data object, but new Y-coordinates are computed as the minimum Y-coordinate at or before the current X-coordinate.

Figure 1 shows an example of an X–Y plot produced by using the **currentMin** function.

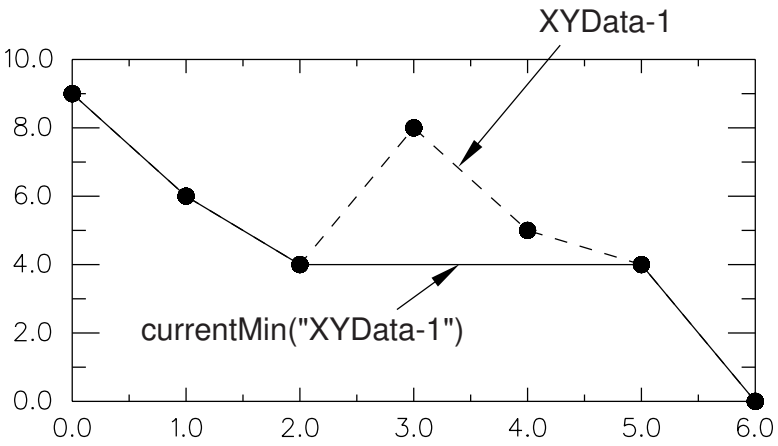

Figure 1: X–Y plot produced using the currentMin function.

Note:

The last value of the new X–Y data object represents the overall minimum Y-coordinate of the original X–Y data object.

For information on how to find the current minimum of two or more X–Y data objects, see *Finding the current minimum of two or more X–Y data objects*.

1. Locate the **Operate on XY Data** dialog box.

   From the main menu bar, select **Tools->XY Data->Create**. Click **Operate on XY data** in the dialog box that appears; then click **Continue**. The **Operate on XY Data** dialog box appears.

2. From the **Operators** listed, click **currentMin(X)**.

   The **currentMin** function appears in the expression window.

3. From the **XY Data** choices, click the name of the X–Y data object on which to operate and click **Add to Expression**. You can choose from all X–Y data objects previously saved within this session (listed alphabetically in the **XY Data** field).

   The X–Y data object name appears within the **currentMin** function parentheses in the expression window.

4. To continue to build your expression, position the cursor in the expression window and type in or select the functions, operators, and X–Y data you want to include.
5. To evaluate and display your expression, click **Plot Expression**.
6. To *save* your new X–Y data object, click **Save As** and then provide a name in the dialog box that appears.

   Saving your data object makes it available for future operations within this session and for inclusion in X–Y plots containing multiple data objects.

7. When you are finished, click **Cancel** to close the dialog box.

Appending two or more X–Y data objects

Use the **append** function to link together two or more *previously saved*X–Y data objects (collections of ordered pairs) to produce a new X–Y data object. The new X–Y data object contains the data objects you specify concatenated in the order you specify.

Figure 1 shows an X–Y plot created by appending an X–Y data object with Y-values varying from 1 to −1 to an X–Y data object with Y-values varying from 0.5 to −0.5.

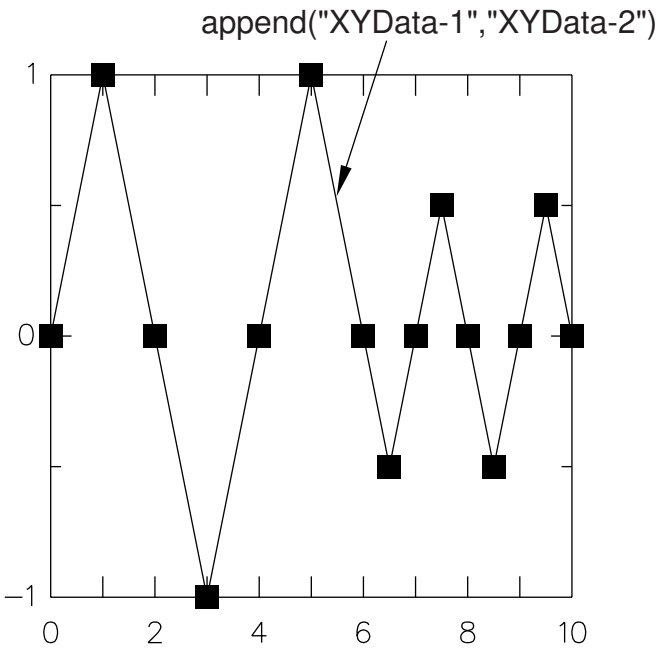

Figure 1: X–Y plot produced using the append function.

1. Locate the **Operate on XY Data** dialog box.

   From the main menu bar, select **Tools->XY Data->Create**. Click **Operate on XY data** in the dialog box that appears; then click **Continue**. The **Operate on XY Data** dialog box appears.

2. From the **Operators** listed, click **append(X,X,...)**.

   The **append** function appears in the expression window.

3. From the **XY Data** choices, click the names of the X–Y data objects to append in the order you want Abaqus to concatenate them and click **Add to Expression**. You can choose from X–Y data objects previously saved within this session (listed alphabetically in the **XY Data** field).

   The X–Y data object names appear, separated by commas, within the **append** function parentheses in the expression window.

4. To continue to build your expression, position the cursor in the expression window and type in or select the functions, operators, and X–Y data you want to include.
5. To evaluate and display your expression, click **Plot Expression**.
6. To *save* your new X–Y data object, click **Save As** and then provide a name in the dialog box that appears.

   Saving your data object makes it available for future operations within this session and for inclusion in X–Y plots containing multiple data objects.

7. When you are finished, click **Cancel** to close the dialog box.

Additional information

- *Combining two X–Y data objects*
- *Using addition on X–Y data objects*
- *Summing two or more X–Y data objects*
- *Using X–Y data operations*

Combining two X–Y data objects

Use the **combine** function to combine two *previously saved*X–Y data objects (collections of ordered pairs) to produce a new X–Y data object. The new X–Y data object contains data pairs consisting of the Y-coordinate values of the first data object and the Y-coordinate values of the second data object, combined wherever X-coordinate values for the two data objects match. For example,

$$\mathbf{XYData1} = [(1,4),(2,4),(3,4),(4,5),(5,6)]$$

and

$$\mathbf{XYData2} = [(1,9),(2,8),(3,7),(4,6),(5,4)];$$

then

$$\mathbf{combine(XYData1, XYData2)} = [(4,9),(4,8),(4,7),(5,6),(6,4)].$$

The arguments of this operation are not commutative. If X-coordinate values for the two data objects do not match, Abaqus/CAE computes the missing data points to allow the X–Y data objects to be aligned. For more information on how missing data points are computed, see *Understanding X–Y data interpolation and extrapolation*.

A typical application of this function would be to combine a data object having X-values of time and Y-values of load with a data object having X-values of time and Y-values of displacement to produce a data object having X-values of displacement and Y-values of load. Another example would be to combine a data object having X-values of time and Y-values of stress with a data object having X-values of time and Y-values of strain to produce a data object having X-values of strain and Y-values of stress, as shown in *Figure 1*.

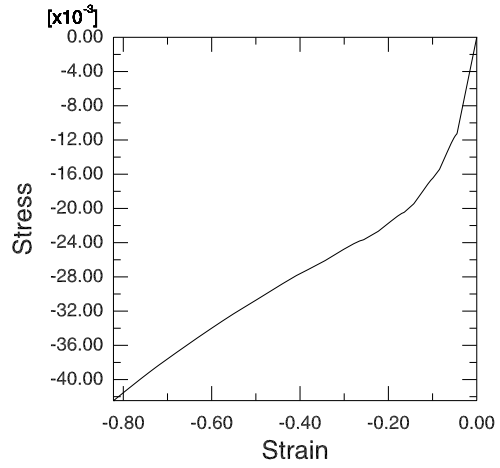

Figure 1: X–Y plot of stress versus strain.

1. Locate the **Operate on XY Data** dialog box.

   From the main menu bar, select **Tools->XY Data->Create**. Click **Operate on XY data** in the dialog box that appears; then click **Continue**. The **Operate on XY Data** dialog box appears.

2. From the **Operators** listed, click **combine(X,X)**.

   The **combine** function appears in the expression window.

3. From the **XY Data** choices, click the names of the two X–Y data objects to combine in the order you want Abaqus to combine them and click **Add to Expression**. Choices include all X–Y data objects previously saved within this session, listed alphabetically.

The *X–Y* data object names appear, separated by commas, within the **combine** function parentheses in the expression window.

4. To continue to build your expression, position the cursor in the expression window and type in or select the functions, operators, and *X–Y* data you want to include.
5. To evaluate and display your expression, click **Plot Expression**.
6. To *save* your new *X–Y* data object, click **Save As** and then provide a name in the dialog box that appears.

   Saving your data object makes it available for future operations within this session and for inclusion in *X–Y* plots containing multiple data objects.
7. When you are finished, click **Cancel** to close the dialog box.

Additional information

- *Understanding X–Y data interpolation and extrapolation*
- *Appending two or more X–Y data objects*
- *Using addition on X–Y data objects*
- *Summing two or more X–Y data objects*
- *Using X–Y data operations*

Converting the angular units used for X–Y data objects

Use the **degreeToRadian** or **radianToDegree** function to operate on a *previously saved*X–Y data object (a collection of ordered pairs) to produce a new *X–Y* data object. The new *X–Y* data object has the same *X*-coordinate values as the original *X–Y* data object. Abaqus/CAE computes the new *Y*-coordinate values by converting each original *Y*-coordinate from degrees to radians or from radians to degrees, depending on the function you specify.

1. Locate the **Operate on XY Data** dialog box.

   From the main menu bar, select **Tools->XY Data->Create**. Click **Operate on XY data** in the dialog box that appears; then click **Continue**. The **Operate on XY Data** dialog box appears.

2. From the **Operators** listed, click **degreeToRadian** to convert from degrees to radians or **radianToDegree** to convert from radians to degrees.

   The respective function appears in the expression window.

3. From the **XY Data** choices, click the name of the *X–Y* data object on which to operate and click **Add to Expression**. You can choose from all *X–Y* data objects previously saved within this session (listed alphabetically in the **XY Data** field).

   The *X–Y* data object name appears within the function parentheses in the expression window.

4. To continue to build your expression, position the cursor in the expression window and type in or select the functions, operators, and *X–Y* data you want to include.
5. To evaluate and display your expression, click **Plot Expression**.
6. To *save* your new *X–Y* data object, click **Save As** and then provide a name in the dialog box that appears.

   Saving your data object makes it available for future operations within this session and for inclusion in *X–Y* plots containing multiple data objects.

7. When you are finished, click **Cancel** to close the dialog box.

Additional information

- *Using X–Y data operations*

Swapping the order of an X–Y data object

Use the **swap** function to exchange the *X*- and *Y*-values of a *previously saved*X–Y data object (a collection of ordered pairs) to produce a new *X–Y* data object. The new *X–Y* data object has as its *X*-coordinate values the *Y*-coordinate values of the original *X–Y* data object and has as its *Y*-coordinate values the *X*-coordinate values of the original data object.

Figure 1 illustrates the type of *X–Y* plot that can be produced by using the **swap** function.

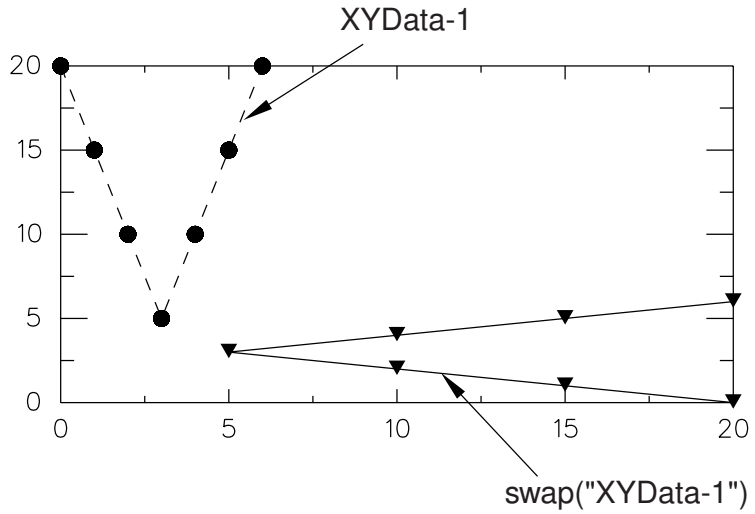

Figure 1: *X–Y* plot produced using the swap function.

1. Locate the **Operate on XY Data** dialog box.

   From the main menu bar, select **Tools->XY Data->Create**. Click **Operate on XY data** in the dialog box that appears; then click **Continue**. The **Operate on XY Data** dialog box appears.

2. From the **Operators** listed, click **swap(X)**.

   The **swap** function appears in the expression window.

3. From the **XY Data** choices, click the name of the *X–Y* data object on which to operate and click **Add to Expression**. You can choose from all *X–Y* data objects previously saved within this session (listed alphabetically in the **XY Data** field).

   The *X–Y* data object name appears within the **swap** function parentheses in the expression window.

4. To continue to build your expression, position the cursor in the expression window and type in or select the functions, operators, and *X–Y* data you want to include.
5. To evaluate and display your expression, click **Plot Expression**.
6. To *save* your new *X–Y* data object, click **Save As** and then provide a name in the dialog box that appears.

   Saving your data object makes it available for future operations within this session and for inclusion in *X–Y* plots containing multiple data objects.

7. When you are finished, click **Cancel** to close the dialog box.

Additional information

- *Using X–Y data operations*

Truncating data from the ends of an X–Y data object

Use the **truncate** function to operate on a *previously saved*X–Y data object (a collection of ordered pairs) to produce a new X–Y data object that excludes data points whose X–coordinate values are less than a user-specified minimum value or data points whose X–coordinate values are greater than a user-specified maximum value.

Figure 1 illustrates an X–Y plot that has been truncated at a maximum of 7 by using the **truncate** function.

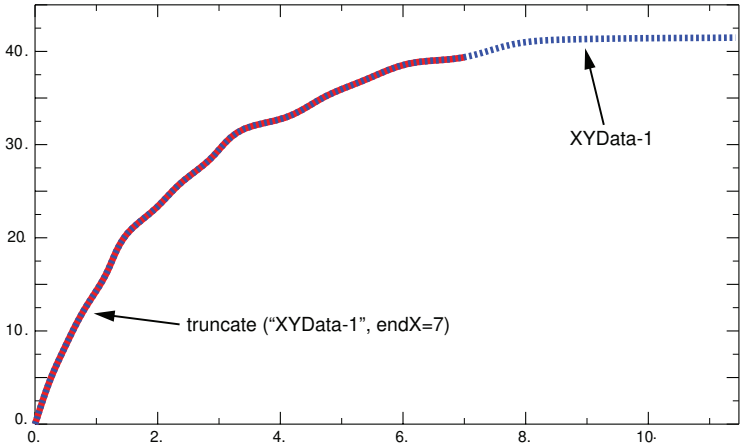

Figure 1: X–Y plot produced using the truncate function.

1. Locate the **Operate on XY Data** dialog box.

   From the main menu bar, select **Tools->XY Data->Create**. Click **Operate on XY data** in the dialog box that appears; then click **Continue**. The **Operate on XY Data** dialog box appears.

2. From the **Operators** listed, click **truncate(X,F)**.

   The **truncate** function appears in the expression window.

3. From the **XY Data** choices, click the name of the X–Y data object on which to operate and click **Add to Expression**. You can choose from all X–Y data objects previously saved within this session (listed alphabetically in the **XY Data** field).

   The X–Y data object name appears within the **truncate** function parentheses in the expression window.

4. Specify the X–coordinate values above which or below which data points should be removed from the X–Y data object. To specify a maximum value, position your cursor in the expression window before the second comma, and enter a number for the maximum value. To specify a minimum value, append `startX=`*value* to the expression in the expression window.

5. If desired, customize the truncation order value, which determines whether Abaqus/CAE should create new data points at the truncation boundary or boundaries you specify and, if so, how these new data points should be calculated. Select one of the following:

   - If `truncOrder=2` (the default value), Abaqus/CAE performs a piecewise, linear fit on the data to determine a new data point at each boundary and includes the new point or points in the new X–Y data object.
   - If `truncOrder=3`, Abaqus/CAE performs a spline interpolation on the data to determine a new data point at each boundary and includes the new point or points in the new X–Y data object.
   - If `truncOrder=1`, Abaqus/CAE does not create any new points at the boundary values.

6. If desired, customize the truncation tolerance value. If you elect to include interpolated values at the truncation boundaries, the truncation tolerance value overrides the creation of these new data points

if Abaqus/CAE finds existing data points that are already very close to the boundaries. By default, the truncation tolerance (`truncTol`) is 0.005, or one half of one percent of the average distance in the *X*-direction between adjacent data points in the *X–Y* data object. If Abaqus/CAE finds an existing data point closer to the truncation boundary than the truncation tolerance value, it does not create a new interpolated data point at that boundary.

7. To continue to build your expression, position the cursor in the expression window and type in or select the functions, operators, and *X–Y* data you want to include.
8. To evaluate and display your expression, click **Plot Expression**.
9. To *save* your new *X–Y* data object, click **Save As** and then provide a name in the dialog box that appears.

   Saving your data object makes it available for future operations within this session and for inclusion in *X–Y* plots containing multiple data objects.
10. When you are finished, click **Cancel** to close the dialog box.

Additional information

• *Using X–Y data operations*

Customizing X–Y plot axes

This section explains how you use the **Axis Options** dialog box to customize the appearance of the plot axes of an *X–Y* plot.

In this section:

- *Using X–Y plot axis options*
- *Plotting multiple X–Y data objects with different variables*
- *Customizing the X–Y plot axis scale*
- *Customizing the X–Y plot axis range*
- *Customizing the X–Y plot axis tick mode*
- *Customizing X–Y plot axis tick marks*
- *Customizing the X–Y plot axis titles*
- *Customizing the placement of X–Y plot axes*
- *Customizing the X–Y plot axis labels*
- *Customizing the X–Y plot axis color and style*

Using X–Y plot axis options

You can use the axis options to customize the appearance of the axes in an *X–Y* plot. *Figure 1* identifies the *X–Y* plot characteristics that you can customize.

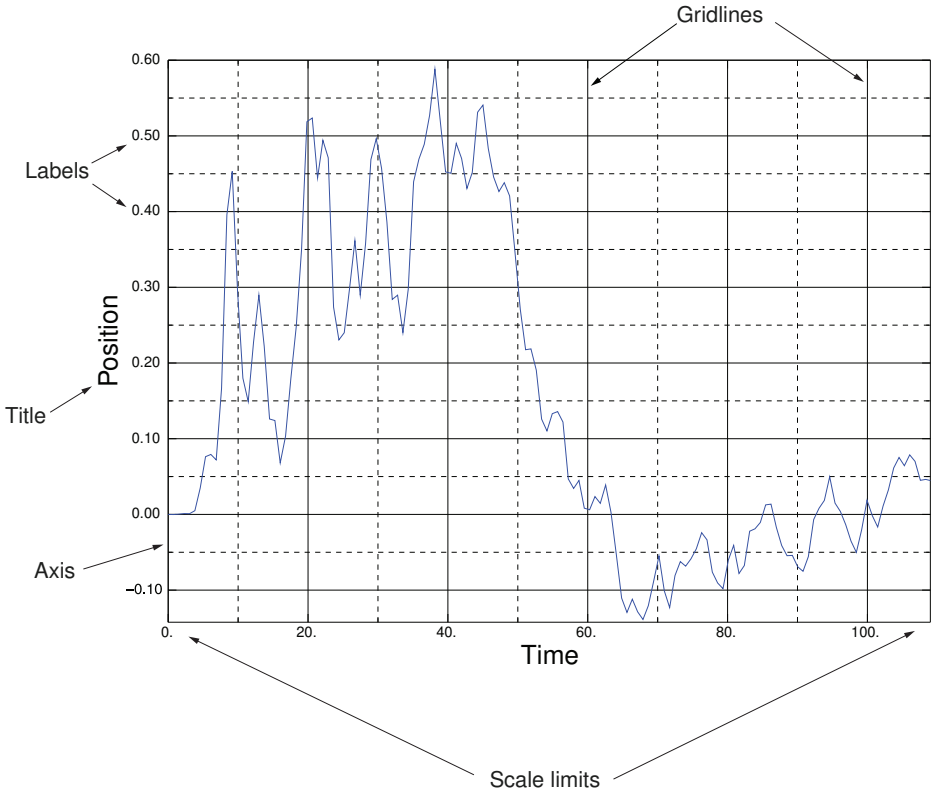

Figure 1: Characteristics of an X–Y plot.

Abaqus/CAE provides access to these options from the **Axis Options** dialog box, which you can open from the following locations in the Visualization module:

- From the main menu bar, select **Options->XY Options->Axis**.
- From the Visualization module toolbox, click .
- From the Results Tree, expand the **X Axes** or **Y Axes** container, highlight the axis or axes you want to modify, click mouse button 3, and select **Axis Options** from the list that appears.
- With an *X–Y* plot displayed in the viewport, double-click one of the axes in the plot.

  Items in an *X–Y* plot are selectable only when there is no active procedure in effect; you might have to cancel the current procedure to activate the components in an *X–Y* plot.

You can click the following tabs to customize the appearance of the selected axes:

- **Scale**: Choose axes scales and limits and customize the occurrence of tick marks.
- **Tick Marks**: Control the appearance and placement of tick marks.
- **Title**: Specify the content and appearance of axes titles.

- **Axes**: Choose axes placement, color, style, and thickness, and control numeric axes labels.

Additional information

- *Plotting multiple X–Y data objects with different variables*
- *Customizing the X–Y plot axis scale*
- *Customizing the X–Y plot axis range*
- *Customizing the X–Y plot axis tick mode*
- *Customizing X–Y plot axis tick marks*
- *Customizing the X–Y plot axis titles*
- *Customizing the placement of X–Y plot axes*
- *Customizing the X–Y plot axis labels*
- *Customizing the X–Y plot axis color and style*

Plotting multiple X–Y data objects with different variables

When you plot *X–Y* data objects with different variables on the same *X–Y* plot, Abaqus/CAE displays an axis for each quantity type used in these data objects. In the *X–Y* plot shown in *Figure 1*, three *X–Y* data objects are plotted: the **ALLKE** and **ALLSE** respectively show kinetic energy and strain energy over time, while **Displacement** shows displacement of a selected node over time. The resultant plot includes only a single axis, **Time**, in the *X*-direction because all three *X–Y* curves share this quantity type along this axis. In the *Y*-direction, where these *X–Y* data objects use different quantity types, the *X–Y* plot displays separate **Energy** and **Displacement** axes.

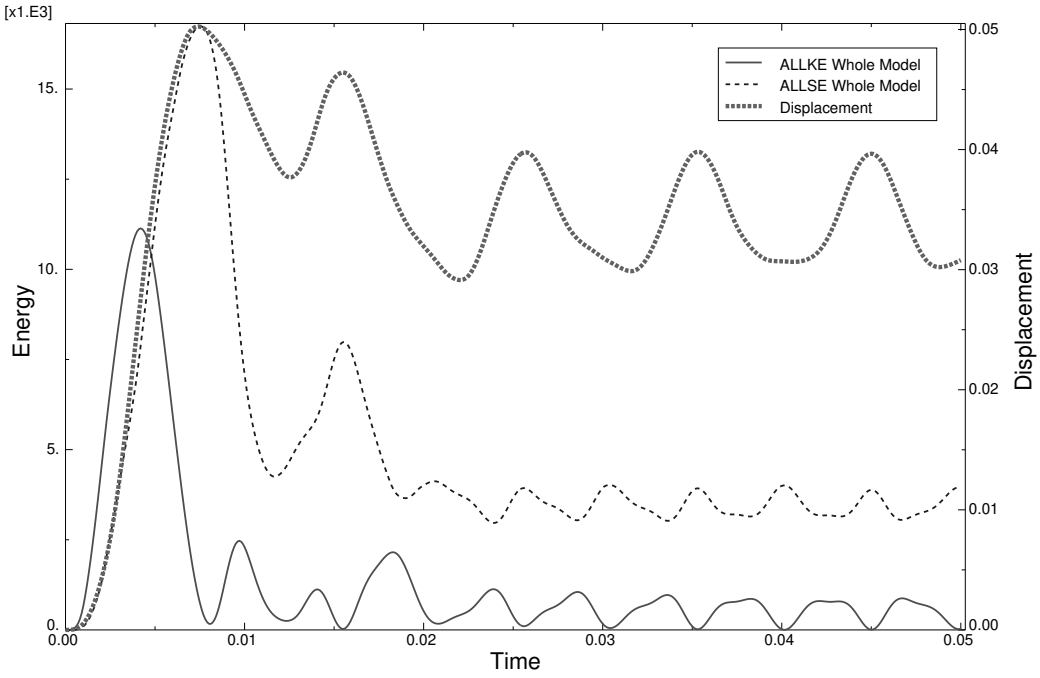

Figure 1: X–Y plot displaying two axes in the *Y*-direction.

When you plot multiple curves on the same *X–Y* plot, Abaqus/CAE sets the minimum and maximum values for the plot along both axes to the minimum and maximum values of the first *X–Y* data object you included in your plot. This *X–Y* data object is listed first in the *X–Y* plot legend and in the **Curves** area of the **Curve Options** dialog box.

When an *X–Y* plot displays multiple axes in the *X*- or *Y*-direction, you can align them on the same side of the *X–Y* plot, on opposite sides, or place one or both in the middle of the *X–Y* plot. You can also manipulate the scale or appearance of these *X–Y* plot axes independently to make their differences more apparent in the viewport.

Additional information

- *Customizing the X–Y plot axis scale*
- *Customizing the X–Y plot axis range*
- *Customizing X–Y plot axis tick marks*
- *Customizing the X–Y plot axis titles*
- *Customizing the X–Y plot axis labels*
- *Customizing the X–Y plot axis color and style*

Customizing the X–Y plot axis scale

Click the **Scale** tab to choose either a linear, logarithmic, or decibel-based scale for the *X*- and *Y*-axes of an *X–Y* plot. The scales of all *X*- and *Y*-axes that you display are independent. By default, Abaqus/CAE uses a linear scale for all axes.

Decibel-based scales

You can rescale data along a particular axis using either of two decibel-based scales. Each scale is suited to a particular type of wave data: the **10 dB** scale is recommended for displaying data about wave power or intensity; the **20 dB** scale is recommended for data about wave amplitude.

When you select a decibel-based axis scale, you can also adjust the decibel reference value. Adjusting this value enables you to rescale your data object according to the environmental conditions for the data in this *X–Y* data object and for the units in your model. The default value is `1`. You may want to adjust this value to display data at different environments or for waves traveling through a different medium, such as water.

1. Locate the **Scale** options.

   Select **Options->XY Options->Axis**; or click , which is located with the *X–Y* plotting tools in the Visualization module toolbox. Click the **Scale** tab in the dialog box that appears.
2. From the **X Axis** or **Y Axis** fields, highlight one or more axes.
3. Select one of the following axis scale options:

Linear

The selected axis is displayed in a linear progression.

Log

The selected axis is displayed in a base 10 logarithmic progression.

10 dB

The selected axis is displayed in a 10 dB progression. The **dB Reference** field becomes available, and you can enter the decibel reference value for the 10 dB–based data along this axis.

20 dB

The selected axis is displayed in a 20 dB progression. The **dB Reference** field becomes available, and you can enter the decibel reference value for the 20 dB–based data along this axis.

4. Click **Dismiss** to close the **Axis Options** dialog box.

Additional information

• *Using X–Y plot axis options*

Customizing the X–Y plot axis range

Click the **Scale** tab to customize the range of the *X*- and *Y*-axes of an *X*–*Y* plot. By default, Abaqus/CAE computes the minimum and maximum axis values based on the minimum and maximum data points included in the plot.

1. Locate the axis **Max** and **Min** options.

   Select **Options**->**XY Options**->**Axis**; or click , which is located with the *X*–*Y* plotting tools in the Visualization module toolbox. Click the **Scale** tab in the dialog box that appears.

   The **Max** and **Min** options appear in the middle of the **Scale** page.
2. From the **X Axis** or **Y Axis** fields, highlight one or more axes.
3. Enter a value in the **Max** field, or toggle on **Auto-compute** next to this field to set the maximum value for the selected axis or axes to the highest available data point.

   Abaqus/CAE updates the selected axis or axes.
4. Enter a value in the **Min** field, or toggle on **Auto-compute** next to this field to set the minimum value for the selected axis or axes to the lowest available data point.

   Abaqus/CAE updates the selected axis or axes.
5. Click **Dismiss** to close the **Axis Options** dialog box.

Additional information

- *Using X–Y plot axis options*

Customizing the X–Y plot axis tick mode

Click the **Scale** tab to customize the tick mode of the *X*- and *Y*-axes of an *X–Y* plot. The tick mode options enable you to control the number of major and minor tick marks that appear along either axis. By default, Abaqus/CAE computes the minimum and maximum axis values based on the minimum and maximum data points included in the plot.

1. Locate the **Tick Mode** options.

   Select **Options->XY Options->Axis**; or click , which is located with the *X–Y* plotting tools in the Visualization module toolbox. Click the **Scale** tab in the dialog box that appears.

   The **Tick Mode** options appear at the bottom of the **Scale** page.

2. From the **X Axis** or **Y Axis** fields, highlight one or more axes.
3. Choose the method of computing the interval between major tick marks along the selected axis.

   From the **Major** options, choose one of the following:

   ### Automatic

   Abaqus computes the interval between major tick marks along the selected axis, rounding to provide reasonable intervals.

   ### By increment

   The **Tick increment** text field becomes available, and you can enter the increment between major tick marks along the selected axis.

   ### By count

   The **Number of ticks per decade** field becomes available, and you can increase or decrease the total number of major tick marks to appear between the minimum and maximum values along the selected axis.

4. Specify the number of minor tick marks.

   From the **Minor** ticks option, click the **Ticks per increment** arrows (for linear or decibel-based axes) or the **Ticks per decade** arrows (for logarithmic axes) to specify the number of minor tick marks between each major tick mark.

5. Click **Dismiss** to close the **Axis Options** dialog box.

Additional information

- *Using X–Y plot axis options*

Customizing X–Y plot axis tick marks

You can customize X–Y plot axis tick marks.

Click the **Tick Marks** tab to control the length, thickness, style, and color of major and minor tick marks that appear along the *X*- and *Y*-axes of an *X*–*Y* plot. The number of major and minor tick marks is controlled separately; see *Customizing the X–Y plot axis tick mode*. You can control the *X*- and *Y*-axis tick marks independently. Examples of major and minor tick marks are shown in *Figure 1*.

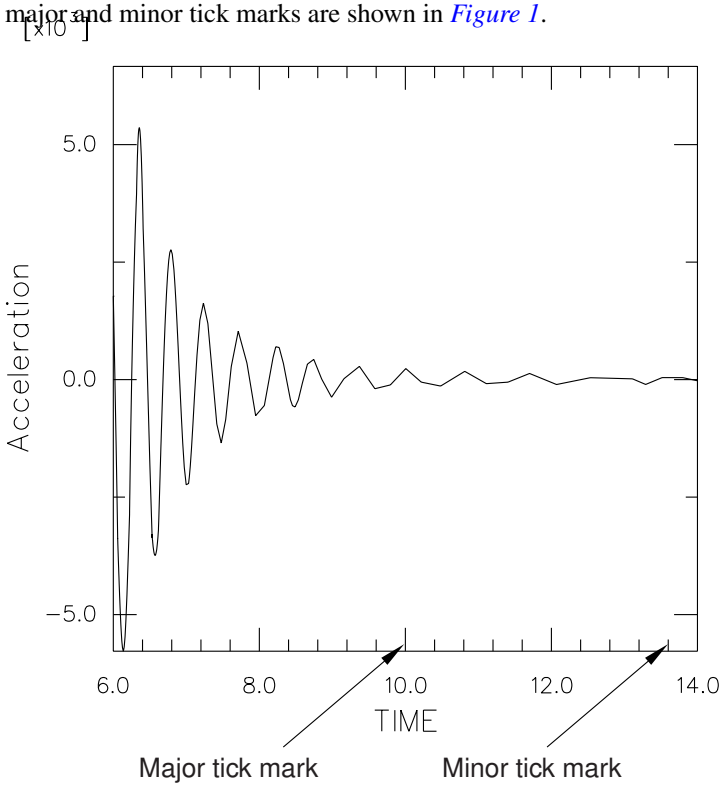

Figure 1: X–Y plot with major and minor tick marks indicated.

Major tick marks govern the placement of the *X*–*Y* plot major *grid* and the *numeric axis labels*. Minor tick marks are shorter, unlabeled marks governing the placement of the minor gridlines.

By default, Abaqus/CAE automatically computes the number of tick marks. You can specify major tick marks by giving the increment between them or the total number of tick marks. You can specify minor tick marks only by giving the total number between each major tick mark.

The color of the tick marks is governed by the color of the axes. For more information, see *Customizing the X–Y plot axis color and style*.

1. Locate the axis **Tick Marks** options.

   Select **Options->XY Options->Axis**; or click , which is located with the *X*–*Y* plotting tools in the Visualization module toolbox. Click the **Tick Marks** tab in the dialog box that appears.

2. From the **X Axis** or **Y Axis** fields, highlight one or more axes.
3. Choose the location in which to place the axis tick marks.

   From the **Placement** options, choose one of the following:

None

Abaqus hides the tick marks completely for the selected axis.

Inside

Abaqus displays the tick marks on the same side of the axis as the *X–Y* curves.

Outside

Abaqus displays the tick marks on the side of the axis opposite the *X–Y* curves.

Across

Abaqus displays tick marks that straddle both sides of the selected axis.

4. Specify the length of the tick marks.

   Click the **Length** arrows to increase or decrease the length of the tick marks. Abaqus/CAE increases the length of the major and minor tick marks.

5. Choose the line style.

   From the **Style** list, click the desired line style (solid, dashed, etc.).

   The specified line style appears for the tick marks along the selected axis and in the **Style** list.

6. Choose the line thickness.

   From the **Thickness** list, click the desired line thickness.

   The specified line thickness appears for the tick marks along the selected axis and in the **Thickness** list.

7. Choose the line color:

   a. Click the color sample .

      Abaqus/CAE displays the **Select Color** dialog box.

   b. Use one of the methods in the **Select Color** dialog box to select a new color. For more information, see *Customizing colors*.

   c. Click **OK** to close the **Select Color** dialog box.

      The tick marks for the selected axis change to the selected color.

8. Click **Dismiss** to close the **Axis Options** dialog box.

Additional information

- *Customizing the X–Y plot axis labels*
- *Using X–Y plot axis options*

Customizing the X–Y plot axis titles

Click the **Title** tab to customize the titles that appear along the *X*- and *Y*-axes of an *X–Y* plot. You can customize the following:

- The text that appears as each title.
- The color of each title.
- The font of each title.

1. Locate the axis **Title** options.

   Select **Options->XY Options->Axis**; or click , which is located with the *X–Y* plotting tools in the Visualization module toolbox. Click the **Title** tab in the dialog box that appears.
2. From the **X Axis** or **Y Axis** fields, highlight one or more axes.
3. To specify title text other than the default for the selected axis, enter the title in the field. You can revert back to the default title by toggling on **Use default**.
4. Select the font of the axis title.

   a. Click .

   Abaqus/CAE displays the **Select Font** dialog box.

   b. Use one of the methods in the **Select Font** dialog box to select a new font, size, and style. For more information, see *Customizing fonts*.

   c. Click **Apply** to see the effect of your font selections.

   d. Click **OK** to close the **Select Font** dialog box.

   The X–Y plot title changes to the selected font, size, and style.
5. Select the color of the axis title.

   a. Click the color sample .

   Abaqus/CAE displays the **Select Color** dialog box.

   b. Use one of the methods in the **Select Color** dialog box to select a new color. For more information, see *Customizing colors*.

   c. Click **OK** to close the **Select Color** dialog box.

   The axis title for the selected axis changes to the selected color.
6. Click **Dismiss** to close the **Axis Options** dialog box.

Additional information

- *Customizing the X–Y plot axis labels*
- *Using X–Y plot axis options*

Customizing the placement of X–Y plot axes

Click the **Axes** tab to customize the placement of the *X*- and *Y*-axes of an *X*–*Y* plot. This section describes the **Placement** options, which control the location of the axes themselves; to customize the location of the axis labels, see *Customizing the X–Y plot axis labels*

1. Locate the **Placement** options.

   Select **Options->XY Options->Axis**; or click , which is located with the *X*–*Y* plotting tools in the Visualization module toolbox. Click the **Axes** tab in the dialog box that appears. The **Placement** options for the axes appear at the top of the **Axes** page.
2. From the **X Axis** or **Y Axis** fields, highlight one or more axes.
3. From the **Placement** options at the top of the **Axes** page, select one of the following:

Min Edge

Abaqus/CAE places an axis on the minimum edge of the *X*–*Y* plot only. For *X*-axes, the minimum edge is the bottom of the viewport; for *Y*-axes, the minimum edge is the left side of the viewport.

Max Edge

Abaqus/CAE places an axis on the maximum edge of the *X*–*Y* plot only. For *X*-axes, the maximum edge is the top of the viewport; for *Y*-axes, the maximum edge is the right side of the viewport.

Min/Max Edge

Abaqus/CAE places the selected axis on both the maximum and minimum edges of the *X*–*Y* plot. For *X*-axes, Abaqus/CAE places the selected axis on the top and bottom of the viewport; for *Y*-axes, Abaqus/CAE the selected axis on the left and right sides of the viewport.

Center

Abaqus/CAE places the axis in the center of the *X*–*Y* plot.

4. Click **Dismiss** to close the **Axis Options** dialog box.

Additional information

- *Customizing X–Y plot axis tick marks*
- *Customizing the X–Y plot axis titles*
- *Using X–Y plot axis options*

Customizing the X–Y plot axis labels

You can customize the X–Y plot axis labels.

Click the **Axes** tab to customize the numeric labels that appear with the major *tick marks* along the *X*- and *Y*-axes of an *X–Y* plot. Examples of axis labels appear in *Figure 1*.

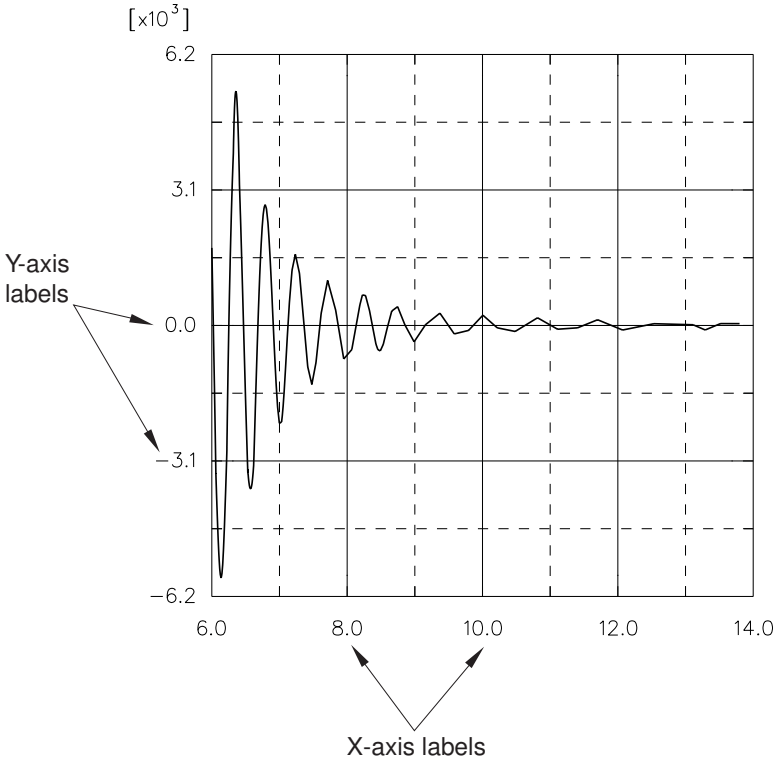

Figure 1: *X–Y* plot with axis labels indicated.

You can customize the following:

- The format of the labels (automatic, decimal, engineering, or scientific).
- The number of decimal places or significant digits in the labels.
- The frequency of the labels in relation to the major tick marks.
- The font of the labels.

The color of the labels is governed by the color of the axes. See *Customizing the X–Y plot axis color and style*, for more information.

1. Locate the **Labels** options.

   Select **Options->XY Options->Axis**; or click ⟼, which is located with the *X–Y* plotting tools in the Visualization module toolbox. Click the **Axes** tab in the dialog box that appears.

   The **Labels** options for the axes appear in the middle of the **Axes** page.

2. From the **X Axis** or **Y Axis** fields, highlight one or more axes.
3. Specify where you would like axis labels to appear.

   From the **Placement** list in the **Labels** options, choose one of the following:

None

Abaqus/CAE hides axis labels for the selected axis.

Inside

Abaqus/CAE displays axis labels on the same side of the axis as the *X–Y* curves.

Outside

Abaqus/CAE displays axis labels on the side of the axis opposite the *X–Y* curves.

4. Click the **Frequency** arrows to specify how often labels are printed relative to each major tick mark. For example, if you select a frequency of two, labels will appear at every second major tick mark along the axis. If you select a frequency of zero, no labels will be displayed along the axis. You can request a label frequency of at most one greater than the number of major tick marks.
5. From the **Labels** options, select the format of the selected labels.
   a. Click the **Format** button to reveal the *X*-axis label format options.
   b. Choose one of the following:

Automatic

Very large values and very small values are expressed in scientific format. All remaining values are expressed with no exponent and using the specified number of significant digits.

Decimal

All values are expressed with no exponent and using the specified number of significant digits.

Engineering

Values greater than or equal to 1000 (or values less than or equal to 0.001) are expressed as a number ranging from 1 to 999 that is multiplied by 10 to the *n*th power, where *n* is a product of 3 (for example, `20.5E+03` or `17.76E+06`). All remaining values are expressed using the specified number of significant digits.

Scientific

All values are expressed as a number between 1 and 10 that is multiplied by an appropriate power of 10 (for example, `2.05E+04` or `1.776E+07`).

6. Click the **Precision** arrows to specify the desired number of significant digits (for non-decimal formats) or decimal places (for decimal format) in each label.
7. Select the font of the axis labels.
   a. Click .
   Abaqus/CAE displays the **Select Font** dialog box.
   b. Use one of the methods in the **Select Font** dialog box to select a new font, size, and style. For more information, see *Customizing fonts*.
   c. Click **Apply** to see the effect of your font selections.

d. Click **OK** to close the **Select Font** dialog box.

The axis labels change to the selected font, size, and style.

8. Select the color of the axis labels.

a. Click the color sample .

Abaqus/CAE displays the **Select Color** dialog box.

b. Use one of the methods in the **Select Color** dialog box to select a new color. For more information, see *Customizing colors*.

c. Click **OK** to close the **Select Color** dialog box.

The axis labels change to the selected color.

9. Click **Dismiss** to close the **Axis Options** dialog box.

Additional information

- *Customizing X–Y plot axis tick marks*
- *Customizing the X–Y plot axis titles*
- *Using X–Y plot axis options*

Customizing the X–Y plot axis color and style

Click the **Axes** tab to customize the color and thickness of the graph axes of an *X–Y* plot. Your selections apply to both the *X*- and *Y*-axes; it is not possible to customize the axes individually.

1. Locate the **Style** options.

   Select **Options->XY Options->Axis**; or click , which is located with the *X–Y* plotting tools in the Visualization module toolbox. Click the **Axes** tab in the dialog box that appears.

   The **Style** options for the axes appear at the bottom of the **Axes** page.
2. From the **X Axis** or **Y Axis** fields, highlight one or more axes.
3. Choose the line style.

   From the **Style** list, click the desired line style (solid, dashed, etc.).

   The specified line style appears for the selected axis and in the **Style** list.
4. Choose the line thickness.

   From the **Thickness** list, click the desired line thickness.

   The specified line thickness appears for the selected axis and in the **Thickness** list.
5. Choose the line color:

   a. Click the color sample .

      Abaqus/CAE displays the **Select Color** dialog box.

   b. Use one of the methods in the **Select Color** dialog box to select a new color. For more information, see *Customizing colors*.

   c. Click **OK** to close the **Select Color** dialog box.

      The axis line changes to the selected color.
6. Click **Dismiss** to close the **Axis Options** dialog box.

Additional information

- *Customizing X–Y plot axis tick marks*
- *Customizing the X–Y plot axis labels*
- *Using X–Y plot axis options*

Customizing X–Y curve appearance

This section explains how you use the **Curve Options** dialog box to customize the appearance of a curve representing a selected *X–Y* data object.
Only curves that appear in the most recent *X–Y* plot are available for customization.

In this section:

- *Using options to customize the appearance of X–Y curves*
- *Selecting one or more X–Y curves to customize*
- *Customizing the X–Y plot legend*
- *Customizing the appearance of an X–Y curve*
- *Customizing the symbols used on an X–Y curve*
- *Editing the list of auto-colors for X–Y plots*

Using options to customize the appearance of X–Y curves

To customize the appearance of *X–Y* curves, expand the **Curves** container in the Results Tree, highlight the curves you want to modify, then click mouse button 3 and select **Curve Options** from the list that appears.
You can customize the line style, symbol style, and legend text of each curve.

Only those curves that appear in the most recent *X–Y* plot are available for customization. You can customize the following:

- The text that appears in the legend describing the data. For more information, see *Customizing the X–Y plot legend*.
- The appearance of the line representing the data (the curve). For more information, see *Customizing the appearance of an X–Y curve*.
- The appearance of the symbols along the curve. For more information, see *Customizing the symbols used on an X–Y curve*.

1. Locate the **Curve Options** dialog box. You can open this dialog box using any of the following methods:
   - From the main menu bar, select **Options->XY Options->Curve**.
   - From the Visualization module toolbox, click .
   - From the Results Tree, expand the **Charts** container, highlight the plot or plots you want to modify, click mouse button 3, and select **Chart Options** from the list that appears.
2. Use the curve options to select and then customize the appearance of the *X–Y* curves in the current viewport.
3. When you have finished customizing the appearance of your *X–Y* curves, click **Dismiss** to close the **Curve Options** dialog box.

Additional information

- *Selecting one or more X–Y curves to customize*
- *Customizing the X–Y plot legend*
- *Customizing the appearance of an X–Y curve*
- *Customizing the symbols used on an X–Y curve*

Selecting one or more X–Y curves to customize

To customize a curve, you first select it and then choose customization options. Use the **Curves** field in the **Curve Options** dialog box to select one or more *X–Y* curves to customize. The **Curves** field lists the displayed *X–Y* curves, identifying each curve by name. For information on curve naming conventions, see *Understanding "Temp" and other X–Y data object names*.

After you have selected one or more *X–Y* curves to customize, you then use the options in the **Attributes** frame to control the line and the symbol representing the data and to enter the text that will appear in the legend.

1. Locate the **Curves** field.

   The **Curves** field is at the top of the dialog box.

2. Select one or more *X–Y* curves to customize. For more information on selecting multiple items in dialog boxes, see *Selecting multiple items from lists and tables*.

   Note:

   To make an *X–Y* curve available for selection, you must first plot it.

   If you have selected one curve, the **Attributes** frame displays the current attributes of that curve.

   If you have selected multiple curves, Abaqus/CAE displays the **Legend text** field as blank. The display in the **Attributes** frame varies depending on whether the selected curves have the same attributes or not. If the attributes are the same, Abaqus/CAE displays them; if the attributes differ, Abaqus/CAE displays the following:

   - The **Show** and **Show symbol** checkboxes are gray.
   - The line **Color** and symbol **Color** text fields display the term **As is**.
   - The **Style**, **Thickness**, **Symbol**, and **Size** buttons are blank.
   - The **Frequency** text field is blank.

3. From the **Attributes** field, you can control the following:

   - The text that appears in the legend describing the data. For more information, see *Customizing the X–Y plot legend*.
   - The appearance of the line representing the data (the curve). For more information, see *Customizing the appearance of an X–Y curve*.
   - The appearance of the symbols along the curve. For more information, see *Customizing the symbols used on an X–Y curve*.

Customizing the X–Y plot legend

The legend of an *X–Y* plot provides a key to associate each curve included in the plot with the *X–Y* data object that it represents. Each legend entry contains a line segment in the color and style shown in the plot. The legend entry also includes text stating, by default, the name of the *X–Y* data represented by the curve. You can customize this text using the **Curve Options**.

The remaining characteristics of the legend are controlled by options in the **Viewport Annotation Options** dialog box. For information on customizing the legend and on including in the legend a report of the minimum and maximum *X–Y* values, see *Customizing the legend*.

1. Locate the **Attributes** options for X–Y curves.

   The **Attributes** frame is at the bottom of the **Curve Options** dialog box.
2. In the **Curves** options, select one or more curves whose legend text you want to modify.
3. In the **Legend Text** field, enter the custom legend text. You can also revert to the default legend text by toggling on **Use default**.
4. Click **Dismiss** to close the **Curve Options** dialog box.

Additional information

• *Selecting one or more X–Y curves to customize*

Customizing the appearance of an X–Y curve

You can customize the appearance of an X–Y curve.

Use the **Curve Options** dialog box to customize the color, style, and thickness of the line used to represent an *X–Y* data object in an *X–Y* plot. *Figure 1* illustrates some of the ways in which *X–Y* data curves can be customized.

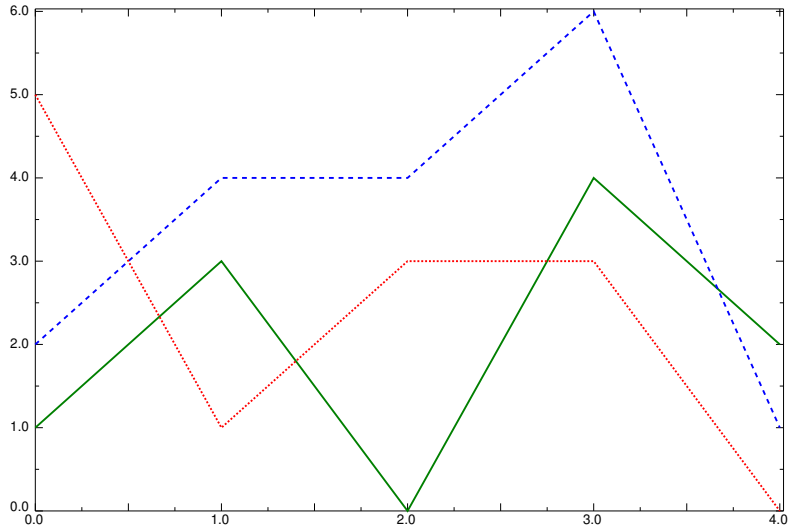

Figure 1: *X–Y* plot with customized curves.

The color, style, and thickness that you select appear along the curve and in the *legend*. The customization options are available only when **Show** is toggled on.

By default, Abaqus/CAE colors the *X–Y* curves in your plot by referring to the list of *X–Y* auto colors. You can modify this list from the **Edit XY-Auto-Colors** dialog box; see *Editing the list of auto-colors for X–Y plots*.

1. Locate the **Show** options.

   The **Show** options appear in the lower right corner of the **Curve Options** dialog box.

2. From the **Curves** field, *select one or more X–Y curves* whose attributes you wish to customize.

   Note:

   To make an *X–Y* curve available for selection, you must first plot it.

   The customization options you choose will apply to all of the curves you have selected; if you want to vary the appearance of multiple curves, you must customize them one at a time.

3. Toggle **Show** to display or suppress the line representing each selected *X–Y* curve.

   When **Show** is on, the curve is displayed and the line attribute options are enabled.

4. Choose the line color:

   a. Click the color sample .

      Abaqus/CAE displays the **Select Color** dialog box.

   b. Use one of the methods in the **Select Color** dialog box to select a new color. For more information, see *Customizing colors*.

   c. Click **OK** to close the **Select Color** dialog box.

      The selected *X–Y* curve changes to the selected color.

5. Choose the line style:
   a. Click the **Style** button to reveal the line style options (solid, dashed, etc.).
   b. From the style list, click the desired line style.

      The selected *X–Y* curve changes to the selected style.

6. Choose the line thickness:
   a. Click the **Thickness** button to reveal the line thickness options.
   b. From the thickness list, click the desired line thickness.

      The selected *X–Y* curve changes to the specified thickness.

7. Click **Dismiss** to close the **Axis Options** dialog box.

Additional information

• *Selecting one or more X–Y curves to customize*

Customizing the symbols used on an X–Y curve

You can customize the symbols used on an X–Y curve.

Use the **Curve Options** dialog box to customize the appearance of the symbols used to represent data points on an *X–Y* curve. For example, in *Figure 1* the plot on the left uses the default symbols, while the plot on the right uses customized symbols.

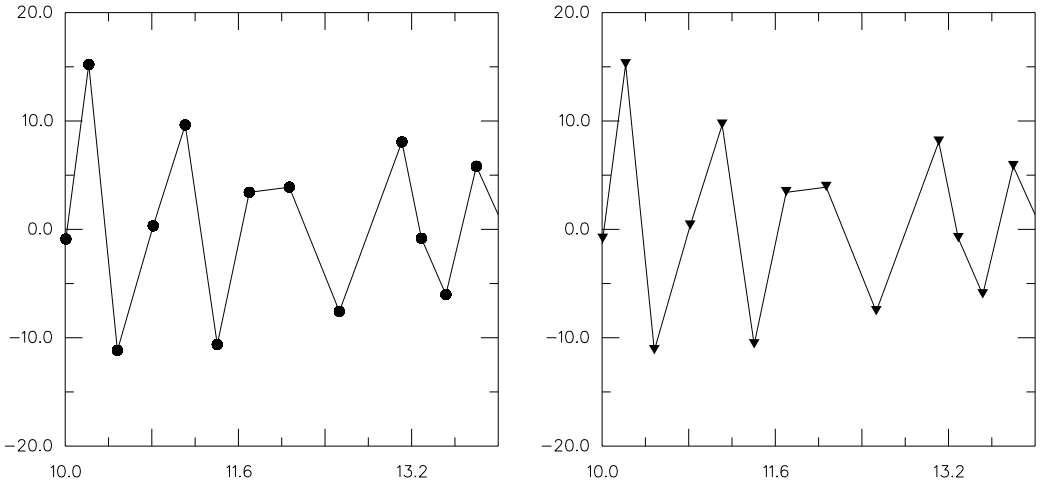

Figure 1: X–Y plots with different data point symbols.

The symbol that you select appears along the curve and in the *legend*. The customization options are available only when **Show symbol** is toggled on.

1. Locate the **Attributes** options.

   The **Attributes** options appear in the lower half of the **Curve Options** dialog box.

2. From the **Curves** field, *select one or more X–Y curves* whose symbols you wish to customize.

   Note:

   To make an *X–Y* curve available for selection, you must first plot it.

   The customization options you choose will apply to all of the curves you have selected; if you want to vary the symbols on multiple curves, you must customize them one at a time.

3. Toggle **Show symbol** to display or suppress the symbols representing each selected *X–Y* curve's data points.

   When **Show symbol** is on, symbols are displayed and the symbol attributes are enabled.

4. Choose the symbol color:

   a. Click the color sample .

      Abaqus/CAE displays the **Select Color** dialog box.

   b. Use one of the methods in the **Select Color** dialog box to select a new color. For more information, see *Customizing colors*.

   c. Click **OK** to close the **Select Color** dialog box.

      The color sample changes to the selected color. The new color does not appear in the viewport until you click **OK** or **Apply** in the **XY Plot Options** dialog box.

5. Choose the symbol:

a. Click the **Symbol** button to reveal the choice of symbols.

b. From the list of symbols, click the desired symbol.

The specified symbol appears on the selected *X–Y* curve.

6. Choose the symbol size:

a. Click the **Size** button to reveal the symbol size options.

b. From the symbol size options, click the desired symbol size.

The specified symbol size appears on the selected *X–Y* curve.

7. Select the frequency of the symbols.

Type an integer into the **Frequency** text field to choose how often symbols appear along the curve. For example, if you enter a frequency of two, Abaqus displays symbols at every second data point. The value zero is not allowed; to suppress the display of symbols, toggle off **Show symbol**.

8. Click **Dismiss** to close the **Curve Options** dialog box.

Additional information

• *Selecting one or more X–Y curves to customize*

Editing the list of auto-colors for X–Y plots

Abaqus/CAE assigns colors to *X–Y* curves automatically by referring to the color definitions in the *X–Y* auto colors list. This list provides colors for *X–Y* curves in the same way that the general **Auto Colors** list is used to color geometry and mesh elements, but these two color lists are separate entities.

This section describes how to edit the *X–Y* auto colors list to modify the set of default color assignments for *X–Y* curves. You can also change the color assignment for an individual *X–Y* curve from the **Curve Options** dialog box. See *Customizing the appearance of an X–Y curve*.

1. In the Results Tree, click mouse button 3 on the **XY Plots** container, then select **Edit XY-Auto-Colors** from the list that appears.

   Abaqus/CAE displays the **Edit XY-Auto-Colors** dialog box.

2. To insert a new color into the *X–Y* auto colors list:

   1. Highlight the color in the *X–Y* auto colors list that you want to precede or follow the color that you add.
   2. Click **Insert Before** or **Insert After** to add a new color in the indicated location in the *X–Y* auto colors list.

      The **Select Color** dialog box opens.
   3. Choose a color by following the steps described in *Customizing colors*; then click **OK** to close the **Select Color** dialog box.

   Abaqus/CAE adds the new color in the selected location.

3. To change one of the colors in the *X–Y* auto colors list, double-click the color and select a new color from the **Select Color** dialog box that appears.
4. To move a color within the *X–Y* auto colors list, highlight the color and click either **Move Up** or **Move Down** to move the color one step in the selected direction.
5. To delete a color from the *X–Y* auto colors list, highlight the color and click **Delete**.
6. Continue adding, changing, moving, and deleting colors until the *X–Y* auto colors list contains the colors you want in the desired order.
7. Click **OK**.

   Abaqus/CAE uses the revised *X–Y* auto colors list for any subsequent color coding of *X–Y* curves.

Customizing X–Y plot appearance

This section explains how you use the **Chart Options** dialog box to customize the display of gridlines and to adjust the general shape, size, and position of an *X–Y* plot.

In this section:

- *Customizing the gridlines for an X–Y plot*
- *Customizing the border and fill color for an X–Y plot*
- *Customizing X–Y plot size and shape*
- *Customizing the position of an X–Y plot*

Customizing the gridlines for an X–Y plot

You can customize the gridlines for an X–Y plot.

Click the **Grid Display** tab to control the appearance of the major and minor gridlines of an *X–Y* plot. Examples of major and minor gridlines are shown in *Figure 1*.

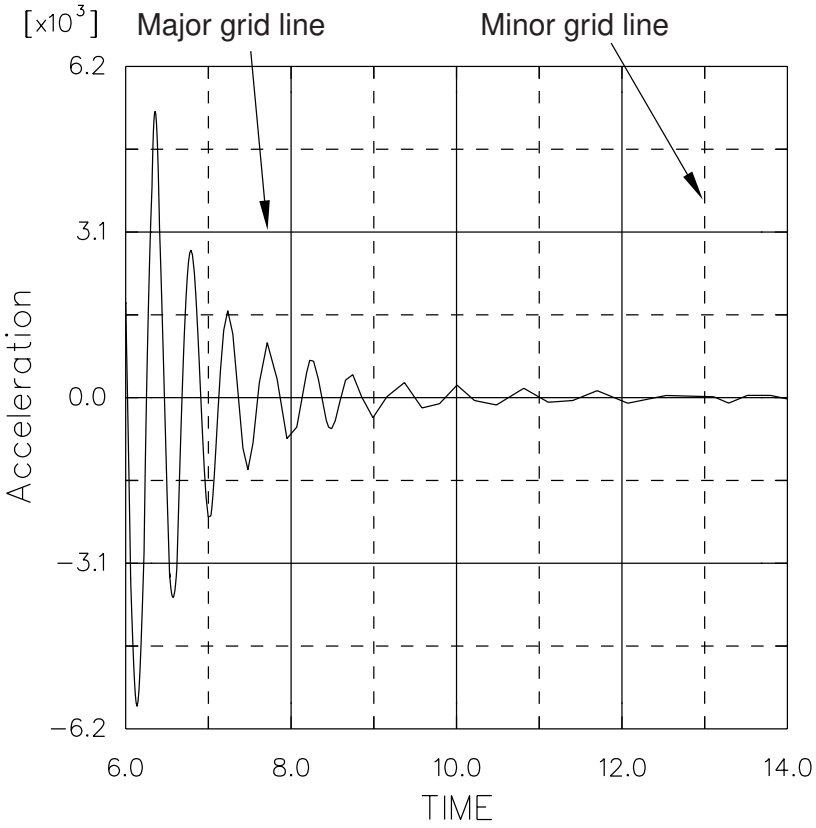

Figure 1: *X–Y* plot with major and minor gridlines indicated.

If your *X–Y* plot uses multiple axes in the same direction, Abaqus/CAE draws gridlines only for the axes of the first curve in the plot.

The **Grid Display** options provide independent control over each of the four sets of gridlines; that is, independent control over the major and minor gridlines in either direction. You can display or hide any of the four sets, and you can modify the color, style, or thickness of the lines for any of the four sets of gridlines.

Note:

Major gridlines originate from major tick marks, and minor gridlines originate from minor tick marks. To control the interval between gridlines, you must adjust the *spacing of the tick marks*.

1. Locate the axis **Grid Display** options.

   Select **Options->XY Options->Chart**; or click , which is located with the *X–Y* plotting tools in the Visualization module toolbox. Click the **Grid Display** tab in the dialog box that appears.

2. Select one or more *X–Y* plots to customize from the **Charts** field.

3. From the **X Gridlines** options, toggle on the **Major** or **Minor** options to display major or minor vertical gridlines, respectively.

   When either **Major** or **Minor** is on, gridline style, color, and thickness options become available for that type of gridline.

4. From the **Y Gridlines** options, toggle on **Major** or **Minor** to display major or minor horizontal gridlines, respectively.

5. Repeat the following steps to customize the horizontal major and minor gridlines and the vertical major and minor gridlines:

   a. Choose the color for the gridlines:

      1. Click the color sample .

      Abaqus/CAE displays the **Select Color** dialog box.

      2. Use one of the methods in the **Select Color** dialog box to select a new color. For more information, see *Customizing colors*.

      3. Click **OK** to close the **Select Color** dialog box.

      The selected gridlines change to the specified color.

   b. Choose the line style:

      1. Expand the style list to reveal the line style options (solid, dashed, etc.). The style list is the upper of the two unlabeled list options.

      2. From the style list, click the desired line style.

      The selected gridlines change to the specified style.

   c. Choose the line thickness:

      1. Expand the thickness list to reveal the line style options (solid, dashed, etc.). The style list is the lower of the two unlabeled list options.

      2. From the thickness list, click the desired line thickness.

      The selected gridlines change to the specified thickness.

6. Click **Dismiss** to close the **Chart Options** dialog box.

Additional information

• *Selecting one or more X–Y curves to customize*

Customizing the border and fill color for an X–Y plot

Click the **Grid Display** tab to access the **Grid Area** options for an *X–Y* plot. These options enable you to customize the grid in an *X–Y* plot, which is the rectangular area where the curves are plotted. You can wrap a border around the grid or fill the grid with a background color.

Note:

You can also control border and background color settings for the entire *X–Y* plot, which includes the portion of the viewport covered by an *X–Y* plot's grid and all of its axes. Abaqus/CAE displays the background color for the grid on top of the background for the entire *X–Y* plot. For more information, see *Customizing border and fill colors for an X–Y plot*.

1. Locate the **Grid Area** options.

   Select **Options->XY Options->Chart**; or click , which is located with the *X–Y* plotting tools in the Visualization module toolbox. Click the **Grid Display** tab in the dialog box that appears.

   The **Grid Area** options are available at the bottom of the **Grid Display** page.
2. Select one or more *X–Y* plots from the top part of the window.
3. Toggle on **Show border** to display a border around the entire grid area.
4. If desired, change the color of the border by performing the following steps:
   a. Click the color sample immediately to the right of the **Show border** label .

      Abaqus/CAE displays the **Select Color** dialog box.
   b. Use one of the methods in the **Select Color** dialog box to select a new color. For more information, see *Customizing colors*.
   c. Click **OK** to close the **Select Color** dialog box.

      The color sample and the grid border change to the selected color.
5. Toggle on **Fill** to fill the grid area with the color displayed to the right of the **Fill** label.
6. If desired, change the grid area fill color by performing the following steps:
   a. Click the color sample immediately to the right of the **Fill** label .

      Abaqus/CAE displays the **Select Color** dialog box.
   b. Use one of the methods in the **Select Color** dialog box to select a new color. For more information, see *Customizing colors*.
   c. Click **OK** to close the **Select Color** dialog box.

      The grid area changes to the selected color.
7. Click **Dismiss** to close the **Chart Options** dialog box.

Additional information

- *Customizing border and fill colors for an X–Y plot*

Customizing X–Y plot size and shape

Use the **Size** options in the **Chart Options** dialog box to customize the size and shape of the *X–Y* plot.

1. Locate the **Chart Options**.

   Select **Options**->**XY Options**->**Chart**; or click , which is located with the *X–Y* plotting tools in the Visualization module toolbox. Click the **Grid Position** tab in the dialog box that appears.
2. From the **Charts** field, select one or more *X–Y* plots whose sizes or shapes you wish to customize.
3. Select one of the following *X–Y* plot sizing and shaping options:

   ### Fit to chart

   Abaqus/CAE fills the entire viewport with the selected *X–Y* plot, adjusting the shape of the plot to match the viewport dimensions.

   ### Square

   The **Size** slider becomes available, which you can drag to increase or decrease the size of the square-shaped *X–Y* plot.

   ### Manual

   The **X** and **Y** sliders become available, which you can drag to increase or decrease the size of the *X–Y* plot along either axis.
4. Click **Dismiss** to close the **Chart Options** dialog box.

Additional information

• *Selecting one or more X–Y curves to customize*

Customizing the position of an X–Y plot

Use the **Position** options in the **Chart Options** dialog box to customize the position of an *X–Y* plot in the viewport.

1. Locate the **Position** options.

   Select **Options**->**XY Options**->**Chart**; or click , which is located with the *X–Y* plotting tools in the Visualization module toolbox. Click the **Grid Position** tab in the dialog box that appears.

2. From the **Charts** field, select one or more *X–Y* plots whose positions or shapes you wish to customize.
3. Select one of the following *X–Y* plot positioning options:

Auto-align

This option enables you to align the selected *X–Y* plot in one of nine positions in the viewport: its center, any of the four corners, or centered along any of the four edges. Expand the **Alignment** list, then select one of the options depicted graphically in the list.

Manual

This option enables you to position the *X–Y* plot origin at a specific *X–Y* location in the viewport. Drag the **X** and **Y** sliders to move the lower left corner of the *X–Y* plot horizontally or vertically in the viewport. When these sliders' values are set to `0`, the *X–Y* plot origin is placed in the lower left corner of the viewport.

4. Click **Dismiss** to close the **Chart Options** dialog box.

Additional information

• *Selecting one or more X–Y curves to customize*

Customizing the X–Y plot title

This section explains how you use the **Plot Title Options** dialog box to create a title for an X–Y plot and to customize the title's appearance and location in the viewport.

In this section:

- *Customizing the contents of the X–Y plot title*
- *Customizing the location of the X–Y plot title*
- *Adding a bounding box and fill color for the X–Y plot title*

Customizing the contents of the X–Y plot title

Use the **Text** options in the **Plot Title Options** to create and display a custom title for an X–Y plot.

1. Locate the **Text** options for plot titles.

   Select **Options->XY Options->Plot Title**; or click , which is located with the *X–Y* plotting tools in the Visualization module toolbox.
2. Click the **Title** tab, if it is not already selected.
3. Select a title for the X–Y plot using one of the following methods:
   - To display the default name of the X–Y plot, toggle on **Use default**.
   - To display a custom title, toggle off **Use default**, enter a title in the **Title** field, and press `Enter`.
4. Select the font of the plot title.
   a. Click .

      Abaqus/CAE displays the **Select Font** dialog box.
   b. Use one of the methods in the **Select Font** dialog box to select a new font, size, and style. For more information, see *Customizing fonts*.
   c. Click **Apply** to see the effect of your font selections.
   d. Click **OK** to close the **Select Font** dialog box.

      The X–Y plot title changes to the selected font, size, and style.
5. Select a color for the X–Y plot title.
   a. Click the color sample .

      Abaqus/CAE displays the **Select Color** dialog box.
   b. Use one of the methods in the **Select Color** dialog box to select a new color. For more information, see *Customizing colors*.
   c. Click **OK** to close the **Select Color** dialog box.

      The plot title text changes to the selected color.

Additional information

• *Selecting one or more X–Y curves to customize*

Customizing the location of the X–Y plot title

Use the **Position** options in the **Plot Title Options** to place the X–Y plot title in a particular location in the viewport.

1. Locate the **Position** options.

   Select **Options->XY Options->Plot Title**; or click , which is located with the *X–Y* plotting tools in the Visualization module toolbox. Click the **Area** tab from the dialog box that appears.
2. Toggle on **Inset** to display the plot title legend within the *X–Y* plot. If **Inset** is off, Abaqus/CAE keeps the plot title and the *X–Y* plot in separate bands of the viewport.
3. Choose one of the following two methods for positioning the plot title:

Auto-align

This option enables you to position the plot title in one of nine positions in the viewport: its center, any of the four corners, or centered along any of the four edges. Expand the **Alignment** list, then select one of the options depicted graphically in the list.

Manual

This option enables you to position the plot title in a specific *X–Y* location in the viewport. Drag the **X** and **Y** sliders to move the title horizontally or vertically in the viewport. When both of these values equal `0`, the plot title is positioned in the lower left corner of the viewport; when both values equal `100`, the plot title is positioned in the upper right corner.

Additional information

• *Selecting one or more X–Y curves to customize*

Adding a bounding box and fill color for the X–Y plot title

Use the **Bounding Box** options in the **Plot Title Options** to draw a rectangular box around the X–Y plot title or to fill the area behind the plot title with a background color.

1. Locate the **Bounding Box** options.

   Select **Options->XY Options->Plot Title**; or click , which is located with the *X–Y* plotting tools in the Visualization module toolbox. Click the **Area** tab from the dialog box that appears. The **Bounding Box** options appear at the bottom of the dialog box.

2. Select one or more *X–Y* plots from the **Charts** field at the top of the dialog box.
3. Perform the following steps to display and modify the bounding box:
   a. Toggle on **Show border** to display a border around the legend.
   b. Select a color for the bounding box line.

      1. Click the color sample .

         Abaqus/CAE displays the **Select Color** dialog box.

      2. Use one of the methods in the **Select Color** dialog box to select a new color. For more information, see *Customizing colors*.
      3. Click **OK** to close the **Select Color** dialog box.

         The bounding box line changes to the selected color.

4. Control the bounding box fill color:
   a. Toggle on **Fill** to display a background color in the bounding box.
   b. Select a fill color to display in the background of the bounding box.

      1. Click the color sample .

         Abaqus/CAE displays the **Select Color** dialog box.

      2. Use one of the methods in the **Select Color** dialog box to select a new color. For more information, see *Customizing colors*.
      3. Click **OK** to close the **Select Color** dialog box.

         The bounding box background changes to the selected color.

Additional information

• *Selecting one or more X–Y curves to customize*

Customizing the appearance of the X–Y plot legend

This section explains how you use the **Chart Legend Options** dialog box to customize the appearance and contents of the legend for an *X–Y* plot. You can also display a title on the *X–Y* plot legend, and you can include on the legend a report of the minimum and maximum *X–Y* values.

In this section:

- *Displaying or hiding the X–Y plot legend*
- *Customizing the title of the X–Y plot legend*
- *Adding minimum and maximum values to the X–Y plot legend*
- *Customizing the location of the legend*
- *Customizing the border and fill for the X–Y plot legend*

Displaying or hiding the X–Y plot legend

The *X–Y* plot legend provides a key to associate each curve included in the plot with the *X–Y* data object that it represents. Each legend entry contains a line segment in the color and style shown in the plot. The legend entry also includes text stating, by default, the description of the *X–Y* data object represented by the curve. You can display or hide the legend using the **Chart Legend Options**.

1. Locate the **Chart Legend Options**.

   Select **Options->XY Options->Chart Legend**; or click , which is located with the *X–Y* plotting tools in the Visualization module toolbox.

   Tip: You can also open this dialog box directly by double-clicking the legend in the viewport when an *X–Y* plot is displayed. You cannot select a component in an *X–Y* plot directly from the viewport when an active procedure is in effect; cancel the current procedure before selecting items from an *X–Y* plot.

2. Click the **Contents** tab, if it is not already selected.
3. Toggle on **Show legend** to display the legend, or toggle it off to hide the legend.
4. Click **Dismiss** to close the **Chart Legend Options** dialog box.

Additional information

• *Selecting one or more X–Y curves to customize*

Customizing the title of the X–Y plot legend

Use the **Title** options to display or hide a title for the *X–Y* plot legend and to customize its contents.

1. Locate the **Text** options.

   Select **Options->XY Options->Chart Legend**; or click , which is located with the *X–Y* plotting tools in the Visualization module toolbox.

   Tip: You can also open this dialog box directly by double-clicking the legend in the viewport when an *X–Y* plot is displayed. You cannot select a component in an *X–Y* plot directly from the viewport when an active procedure is in effect; cancel the current procedure before selecting items from an *X–Y* plot.

   The **Text** options for the legend appear in the lower half of the **Contents** page.

2. From the **Charts** field, select one or more *X–Y* plots whose legends you wish to customize.

   Note:

   To make an *X–Y* curve available for selection, you must first plot it.

3. Click the **Contents** tab, if it is not already selected.
4. If desired, enter a title for the *X–Y* plot legend in the **Title** field.
5. Select the font of the *X–Y* plot legend title.

   a. Click .

   Abaqus/CAE displays the **Select Font** dialog box.

   b. Use one of the methods in the **Select Font** dialog box to select a new font, size, and style. For more information, see *Customizing fonts*.
   c. Click **Apply** to see the effect of your font selections.
   d. Click **OK** to close the **Select Font** dialog box.

   The X–Y plot legend title changes to the selected font, size, and style.

6. Select the color of the *X–Y* plot legend title.

   a. Click the color sample .

   Abaqus/CAE displays the **Select Color** dialog box.

   b. Use one of the methods in the **Select Color** dialog box to select a new color. For more information, see *Customizing colors*.
   c. Click **OK** to close the **Select Color** dialog box.

   The X–Y plot legend title text changes to the selected color.

7. Click **Dismiss** to close the **Chart Legend Options** dialog box.

Additional information

- *Selecting one or more X–Y curves to customize*

Adding minimum and maximum values to the X–Y plot legend

You can include on the plot legend a report of the minimum and maximum *X–Y* values in the plot, and you can customize the format and precision of these values.

1. Locate the **Chart Legend Options**.

   Select **Options->XY Options->Chart Legend**; or click , which is located with the *X–Y* plotting tools in the Visualization module toolbox.

   Tip: You can also open this dialog box directly by double-clicking the legend in the viewport when an *X–Y* plot is displayed. You cannot select a component in an *X–Y* plot directly from the viewport when an active procedure is in effect; cancel the current procedure before selecting items from an *X–Y* plot.

2. From the **Charts** field, select one or more *X–Y* plots whose legends you wish to customize.
3. Click the **Contents** tab, if it is not already selected.
4. Toggle on **Show min/max** to report the minimum and maximum *X–Y* values in the legend.
5. Select one of the following number formats for the minimum and maximum values displayed in the legend:

   ### Automatic

   Very large values and very small values are expressed in scientific format. All remaining values are expressed with no exponent and using the specified number of significant digits.

   ### Decimal

   All values are expressed with no exponent and using the specified number of significant digits.

   ### Engineering

   Values greater than or equal to 1000 (or values less than or equal to 0.001) are expressed as a number ranging from 1 to 999 that is multiplied by 10 to the *n*th power, where *n* is a product of 3 (for example, `20.5E+03` or `17.76E+06`). All remaining values are expressed using the specified number of significant digits.

   ### Scientific

   All values are expressed as a number between 1 and 10 that is multiplied by an appropriate power of 10 (for example, `2.05E+04` or `1.776E+07`).

6. Click the **Precision** arrows to specify the desired number of significant digits (for non-decimal formats) or decimal places (for decimal format) in each label.
7. Click **Dismiss** to close the **Chart Legend Options** dialog box.

Additional information

• *Selecting one or more X–Y curves to customize*

Customizing the location of the legend

You can move the *X–Y* plot legend by dragging it around the viewport or by specifying a viewport location from the **Position** options in the **Chart Legend Options** dialog box. You can drag the legend only when Abaqus/CAE does not have a procedure active; if you cannot drag the legend or select any other *X–Y* plot components from the viewport, cancel the current procedure.

1. Locate the **Chart Legend Options**.

   Select **Options->XY Options->Chart Legend**; or click , which is located with the *X–Y* plotting tools in the Visualization module toolbox.

   Tip: You can also open this dialog box directly by double-clicking the legend in the viewport when an *X–Y* plot is displayed. You cannot select a component in an *X–Y* plot directly from the viewport when an active procedure is in effect; cancel the current procedure before selecting items from an *X–Y* plot.

2. From the **Charts** field, select one or more *X–Y* plots whose legends you wish to move.
3. Click the **Area** tab, if it is not already selected.
4. Toggle on **Inset** to display the *X–Y* plot legend within the *X–Y* plot grid. If **Inset** is off, Abaqus/CAE keeps the legend and the *X–Y* plot in separate bands of the viewport.
5. Select one of the following positioning options:

Auto-align

This option enables you to align the legend in one of nine positions in the viewport: its center, any of the four corners, or centered along any of the four edges. Expand the **Alignment** list, then select one of the options depicted graphically in the list.

Manual

This option enables you to position the legend at a specific *X–Y* location in the viewport. Drag the **X** and **Y** sliders to move the legend horizontally or vertically in the viewport. When these sliders' values are set to `0`, the legend is placed in the lower left corner of the viewport.

6. Click **Dismiss** to close the **Chart Legend Options** dialog box.

Additional information

• *Selecting one or more X–Y curves to customize*

Customizing the border and fill for the X–Y plot legend

Use the **Bounding Box** options in the **Chart Legend Options** dialog box to customize the appearance of the legend by wrapping it with a border or filling it with a specified color.

1. Locate the **Chart Legend Options**.

   Select **Options->XY Options->Chart Legend**; or click , which is located with the *X–Y* plotting tools in the Visualization module toolbox.

   Tip: You can also open this dialog box directly by double-clicking the legend in the viewport when an *X–Y* plot is displayed. You cannot select a component in an *X–Y* plot directly from the viewport when an active procedure is in effect; cancel the current procedure before selecting items from an *X–Y* plot.

2. From the **Charts** field, select one or more *X–Y* plots whose legends you wish to customize.

   Note:

   To make an *X–Y* curve available for selection, you must first plot it.

3. Click the **Area** tab, if it is not already selected.
4. Perform the following steps to display and modify the bounding box:
   a. Toggle on **Show border** to display a border around the legend.
   b. Select a color for the bounding box line.

      1. Click the color sample .

         Abaqus/CAE displays the **Select Color** dialog box.

      2. Use one of the methods in the **Select Color** dialog box to select a new color. For more information, see *Customizing colors*.
      3. Click **OK** to close the **Select Color** dialog box.

         The bounding box line changes to the selected color.

5. Control the bounding box fill color:
   a. Toggle on **Fill** to display a background color in the bounding box.
   b. Select a fill color to display in the background of the bounding box.

      1. Click the color sample .

         Abaqus/CAE displays the **Select Color** dialog box.

      2. Use one of the methods in the **Select Color** dialog box to select a new color. For more information, see *Customizing colors*.
      3. Click **OK** to close the **Select Color** dialog box.

         The bounding box background changes to the selected color.

6. Click **Dismiss** to close the **Chart Legend Options** dialog box.

Additional information

• *Selecting one or more X–Y curves to customize*

Customizing border and fill colors for an X–Y plot

Use the options in the **Plot Options** dialog box to create a custom border color and a custom background fill color for one or more *X–Y* plots in your session. By default, *X–Y* plots have no border and they are filled with a light grey background color. You might want to adjust the border color to distinguish between different *X–Y* plots used in an overlay plot; you might want to adjust the fill color if the *X–Y* curves used in your plot do not stand out clearly against the default background.

1. Select **Options->XY Options->Plot Options**; or click , which is located with the *X–Y* plotting tools in the Visualization module toolbox.

   The **Plot Options** dialog box opens.
2. From the **Plots** frame, highlight one or more *X–Y* plots that you want to modify. This frame lists plot names and the viewports in which they are displayed.
3. Toggle on **Show border** to display a border around the *X–Y* plot.
4. If desired, change the color of the *X–Y* plot border by performing the following steps:
   a. Click the color sample immediately to the right of the **Show border** label .

      Abaqus/CAE displays the **Select Color** dialog box.
   b. Use one of the methods in the **Select Color** dialog box to select a new color. For more information, see *Customizing colors*.
   c. Click **OK** to close the **Select Color** dialog box.

      The color sample and the *X–Y* plot border change to the selected color.
5. Toggle on **Fill** to fill the *X–Y* plot with the color displayed to the right of the **Fill** label.
6. If desired, change the *X–Y* plot fill color by performing the following steps:
   a. Click the color sample immediately to the right of the **Fill** label .

      Abaqus/CAE displays the **Select Color** dialog box.
   b. Use one of the methods in the **Select Color** dialog box to select a new color. For more information, see *Customizing colors*.
   c. Click **OK** to close the **Select Color** dialog box.

      The *X–Y* plot fill color changes to the selected color.

Viewing results along a path

A path is a series of connected lines that you define by specifying a series of points or edges through your model. You can view results along the path in the form of an *X–Y* plot. This chapter explains how to view results along a path.

In this section:

- *Understanding results along a path*
- *Creating a path through your model*
- *Obtaining X–Y data along a path*

Understanding results along a path

To view results along a path through your model, you first select **Tools->Path** to specify the path and then select **Tools->XY Data** to obtain *X*–*Y* data along the path.

In this section:

- *Path specification*
- *How Abaqus/CAE obtains results along a path*

Path specification

A path is a line you define by specifying a series of points or line segments through your model. The points can be nodes or coordinate locations; the line segments can be element edges or lines joining the ends of element edges. Paths can cross more than one part instance. Abaqus/CAE offers four distinct types of paths:

Node list

The points making up the path consist of nodal locations only. You specify the points using node labels and node label ranges. A node label is a persistent means of referring to a given node; that is, node labels do not change as your model deforms. Because of this, the node labels that comprise a node list path are equally applicable to the undeformed or the deformed model shape. However, node labels are part instance-specific. In other words, you can have the same node label for multiple part instances; therefore, you must specify to which part instance you are referring when you use node labels. For more information, see *Creating or editing a node list path*.

Point list

The points making up the path consist of coordinate locations within your model. These locations may or may not coincide with nodal locations. Point list coordinates remain fixed in space and are independent of your model. For example, coordinates that coincide with a nodal location on the undeformed shape may not coincide with any location on the deformed shape. By the same logic, point list coordinates are independent of specific part instances. For more information, see *Creating or editing a point list path*.

Edge list

The points making up the path consist of edges that connect nodes within your model. You specify the edges by selecting individual element edges from the viewport or by selecting the starting edge and direction and allowing Abaqus/CAE to automatically complete the path to the end of the feature edge or to an endpoint that you select. Edges are defined by the elements in the model. Because of this, the edges that comprise an edge list path are equally applicable to the undeformed or the deformed model shape. However, element labels are part instance-specific. In other words, you can have the same element label for multiple part instances; therefore, you must specify to which part instance you are referring when you use edges. For more information, see *Creating or editing an edge list path*.

Circular

The points making up the path consist of coordinate locations within your model. You can create two types of circular paths in Abaqus/CAE: circumferential and radial. A circumferential path lies along the edge of a circle or an arc; a radial path lies along a radius. You specify either type of path by selecting coordinates that define a circle or circular arc and then defining the starting point, ending point, and number of points along the path. Once you have defined the original circle or arc, you can select a new radius length to create any path that shares the same center point as the original. You can use circumferential paths to obtain cross-sectional results in a curved portion of a model, as shown in *Figure 1*.

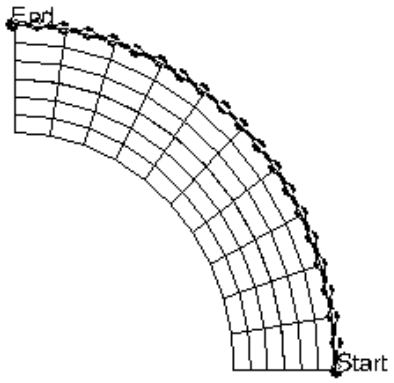

Figure 1: A circumferential path.

You can use radial paths to obtain results spanning from the inner to the outer face of a curve, as shown in *Figure 2*; radial paths are ideal for use in stress linearization (for more information on stress linearization, see *Calculating linearized stresses*).

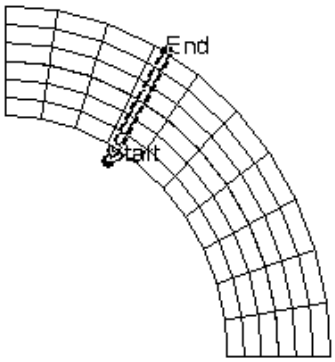

Figure 2: A radial path.

You can select coordinates by picking nodes from the viewport or by entering values in the prompt area; in either case, the coordinates remain fixed in space and are independent of your model. For example, coordinates that coincide with a nodal location on the undeformed shape may not coincide with any location on the deformed shape. By the same logic, circular path coordinate definitions are independent of specific part instances. For more information, see *Creating or editing a circular path*.

Abaqus/CAE forms the path by connecting the nodes, points, or edges that you specify in the order you have given.

After you create a path, you can select **Tools->Path** from the main menu bar to edit, copy, rename, delete, or plot it. Plotting the path itself is a means to verify visually that you have specified the intended line; to view results along the path, you must form *X–Y* data pairs and produce an *X–Y* plot. For more information on managing paths, see *Managing objects using manager dialog boxes*; for more information on producing an *X–Y* plot of path data, see *Obtaining X–Y data along a path*.

How Abaqus/CAE obtains results along a path

Abaqus/CAE obtains results along a path in the form of *X*–*Y* data pairs.
Abaqus determines the data pair *X*-values based on the points that make up the path. These points define model locations at which to obtain data. Abaqus determines the data pair *Y*-values based on analysis results at those model locations. Abaqus/CAE considers only the entities in the current display group when calculating the data pairs.

Path data X-values

You can choose to form *X*-values based only on the points you have specified for the path or to additionally include all locations at which the path intersects the model. (An intersection occurs where the path crosses an element face, element edge, surface face, or surface edge. You can omit individual intersections from the path definition if the intersection lies within a user-specified distance of an actual data point. You can set this intersection tolerance value using Abaqus Scripting Interface commands; for more information, see *Session object*.)

You can also choose whether Abaqus/CAE interprets the points that make up the path as locations on the undeformed or the deformed model shape. When the deformed model shape is chosen, Abaqus/CAE computes the deformed coordinates at a node as the sum of the base coordinates and the deformation at that node multiplied by the viewport-specific deformation scale factor. Node list labels and edge lists indicate model locations and are equally applicable to the undeformed or the deformed model shape. Point list and circular path coordinates are fixed locations independent of the model geometry. Abaqus does not form data pairs for points that do not coincide with the model shape you have chosen.

The node labels or point coordinates that comprise a path are usually not in a form suitable for direct use as *X*-values. Abaqus/CAE offers several options for you to convert this series of points to useful *X*-values and subsequent *X*–*Y* plot axis labels. You can choose one of the following options to convert path points to *X*-values:

- **True distance**: *X*-values correspond to each point's actual distance along the path in model space coordinates, starting with zero.
- **Normalized distance**: *X*-values correspond to each point's distance along the path as a fraction of the total length of the path.
- **Sequence ID**: *X*-values correspond to the order in which each point occurs in the path result list.
- **X, Y, or Z distance**: *X*-values correspond to each point's actual distance along the path in the single coordinate direction you specify, starting with zero. This option is particularly useful for generating a plot of results versus radius in an axisymmetric model.
- **X, Y, or Z coordinate**: *X*-values correspond to each point's distance from the origin along the axis you specify.

Path data Y-values

You can control data pair *Y*-values by choosing the results step, frame, and field output variable for which Abaqus/CAE obtains results and by controlling how Abaqus/CAE computes certain types of results, as follows:

- For node-based field output variables such as displacement to be obtained at nodal locations, Abaqus/CAE reads results directly from the output database with no further computations.
- For element-based field output variables such as stress or strain to be obtained at nodal locations, Abaqus/CAE reads results from the output database, extrapolates those values to the nodes, then conditionally averages multiple contributions according to options you select.
- For both node-based and element-based variables to be obtained at path points that do not coincide with nodal locations, Abaqus/CAE computes values by interpolating from the nodes to the requested location using a geometric approximation of the element's shape. You cannot control this computation.

The averaging options for element-based variables and the complex form options for complex number values are located in the **Result Options** dialog box. Averaging reduces multiple contributions into a single value. When you select result options to partially or fully suppress averaging, path points receiving multiple contributions produce multiple data pairs. Such data pairs share the same *X*-value but have a separate *Y*-value for each contribution. Depending on your path and on the characteristics of your model, the following techniques may be necessary to avoid multiple data pairs sharing the same *X*-value:

- Set result options to fully enable averaging.
- Set result options to ignore region boundaries when computing values.
- Avoid paths that traverse region discontinuities.
- Avoid paths along a line separating discontinuous regions.
- Use display groups to isolate individual regions prior to obtaining results along a path.
- Avoid point list paths that traverse one or more spatial points that lie visually outside of highly deformed elements and cylindrical elements that subtend a large angle but, due to isoparametric mapping, lie mathematically inside the elements. Such spatial points tend to be shared by two or more elements, leading to multiple *Y*-values.

For more information on value averaging, see *Understanding result value averaging*.

The *Y*-value of the data pairs is affected by the current complex form if your selected field output variable contains complex number results. An abbreviation of the complex form is appended to the *Y*-axis title when you plot the path. For example, if `S-Mises` is the selected field output variable and `Magnitude` is the complex form, the *Y*-axis title is `S-Mises CPX:Mg`. Other complex forms are similarly abbreviated. For more information on complex forms, see *Controlling the form of complex results*.

Abaqus/CAE does not form data pairs for points that do not have results for the specified step, frame, or field output variable.

Creating a path through your model

A path is a line you define by specifying a series of points or line segments through your model; the points can be nodes or coordinate locations, the line segments can be element edges or lines joining the ends of element edges.

In this section:

- *Creating or editing a node list path*
- *Creating or editing a point list path*
- *Creating or editing an edge list path*
- *Creating or editing a circular path*

Creating or editing a node list path

A path is a line you define by specifying a series of points through your model. In a node list path all of the points are nodal locations.

For information on including locations other than nodes in a path, see *Creating a path through your model*.

You create a node list path by entering part instance names, node labels, and node label ranges into a table. You can use the editing techniques described in the following procedures to create a path by selecting nodes directly from the viewport or from node sets. Alternatively, you can create a node list path by entering values directly into the table. If you do not know the part instance names in the model, use the Query toolset to query nodes in the viewport. To help determine node labels of interest, you may want to produce a model plot with node symbols and node numbers visible prior to creating the path. For more information, see *Customizing model labels*.

1. Locate the path creation and editing options.

   Use the following techniques to create or edit a node list path:

   Create a new path

   a. From the main menu bar, select **Tools->Path->Create**. The **Create Path** dialog box appears.
   b. Abaqus/CAE displays a default name for the path in the **Name** text field. To provide a more meaningful name, replace this default with the name of your choice (including blank spaces if you wish).
   c. In the **Create Path** dialog box, click **Node list**; then click **Continue**.

   Edit an existing path

   a. From the main menu bar, select **Tools->Path->Edit**. From the menu that appears, select the path you want to edit.

      Tip: You can also use the **Path Manager** to edit a path. From the main menu bar, select **Tools->Path->Manager** to display the manager. Select the path you want to edit, and click **Edit** from the buttons on the right side of the manager.

   The **Edit Node List Path** dialog box appears.

2. Specify the nodes along your path.

   Use any of the following techniques:

   Select the nodes directly from the viewport

   a. Click **Add Before** or **Add After** to begin making **Viewport selections**.

      Abaqus/CAE prompts you to **Select nodes to be inserted into the path** and closes the **Edit Node List Path** dialog box.

   b. Select one or more nodes from the viewport (for more information, see *Selecting objects within the viewport*). If a desired node exists in more than one part instance, toggle off the **Select the Entity Closest to the Screen** tool in the **Selection** toolbar. If you make an ambiguous selection, the part instance name and node label will appear in the lower left corner of the viewport in the form `Highlighting Node Instance.Node`. Use the **Next** and **Previous** buttons to cycle through the possible selections, and click **OK** to confirm your selection.

      Abaqus/CAE highlights the nodes as you select them and displays the node labels and the path connectivity.

      Note:

      You can only select nodes that are in the current display group.

   c. Click **Done** in the prompt area when you have finished.

Abaqus/CAE displays the **Edit Node List Path** dialog box; the part instances and nodes in your path are listed in the path definition table.

d. If desired, repeat the preceding steps to add additional nodes.

The **Add Before** and **Add After** buttons determine where your selections will be added in relation to the currently highlighted line in the path definition table.

Select the nodes from a node set

a. Click **Add Before** or **Add After** to begin making **Node set selections**.

The **Select Node Sets** dialog box displays the node sets available in the current output database in the table on the left side.

b. To limit the list for easier selection, type a filter pattern into the **Filter** field, and press **[Enter]** to apply the filter.

Abaqus/CAE lists only those node sets that meet your specification.

c. From the list of node sets, select one or more node sets to include in the path.

- Use the top two arrows in the middle of the dialog box to move the selected node sets into or out of the table on the right side of the dialog box.
- Use the bottom two arrows in the middle of the dialog box to move all of the node sets into or out of the table on the right side of the dialog box.

d. Click **OK** when you have completed your selection.

Abaqus/CAE displays the **Edit Node List Path** dialog box; the part instances and nodes in your path are listed in the path definition table.

e. If desired, repeat the preceding steps to add additional nodes.

The **Add Before** and **Add After** buttons determine where your selections will be added in relation to the currently highlighted line in the path definition table.

Enter the node labels directly into the table

a. In the **Path Definition** table, use standard keyboard and mouse editing techniques to insert, modify, or delete part instance names and node label expressions. If you do not know the part instance names in the model, use the Query toolset to query nodes in the viewport. For special table editing options or to read data from an ASCII file, press mouse button 3. (For more information, see *Entering tabular data*.) A node label expression is either of the following:

- A single node label; for example, 5.
- A range of nodes that you specify with a starting and ending node label optionally followed by an increment; for example, 5:10 or 5:10:2.

Note:

If you read node labels from an ASCII file, you must read the table values starting with the first column, and each row must include a part instance name and a node label expression. The part instance name is case sensitive and must be enclosed in quotation marks as follows:`"INSTANCE_NAME"`

b. After each node label expression, press **[Enter]**.

Abaqus highlights all nodes included in the path and displays the node labels and the path connectivity.

3. When you are done selecting nodes, click **OK**.

If you created a new path, Abaqus/CAE adds the path name to the **Path Manager** list. By default, Abaqus/CAE saves the path you have specified for the duration of the session. If you want to retain a path for use in subsequent sessions, save it to an XML file, to the model database, or to an output database; for more information, see *Managing session objects and session options*.

Additional information

- *Understanding results along a path*
- *Obtaining X–Y data along a path*

Creating or editing a point list path

A path is a line you define by specifying a series of points through your model. In a point list path all of the points are model coordinate locations. These locations may or may not coincide with nodes.
For information on alternative forms of path specification, see *Creating a path through your model*.

You create a point list path by entering the coordinates of points into a table. For points that coincide with nodal locations, you can specify the node label or select the node in the viewport and Abaqus will enter the undeformed coordinates of the node into the table. You can also select a node list path to enter nodal coordinates into the table. To help determine which node labels are of interest, you may want to produce a model plot with node symbols and node numbers visible prior to creating the path. For more information, see *Customizing model labels*.

1. Locate the path creation and editing options.

   Use the following techniques to create or edit a point list path:

   Create a new path

   a. From the main menu bar, select **Tools->Path->Create**. The **Create Path** dialog box appears.
   b. Abaqus displays a default name for the path in the **Name** text field. To provide a more meaningful name, replace this default with the name of your choice (including blank spaces if you wish).
   c. In the **Create Path** dialog box, click **Point list**; then click **Continue**.

   Edit an existing path

   a. From the main menu bar, select **Tools->Path->Edit**. From the menu that appears, select the path you want to edit.

      Tip: You can also use the **Path Manager** to edit a path. From the main menu bar, select **Tools->Path->Manager** to display the manager. Select the path you want to edit, and click **Edit** from the buttons on the right side of the manager.

   The **Edit Point List Path** dialog box appears.

2. In the **Point Coordinates** table, use standard keyboard and mouse editing techniques to enter, modify, or delete coordinates.

   To enter coordinates, use any of the following techniques:

   Type in the coordinate values of a point

   a. Specify the values as *X*-, *Y*-, *Z*-coordinates separated by spaces or commas; for example, 1.0, 3.4, 2.0.
   b. Press **[Enter]**.

   Include the coordinates of a nodal location by querying the node

   a. Select **Node query**.
   b. Choose the part instance for which you want to determine nodal coordinates. Click the arrow next to the **Part instance** field to see a list of the available part instances.

      To obtain the coordinates of a node, do one of the following:

      - Type the node label into the **Node label** field, and press **[Enter]** or click **Query**.
      - Click **Select from Viewport** , and select a node.

      Abaqus displays the undeformed *X*-, *Y*-, and *Z*-coordinates of the node.

   c. To enter these coordinates into the path definition table before, after, or at the currently highlighted row, click **Add Before**, **Add After**, or **Replace**, respectively.

      For special table editing options or to read data from an ASCII file, press mouse button 3. (For more information, see *Entering tabular data*.)

Include the coordinates of nodes from a node list path

a. Select **Node list path**.

b. Choose the node path list from which you want to enter the nodal coordinates. Click the arrow next to the **Node list path** field to see a list of the available paths.

c. To enter these coordinates into the path definition table before, after, or at the currently highlighted row, click **Add Before**, **Add After**, or **Replace**, respectively.

On the model plot in the current viewport, Abaqus highlights all points included in the path and displays the path connectivity.

3. When you are done, click **OK**.

If you created a new path, Abaqus/CAE adds the path name to the **Path Manager** list. By default, Abaqus/CAE saves the path you have specified for the duration of the session. If you want to retain a path for use in subsequent sessions, save it to an XML file, to the model database, or to an output database; for more information, see *Managing session objects and session options*.

Additional information

- *Understanding results along a path*
- *Obtaining X–Y data along a path*

Creating or editing an edge list path

A path is a line you define by specifying a series of line segments in your model. In an edge list path the segments are defined by element edges and lines joining the ends of element edges.
For information on including locations other than edges in a path, see *Creating a path through your model*.

You create an edge list path by entering part instance names and edge labels into a table. Each edge label consists of an element number, a face number, an edge number, and a direction along the edge. Select edges from the viewport for entry into the table using a combination of three methods:

- Select individual element edges.
- Select an element edge and a direction along a feature edge and let Abaqus/CAE automatically add the remaining edges up to one end of the feature.
- Select an element edge and a node and let Abaqus/CAE choose a shortest distance path along the element edges between them.

You can also edit the table directly, using the viewport to track your progress. However, some components of the edge labels depend on the element type, orientation, and desired connectivity, which are more easily determined by making selections from the viewport.

1. Locate the path creation and editing options.
   To create a new path:
   a. From the main menu bar, select **Tools->Path->Create**. The **Create Path** dialog box appears.
   b. Abaqus displays a default name for the path in the **Name** text field. To provide a more meaningful name, replace this default with the name of your choice (including blank spaces if you wish).
   c. In the **Create Path** dialog box, click **Edge list**; then click **Continue**.

   To edit an existing path:
   a. From the main menu bar, select **Tools->Path->Edit**. From the menu that appears, select the path you want to edit.

   Tip: You can also use the **Path Manager** to edit a path. From the main menu bar, select **Tools->Path->Manager** to display the manager. Select the path you want to edit, and click **Edit** from the buttons on the right side of the manager.

   The **Edit Edge List Path** dialog box appears.
2. To create or edit a path by selecting edges in the viewport, click **Add Before** or **Add After** to begin making selections.
   Abaqus/CAE prompts you to **Select edges to be inserted into the path** and closes the **Edit Edge List Path** dialog box.
3. Use the selection methods in the prompt area to select edges. Three edge selection methods are available:

Individually

Select individual element edges in the order that they should appear in the path; the selected edges need not be adjacent. If necessary, click **Flip** in the prompt area to reverse the connectivity of the last edge that you selected.

By feature edge

Select a starting edge that lies along a feature edge; Abaqus/CAE will automatically select all the edges between your selection and the end of the feature edge. Click **Flip** to reverse the connectivity of the edge that you selected and the direction used for automatic selection.

By shortest distance

Select a starting edge and an endpoint (node); Abaqus/CAE will automatically select the element edges that define the shortest path between your selections. Click **Flip** to reverse the connectivity of the edge that you selected and the direction used for automatic edge selection. If multiple routes exist with the same distance, Abaqus/CAE selects one of them.

Note:

The edge and node that you select must be on the same part instance.

If a desired edge exists in more than one part instance, toggle off the **Select the Entity Closest to the Screen** tool in the **Selection** toolbar. If you make an ambiguous selection, the part instance name and edge label (without the direction value) will appear in the lower-left corner of the viewport in the form `Highlighting Element Edge Element.Face.Edge`. Use the **Next** and **Previous** buttons to cycle through the possible selections, and click **OK** to confirm your selection.

Abaqus highlights the edges as you select them and displays the node labels and the path connectivity. In addition, Abaqus labels the first node in the path `Start` and the last node in the path `End`.

4. Click **Done** in the prompt area when you have finished.

   Abaqus/CAE displays the **Edit Edge List Path** dialog box; the part instances and edges in your path are listed in the path definition table.

5. If desired, repeat the preceding steps to add additional edges.

   The **Add Before** and **Add After** buttons determine where your selections will be added in relation to the currently highlighted line in the path definition table.

6. If desired, you can use standard keyboard and mouse editing techniques to insert, modify, or delete part instance names and edge labels in the **Path Definition** table. Edge labels are of the form (`element number, face number, edge number, direction`).

   Tip: Use the Query toolset to query nodes in the viewport to obtain part instance names. Display element and face labels in the viewport using the plot state-independent options. (For more information, see *Customizing model labels*.) Edges are numbered counterclockwise around a face as viewed from outside the element. The direction (−1 or 1) depends on your desired path connectivity.

   For special table editing options or to read data from an ASCII file, press mouse button 3. (For more information, see *Entering tabular data*.)

7. After editing the **Path Definition** table, press **[Enter]**.

   Abaqus updates the path displayed in the viewport.

8. When you are done selecting edges, click **OK**.

   If you created a new path, Abaqus/CAE adds the path name to the **Path Manager** list. By default, Abaqus/CAE saves the path you have specified for the duration of the session. If you want to retain a

path for use in subsequent sessions, save it to an XML file, to the model database, or to an output database; for more information, see *Managing session objects and session options*.

Additional information

- *Understanding results along a path*
- *Obtaining X–Y data along a path*

Creating or editing a circular path

A path is a line you define by specifying a series of points through your model. In a circular path, all of the points are model coordinate locations that lie on the circumference or along a radius of a circle. For information on alternative forms of path specification, see *Creating a path through your model*.

You create a circular path by selecting nodes or entering coordinates to define the circle. After you define the circle, you use the circle's edge or a radius to define either a curved circumferential path or a straight radial path.

1. Locate the path creation and editing options.
   To create a new path:
   a. From the main menu bar, select **Tools->Path->Create**. The **Create Path** dialog box appears.
   b. Abaqus displays a default name for the path in the **Name** text field. To provide a more meaningful name, replace this default with the name of your choice (including blank spaces if you wish).
   c. In the **Create Path** dialog box, click **Circular**; then click **Continue**.

   To edit an existing path:

   a. From the main menu bar, select **Tools->Path->Edit**. From the menu that appears, select the path you want to edit.

      Tip: You can also use the **Path Manager** to edit a path. From the main menu bar, select **Tools->Path->Manager** to display the manager. Select the path you want to edit, and click **Edit** from the buttons on the right side of the manager.

   The **Edit Circular Path** dialog box appears.

2. Select the path type, **Circumferential** or **Radial**.

   Abaqus/CAE updates the dialog box to reflect the type of path you are creating. A **Circumferential Path** lies along the edge of the circle and requires a radius, a start angle, and an end angle to define its position and length. A **Radial Path** lies along a radius of the circle and requires a radial angle, a start value, and an end value to define its position and length.

3. In the **Circle Definition** portion of the dialog box, select **Origin and axis** or **3 Points on Arc** as the method to define the circle.

   The origin and axis method uses two points to define the axis of rotation and one point in the plane of the circle to define the default radius length and the starting point of rotation. The three points on arc method fits a circle to three edge points.

4. Click **Select from Viewport** to select nodes or enter coordinates to define the circle.

   Abaqus/CAE closes the **Edit Circular Path** dialog box and displays prompts in the prompt area to guide you through the procedure.

5. Select nodes from the viewport or use the text field in the prompt area to specify each point as *X*-, *Y*-, *Z*-coordinates separated by spaces or commas; for example, 1.0, 3.4, 2.0.

   Abaqus/CAE opens the **Edit Circular Path** dialog box; the coordinates that you selected appear in the circle definition table. If you selected nodes, the coordinates used correspond to the current deformation state of the model.

   On the model plot in the current viewport, Abaqus highlights all points included in the path and displays the path connectivity.

6. You can edit a single point in the **Circle Definition** as follows:
   a. Position the cursor over the coordinates of the point.
   b. Click mouse button 3, and choose **Edit selection**.
   c. Select a node in the viewport, or edit the coordinates in the prompt area.

When you make your selection or enter the new coordinates, Abaqus/CAE returns to the **Edit Circular Path** dialog box and displays the redefined circle in the viewport.

7. Select the number of segments to include in the path.

   Abaqus/CAE modifies the path in the viewport to show the selected number of equal length segments.

8. Complete the editing or creation of the circular path as follows:

Circumferential paths

Select the **Radius**, and select the **Start angle** and **End angle** of rotation. By default, Abaqus uses the radius of the circle that you defined and rotates a full 360° starting at the first point that you selected on the circle—the only point on the circle if you chose the origin and axis method.

Radial paths

Select the **Radial Angle**, **Start Radius**, and **End Radius**. The default radial angle (0°) is from the center to the first point that you selected on the circumference of the circle—the only point on the circle if you chose the origin and axis method. The default starting radius is `0.0` (the center of the circle), and the default end radius is equal to the radius of the circle.

9. When you are done, click **OK**.

   If you created a new path, Abaqus/CAE adds the path name to the **Path Manager** list. By default, Abaqus/CAE saves the path you specified for the duration of the session. If you want to retain a path for use in subsequent sessions, save it to an XML file, to the model database, or to an output database; for more information, see *Managing session objects and session options*.

Additional information

- *Understanding results along a path*
- *Obtaining X–Y data along a path*

Obtaining X–Y data along a path

This section explains how to obtain *X*–*Y* data along a path.

In this section:

- *Choosing the path locations at which to obtain data*
- *Controlling data pair X-values*
- *Controlling data pair Y-values*

Choosing the path locations at which to obtain data

Abaqus/CAE obtains results along a path in the form of *X*–*Y* data pairs. The data pair *X*-values define the model locations at which to obtain data; the *Y*-values are analysis results at those locations.
Abaqus considers only the entities in the current display group when calculating the data pairs.

Abaqus calculates the data pair *X*-values based on the points you have specified for the path. You can choose to form *X*-values based only on the points you have specified or to additionally include all locations at which the path intersects the model. (An intersection occurs where the path crosses an element face, element edge, surface face, or surface edge.)

You can also choose whether Abaqus interprets the points that make up the path as locations on the undeformed or the deformed model shape. For node list paths, the node labels that constitute the path are equally applicable to undeformed and deformed model shapes. However, point list path coordinates remain fixed in space and are independent of your model. For example, coordinates that coincide with a nodal location on the undeformed shape may not coincide with any location on the deformed shape. Values obtained using point list path coordinates and the deformed model are affected by the deformation scale factor. Abaqus does not form data pairs for coordinate locations that do not coincide with your model.

1. Locate the **XY Data from Path** options.

   From the main menu bar, select **Tools->XY Data->Create**. From the dialog box that appears, select **Path**; then click **Continue**. The **XY Data from Path** dialog box appears.

2. Click the **Path** arrow to select the path for which to obtain data.

   The model plot in the current viewport changes to highlight the path you have selected.

3. Click the **Undeformed** or **Deformed** to choose whether Abaqus interprets the points that make up the path as locations on the undeformed or the deformed model shape, respectively.

4. Select **Project onto mesh** and specify a tolerance to obtain data from point locations that do not lie on or inside the mesh.

   Path points or interpolated locations that lie between path points are projected onto an element face in the mesh. If the projected distance is less than the specified tolerance, data are extracted from the projected location. This option has no effect on one-dimensional elements (such as beams) and surface variables (such as CPRESS).

5. From the **Point Locations** options, choose either of the following:

   - Select **Path points** to obtain data only at the points that make up the path. You can obtain *X*–*Y* data at locations where the path intersects the model as well as at the points that make up the path by toggling on **Include intersections**.
   - Select **Uniform spacing** to obtain data at regular, interpolated intervals along the path, but not necessarily at the points that comprise the path definition. You can change the value specified in the **Number of intervals** field to increase or decrease the number of locations for which interpolated data are obtained along the path.

6. To evaluate and display the data, click **Plot**.

   An *X*–*Y* plot appears in the current viewport. The plot represents the data you have configured in the dialog box, which Abaqus considers temporary data whether or not you have clicked **Save As** to save it.

7. To save the data you have configured, click **Save As**.

   Note:

   To plot your saved *X*–*Y* data object, select **Tools->XY Data->Plot** from the main menu bar and choose the *X*–*Y* data object from the pull-right menu.

8. When you have finished, click **Cancel** to close the dialog box.

Additional information

- *Understanding results along a path*
- *Creating a path through your model*
- *Controlling data pair X-values*
- *Controlling data pair Y-values*
- *X–Y plotting*

Controlling data pair *X*-values

Abaqus obtains results along a path in the form of *X*–*Y* data pairs, calculating the data pair *X*-values based on the points you have specified for the path and optionally on additional points where your path intersects the model. For more information, see *Choosing the path locations at which to obtain data*.

The node labels or point coordinates that comprise a path are usually not in a form suitable for direct use as *X*-values. Abaqus offers several options for you to convert this series of points to useful *X*-values and subsequent *X*–*Y* plot axis labels.

1. Locate the **XY Data from Path** options.

   From the main menu bar, select **Tools->XY Data->Create**. From the dialog box that appears, select **Path**; then click **Continue**. The **XY Data from Path** dialog box appears.

2. At the top of the dialog box, click the **Path** arrow to select the path for which to obtain data.

   The model plot in the current viewport changes to highlight the path you have selected.

3. In the **X-Values** field, choose one of the following options to convert path points to *X*-values:

   - **True distance**: *X*-values correspond to each point's actual distance along the path in model space coordinates, starting with zero.
   - **Normalized distance**: *X*-values correspond to each point's distance along the path as a fraction of the total length of the path.
   - **Sequence ID**: *X*-values correspond to the order in which each point occurs in the path result list.
   - **X, Y, or Z distance**: *X*-values correspond to each point's actual distance along the path in the single coordinate direction you specify, starting with zero. This option is particularly useful for generating a plot of results versus radius in an axisymmetric model.
   - **X, Y, or Z coordinate**: *X*-values correspond to each point's distance from the origin along the axis you specify.

4. To evaluate and display the data, click **Plot**.

   An *X*–*Y* plot appears in the current viewport. The plot represents the data you have configured in the dialog box, which Abaqus considers temporary data whether or not you have clicked **Save As** to save it.

5. To save the *X*–*Y* data pairs you have configured as an *X*–*Y* data object , click **Save As**.

   Note:

   To plot your saved *X*–*Y* data object, select **Tools->XY Data->Plot** from the main menu bar and choose the *X*–*Y* data object from the pull-right menu.

6. When you have finished, click **Cancel** to close the dialog box.

Additional information

- *Understanding results along a path*
- *Controlling data pair Y-values*
- *X–Y plotting*

Controlling data pair *Y*-values

Abaqus obtains results along a path in the form of *X*–*Y* data pairs. The data pair *X*-values define the model locations at which to obtain data; the *Y*-values are based on analysis results at those locations. You can control these *Y*-values by choosing the results step, frame, and field output variable for which Abaqus obtains results; by controlling how Abaqus averages certain types of results; and by selecting the display form of complex number results (if applicable).

1. Locate the **XY Data from Path** options.

   From the main menu bar, select **Tools->XY Data->Create**. From the dialog box that appears, select **Path**; then click **Continue**. The **XY Data from Path** dialog box appears.

2. At the top of the dialog box, click the **Path** arrow to select the path for which to obtain data.

   The model plot in the current viewport changes to highlight the path you have selected.

3. The **Y-Values** field identifies the step, frame, and field output variable for which Abaqus will obtain results.

   - To change the step or frame, click **Step/Frame**. For more information, see *Selecting the results step and frame*.
   - To change the field output variable, click **Field Output**. For more information, see *Selecting the primary field output variable*.
   - To remove duplicate XY data pairs, toggle on **Remove duplicate XY pairs**.
   - When extracting results from a node list path, toggle on **Include all elements** to include values from all the elements attached to the selected nodes irrespective of whether it is along the direction of path or not.
   - The averaging of element-based field output values is controlled by the result options settings for the current viewport. To view or change these settings, select **Result->Options** from the main menu bar. For more information, see *Controlling result averaging*.
   - The form of values for complex numbers is controlled by the result options settings for the current viewport. To view or change these settings, select **Result->Options** from the main menu bar. For more information, see *Controlling the form of complex results*.

   Abaqus refreshes the **Y-Values** field and the deformed, contour, or symbol plot in the current viewport according to any changes you apply to the step, frame, field output variable, or result options.

4. To evaluate and display the data, click **Plot**.

   An *X*–*Y* plot appears in the current viewport. The plot represents the data you have configured in the dialog box, which Abaqus considers temporary data whether or not you have clicked **Save As** to save it.

5. To save the *X*–*Y* data pairs you have configured as an *X*–*Y* data object, click **Save As**.

   Note:

   To plot your saved *X*–*Y* data object, select **Tools->XY Data->Plot** from the main menu bar and choose the *X*–*Y* data object from the pull-right menu.

6. When you have finished, click **Cancel** to close the dialog box.

Animating plots

An animation is a sequence of images that Abaqus/CAE displays in rapid succession, resulting in a movie-like effect.

In this section:

- *Understanding animation*
- *Object-based animation*
- *Saving an animation file*
- *Controlling animation playback*

Understanding animation

Abaqus/CAE offers two means of animation: object-based and image-based.

Object-based animation

Object-based animation is the display of a sequence of deformed shape plots, contour plots, symbol plots, or material orientation plots. Abaqus/CAE can produce three different types of sequences of these plots. These three sequence types are called “time history animation,”“scale factor animation,” and “harmonic animation.”

Time history animation produces a sequence of deformed shape, contour, symbol, or material orientation plots that vary over time according to actual analysis results. Scale factor animation produces a sequence of images that vary only in the scaling of a single deformed shape, contour, or symbol plot. Harmonic animation produces a sequence of images that represents complex result values varying according to applied angles. To better understand these three types of animation, see *Time history animation*; *Scale factor animation*; and *Harmonic animation*; respectively.

While an object-based animation is playing, you can dynamically change display characteristics such as the view, any viewport annotations, and plot state-dependent customization options.

Image-based animation

Image-based animation is the playback of an animation file. You create an animation file in Abaqus/CAE by first playing object-based animations in one or more viewports and then selecting **Animate->Save As** from the main menu bar. Once saved, your animation can be played external to Abaqus/CAE using industry-standard animation software. You can choose to save your image-based animation file in various formats, such as MP4 or QuickTime.

From within Abaqus/CAE you can also display an image-based animation by selecting the animation file as a background movie. When active, the background movie is displayed in a viewport in the Visualization module. For more information, see *Displaying and customizing a background movie*.

Note: Abaqus/CAE also enables you to save an animation in VRML format, which creates a three-dimensional rendition of the animation. Because these files are three-dimensional, they are not strictly image-based; however, you can play and distribute animation files in VRML format as you would files in another format like QuickTime.

In general, animation playback from a file provides better performance than object-based animation, particularly for large models. While an image-based animation is playing, you cannot change its display characteristics.

In this section:

- *Time history animation*
- *Scale factor animation*
- *Harmonic animation*

Time history animation

In a time history animation Abaqus/CAE creates the images in the sequence by redrawing the deformed shape, contour, symbol, or material orientation plot for every specified frame found in the output database for the active steps and frames. Each image in a time history animation displays actual analysis results. The deformation scale factor remains constant for each image in a time history animation. Result frames can be drawn sequentially or selected from the active frames based on time intervals.

If you are animating a contour plot, the display of the field output values depends on options you select. The default behavior is for the values within the legend to be fixed based on the minimum and maximum values for the first and last animation frame. To learn how to set contour limits, see *Setting contour limits*.

Additional information

- *Customizing the display of steps and frames in the results*
- *Producing a time history animation*
- *Activating and deactivating steps and frames*

Scale factor animation

In a scale factor animation Abaqus/CAE creates all of the deformed shape, contour, or symbol plot images in the sequence from a single step and frame of the output database. Abaqus/CAE generates animation scale factors ranging from 0 to 1 or from −1 to 1, according to your specification. Individual images are formed by applying the range of animation scale factors to the field output values displayed in the plot. This gives the appearance of the field output evolving over time, although all images are produced from a single step and frame of your results. (To view the actual evolution of results over time, you must produce a time history animation.)

If you are animating a contour plot, the display of the field output values depends on options you select. The default behavior is for the values within the legend to be fixed based on the scaled minimum and maximum values for the selected results step and frame. To learn how to set contour limits, see *Setting contour limits*. To learn how to customize the legend, see *Customizing the legend*.

Additional information

- *Producing a scale factor animation*
- *Customizing a scale factor or harmonic animation*

Harmonic animation

Harmonic animation is valid only for field output containing complex numbers. In a harmonic animation Abaqus/CAE creates all of the deformed shape, contour, or symbol plot images in the sequence from a single step and frame of the output database. Abaqus/CAE generates angles ranging from 0 to 180° or from −180° to 180°, according to your specification, and displays the value of the complex field output at each of these angles. This gives the appearance of the field output evolving over time, although all images are produced from a single step and frame of your results. (To view the actual evolution of results over time, you must produce a time history animation.) Harmonic animation is useful for simulating the vibration modes computed by an eigenvalue analysis.

If you are animating a contour plot, the display of the field output values depends on options you select. The default behavior is for the values within the legend to be fixed based on the range of the real component. To learn how to set contour limits, see *Setting contour limits*. To learn how to customize the legend, see *Customizing the legend*. To learn more about complex results, see *Understanding complex results*.

Additional information

• *Producing a harmonic animation*

Object-based animation

This section explains how to produce and customize Abaqus/CAE object-based time history, scale factor, and harmonic animations.

In this section:

- *Producing and customizing an object-based animation*
- *Producing a time history animation*
- *Producing a scale factor animation*
- *Producing a harmonic animation*
- *Customizing a scale factor or harmonic animation*
- *Customizing the underlying plot of an animation*

Producing and customizing an object-based animation

In a time history animation you can customize the analysis steps and frames that Abaqus/CAE includes in your animation. In a scale factor or a harmonic animation you can customize the apparent motion of your model.
For all three types of animation you can customize the underlying deformed shape, contour, symbol, or material orientation plot.

At any time before or during object-based animation playback you can customize the deformed shape, contour, symbol, or material orientation plot that underlies your animation. For example, you can toggle the legend, adjust the deformation scale factor, or choose a different field output variable. Use the **View**, **Result**, and **Options** menus to customize the underlying plot of your animation.

Additional information

- *Producing a time history animation*
- *Producing a scale factor animation*
- *Producing a harmonic animation*

Producing a time history animation

Animating by time history produces a sequence of plots that vary over time according to actual analysis results. You can choose to animate a deformed shape, contour, symbol, or material orientation plot.

1. Use the **File** menu to open the *output database* containing your analysis results.
2. To plot variables other than those Abaqus selects by default, use the **Result** menu.
   - For animation of a deformed or material orientation plot, select the *deformed field output variable* for which Abaqus obtains values over time.
   - For animation of a contour or symbol plot, select the *primary field output variable* or *symbol field output variable* to display. If you want to display your animating contour or symbol plot on the deformed shape, select the *deformed field variable*. For more information on field output variable selection, see *Selecting field output variables*.
3. To customize the steps and frames that Abaqus/CAE includes in the animation, locate the **Active Steps/Frames** dialog box.

   From the main menu bar, select **Result->Active Steps/Frames**. For more information about activating steps and frames, see *Customizing the display of steps and frames in the results*.
4. Use the **Options** and **View** menus to select the *customization options* that you want. These may include deformed, contour, symbol, orientation, and view options.
5. To initiate the animation, select **Animate->Time History** from the main menu bar.

    **Tip:** You can also produce a time history animation using the  tool in the toolbox.

   Animation begins in all animated viewports, and the animation controls appear in the right side of the context bar. Abaqus is now in the time history animation plot state. In this state Abaqus automatically refreshes your plot each time you click **Apply** or **OK** in the **Results**, **Options**, or **View** menu dialog boxes. All animated viewports remain in the time history animation state until you produce a plot in some other state, such as the undeformed or deformed state. To learn how to control the animation, see *Controlling animation playback*.

Additional information

- *Customizing the display of steps and frames in the results*
- *Controlling animation playback*

Producing a scale factor animation

Animating by scale factor produces a sequence of images created from a single step and frame of the output database. These images can consist of either deformed shape, contour, or symbol plots. For deformed shape plots and for contour and symbol plots on the deformed shape, the images vary in the scale factors applied to the deformations. For contour and symbol plots, the images also vary in the scale factors applied to the field output.

1. Use the **File** menu to *open the output database* containing your analysis results.
2. Use the **Result** menu to select the analysis results to be plotted, including the step and frame, the deformed field output variable, and, for contour or symbol plot animation, the *primary field output variable* or *symbol field output variable* to be plotted. For more information on field output variable selection, see *Selecting field output variables*.
3. Use the **Options** and **View** menus to select the *customization options* that you want.
4. To initiate the animation, select **Animate->Scale Factor** from the main menu bar.

    **Tip:** You can also produce a scale factor animation using the  tool in the toolbox.

   Animation begins in all animated viewports, and the animation controls appear in the right side of the context bar. Abaqus is now in the scale factor animation plot state. In this state Abaqus automatically refreshes your plot each time you click **Apply** or **OK** in the **Results**, **Options**, or **View** menu dialog boxes. All animated viewports will remain in the scale factor animation state until you produce a plot in some other state, such as the undeformed or deformed state. For more information on customizing the underlying model shape, see *Customizing model shape*.

Additional information

- *Scale factor animation*
- *Controlling animation playback*
- *Customizing a scale factor or harmonic animation*

Producing a harmonic animation

Harmonic animation produces a sequence of images created from a single step and frame of the output database. These images can consist of either deformed shape, contour, or symbol plots. For deformed shape plots and for contour and symbol plots on the deformed shape, the images vary in the angle applied to the value of the deformations. For contour and symbol plots, the images vary in the angle applied to the field output; both the real and the imaginary components of the results are used.

By default, Abaqus/CAE displays a frame counter during harmonic animation. The frame counter indicates the current angle when complex results are viewed.

1. Use the **File** menu to *open the output database* containing your analysis results.
2. Use the **Result** menu to select the analysis results to be plotted, including the step and frame, the deformed field output variable, and, for contour or symbol plot animation, the *primary field output variable* or *symbol field output variable* to be plotted. For more information on field output variable selection, see *Selecting field output variables*.
3. Use the **Options** and **View** menus to select the *customization options* that you want.
4. To initiate the animation, select **Animate->Harmonic** from the main menu bar.

    **Tip:** You can also produce a harmonic animation using the  tool in the toolbox.

   Animation begins in all animated viewports, and the animation controls appear in the prompt area. Abaqus is now in the harmonic animation plot state. In this state Abaqus automatically refreshes your plot each time you click **Apply** or **OK** in the **Results**, **Options**, or **View** menu dialog boxes. All animated viewports will remain in the harmonic animation state until you produce a plot in some other (for example, undeformed, deformed) state. For more information on customizing the underlying model shape, see *Customizing model shape*.

Additional information

- *Harmonic animation*
- *Controlling animation playback*
- *Customizing a scale factor or harmonic animation*

Customizing a scale factor or harmonic animation

You can customize the apparent motion of your animated model by choosing between the scale factor range **Half cycle** and the extended range **Full cycle**. The extended range is useful, for instance, to visualize a vibration mode obtained by modal analysis. You can also vary the number of frames (separate images) in the animation. A greater number of frames produces a smoother animation.

In a scale factor animation Abaqus/CAE divides the scale factor range by the number of frames to compute the animation scale factor values. These values are applied to the *deformation scale factors* in each coordinate direction and to the *field output variable values* to produce each image in the animation sequence.

In a harmonic animation Abaqus/CAE divides the angle range by the number of frames to compute the animation angle values. These values are applied to compute the value of the field output variable at that angle and to produce each image in the animation sequence.

1. Locate the **Scale Factor/Harmonic** options.

   From the main menu bar, select **Options->Animation**; then click the **Scale Factor/Harmonic** tab in the dialog box that appears. The **Scale Factor/Harmonic** options appear.

2. To control the range, click the **Relative Scaling** that you want:

   - **Full cycle**: for scale factor animation (real numbers) this selection corresponds to the range −1 to 1; for harmonic animation (complex numbers having real and imaginary components) this selection corresponds to the range −180° to 180°.
   - **Half cycle**: for scale factor animation (real numbers) this selection corresponds to the range 0 to 1; for harmonic animation (complex numbers having real and imaginary components) this selection corresponds to the range 0 to 180°.

3. To choose the number of separate images in your animation, click the **Frames** arrow.

   The specified number of frames appears in the **Frames** box.

4. Click **Apply** to implement your changes.

   The scale factor or harmonic animation in all animated viewports changes to reflect the relative scaling and the number of frames you have specified.

   Your changes are saved for the duration of the session and will affect all subsequent plots in the harmonic or scale factor animation state.

Additional information

- *Scale factor animation*
- *Producing a scale factor animation*
- *Harmonic animation*
- *Producing a harmonic animation*
- *Customizing the underlying plot of an animation*
- *Scaling deformations*

Customizing the underlying plot of an animation

Time history, scale factor, and harmonic animations all display a series of deformed shape, contour, symbol, or (for time history animations only) material orientation plots in rapid succession. At any time before or during animation playback you can customize the deformed shape, contour, symbol, or material orientation plot that underlies your animation. For example, you can toggle the legend, adjust the deformation scale factor, or choose a different field output variable. Use the **View**, **Result**, and **Options** menus to customize the underlying plot of your animation.

1. Locate the customization options applicable to the current plot state.
   - For contour plot animation, select **Options->Contour** from the main menu bar.
   - For symbol plot animation, select **Options->Symbol** from the main menu bar.
   - For material orientation plot animation, select **Options->Material Orientation** from the main menu bar.
2. From the dialog box that appears, select the plot state–dependent customization options that you want. For more information, see *Customizing your plots*.
3. Set the plot state–independent customization options that you want by selecting the **Options->Common**, **Options->Superimpose**, **Viewport->Viewport Annotation Options**, **View->Graphics Options**, or **View->ODB Display Options**.
4. Choose the *results variables* to be animated by selecting **Result->Field Output**.
5. Select the results steps and frames to be animated:
   - For scale factor or harmonic animation, choose the single step and frame to be animated by selecting **Result->Step/Frame**.
   - For time history animation, choose the steps and frames to be animated by selecting **Result->Active Steps/Frames**.

Saving an animation file

You can save animations playing in one or more viewports to a file. Once saved, your animation can be played using industry-standard animation software. This section explains how to save animations to a file and how to control the format of that file.

In this section:

- *Saving animations*
- *Choosing the animation file format*

Saving animations

You save animations to a file by first playing animations in one or more viewports and then selecting **Animate->Save As** from the main menu bar.

You can choose to save all or just selected viewports. Viewports that you save can be in any plot state (for example, deformed, *X–Y*, or animation). For viewports currently in the animation plot state Abaqus/CAE saves all frames of the animation, starting with the first frame; it does not matter whether the animation is playing at the time you perform the save. If you save multiple viewports containing animations, Abaqus/CAE saves them all as a single image-based animation. Abaqus/CAE synchronizes multiple animations of the file by repeating the last frame of any animations that have fewer frames than the others.

1. Produce one or more time history, scale factor, or harmonic animations.

   For more information, see *Object-based animation*.

2. From the main menu bar, select **Animate->Save As**.

   The **Save Image Animation** dialog box appears.

3. For MP4, AVI, QuickTime, or GIF format, use the **Selection** field to choose the viewports to save:

   a. Click the arrow next to the **Capture** field to save **All Viewports** (the default) or the **Current Viewport**.

   b. Toggle **Capture viewport decorations** to control whether Abaqus/CAE saves visible viewport decorations.

   For VRML or Compressed VRML format, the saved animation will display the current viewport only and omit viewport decorations.

4. Use the **Settings** field to specify the name and format of your animation file:

   a. Click  to filter and browse file names, or enter the file name of your choice in the **File name** field. For more information, see *Using file selection dialog boxes*.

   b. From the **Format** options, select **MP4** (the default), **AVI**, **QuickTime**, **GIF**, **VRML**, or **Compressed VRML** format for your file. To learn more about these format options, see *Choosing the animation file format*.

5. For MP4, AVI, QuickTime, or GIF format, use the **Frame Rate** field to specify the number of frames that display per second in the saved animation.

   You can specify any positive integer as the frame rate by entering a value in the **Rate** field or drag the slider to select a frame rate between 1 and 50 frames/second. By default, the frame rate matches the frame rate currently selected on the **Player** page.

6. Click **Apply** to save your animation.

   Abaqus/CAE captures canvas viewports to a file according to your specifications.

Additional information

• *Saving an animation file*

Choosing the animation file format

You can choose to save animations to a file in MP4 (the default), AVI, QuickTime (MOV), animated GIF, or Virtual Reality Modeling Language (VRML) format.
You can choose between compressed and uncompressed files in VRML, AVI, and QuickTime formats. Additional image size and compression options are available for MP4, AVI, and QuickTime formats.

When you save animations in MP4 format, you can compress the file using the H.264 codec if an installation of the FFmpeg program that supports H.264 encoding can be found on your system. Otherwise, the file is encoded using the MPEG-4 (Part 2) codec. For H.264 encoding, the FFmpeg program location should be included in the PATH environment where Abaqus/CAE is launched. For more information about FFmpeg, visit *https://ffmpeg.org*.

When you save animations in AVI format on Windows systems, you can compress the file using any codec on your system and you can set the quality level of the file. These options are not available on Linux systems.

Improving playback of VRML animations

Animations in VRML or Compressed VRML format might require further customizations to play back properly on client computers. Several components on the client's computer determine the quality of VRML playback, including the graphics hardware, VRML plug-in software, and the settings selected for the plug-in software. When these components differ from the components on the computer that created the VRML animation, VRML playback on the client's computer can exhibit display problems such as blurry text in the viewport annotations. You can improve client playback of a particular VRML file either by configuring plug-in settings on the client's computer or by creating a new version of the VRML animation with different viewport annotation settings.

- To customize VRML display on the client's computer, open the settings for the VRML plug-in on the client's computer, and toggle on any antialiasing settings. Enabling antialiasing can help clarify text in a VRML image or animation but can degrade performance.
- To create a new VRML animation, return to Abaqus/CAE and increase the text size or choose a different font for each of the viewport annotations in the viewport and save a new copy of the VRML animation. For more information about changing the font and type size, see *Customizing viewport annotations*.

Additional information

• *Saving animations*

Choose VRML or Compressed VRML format

1. Locate the animation file format options.
   From the main menu bar, select **Animate->Save As**; the **Save Image Animation** dialog box appears.
2. From the **Format** options, select **VRML**, or **Compressed VRML** format.
   For both VRML formats, Abaqus/CAE deactivates the **Selection** and **Frame Rate** fields; you cannot customize these settings for **VRML** or **Compressed VRML** animations.

Choose MP4 format

1. Locate the animation file format options.
   From the main menu bar, select **Animate->Save As**; the **Save Image Animation** dialog box appears.
2. From the **Format** options, select **MP4**.
3. To select additional MP4 format options, click

.

The **MP4 Options** dialog box appears.

4. In **MP4 Options** dialog box, choose one of the following methods to specify the size (in pixels) of the animation image:

   - Click **Use size on screen** to use the size of the image on the screen. (Abaqus/CAE indicates the current image size in the **MP4 Options** dialog box.) This method is the default.
   - Click **Use settings below** to set the width or height; then enter the value of your choice in the **Width** or **Height** field. You specify only one dimension; Abaqus/CAE computes the other dimension to maintain the aspect ratio of the viewports.

5. Specify in the **MP4 Options** dialog box your preferred encoding.
   a. From the **Codec** list, select either **H.264 / AVC** or **MPEG-4 Part 2**. **H.264 / AVC** is widely supported by video editing and playback software, and offers generally a superior compression versus quality tradeoff, but it is available only if an FFmpeg installation with H.264 encoding enabled can be found on your system, as described above.
   b. Drag the **Quality** slider to specify the compression quality of the file. The highest value, 100, produces the highest quality animation file with the smallest degree of compression.
6. Click **OK** to close the **MP4 Options** dialog box.

   Your options settings are saved for the duration of the session.

Choose AVI format

1. Locate the animation file format options.

   From the main menu bar, select **Animate->Save As**; the **Save Image Animation** dialog box appears.
2. From the **Format** options, select **AVI**.
3. To select additional AVI format options, click

.

The **AVI Options** dialog box appears.

4. In the **AVI Options** dialog box, choose one of the following methods to specify the size (in pixels) of the animation image:

   - Click **Use size on screen** to use the size of the image on the screen. (Abaqus/CAE indicates the current image size in the options dialog box.) This method is the default.
   - Click **Use settings below** to set the width or height; then enter the value of your choice in the **Width** or **Height** field. You specify only one dimension; Abaqus/CAE computes the other dimension to maintain the aspect ratio of the viewports.

5. For Linux systems, specify in the **AVI Options** dialog box whether your file should be compressed (run length encoded) or uncompressed (raw).

   From the **Compression** list in the **AVI Options** dialog box, select **Rle (8 bits/pixel)**, **Raw (8 bits/pixel)**, or **Raw (32 bits/pixel)**. Choosing **Rle (8 bits/pixel)** compression or **Raw (8 bits/pixel)** can result in a loss of colors.

6. For Windows systems, specify in the **AVI Options** dialog box whether your file should be compressed or uncompressed (raw). If you elect to compress the file, you can select one of the Abaqus/CAE predefined compressors or one of the video codecs available on your system. You can specify the compression quality of the saved animation file.
   a. From the **Codec** list, select one of the following:
      - Select **None - 8 bits/pixel** to create a raw animation using a reduced set of colors. Choosing this option can result in a loss of colors.
      - Select **None - 24 bits/pixel** to create a raw animation file without any compression.
      - Select one of the video codecs. The **Codec** list displays every codec that is available on your system.

      Some video codecs include configurable options that enable you to change certain aspects of the video file. When you select a codec that allows this configuration, the **Configure** button becomes active. You can also learn more about a particular codec by clicking the **About** button when the codec is selected.
   b. To configure a codec, click **Configure** and then choose configuration options from the dialog box that appears. Each configurable video codec provides different configuration options; for example, some codecs allow you to control the transparency of the animation or to create a scalable file.

      Note: You might encounter problems while saving an animation in AVI format with MPEG-4 codec compression using a Python script. To avoid these problems, you can use the GUI described in this procedure or you can configure the Xvid codec to switch off the encoding status window (**Xvid configuration->Other options->Encoder**: toggle off **Display encoding status**).

   c. Drag the **Quality** slider to specify the compression quality of the file. The highest value, 100, produces the highest quality animation file with the smallest degree of compression.
7. Click **OK** to close the **AVI Options** dialog box.
   Your options settings are saved for the duration of the session.

Choose QuickTime format

1. Locate the animation file format options.
   From the main menu bar, select **Animate->Save As**; the **Save Image Animation** dialog box appears.
2. From the **Format** options, select **QuickTime**.
3. To select additional QuickTime format options, click

   .
   The **QuickTime Options** dialog box appears.
4. In **QuickTime Options** dialog box, choose one of the following methods to specify the size (in pixels) of the animation image:
   - Click **Use size on screen** to use the size of the image on the screen. (Abaqus/CAE indicates the current image size in the **QuickTime Options** dialog box.) This method is the default.

- Click **Use settings below** to set the width or height; then enter the value of your choice in the **Width** or **Height** field. You specify only one dimension; Abaqus/CAE computes the other dimension to maintain the aspect ratio of the viewports.

5. Specify in the **QuickTime Options** dialog box whether your file should be compressed (run length encoded) or uncompressed (raw).

   From the **Compression** list, select either **Raw (24 bits/pixel)** or **Rle (24 bits/pixel)**. **Rle (24 bits/pixel)** compression is a form of run length encoding, which provides lossless compression with no image degradation.

6. Click **OK** to close the **QuickTime Options** dialog box.

   Your options settings are saved for the duration of the session.

Choose GIF format

1. Locate the animation file format options.

   From the main menu bar, select **Animate->Save As**; the **Save Image Animation** dialog box appears.

2. From the **Format** options, select **GIF**.
3. To select additional GIF format options, click

   .

   The **GIF Options** dialog box appears.

4. In **GIF Options** dialog box, choose one of the following methods to specify the size (in pixels) of the animation image:

   - Click **Use size on screen** to use the size of the image on the screen. (Abaqus/CAE indicates the current image size in the **GIF Options** dialog box.) This method is the default.
   - Click **Use settings below** to set the width or height; then enter the value of your choice in the **Width** or **Height** field. You specify only one dimension; Abaqus/CAE computes the other dimension to maintain the aspect ratio of the viewports.

5. Click **OK** to close the **GIF Options** dialog box.

   Your options settings are saved for the duration of the session.

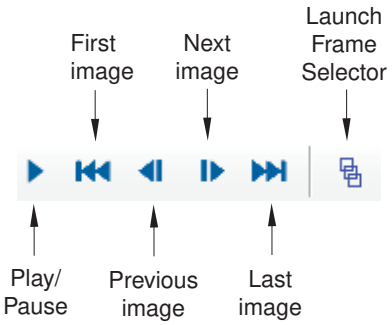
Controlling animation playback

During an object-based animation you can control the speed and repetition of playback, and you can stop, restart, and step through your animation.

Most industry-standard animation software supports the same functions for image-based animation, but the available options are based on the application that you choose. For object-based animations one additional option is available: you can display or suppress status information while the animation is playing.

If you are using multiple viewports to display animations, you can include or exclude individual viewports from the common animation time line. By default, each new viewport you create will be included in the synchronization.

This section explains how to control animation playback.



In this section:

- *Stopping, restarting, and stepping through an animation*
- *Navigating to a specific frame in the animation*
- *Controlling animation speed and repetition*
- *Showing the animation frame counter*
- *Customizing animation of X–Y plots*
- *Controlling animations in multiple viewports*
- *Customizing the time history of synchronized viewports*

Stopping, restarting, and stepping through an animation

You can use the movie player controls to play and pause your animation, to step forward or backward through the animation images, and to step to the first or last image in the animation sequence.

During animation, the movie player controls appear on the right side of the context bar.

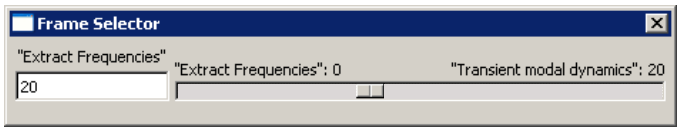
If you display animations in multiple viewports, the movie player controls stop, restart, and step through frames in all synchronized viewports.

You can also use the right-most button in the movie player controls to launch the **Frame Selector** dialog box, which allows you to navigate directly to a particular frame in the animation. This tool is discussed in *Navigating to a specific frame in the animation*.

1. Locate the movie player controls on the right side of the context bar.
2. Click the movie player controls to execute the functions you want. The controls are listed below in the order in which they appear in the context bar, starting with the left-most arrow.

Play/Pause	Plays or pauses. When your animation is playing, this button displays the Pause symbol; when paused, this button displays the Play symbol.
First image	Stops play and displays the first image in the animation sequence.
Previous image	Stops play and steps to the previous image in the animation sequence.
Next image	Stops play and steps to the next image in the animation sequence.
Last image	Stops play and displays the last image in the animation sequence.
Launch Frame Selector	Opens the **Frame Selector** dialog box, from which you can navigate to a specific frame of the animation.

Additional information



- *Controlling animation playback*
- *Navigating to a specific frame in the animation*
- *Controlling animations in multiple viewports*

Navigating to a specific frame in the animation

The **Frame Selector** dialog box allows you to navigate quickly to a particular frame in the output database in the current viewport. This tool provides two methods for controlling the current frame: you can enter a frame index or time value directly into a field on the left side of the dialog box, or you can drag the slider on the right side of the dialog box to the desired frame or time.

The labels in the dialog box are context-sensitive and depend on whether an animation is being displayed, the type of animation, and for time history animations, whether the time history is frame-based or time-based.

- When no animation is displayed in the current viewport, the **Frame Selector** labels display step names. The name of the current step appears above the field on the left side of the dialog box. The names of the first and last active steps in the output database appear above the slider. In the example below, the current frame is frame 20 of the **Extract frequencies** step, the first step is **Extract frequencies**, and the last step is **Transient modal dynamics**.

- For scale factor or harmonic animations the **Frame Selector** labels displays the frame index of the current frame, and the slider shows the frame index of the first and last active frames. The dialog box displays **Frame** above the field and the numbers of the first and last active frames above the slider.
- For time history animations the **Frame Selector** labels display frame information when you select a frame-based time history and display time information when you select a time-based time history. In the latter case the dialog box displays **Time** above the field and the time values of the first and last active frames above the slider. For more information about selecting a time history option, see *Customizing the time history of synchronized viewports*.

1. Open the **Frame Selector** dialog box.

   From the movie player controls on the right side of the context bar, click the button.

   The **Frame Selector** dialog box appears.

2. Choose one of the following methods to specify the frame you want to display:

   - Enter a number directly into the **Frame Selector** field.

     You can enter the overall frame number in the entire output database for scale factor animations, harmonic animations, or frame-based time history animations; you can enter the time for time-based time history animations; or you can enter the frame number within the current step when no animation is displayed.

   - Drag the slider to the frame index or time value that you want to display. The current viewport changes as you drag the slider.

Additional information

- *Controlling animation playback*
- *Stopping, restarting, and stepping through an animation*

Controlling animation speed and repetition

You can control the speed of your object-based animation playback, and you can choose to play your animation once or to repeat it.

If you choose to repeat the animation, you can select one of three repetition modes: loop, loop backward, or swing. **Loop** repeats by jumping from the last animation frame to the beginning of your movie. **Loop backward** plays the animation backward and repeats by jumping from the first animation frame to the end of your movie. **Swing** repeats smoothly by playing your movie from beginning to end and then playing from the end back to the beginning.

The speed control settings you specify before you create image-based animations determine the default frame rate that is used when the animation files (for example, MP4 or QuickTime) are replayed from within industry-standard animation software.

1. In the prompt area, click **Animation Options**; and click the **Player** tab in the dialog box that appears.
2. To control the playback speed of your animation, drag the **Frame rate** slider to the rate that you want.
3. To control the repetition of the images in your animation sequence:
   - Click **Play once** to suppress repetition.
   - Click **Loop** to play the images in order from the first to the last, repeatedly.
   - Click **Loop backward** to play the images in order from the last to the first, repeatedly.
   - Click **Swing** to play the images from the first to the last and then in reverse order from the last back to the first, repeatedly.
4. Click **Apply** to implement your changes.

   The animation in all animated viewports changes according to your specifications.

   Your changes are saved for the duration of the session and will affect all subsequent plots in this state.

Additional information

• *Stopping, restarting, and stepping through an animation*

Showing the animation frame counter

For object-based animations you can display or suppress animation frame count information, which is displayed in the upper-right corner of the viewport and consists of

- the scale factor of each image in your scale factor animation,
- the phase angle of each image in your harmonic animation, or
- the step and frame (plot number within the step) of each image contained in your time history animation.

You cannot customize the content or appearance of the counter, other than to turn it off entirely.

The step and increment associated with each animation step and frame are given by the state block. All of the images in a scale factor animation are based on a single step and frame. For more information on customizing the state block, see *Customizing the state block*.

1. Find the **Show frame counter** option.

   In the prompt area, click **Animation Options**; and click the **Player** tab in the dialog box that appears. The **Show frame counter** option is near the bottom of the page.

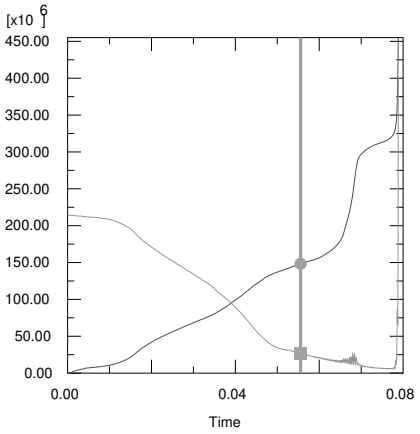
2. Toggle **Show frame counter** to display or suppress animation frame count information.
3. Click **Apply** to implement your changes.

   The animation in all animated viewports changes according to your specifications. When **Show frame counter** is on, Abaqus/CAE displays status information in the upper right corner of all animated viewports. This information is updated for every image in your animation sequence. You may need to *stop* playback to read it.

   Your changes are saved for the duration of the session and will affect all subsequent plots in this state.

Additional information

• *Stopping, restarting, and stepping through an animation*



Customizing animation of X–Y plots

You can customize the appearance of the time tracker line and symbols.

When you animate a time-dependent *X–Y* plot, Abaqus/CAE adds a vertical line to the plot that moves along the *X*-axis to highlight the current time. The plot also displays a colored symbol at the data point on each *X–Y* curve that occurred closest to the current time; time tracker symbols do not appear at the exact intersection of the time tracker line and an *X–Y* curve unless that curve contains a data point at the currently displayed time.

For *X–Y* plots whose axes are not time but are obtained from output database results (for example, by combining two time-dependent *X–Y* data objects), Abaqus/CAE also adds a vertical line. In such cases, the line is added if there is only one curve in the plot.

The figure below shows an *X–Y* plot with the time tracker line and symbols displayed.

By default, the time tracker line and symbols are displayed using the highlight method that you have selected for your session; see *Choosing a highlight method* for more information. However, you can customize their appearance by changing the color, thickness, and style of the time tracker line and the color, shape, and size of the time tracker symbols. Alternatively, you can completely suppress either time tracker component. The default highlight method offers the best performance.

Note:

These line and symbol options control the appearance of the time tracker only. You can also customize the lines and symbols used to display the *X–Y* curves themselves; see *Customizing the appearance of an X–Y curve*.

1. Locate the **XY** options.

   In the prompt area, click **Animation Options**; and click the **XY** tab in the dialog box that appears.
2. Toggle off **Draw using highlight method** if you want to customize the appearance of the *X–Y* plot time tracker.
3. Toggle **Show line** to display or suppress the time tracker line.

   When **Show line** is on, the time tracker line is displayed and the line attribute options are enabled.
4. Choose the time tracker line style:
   a. Click the **Style** button to reveal the line style options (solid, dashed, etc.).
   b. From the style list, click the desired line style.

The specified line style appears on the **Style** button.

5. Choose the time tracker line thickness:
   a. Click the **Thickness** button to reveal the line thickness options.
   b. From the thickness list, click the desired line thickness.

      The specified thickness appears on the **Thickness** button.

6. Choose the time tracker line color:
   a. Click the color sample .

      Abaqus/CAE displays the **Select Color** dialog box.
   b. Use one of the methods in the **Select Color** dialog box to select a new color. For more information, see *Customizing colors*.
   c. Click **OK** to close the **Select Color** dialog box.

      The color sample changes to the selected color.

7. Toggle **Show symbol** to display or suppress the symbols representing the current value of each selected *X–Y* curve's data points.

   When **Show symbol** is on, symbols are displayed and the symbol attributes are enabled.

8. Choose the symbol:
   a. Click the **Symbol** button to reveal the choice of symbols.
   b. From the list of symbols, click the desired symbol.

      The specified symbol appears on the **Symbol** button.

9. Choose the time tracker symbol color:
   a. Click the color sample .

      Abaqus/CAE displays the **Select Color** dialog box.
   b. Use one of the methods in the **Select Color** dialog box to select a new color. For more information, see *Customizing colors*.
   c. Click **OK** to close the **Select Color** dialog box.

      The color sample changes to the selected color.

10. Choose the time tracker symbol size:
    a. Click the **Size** button to reveal the symbol size options.
    b. From the symbol size options, click the desired symbol size.

       The specified symbol size appears on the **Size** button.

11. Click **Apply**.

    The current viewport displays your color, thickness, style, and symbol selections.

Additional information

- *Customizing the time history of synchronized viewports*

Controlling animations in multiple viewports

By default, Abaqus/CAE animates data in every animation-eligible viewport in your session. All animations are synchronized, so the viewports play, stop, and increment together when you examine data frame by frame, animate a model plot, or animate a time-dependent *X*–*Y* plot.

You can activate and deactivate the animation of individual viewports, which enables you to display animations only for a subset of the animation-eligible viewports in your session. From the **Linked Viewports Manager**, toggle on **Link viewports** and **Animation** and use the **Linked Viewports** portion of the **Linked Viewports Manager** to deselect the viewports that you want to remain independent.

1. Link viewports using one of the following methods:
   - From the main menu, select **Viewport->Link Viewports**.

     Tip: You can activate or deactivate linked viewports by clicking  in the *Viewport toolbar*.

   - From the main menu, select **Viewport->Linked Viewports Manager** and toggle on **Link viewports**.

     Tip: You can also display the **Linked Viewports Manager** by clicking  in the *Viewport toolbar*.

2. In the **Linked Viewports Manager**, ensure that **Animation** is toggled on and the required viewports are selected in the **Linked Viewports** table.
3. If you made changes in the **Linked Viewports Manager**, click **Apply**. Alternatively, click **OK** to apply your changes and to close the manager.
4. Start a time history, scale factor, and harmonic animation using any method.

Additional information

• *Customizing the time history of synchronized viewports*

Customizing the time history of synchronized viewports

The time history settings control whether Abaqus/CAE uses a frame-based history or a time-based history when you display time history animations. Frame-based synchronization allows all synchronized viewports to increment together one frame at a time, while time-based synchronization allows viewports to display data according to a common time line.

When you choose time-based animation, you can also customize three aspects of the common time line:

- The time step, which controls how much time elapses each time you increment your display of the data.
- The minimum time, which is the earliest point from which data will be included. If you auto-compute the minimum time, Abaqus/CAE includes data starting from the beginning of the common time line.
- The maximum time, which is the latest point from which data will be included. If you auto-compute the maximum time, Abaqus/CAE includes data up to the end of the common time line.

1. Find the **Time History** options.

   In the prompt area, click **Animation Options**; and click the **Time History** tab in the dialog box that appears.
2. From the options at the top of the page, choose either **Frame-based** or **Time-based**.
3. If desired, change the **Time increment** value. The time increment applies to time-based animation only.
4. If desired, customize the **Min time** and **Max time** by entering values in the appropriate **Specify** fields. These values apply to time-based animation only.
5. Click **Apply**.

- *Controlling animations in multiple viewports*

Querying the model in the Visualization module

This section explains how you can use the Query toolset to obtain general information about the mesh and specific Visualization module information.

In this section:

- *Understanding the Query toolset in the Visualization module*
- *Using the Query toolset*

Understanding the Query toolset in the Visualization module

The Query toolset allows you to obtain general information about your model.
The Visualization module displays the requested information in the message area, and the same information is written to the replay file.

Select **Tools->Query** from the main menu bar, or select the  tool from the Query toolset to use the Query toolset.

Items under **General Queries** provide the following information:

Node

You can obtain information on a selected node's label, deformed and undeformed coordinates, and displacement. You can select a local CSYS in which to display the coordinates.

Distance

You can obtain information on the deformed and undeformed distance between two selected nodes and the relative displacement between the nodes. You can select a local CSYS in which to display the coordinates of the picked points and the components of the result.

Angle

- You can obtain information on the deformed and undeformed angle formed between three selected nodes. The second node that you select is the angle's vertex.
- You can obtain the undeformed angle between two edges or faces or between an edge and a face.

Element

You can obtain information on a selected element's mesh type, material, section, connectivity, and current field output variables at the integration point locations. This query is available only when an output database is selected.

Mesh

You can obtain information on the name of the current output database, the number of nodes and elements in your model, and the element types.

Mass properties

You can obtain basic mass properties for the whole model in the output database or for a portion of the model. In the Visualization module, the mass properties are always calculated based on model data (undeformed shape). This query is available only when an output database is selected. Abaqus/CAE returns the following information:

- Volume
- Volume centroid
- Mass
- Center of mass
- Moments of inertia about the center of mass or about a specified point

Element face normal

You can obtain the surface normal components for an element face. You can select a local CSYS in which to display the normal.

Advanced distance

Whereas the regular distance query allows you to find the distance between two selected single entities, the advanced distance query allows you to find the minimum distance between groups of entities. These entities can be nodes, elements, vertices, edges, faces, or cells, and you can select them from the viewport or by set. You can select a local CSYS in which to display the coordinates of the closest points and the components of the result.

For more information on general model queries, see *Querying the model in the Visualization module*.

Items under **Visualization Module Queries** provide the following information:

Probe values

Abaqus/CAE displays information in the **Probe Values** dialog box as you move the cursor around the current viewport. Probing a model plot displays model data and analysis results; probing an *X–Y* plot displays *X–Y* curve data. For more information on probing, see *Probing the model*.

Stress linearization

Stress linearization is the separation of stresses through a section into constant membrane and linear bending stresses. Abaqus performs stress linearization calculations and displays the results in the form of an *X–Y* plot. Stress linearization is available for output databases only. For more information on stress linearization, see *Calculating linearized stresses*.

Active elements and nodes

Abaqus/CAE displays the label numbers of all the active nodes or active elements in the current viewport. For more information, see *Querying active node or element labels*.

Ply stack plot

Abaqus/CAE creates a new viewport and displays a representative image of a composite layup. The image shows the plies in the layup along with details of each ply, such as its fiber orientation, thickness, reference plane, and integration points. Ply stack plots are available for output databases only. For more information, see *Viewing a ply stack plot*.

- *Probing the model*
- *Calculating linearized stresses*
- *Viewing a ply stack plot*

Using the Query toolset

You can use the Query toolset to obtain general model information.

In this section:

- *Querying the model in the Visualization module*
- *Querying active node or element labels*

Querying the model in the Visualization module

1. Locate the **Query** dialog box.

   From the main menu bar, select **Tools**->**Query** or click the  tool in the Query toolset.
   The **Query** dialog box appears.

2. To obtain information on a particular node, do the following:
   a. Select **Node** from the **General Queries** field of the **Query** dialog box.
      Abaqus/CAE displays a prompt in the prompt area.
   b. Select a node from the viewport.

      The undeformed and deformed *X*-, *Y*-, and *Z*-coordinates of that node appear in the message area, along with the node's displacement. The same information that appears in the message area is also written to the replay file.
   c. Select a local CSYS from the viewport to display the node coordinates in the local coordinate system. If a local CSYS is not selected, the node coordinates will be displayed in the global Cartesian system.

       **Note:**

      To resize the message area, drag the top edge; to see information that has scrolled out of the message area, use the scroll bar on the right side.

3. To obtain information on the distance between two nodes, do the following:
   a. Select **Distance** from the **General Queries** field of the **Query** dialog box.
      Abaqus/CAE displays a prompt in the prompt area.
   b. Select two nodes from the viewport.

      The following information appears in the message area:

      - The undeformed and deformed *X*-, *Y*-, and *Z*-coordinates of each node, along with the node's displacement.
      - The absolute undeformed and deformed distances between the nodes.
      - The *X*-, *Y*-, and *Z*-components of the undeformed and deformed vector between the two nodes.
      - The absolute relative displacement between the nodes.
      - The *X*-, *Y*-, and *Z*-components of the relative displacement between the two nodes.

   c. Select a local CSYS from the viewport to display the coordinates of the picked nodes and the components of the result in the local coordinate system. The last chosen CSYS will be used for the calculations. If any local CSYS is not selected, the results will be displayed in the global Cartesian system.

4. To obtain angle information, select **Angle** from the **General Queries** field of the **Query** dialog box, and select **3 Nodes** or **Face/Edge** from the prompt area.

   - If you selected **3 Nodes**, select three nodes from the viewport. The second node that you select is the vertex of the angle.

     The following information appears in the message area:

- The undeformed and deformed *X*-, *Y*-, and *Z*-coordinates of each node, along with the node's displacement.
- The absolute undeformed and deformed angle between the nodes.

- If you selected **Face/Edge**, select two faces or two edges or select a face and an edge. The undeformed angle between the selected faces/edges is displayed in the message area.

5. To obtain information on a particular element in an output database, do the following:

a. Select **Element** from the **General Queries** field of the **Query** dialog box.

Abaqus/CAE displays a prompt in the prompt area.

b. Select an element from the viewport.

The following information appears in the message area:

- The element's label, element type, material, and section.
- The labels of connecting elements.
- The current field output variables at the integration point locations.

6. To obtain general information on the mesh, select **Mesh** from the **General Queries** field of the **Query** dialog box.

The following information appears in the message area:

- The name of the current output database.
- The number of nodes.
- The number of elements.
- The element types.

7. To obtain general information on the mass properties in an output database, do the following:

a. Select **Mass properties** from the **General Queries** field of the **Query** dialog box.

Abaqus/CAE displays a prompt in the prompt area for the last selection method used or **All elements** if this is the first time using the **Mass properties** query in the current session.

b. Choose one of the following selection methods from the list in the prompt area:

- **All elements**
- **Select elements from viewport**
- **Part instances**
- **Element sets**
- **Sections**
- **Materials**
- **Element types**
- **Display groups**

Abaqus/CAE displays additional selection fields in the prompt area, depending on the selection method that you chose.

c. Complete your selection as follows:

- If your selection from the previous step is **All elements**, click **Done** to perform the query.

- If you chose **Select elements from viewport** in the previous step, make selections from the viewport (for more information, see *Selecting objects within the viewport*"). You can select a part instance in the prompt area and enter a single element number to get mass information for that element.
- For the remaining selection methods, select the part instance, element set, section, material, element type, or display group name from the list in the prompt area, or make selections from the viewport.

When you select an object from the prompt area or when you click **Done** to complete a viewport selection, Abaqus/CAE displays the mass properties for your selection in the message area.

d. If any items in your selection have poorly defined density or thickness, click **Options** in the prompt area to display the **Mass Properties Query Options** dialog box and specify a value to be substituted by Abaqus/CAE for the undefined quantity.

Click **OK** in the dialog box to save your entries and close the dialog, or click **Reset** to return to the previous settings.

Abaqus/CAE displays the mass properties in the message area for the items you selected. The following properties are available:

- Surface area (for shell elements only)
- Area centroid
- Volume
- Volume centroid
- Mass
- Center of mass
- Moments of inertia about the center of mass or about a specified point

8. To obtain the surface normal components, do the following:

a. Select **Element face normal** from the **General Queries** field of the **Query** dialog box.

Abaqus/CAE displays a prompt in the prompt area.

b. Select an element face in the viewport, and click **Done**.

The surface normal components in the global Cartesian coordinate system of the element face appear in the message area.

c. Select a local CSYS from the viewport to display the surface normal components in the local coordinate system. If any local CSYS is not selected, the surface normal components will be displayed in the global Cartesian system.

The surface normal components will differ if you query the same element face on the undeformed shape and the deformed shape.

9. Close the **Query** dialog box when you have finished requesting information.

Additional information

- *Understanding the Query toolset in the Visualization module*
- *Querying mass properties*

Querying active node or element labels

You can use the Query toolset to request the label numbers of all currently active nodes or active elements in the current viewport. The active nodes and elements are those that are in the current display group, less any entities removed from the display by the active view cut. Abaqus/CAE displays label numbers in the prompt area for each applicable part instance and prints label numbers to the replay file.

When you request the active nodes or elements, Abaqus/CAE displays the label numbers only; it does not provide any other nodal or element data and results. To display more information about a single node or element, see *Probing nodes*, or *Probing elements*, respectively.

1. Locate the **Visualization Module Queries** options.

   From the main menu bar, select **Tools->Query** or click the  tool in the Query toolset. The **Query** dialog box appears, and the **Visualization Module Queries** are displayed in the lower portion of the dialog box.

2. Click either **Active nodes** or **Active elements**.

   In the prompt area, Abaqus/CAE displays a list of labels for all active nodes or active elements for each part instance in the model.

Additional information

- *Probing nodes*
- *Probing elements*

Probing the model

This chapter explains how you can use the Query toolset in the Visualization module to probe model and *X*–*Y* plots for output data and to probe an Abaqus/CAE model for attribute values.

For information on writing selected probe values to a file, see *Generating tabular data reports*.

In this section:

- *Understanding probing*
- *Using the Query toolset to probe the model*

Understanding probing

This section explains probing model plots and *X*–*Y* plots.

When you click the  tool in the Visualization module toolbox, Abaqus/CAE enters probe mode and displays information in the **Probe Values** dialog box as you move the cursor over the model in the current viewport. You can also enter probe mode using the  tool in the Query toolbar. Probing a model plot displays model data and analysis results; probing an *X*–*Y* plot displays *X*–*Y* curve data; and probing a model from the current model database displays the model data and the values of attributes such as loads and predefined fields. You can write this information to a file.

The data table in the bottom portion of the **Probe Values** dialog box contains two dynamic display rows (the row immediately above the row headings and the bold data row that appears first in the table) and a series of additional storage rows. Abaqus/CAE updates the dynamic rows continuously to show the probe values as you move the cursor over the model in the current viewport, and you can change the value displayed in the top display row by clicking a column heading. Abaqus/CAE updates the table with additional rows only when you select values of interest by clicking in the viewport, specifying a node or element label, or selecting the nodes or elements in a particular display group. Values accumulate in the bottom portion of the dialog box until you delete them, clear the table, or cancel probe mode. You can also add selected values to a new display group, and you can annotate individual nodes or elements with field output values at that location.

Probes of models or model plots

If the current viewport contains a model plot (an undeformed, deformed, contour, symbol, or material orientation plot) or a model from the current model database,, Abaqus/CAE allows you to probe results from the selected model or output database. The **Probe Values** dialog box identifies the step, frame, user selected csys from Results Options dialog and field output variable for which Abaqus/CAE will obtain values. To learn how to change the step, frame, csys or field output variable, see *Selecting the results step and frame*, *Transforming results into a new coordinate system*, and *Selecting the primary field output variable*.

When you probe a model plot of a three-dimensional shell or a composite solid, the results that Abaqus/CAE returns depend on your choice of active location in the **Section Points** dialog box. Abaqus/CAE returns results from the **Top Location** section point when **Top** is the active location and returns results from the **Bottom Location** section point when the active location is set to **Bottom** or **Top and bottom**. For more information about section points, see *Selecting section point data*.

For model plots you can choose to obtain node-based or element-based data and results, as follows:

Probing nodes

When you choose to probe nodes and position the cursor over a nodal location in the current viewport, Abaqus/CAE highlights the node and displays the following information about the node in the data table:

- the node's label,
- the node's original coordinates,
- the node's deformed coordinates (using the current deformed field output variable),
- the elements sharing the node, and
- the current field output variable (including component values, if the current field output variable is a tensor or vector quantity). If a model is selected in the current viewport, the current field output variable reflects the value of a model attribute such as a load at the selected node.

You can display field output at the node whether the current primary variable was originally saved to the output database at nodal, centroidal, or integration point locations. Abaqus/CAE calculates nodal values for centroidal

and integration point data by extrapolating to the nodes and averaging according to options you select. If the node refers to unaveraged element data, all element data associated with the probed node will be displayed. For more information on averaging, see *Understanding result value averaging*.

You can also display or hide annotations that appear in the viewport for each node you select. Probe annotations show the node's label and the results at that node for the current field output variable. You can customize the font and color of the probe annotation text.

Probing elements

When you choose to probe elements and position the cursor over an element in the current viewport, Abaqus/CAE highlights the element and displays the following information about the element in the data table:

- the element's label,
- the element's connectivity, and
- the current field output variable (including component values, if the current field output variable is a tensor or vector quantity). If a model is selected in the current viewport, the current field output variable reflects the value of a model attribute such as a load at the selected element.

You can display field output at the element only if the current primary variable is an element-based variable, such as stress or strain. You can choose the output position at which field output results are calculated: integration point, centroid, element node, or element face. For each of these output positions, Abaqus/CAE calculates probe results on an element-by-element basis with no averaging.

You can also display or hide annotations that appear in the viewport for each element you select. Probe annotations show the element's label and the results at that element for the current field output variable. You can customize the font and color of the probe annotation text.

Regardless of the render style in which the model is displayed, only visible elements can be probed. If necessary, you can create a display group or use a view cut to reveal otherwise unavailable interior elements.

When an element is cut through by a crack, the cracked element splits into two parts, each part formed by a real domain and a phantom domain. When you probe cracked elements, only the contribution from one part of the elements is reported. For more information, see *Visualization*.

X–Y plot probes

If the current viewport contains an *X*–*Y* plot, Abaqus/CAE displays as probe values the *X*–*Y* curve legend text, the sequence identification of each point within the curve, and the *X*- and *Y*-coordinates of curve points. You can choose to display only the curve points that comprise an *X*–*Y* data object or to interpolate to display arbitrary points along the curve. If the *X*–*Y* data name differs from the *X*–*Y* curve legend text, the **Legend** value in the **Probe Values** dialog box displays the *X*–*Y* data name prepended to the legend text. For more information, see *Probing X–Y plots*.

Using the Query toolset to probe the model

You can use the Query toolset to probe model and *X–Y* plots, and to write the resulting probe values to a file.

For information on writing selected probe values to a file, see *Generating tabular data reports*.

In this section:

- *Using probe options*
- *Probing nodes*
- *Probing elements*
- *Probing X–Y plots*

Using probe options

You can use the probe options in the Query toolset to specify the values you want to obtain while probing a model or an *X–Y* plot.

Click  in the Visualization module toolbox to access the **Probe Values** dialog box. Use the options in this dialog box to control probing in the current viewport.

For model data from the current model database

Use the **Field Output** dialog box to choose the step and field output variable. For model data, the field output variable you select is actually the value of an attribute in the model, such as a load or predefined field.

For model plots

Use the **Field Output** dialog box to choose the step, frame, and field output variable. Use the **Result Options** dialog box to choose the computation methods governing the probe data and results Abaqus/CAE displays.

For model and X–Y plots

Use the **Probe Values** options to select the type of information you want to obtain while probing.

Additional information

- *Probing nodes*
- *Probing elements*
- *Probing X–Y plots*

Probing nodes

You can use the Query toolset to obtain nodal data and either the values of attributes in the selected model or analysis results from the selected model plot. As you position the cursor over a node in the model or in the model plot in the current viewport, Abaqus/CAE highlights the node. You can choose to display the following information about the node in the data table:

- the node's label,
- the node's original coordinates,
- the node's deformed coordinates (using the current deformed field output variable),
- the elements sharing the node, and
- the current field output variable (including component values, if the current field output variable is a tensor or vector quantity). If a model is selected in the current viewport, the current field output variable reflects the value of a model attribute such as a load at the selected node.

Note:

You can display or hide any of the columns in the table by clicking mouse button 3 in the table, selecting **Edit Visible Columns**, and toggling any of the columns in the dialog box that appears.

You can also obtain a node's data by entering its node label directly, and you can obtain data for all the nodes included in a selected display group. These methods enable you to probe nodal data without positioning the cursor over its location in the model plot.

When you add a node to the data table, you can toggle on the check box for that row to display a probe annotation in the viewport for that node, or you can toggle on the check box in the header row to display probe annotations for all selected nodes. Probe annotations display the node's label and the results at the node for the current field output variable. You can customize the font and color of the annotation text.

To help locate nodes in the viewport, you may want to produce a model plot with node symbols visible before using the Query toolset. For more information, see *Customizing node symbols*.

1. Locate the **Probe Values** dialog box.

   In the Visualization module toolbox, click . The **Probe Values** dialog box appears.

2. Select the step, frame, field output variable, and result options governing the probe data and results Abaqus/CAE will display. If you are probing data from the current model database, frame selections are not available, and your selection of field output variable is an attribute from the model displayed in the current viewport.

   In the **Probe Values** dialog box, the **Field Output** field identifies the current step, frame, and field output variable.

   - To change the step or frame, click .
   - To change the field output variable, click .
   - To change the result options, select **Result->Options** from the main menu.

3. In the **Probe Values** portion of the dialog box, do the following:

   a. Click the **Probe** arrow, and select **Nodes**.

b. If the current primary output variable is a tensor or vector variable, click the **Components** arrow and do either of the following:

- For tensor variables choose **Selected** to display only the selected component of the variable, **All Direct** to include all direct components of the tensor variable in the query, or **All Principals** to include all principal invariants of the tensor variable in the query.
- For vector variables choose **Selected** to display only the selected component of the variable or **All** to include all components of the vector tensor variable in the query.

Note:

If you choose the **All Direct** or **All Principals** option for tensor variables, the results averaging option **Compute scalars before averaging** is not valid; the scalars or invariants are always computed after averaging.

The types of node information available are displayed in the columns of the data table.

4. Click mouse button 3 anywhere in the data table, select **Edit Visible Columns** from the list that appears, and toggle on the node information types that you want to display as columns in the data table.

When a desired information type is toggled on, Abaqus/CAE displays that type of data as a column in the data table. However, all columns, visible or not, are included in the probe values output file.

Note:

Field output is available only if the current primary variable is an element-based variable, such as stress or strain.

5. To specify the nodes that you want to probe, choose **Select from viewport**, **Key-in label**, or **Select a display group**, and use one of the following techniques:
Select the nodes directly from the viewport:

a. Move the cursor to probe the model plot in the current viewport.

As you position the cursor over a node, Abaqus/CAE displays the values of the items you have requested in the first row of the data table.

b. To select and accumulate values of interest, and to allow subsequent writing of these values to a file, click mouse button 1 while positioning the cursor over a node.

Abaqus/CAE stores the data from the first row of the data table into the storage rows of the data table.

Enter the node labels directly into the table:

a. Click the **Part instance** arrow, and select the part instance from which you want to select node labels.

b. Enter the node label or labels that you want to include. You can specify multiple node labels at the same time by separating them with commas.

Select the nodes included in a display group:

a. Click the **Display group** arrow, and select the display group containing the nodes that you want to include in your query.

If you change your selection of display group, Abaqus/CAE replaces the contents of the data table with nodes from the newly selected display group.

b. If desired, append additional nodes to your list by selecting them from the viewport or keying them in by node label.

6. Repeat the node selection steps until the data table in the **Probe Values** dialog box includes all the nodes you want to query.
7. To delete data from the data table or to clear or sort the table, click mouse button 3. For more information, see *Entering tabular data*.
8. To create a display group using the nodes in the data table, do the following:
   a. Click mouse button 3 in the data table, and select **Create Display Group** from the menu that appears.

      The **Create Display Group** dialog box appears.

   b. Enter a name for the new display group, and click **OK**.
9. To display probe annotations for any of the nodes in the data table, toggle on the check box for the rows corresponding to the nodes you want to annotate or toggle on the check box in the header row to display probe annotations for all selected nodes.

   Note:

   You can customize the color and font for probe annotations of nodes in the **Common Plot Options** dialog box. For more information, see *Using common plot options*.

10. To save the data you have selected, click **Write to File**. For more information, see *Generating tabular data reports*."
11. To exit probe mode, do one of the following:

    - Click the cancel button in the prompt area.
    - Click **Cancel** in the **Probe Values** dialog box.
    - Click mouse button 2.
    - Produce a plot in some other (e.g. undeformed, deformed) mode.

Additional information

- *Controlling result averaging*
- *Probes of models or model plots*
- *Probing elements*
- *Querying active node or element labels*

Probing elements

You can use the Query toolset to obtain element data and either the values of attributes in the selected model or analysis results from the selected model plot. As you position the cursor over an element in the model or in the model plot in the current viewport, Abaqus/CAE highlights the element. You can choose to display the following information about the element in the data table:

- the element's label,
- the element's connectivity, and
- the current field output variable (including component values, if the current field output variable is a tensor or vector quantity). If a model is selected in the current viewport, the current field output variable reflects the value of a model attribute such as a load at the selected element.

You can also obtain an element's data by entering its element label directly, and you can obtain data for all the elements included in a selected display group. These methods enable you to probe element data without positioning the cursor over its location in the model plot.

Only exterior elements can be queried. If necessary, you can create a display group or use a view cut to reveal otherwise unavailable interior elements. For more information, see *Using display groups to display subsets of your model*."

When you add an element to the data table, you can toggle on the check box for that row to display a probe annotation in the viewport for that element, or you can toggle on the check box in the header row to display probe annotations for all selected elements. Probe annotations display the element's label and the results at the element for the current field output variable. You can customize the font and color of the annotation text.

To help locate elements in the viewport, you may want to produce a model plot with all element edges visible before using the Query toolset. For more information, see *Controlling element and surface edge visibility*.

1. Locate the **Probe Values** dialog box.

   In the Visualization module toolbox, click . The **Probe Values** dialog box appears.

2. Select the step, frame, and field output variable for which Abaqus/CAE will obtain values. If you are probing data from the current model database, frame selections are not available, and your selection of field output variable is an attribute from the model displayed in the current viewport.

   In the **Probe Values** dialog box, the **Field Output** field identifies the current step, frame, and field output variable.

   - To change the step or frame, click .
   - To change the field output variable, click .
   - To change the result options, select **Result->Options** from the main menu bar.

3. In the **Probe Values** portion of the dialog box, do the following:
   a. Click the **Probe** arrow, and select **Elements**.
   b. If the current primary output variable is a tensor or vector variable, click the **Components** arrow and do either of the following:
      - For tensor variables choose **Selected** to display only the selected component of the variable, **All Direct** to include all direct components of the tensor variable in the query, or **All Principals** to include all principal invariants of the tensor variable in the query.
      - For vector variables choose **Selected** to display only the selected component of the variable or **All** to include all components of the vector tensor variable in the query.

c. To choose the output position at which a field output variable is displayed, click the **Position** arrow and select **Integration Pt**, **Centroid**, **Element Nodal**, or **Element Face**.

Note:

If you choose the **All Direct** or **All Principals** option for tensor variables and the **Element Nodal** output position, the results averaging option **Compute scalars before averaging** is not valid; the scalars or invariants are always computed after averaging.

The types of element information available are displayed in the columns of the data table.

4. Click mouse button 3 anywhere in the data table, select **Edit Visible Columns** from the list that appears, and toggle on the element information types that you want to display as columns in the data table.

When a desired information type is toggled on, Abaqus/CAE displays that type of data as a column in the data table. However, all columns, visible or not, are included in the probe values output file.

Note:

Field output is available only if the current primary variable is an element-based variable, such as stress or strain.

5. To select the elements that you want to probe, choose **Select from viewport**, **Key-in label**, or **Select a display group**, and use one of the following techniques:
Select the elements directly from the viewport:

a. Move the cursor to probe the model plot in the current viewport.

As you position the cursor over an element, Abaqus/CAE displays the values of the items you have requested in the first row of the data table in the **Probe Values** dialog box.

b. To select and accumulate values of interest, and to allow subsequent writing of these values to a file, click mouse button 1 while positioning the cursor over an element.

Abaqus/CAE stores the data from the first row of the data table into the storage rows of the data table.

Enter the element labels directly into the table:

a. Click the **Part instance** arrow, and select the part instance from which you want to select element labels.

b. Enter the element label or labels. You can specify multiple element labels at the same time by separating them with commas.

Select the elements included in a display group:

a. Click the **Display group** arrow, and select the display group containing the elements that you want to include in your query.

Note:

If you change your selection of display group, Abaqus/CAE replaces the contents of the data table with elements from the newly selected display group. If you want to append additional elements to your list, you must select them from the viewport or key them in by element label.

6. Repeat the element selection steps until the data table in the **Probe Values** dialog box includes all the elements you want to query.

7. To delete data from the data table or to clear or sort the table, click mouse button 3. For more information, see *Entering tabular data*.

8. To create a display group using the elements in the data table, do the following:
   a. Click mouse button 3 in the data table, and select **Create Display Group** from the menu that appears.

      The **Create Display Group** dialog box appears.
   b. Enter a name for the new display group, and click **OK**.
9. To display probe annotations for any of the elements in the data table, toggle on the check box for the rows corresponding to the elements you want to annotate or toggle on the check box in the header row to display probe annotations for all selected elements.

   Note:

   You can customize the color and font for probe annotations of elements in the **Common Plot Options** dialog box. For more information, see *Using common plot options*.
10. To save the data you have selected, click **Write to File**. For more information, see *Generating tabular data reports*."
11. To exit probe mode, do one of the following:

    - Click the cancel  button in the prompt area.
    - Click **Cancel** in the **Probe Values** dialog box.
    - Click mouse button 2.
    - Produce a plot in some other (e.g. undeformed, deformed) mode.

Additional information

- *Controlling result averaging*
- *Probes of models or model plots*
- *Probing nodes*
- *Querying active node or element labels*

Probing X–Y plots

You can use the Query toolset to obtain information about curves in an *X*–*Y* plot.
As you position the cursor over an *X*–*Y* curve in the current viewport, Abaqus/CAE highlights the nearest curve point and displays the curve legend text, the point's sequence identification, and the *X*- and *Y*-coordinates of the point in the **Probe Values** dialog box. Abaqus/CAE also highlights the selected curve point with a symbol and displays the *X*- and *Y*-coordinates of that curve point next to the symbol. These symbols and coordinates persist on the *X*–*Y* plot until you leave Probe mode. You can choose to display only the curve points that comprise an *X*–*Y* data object or to interpolate to display arbitrary points along the curve.

When you select a point in Probe mode, Abaqus/CAE adds the legend text, sequence identification, and *X*- and *Y*-coordinates of the current point to the data table, which appears at the bottom of the **Probe Values** dialog box. You can clear or sort this table, delete individual rows, and write these data to a file. If the *X*–*Y* data name differs from the *X*–*Y* curve legend text, the **Legend** value in the **Probe Values** dialog box displays the *X*–*Y* data name prepended to the legend text.

While Probe mode is active, Abaqus/CAE also tracks the position of the cursor in the *X*–*Y* plot with arrows that run along the *X*- and *Y*-axes. These arrows respectively track the current *X*- and *Y*-position of the cursor, so they enable you to select your curve points with greater precision.

To help locate *X*- and *Y*-data points, you may want to produce an *X*–*Y* plot with curve symbols visible before using the Query toolset. For more information, see *Customizing the symbols used on an X–Y curve*.

1. Locate the **Probe Values** dialog box.

   In the Visualization module toolbox, click . The **Probe Values** dialog box appears.

2. At the top of the dialog box, toggle **Interpolate between points** to enable or disable the display of probe values for arbitrary points along the curve.

   When you enable interpolation, Abaqus/CAE displays the sequence identification of arbitrary points by listing the bracketing *X*–*Y* data object points in parentheses.

3. Select the information types that you want to include in your query.

   Click mouse button 3 anywhere in the data table, select **Edit Visible Columns** from the list that appears, and toggle on the information types that you want to include in the query and display as columns in the data table. When an information type is toggled on, Abaqus/CAE can display that type of data in two locations for the selected element: in the data table when you mouse over or select the element in the viewport, and in the probe values output file.

4. Move the cursor to probe the *X*–*Y* plot in the current viewport.

   As you position the cursor over a curve point, Abaqus/CAE displays the *X*- and *Y*-coordinates of the current point on the curve itself and displays the current position of your cursor along the *X*- and *Y*-axes of the *X*–*Y* plot.

5. To select and accumulate values of interest and to allow subsequent writing of these values to a file, click mouse button 1 while positioning the cursor over a curve point.

   Abaqus/CAE stores the legend text, sequence identification, and *X*- and *Y*-coordinates of the current point into the data table. Abaqus/CAE also tags the points you select in the viewport by placing a symbol at the curve point you selected and displaying the *X*- and *Y*-coordinates next to that point.

6. To delete data from the data table or to clear or sort the table, click mouse button 3. For more information, see *Entering tabular data*.
7. To save the data you have selected, click **Write to File**. For more information, see *Generating tabular data reports*.
8. To exit probe mode, do one of the following:

- Click the cancel  button in the prompt area.
- Click **Cancel** in the **Probe Values** dialog box.
- Click mouse button 2.
- Produce a plot in some other (e.g., undeformed, deformed) mode.

Calculating linearized stresses

The calculation of linearized stresses is a capability for advanced Abaqus users.
It is most commonly used for two-dimensional axisymmetric models.

For detailed information on linearized stress result quantities and the methods of calculation used, see *Computing the stress components*.

In this section:

- *Understanding stress linearization*
- *Stress linearization example*
- *Obtaining linearized stress results*

Understanding stress linearization

Stress linearization is the separation of stresses through a section into constant membrane and linear bending stresses. Stress linearization is available for output databases only.
To linearize stresses in Abaqus/CAE, the following procedure is used:

- You define a section through your model. You specify the endpoints of the section by selecting nodes in the model, coordinates in space, or a saved path.
- Abaqus/CAE defines the stress line by interpolating between the two endpoints to obtain a user-specified number of equal intervals along a straight line.
- You can save the stress line as a path; the saved path includes the endpoints and each interval point along the stress line. If you save the stress line as a path, Abaqus/CAE always creates a point list path, regardless of the method that you used to define the endpoints.
- The specified stress results are obtained at equally spaced intervals along the line in a local coordinate system defined by the line.
- Abaqus/CAE performs stress linearization calculations and displays the results in the form of an *X*–*Y* plot. You can choose to save the data and/or to write it to a file.

If you linearize stresses across multiple part instances, the results will be averaged for any points that exist in more than one part instance.

To obtain linearized stresses along a line, select **Tools->Query** from the main menu bar, then select **Stress linearization** from the **Visualization Module Queries** options.

In this section:

- *Defining the stress line*
- *Extraction of the stress results*

Defining the stress line

You can define the endpoints of the section for which you want to obtain linearized stresses by selecting nodes in the model, points in space, or a saved path. You select nodes in the model by selecting the nodes directly from the viewport or by typing the node labels, and you define points in space by typing the point coordinates. If you select a saved path, Abaqus/CAE uses the path endpoints as the endpoints of the stress line—other points along the path are ignored. (For more information on paths, see *Viewing results along a path*.)

A node label is a persistent means of referring to a given node in a part instance; that is, node labels do not change as your model deforms. Therefore, if you specify the endpoints of the section using node labels or a saved node list path, these points will be equally applicable to the undeformed or the deformed model shape. However, points in space remain fixed and are independent of your model. For example, coordinates that coincide with a nodal location on the undeformed shape may not coincide with any location on the deformed shape. If you specify the endpoints of the section using coordinates in space, a point list path, or a radial path, be sure to specify the coordinates with respect to the correct shape. Edge list paths cannot be used to define a stress line.

For the best results for an axisymmetric model, the endpoints chosen should be normal to the interior and exterior surfaces of your model and to the midplane (see *Figure 1*).

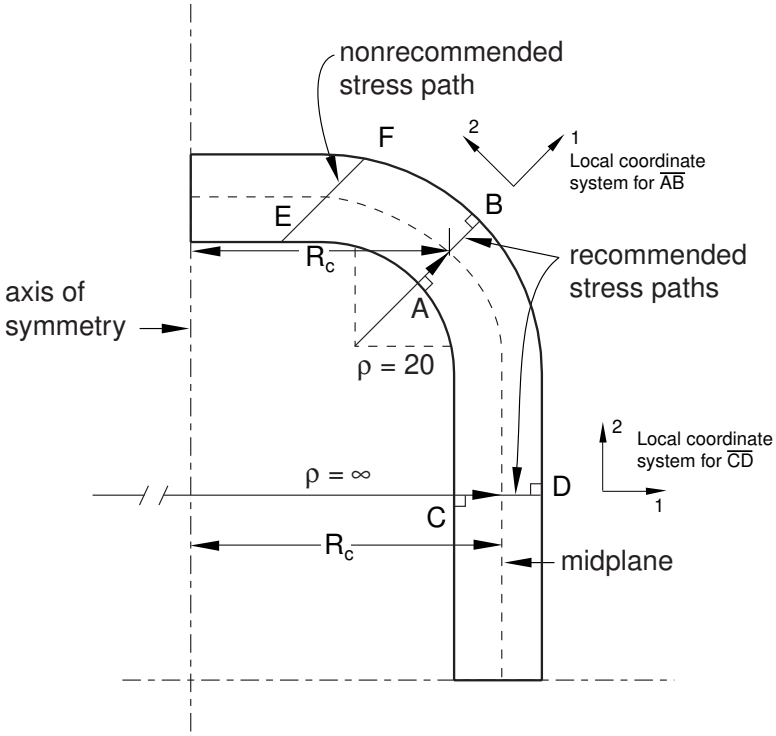

Figure 1: Recommended stress paths.

The section can extend from surface to surface, or it can be entirely in the interior of the model. The section can also pass through more than one part instance. The following guidelines should also be considered when selecting the endpoints for the section:

- Avoid paths that traverse spatial discontinuities.
- Avoid paths along a line separating discontinuities.
- Use display groups to isolate individual regions prior to specifying the section.

If the section extends across spatial discontinuities, such as a hole within a part instance or a space between part instances, an error message will be given.

After you choose the endpoints of the section, you can specify the number of segments into which the line should be divided or you can accept the default number. Abaqus/CAE defines the stress line by interpolating between the two endpoints to obtain the specified number of equal intervals along a straight line.

Extraction of the stress results

The stresses at each point along the stress line are obtained by interpolating the unique nodal stress values using the averaging criteria defined in the **Result Options** dialog box (for more information on specifying the averaging criteria, see *Controlling result averaging*). Abaqus/CAE uses a local coordinate system that is defined by the stress line to obtain the stress results. The local *x*-axis lies along the stress line; it originates at the first point on the stress line and is defined by the vector connecting the first and second points on the stress line. The local *y*- and *z*-axes are determined as follows:

For two-dimensional models:

The local *y*-axis is obtained by vector multiplication of the global *z*-axis with the local *x*-axis. The local *z*-axis is the same as the global *z*-axis.

For three-dimensional models:

If the local *x*-axis is parallel to the global *y*-axis:

If the positive local *x*-axis lies along the positive global *y*-axis, the local *y*-axis will be the negative of the global *x*-axis. If the positive local *x*-axis lies along the negative global *y*-axis, the local *y*-axis will be the global *x*-axis. The local *z*-axis is obtained by vector multiplication of the local *x*-axis and the local *y*-axis.

If the local *x*-axis is not parallel to the global *y*-axis:

The local *z*-axis is obtained by vector multiplication of the local *x*-axis and the global *y*-axis. The local *y*-axis is obtained by vector multiplication of the local *z*-axis and the local *x*-axis.

The stresses are then linearized. The stress linearization calculations differ for nonaxisymmetric and axisymmetric models. For more information on these calculations, see *Computing the stress components*.

Abaqus displays the resulting linearized stresses in the form of an *X–Y* plot. Three separate curves are presented for each stress component representing the following:

1. The actual stress distribution across the stress line.
2. The linearized membrane stress.
3. The sum of the linearized membrane stress and the linearized bending stresses.

In addition, the linearized stress output for each stress component and the stress invariant calculations for the linearized stresses are written to a report file.

Stress linearization example

Figure 1 shows an example of a stress line defined for an axisymmetric model of a pressure vessel.

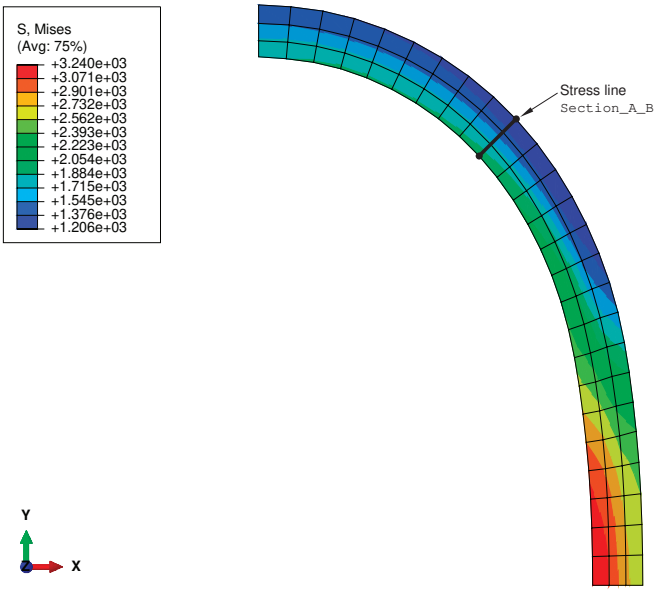

Figure 1: Stress line through an axisymmetric model of a pressure vessel.

The stress line `Section_A_B` is defined through the vessel wall. *Figure 2* and *Figure 3* show the basic settings and computations, respectively, that you use to linearize the S22 stress component for the undeformed model shape.

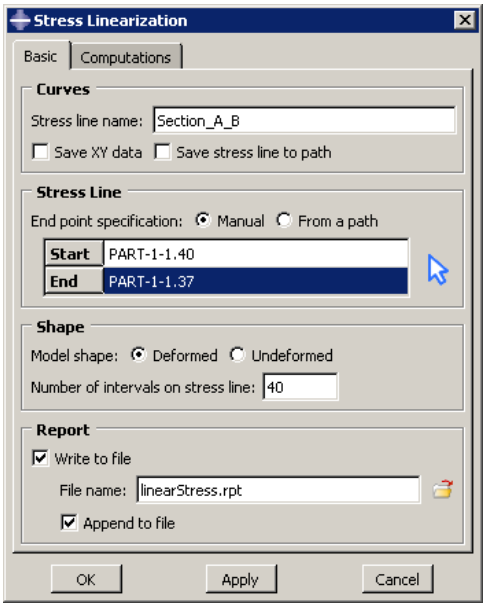

Figure 2: Stress linearization basic specifications.

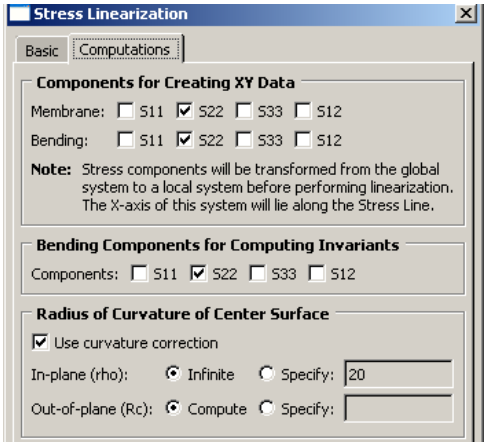

Figure 3: Stress linearization computations.

When you click **OK** or **Apply** in the **Stress Linearization** dialog box, Abaqus/CAE creates an *X*–*Y* plot of the S22 stress component (oriented normal to the stress line) and of the resulting linearized stresses, as shown in *Figure 4*.

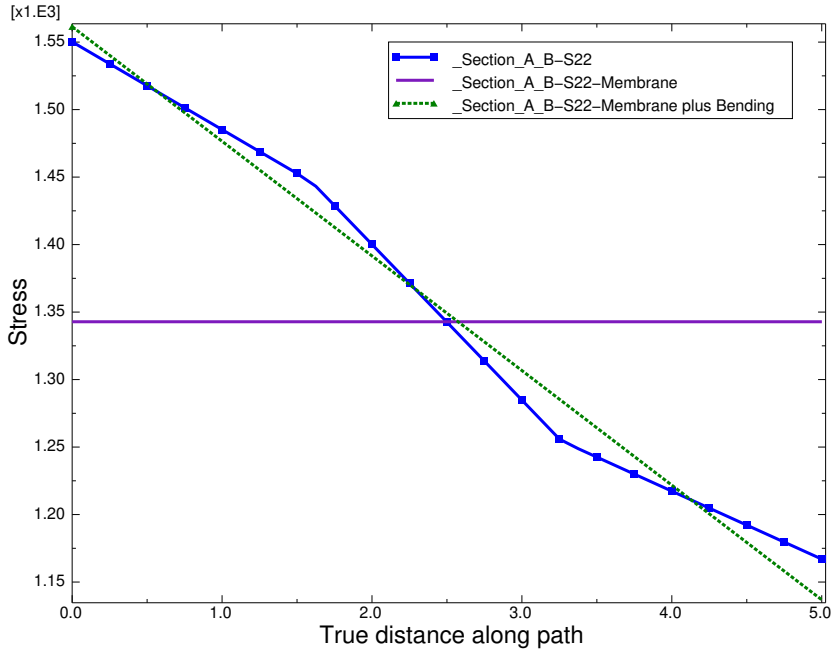

Figure 4: Linearized stress plot.

The following output is also written to a file called `linearStress.rpt`:

```

The `S22` corresponds to the S22 stress shown in *Figure 4*. The actual stress values plotted in the curve `Section_A_B_S22` do not appear in the report. The linearized membrane and membrane-plus-bending stress curves are generated from the values shown for `S22`. The reported invariants are calculated from the selected linearized components.

Obtaining linearized stress results

You can obtain linearized stresses along a line through your model. Abaqus/CAE separates the stress results along the line into constant membrane and linear bending stresses and displays the results in the form of an *X*–*Y* plot.

1. Locate the stress linearization options.

   From the main menu bar, select **Tools->Query** or click the  tool in the Query toolset.

   The **Query** dialog box appears.

2. Select **Stress linearization**.

   The **Stress Linearization** dialog box appears.

3. In the **Stress line name** field, provide a name for the stress line. This name will be used as a prefix for the linearized results.
4. To save the *X*–*Y* data that will be generated, toggle on **Save XY data**. The data will be available for the duration of your Abaqus/CAE session.
5. To save the endpoints and interval points as a path, toggle on **Save stress line to path**. The points of the stress line will be saved for the duration of your Abaqus/CAE session as a point list path with the same name as the stress line.
6. Select the endpoints for the stress line by selecting nodes or points in space or by selecting a saved path.

Manual

This is the default method. You can select nodes directly from the viewport or type in node labels or points in space.

To select nodes directly from the viewport:

Click  to the right of the **Start** and **End** fields, and click on the desired nodes in the viewport.

The node labels, including the part instance name, will appear in the text field for the **Start** and **End** points of the stress line.

To type in node labels or points in space:

1. In the **Start** text field, enter a part instance name and node label or the coordinates of a point in space. The part instance name and node label must be of the form `Instance.Node`; specify coordinate values as *X*-, *Y*-, and *Z*-coordinates separated by spaces or commas.

   If you do not know the part instance names in the model, use the previous method to select a node directly from the viewport. Alternatively, you can select **Tools->Query** or click the  tool in the Query toolset and choose the **Probe values** method to determine the instance name and node label (for more information, see *Understanding probing*).

2. Repeat the preceding step to complete the **End** text field.

From a path

Toggle on **From a path**, and select a path name from the list that appears; you cannot use an edge list path to define the endpoints of a stress line. (For more information on paths, see *Viewing results along a path*.)

Abaqus/CAE uses the endpoints of the saved path as the endpoints of the stress line. The points are defined in the same manner as they were originally defined in the path—a node list path provides node points on the model, and a point list path or circular list path provides the coordinates of points in space.

Regardless of the method you use to select the endpoints, Abaqus highlights the stress line in the viewport and labels the start and end. If you selected node points or a node list path to define the endpoints of the stress line, the labels in the viewport indicate the node numbers.

Note:

If you chose to save the stress line as a path in Step 5, Abaqus/CAE*always* saves a point list path—even if you selected nodes, node labels, or a node list path to define the stress line.

7. Choose the model shape for which to obtain the stress results. The default is to obtain the results for the deformed model shape. Toggle on **Undeformed** to obtain results for the undeformed model shape.
8. Specify the number of intervals into which the stress line should be divided. Type a positive integer greater than 0 into the **Number of intervals on stress line** text field. If you do not enter a number, Abaqus will use a default number of intervals.
9. Select **Use Maximum Stress Value** to use the maximum available value at a point.

   By default, Abaqus/CAE will use the average of multiple values available at a point.
10. By default, Abaqus/CAE writes the linearized stress values (including all available components of stress and the computed linearized stress invariants) to a file called `linearStress.rpt`. If you do not wish to write this report, you can toggle off **Write to file** in the **Report** area of the dialog box.

    You can specify a new name for the report file by entering the name in the **File name** field or clicking  and choosing from the list of existing files that appears.

    If you write the report to an existing file, the new data will be appended to the file by default; if you wish to overwrite the file, toggle off **Append to file**.
11. Click the **Computations** tab.
12. Select the stress components to be linearized by toggling on each membrane and bending component.
13. Select the bending components to use for calculating invariants.
14. For axisymmetric models enter an approximate value for the in-plane radius of curvature of the midplane of your model at the location of the stress line. The default value is **Infinite**, which implies a lack of curvature. To specify a radius of curvature, click **Specify** and enter a number in the text field.
15. For axisymmetric models enter an approximate value for the out-of-plane radius of curvature of the midplane of your model at the location of the stress line. The default value is **Compute**, which allows Abaqus to calculate the radius based on the axisymmetric shape and the position of the selected stress line. To specify a radius of curvature, click **Specify** and enter a number in the text field.
16. For nonaxisymmetric models select whether Abaqus should use curvature correction. If curvature correction is selected, specify a local coordinate system or use the default (global) coordinate system; if you use a local coordinate system for curvature correction, you can also use that local coordinate system to evaluate stress line orientation.
17. Click **OK**.

An *X–Y* plot similar to the one shown in *Figure 1* appears in the viewport.

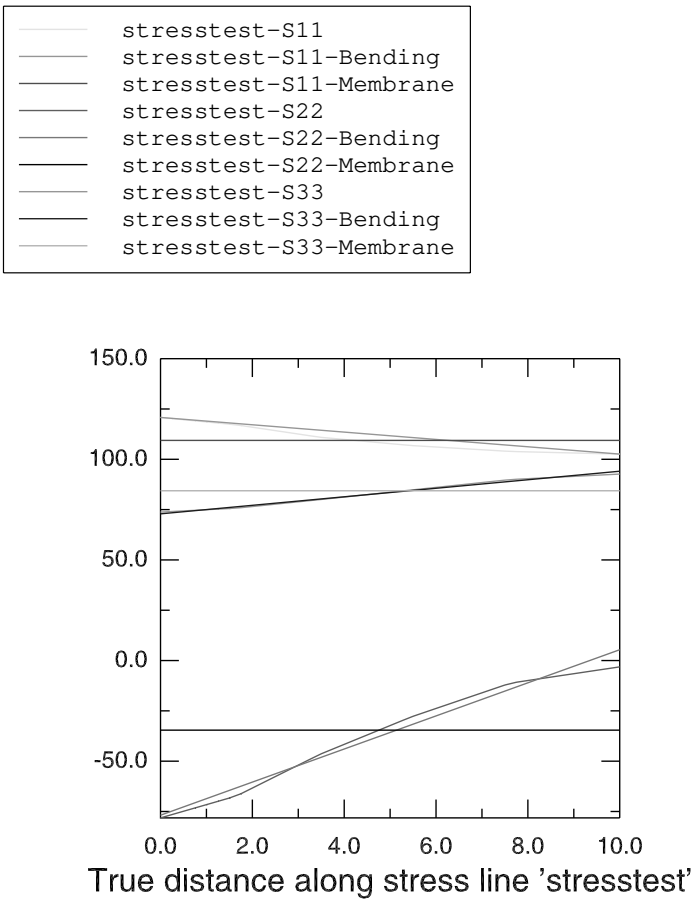

Figure 1: Stress linearization results.

Additional information

• *X–Y plotting*

Viewing a ply stack plot

A ply stack plot shows the plies from the selected region of a composite model. You can create a ply stack plot in either the Property module or the Visualization module. This chapter describes ply stack plotting.

In this section:

- *Understanding ply stack plots*
- *Customizing ply stack plots*

Understanding ply stack plots

A ply stack plot is a graphical representation of the plies from a selected region of a composite model. In effect, a ply stack plot is a core sample of the plies in the selected region. The region can be from a composite layup or from a composite section.

You can customize the appearance of a ply stack plot. For example, the image can show the sequence of plies, the orientation of the fibers in each ply, the material in each ply, the relative thickness of the ply, and the location of the reference surface. *Figure 1* illustrates a ply stack plot.

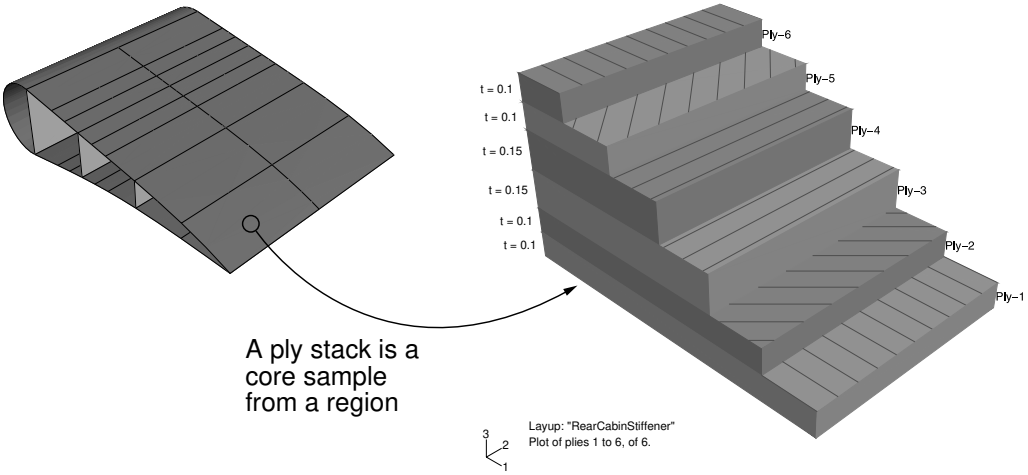

Figure 1: A ply stack plot.

The staircase appearance has no corresponding physical meaning; it is just a mechanism that allows you to view all of the plies in a region. For example, the plies are not ending at each stair.

The triad in a ply stack plot represents the element orientation system, and it shows the shell normal or stacking direction (the 3-direction) and the 1- and 2-directions for the plies. The fibers are always drawn in the 1–2 plane at an angle with respect to the 1-direction. In solid composite layups the fibers in a ply do not always run parallel to the 1–2 plane (e.g., if the 3-direction of the ply orientation and the element stacking direction are not aligned). In this situation the fibers in the ply stack plot are not a true depiction of the fibers in the composite, but rather a graphical representation of the rotation angles in the composite section or layup definition: the angle drawn in the ply stack plot is the rotation angle specified in the ply table measured about the element stacking direction axis. For more information, see *Understanding composite layups and orientations*.

Ply stack plots do not draw fibers for ply orientations that are based on a user-defined coordinate system or a rotation angle distribution. Abaqus/CAE displays an asterisk (for coordinate systems) or a caret (for rotation angle distributions) on such plies to signify that it cannot draw lines in the 1–2 plane that accurately represent the fiber direction for the ply. Similarly, if you use a discrete field distribution to define a ply's thickness, Abaqus/CAE draws the ply in the ply stack plot based on the average thickness of the other uniform plies in the layup and displays the discrete field name next to the plot (if thickness labels are turned on).

It is important to know the position of the reference surface when you are modeling a composite with conventional shell elements. The mesh will be positioned on the reference surface, and contact is defined relative to the reference surface. The ply stack plot allows you to view the reference surface relative to other plies in the composite, as shown in *Figure 2*.

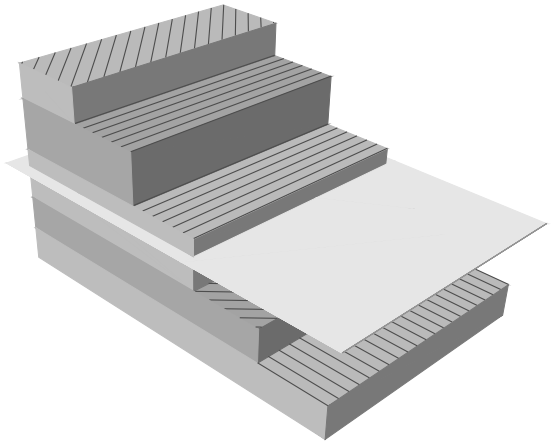

Figure 2: The reference surface in a ply stack plot.

You can display a ply stack plot in the Property module after you have created a composite layup or assigned a composite section to a region. You can also display a ply stack plot in the Visualization module after you have analyzed a model with a composite layup or a composite section. For more information, see *Defining composite layups* and *Creating composite shell sections*.

To produce a ply stack plot, select **Tools->Query** from the main menu bar and select **Ply stack plot** from the dialog box that appears. After you have displayed a ply stack plot, you can customize its appearance by clicking the **Ply Stack Plot Options** button from the prompt area or by clicking the tool in the toolbox (in the Visualization module). For detailed instructions on customizing a ply stack plot, see *Customizing ply stack plots*.

Customizing ply stack plots

This section explains how you use the **Ply Stack Plot Options** dialog box to customize the appearance of a ply stack plot.

In this section:

- *Using ply stack plot options*
- *Customizing basic ply stack plot options*
- *Customizing the appearance of fibers in a ply stack plot*
- *Customizing the reference surface in a ply stack plot*
- *Customizing the labels in a ply stack plot*

Using ply stack plot options

Understanding ply stack plots describes how you can create a ply stack plot. After you have displayed a ply stack plot, you can customize its appearance by clicking the **Ply Stack Plot Options** button from the prompt area. Alternatively, you can do the following:

- In the Property module, choose **View->Ply Stack Plot Options**.
- In the Visualization module, choose **Options->Ply Stack Plot** or click the  tool in the toolbox.

Abaqus/CAE displays the **Ply Stack Plot Options** dialog box, which allows you to do the following:

- Choose which plies are displayed in the ply stack plot and how the plies are displayed. For more information, see *Customizing basic ply stack plot options*.
- Choose whether fibers are displayed in the ply stack plot and the appearance of the fibers. For more information, see *Customizing the appearance of fibers in a ply stack plot*.
- Choose whether the reference surface is displayed in the ply stack plot and the appearance of the reference surface. For more information, see *Customizing the reference surface in a ply stack plot*.
- Customize the text and symbols that are displayed in a ply stack plot. For more information, see *Customizing the labels in a ply stack plot*.

Customizing basic ply stack plot options

Click the **Basic** tab to choose which plies are displayed in the ply stack plot and how the plies are arranged. If your composite layup contains many plies, the ply stack plot can become confusing and hard to interpret. To make the ply stack plot more readable, the basic ply stack plot options allow you to view only a manageable number of plies.

1. Locate the basic options.
   1. Click the **Ply Stack Plot Options** button from the prompt area, or do one of the following:
      - In the Property module, choose **View->Ply Stack Plot Options**.
      - In the Visualization module, choose **Options->Ply Stack Plot** or click the  tool in the toolbox.
   2. Click the **Basic** tab in the **Ply Stack Plot Options** dialog box that appears.
2. From the **Display** options, do the following:
   - Select the render style—shaded, filled, or wireframe.
   - Choose whether to display the edges of each ply and the style and thickness of the edges.
   - Choose whether to display the plies as a “staircase” image descending from the last ply to the first ply or as an image that is symmetric about the center ply or plies.
3. From the **Visible Plies** options, choose which plies to display. Abaqus/CAE updates the ply stack plot when you modify the display parameters, which allows you to quickly and conveniently display the plies in a composite. You can choose the following:
   - Display the specified plies, starting with the **Start** ply and ending with the **End** ply.
   - Display **Number** of plies, starting with the **Start** ply. Click **Increment by Number** to increment the **Start** value by **Number** of plies instead of by 1. This allows your ply stack plot to be a window that moves incrementally across the layup, with each increment displaying the next adjacent group of plies.
   - Display **Number** of plies, centered around the **Center** ply. Click **Increment by Number** to increment the **Center** value by **Number** of plies instead of by 1. This allows your ply stack plot to be a window that moves incrementally across the layup, with each increment displaying the next adjacent group of plies.
   - Display **Number** of plies, centered around the **Center** ply. Drag the **Center** slider to move across the layup.
4. Choose the color of the **Even** and **Odd** plies:
   a. Click the color sample .
      Abaqus/CAE displays the **Select Color** dialog box.
   b. Use one of the methods in the **Select Color** dialog box to select a new color. For more information, see *Customizing colors*.
   c. Click **OK** to close the **Select Color** dialog box.
      The color sample changes to the selected color.

   Abaqus/CAE applies your choice of color relative to the plies that are displayed, not to the actual ply number. For example, if you are displaying plies 2, 3, and 4; Abaqus/CAE will apply the **Odd** color to plies 2 and 4 and the **Even** color to ply 3.

5. Click **Apply** to implement your changes.

   The ply stack plot changes to reflect your specifications.

   By default, your changes are saved for the duration of the session and will affect all subsequent ply stack plots in that viewport. If you want to retain your changes for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

Customizing the appearance of fibers in a ply stack plot

Click the **Fiber** tab to choose whether fibers are displayed in the ply stack plot and the appearance of the fibers. The fibers are always drawn in the 1–2 plane at an angle with respect to the 1-direction. For more information, see *Understanding composite layups and orientations*.

If you use a coordinate system to define the ply's orientation, Abaqus/CAE cannot determine the orientation within an element without knowing the spatial orientation of the element. Therefore, Abaqus/CAE displays an asterisk (*) in place of the ply fibers to signify that it cannot draw lines in the 1–2 plane that represent the fiber direction. For the same reason, Abaqus/CAE cannot draw lines that accurately represent the fiber direction if the ply's orientation is defined using a discrete field distribution; a caret (^) in place of the ply fibers indicates that the additional rotation in a ply's orientation is defined using a discrete field.

In solid composite layups the fibers in a ply do not always run parallel to the 1–2 plane (e.g., if the 3-direction of the ply orientation and the element stacking direction are not aligned). Since fibers in a ply stack plot are always drawn in the 1–2 plane, they are not a true depiction of the fibers in the solid composite. Instead the fibers are a graphical representation of the rotation angles in the composite section or layup definition: the angle drawn in the ply stack plot is the rotation angle specified in the ply table measured about the element stacking direction axis.

1. Locate the fiber options.
   1. Click the **Ply Stack Plot Options** button from the prompt area, or do one of the following:
      - In the Property module, choose **View->Ply Stack Plot Options**.
      - In the Visualization module, choose **Options->Ply Stack Plot** or click the  tool in the toolbox.
   2. Click the **Fiber** tab in the **Ply Stack Plot Options** dialog box that appears.
2. Do the following:
   - Toggle on **Show fibers** to display fibers in the ply stack plot.
   - Choose the color, style, and thickness of the lines that represent fibers in the ply stack plot.
   - Drag the **Spacing** slider to change the number of fibers that are displayed.
3. Click **Apply** to implement your changes.

   The ply stack plot changes to reflect your specifications.

   By default, your changes are saved for the duration of the session and will affect all subsequent ply stack plots in that viewport. If you want to retain your changes for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

Customizing the reference surface in a ply stack plot

Click the **Reference Plane** tab to choose whether the reference surface is displayed in the ply stack plot and to control the appearance of the reference surface. Conventional shell elements use the reference surface to define the geometry of the part. Therefore, you can display the reference surface only on shell composites; you cannot display the reference surface on continuum shell composite layups or solid composite layups. In addition, if the ply's offset is defined by a distribution, Abaqus/CAE cannot display the reference surface.

1. Locate the reference surface options.
   1. Click the **Ply Stack Plot Options** button from the prompt area, or do one of the following:
      - In the Property module, choose **View->Ply Stack Plot Options**.
      - In the Visualization module, choose **Options->Ply Stack Plot** or click the  tool in the toolbox.
   2. Click the **Reference Plane** tab in the **Ply Stack Plot Options** dialog box that appears.
2. Do the following:
   - Toggle on **Show reference surface** to display the reference plane in the ply stack plot.
   - Choose the color and translucency of the reference surface.
   - Toggle on **Show reference outline** to display lines around the edge of the reference surface. Choose the color, style, and thickness of the lines.
3. Click **Apply** to implement your changes.

   The ply stack plot changes to reflect your specifications.

   By default, your changes are saved for the duration of the session and will affect all subsequent ply stack plots in that viewport. If you want to retain your changes for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

Customizing the labels in a ply stack plot

Click the **Labels** tab to customize the text and symbols that are displayed in a ply stack plot; for example, material and ply names, the state block, and integration points.

1. Locate the labels options.
   1. Click the **Ply Stack Plot Options** button from the prompt area, or do one of the following:
      - In the Property module, choose **View->Ply Stack Plot Options**.
      - In the Visualization module, choose **Options->Ply Stack Plot** or click the  tool in the toolbox.
   2. Click the **Labels** tab in the **Ply Stack Plot Options** dialog box that appears.
2. Select the font of all the text in the ply stack plot.
   a. Click **Set Font for All Labels** to display the **Select Font** dialog box.
   b. Use the font selector dialog box to set the font properties that you want.
   c. Click **OK** to close the **Select Font** dialog box and to return to the **Ply Stack Plot Options** dialog box.
3. Toggle on an option to display it.
4. Choose the color of the text:
   a. Click the color sample .
      Abaqus/CAE displays the **Select Color** dialog box.
   b. Use one of the methods in the **Select Color** dialog box to select a new color. For more information, see *Customizing colors*.
   c. Click **OK** to close the **Select Color** dialog box.
      The color sample changes to the selected color.
5. Click **Apply** to implement your changes.
   The ply stack plot changes to reflect your specifications.
   By default, your changes are saved for the duration of the session and will affect all subsequent ply stack plots in that viewport. If you want to retain your changes for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

Generating tabular data reports

You can produce a tabular data report of *X*–*Y* data objects, field output results, probe values, or free body cuts. Abaqus/CAE writes the report to the file name of your choice. Generate a tabular report to save data values beyond the duration of the session or to print these values. In addition, you can use a tabular report as ASCII input in subsequent Abaqus/CAE sessions.

This chapter explains how to produce and customize a tabular report.

In this section:

- *Producing a tabular report*
- *Using tabular report options*
- *Selecting report data*
- *Specifying your report file name*
- *Controlling report layout, width, format, and coordinate system*
- *Sorting field output data*
- *Formatting report values*
- *Reporting data values, minimums, maximums, and totals*

Producing a tabular report

You can produce tabular reports of *X–Y* data objects, field output results, free body cuts, and probe values.

To produce a tabular report of *X–Y* data objects, field output results, or free body cuts, you first specify the report content, format, and destination. Abaqus/CAE generates the report when you apply these customization selections.

To produce a report of probe values, you first produce and then probe a model or *X–Y* plot. While probing, you can select probe values of interest and you can write the selected values to a file.

Depending on your selections, your report may include negative element labels. Negative labels indicate internal elements created by Abaqus/CAE. These elements are given negative labels so you can easily distinguish them from elements that you created while defining the model.

Produce a report of X–Y data, field output results, or free body cuts

1. From the main menu bar, select **Report->XY**, **Report->Field Output**, or **Report->Free Body Cut**. The **Report XY Data**, **Report Field Output**, or **Report Free Body Cut** dialog box becomes available.
2. Use the options to customize the report content, format, and destination.
3. When you have finished, click **Apply** to generate the report.

Produce a report of probe values

1. From the main menu bar, select **Tools->Query**, then click **Probe values** in the dialog box that appears. The **Probe Values** dialog box appears.
2. Move the cursor to probe the model or *X–Y* plot in the current viewport.
3. To select and accumulate values of interest in the data table in the bottom portion of the **Probe Values** dialog box, click mouse button 1 while probing.
4. When you have finished, click **Write to File** to access the report file options and to generate the report.

Using tabular report options

You can customize tabular report characteristics such as the objects to include, report layout, and sort order. Select **Report->XY**, **Report->Field Output**, or **Report->Free Body Cut** to customize and generate a tabular listing of *X–Y* data objects, field output variable values, or free body cuts, respectively. Select **Tools->Query** to generate a tabular report of probe values. The following list identifies the tabular report characteristics that you can customize and the sections where you can find information.

You can customize:

- The *X–Y* data objects or field output variables to include in the report. See *Selecting report data*.
- The free body cuts to include in the report. Abaqus/CAE includes all active free body cuts in the current output database in a free body cut report. You can activate and suppress free body cuts from the **Free Body Cut Manager**. See *Displaying, hiding, and highlighting free body cuts*.
- The probe values to include in the report. See *Probing the model*.
- The file name to which the report is written. See *Specifying your report file name*.
- The layout and width of the report. See *Controlling report layout, width, format, and coordinate system*.
- How field output or probe values are sorted. For field output, see *Sorting field output data*; for probe values, see *Entering tabular data*.
- The format and significant digits of report values. See *Formatting report values*.
- Whether or not to include minimum and maximum value summaries or column totals. See *Reporting data values, minimums, maximums, and totals*.
- The form of complex results in the report. See *Controlling the form of complex results*.

Selecting report data

This section explains how to select *X–Y* data objects to include in an *X–Y* data report, how to select field output variables to include in a field output report, and how to select the options and thresholds to use for a free body cut report.

To learn how to control the contents of a tabular report of probe values, see *Probing the model*.

In this section:

- *Selecting X–Y data objects*
- *Selecting field output variables*
- *Selecting field output section points*
- *Selecting options and thresholds for free body cut reports*

Selecting X–Y data objects

You can select one or more *X–Y* data objects to include in your *X–Y* report.

1. Locate the *X–Y* report **XY Data** options.

   From the main menu bar, select **Report->XY**; then click the **XY Data** tab in the dialog box that appears.

2. Select the *X–Y* data objects to include in your report from the list of available data objects. By default, all *previously saved* *X–Y* data objects are listed. Choose one of the following options to adjust the contents of this list:

   - Click **All XY data** to browse all previously saved *X–Y* data objects.
   - Click **XY plot in current viewport** to browse only those *X–Y* data objects included in the *X–Y* data plot in the current viewport.

   Abaqus/CAE lists the *X–Y* data objects you have requested.

3. To limit the list for easier selection, type a filter pattern into the **Name filter** field, and press the **[Enter]** key to apply the filter. Click  to the right of the text field to display information about how to construct a filter.

   Abaqus/CAE lists only those *X–Y* data objects that meet your specification.

4. From the list of *X–Y* data object names and descriptions, select one or more data objects to include in your report. For more information on selecting multiple items in dialog boxes, see *Selecting multiple items from lists and tables*.

To generate your report, configure any desired customization options on the **Setup** page, which is also in the **Report XY Data** dialog box; and click **Apply**. When you have finished, click **Cancel** to close the dialog box.

Additional information

• *Using tabular report options*

Selecting field output variables

You can select one or more field output variables to include in your tabular report.
The variables that are available consist of those you have saved to the output database. You can generate reports for the current frame or for multiple frames.

Abaqus/CAE can calculate and report values for a given variable at a variety of positions. The possible report positions are: integration point, centroid, element nodal, and unique nodal.

Element nodal and unique nodal positions both involve reporting results at the nodes of the model; however, reporting of unique nodal values produces only a single value at each node, whereas reporting of element nodal values produces one value for each element that has a contribution at that node. Only unique nodal values are provided in the case of node-based variables such as displacement. For element-based variables such as stress, extrapolation and averaging must be carried out to obtain unique nodal values. The use of averaging threshold values and the control of averaging across regional and material boundaries will affect the element nodal values reported for element based results (for more information, see *Selecting result options*).

The following table summarizes which output positions can be reported, depending on what position was used when the variable was saved to the output database:

	Report Position			
Output Database Position	**Integration point**	**Centroid**	**Element Nodal**	**Unique Nodal**
Integration Point	Yes	Yes	Yes	Yes
Centroid	No	Yes	Yes	Yes
Element Nodal	No	No	Yes	Yes
Unique Nodal	No	No	No	Yes

Contact surface variables such as CNORMF, CSHEARF, CPRESS, COPEN, CSLIP, CSHEAR1, and CSHEAR2 can be reported only at the element nodal position.

When generating the field output report for element-based field output at any output position, Abaqus/CAE writes the field values from the specified position if the same position is available in the output database.

For information on selecting the section point locations at which to report output variables, see *Selecting field output section points*.

1. Locate the options for field output reports.

   From the main menu bar, select **Report->Field Output**.

2. Choose the frames from which Abaqus/CAE reads field output data.

   - Choose **Specify** to use the current step/frame. To change the current step or frame, click . For more information, see *Selecting the results step and frame*.
   - Choose **All active steps/frames** to use all active steps/frames. Click **Active Steps/Frames** to change the steps or frames from which Abaqus/CAE reads field output data. For more information, see *Activating and deactivating steps and frames*.

3. Click the **Variable** tab to display the **Output Variables** options.
4. Click the **Position** arrow to reveal possible positions at which to list variables for your selection; then choose the desired position. Multiple variables can be *combined in a single table* only if they are reported at the same position.

The list of variables is refreshed to show only those that can be reported at the selected position.

5. Select the field output variables to include in your report using either the check box next to each variable in the list (this method is the default) or the **Edit** text field at the bottom of the page.

Note:

You must use the check box method if you want to specify an individual section point at which to report values.

To use the check box method:

1. To select a variable and all of its components, click that variable's check box.
2. To choose among the individual components of a variable, click the arrow next to that variable's check box to list its components; then click individual component check boxes to select them.

To use the edit method:

In the **Edit** text field, enter the names of the variables and components to include in your report. To be valid, a variable must be available on the output database and reportable at the current position.

To generate your report, configure the remaining options on the **Setup** page, which is also in the **Report Field Output** dialog box; then click **Apply**. When you have finished, click **Cancel** to close the dialog box.

Additional information

- *Selecting the results step and frame*
- *Using tabular report options*

Selecting field output section points

If your field output report includes section point variables, you can choose the section point at which Abaqus/CAE reports values for those variables. The default is to report values at all available section points.

1. Locate the section point options.

   From the main menu bar, select **Report->Field Output**; then click the **Variables** tab in the dialog box that appears.

2. *Use the check box method* to select section variables.
3. At the **Section point** label at the bottom of the dialog box, do one of the following:

   - click **All** to report values at all available section points, or
   - click **Single** to indicate that you will select one section point at which to report values.

     If you have selected at least one element section point variable, the section point **Settings** button becomes available.

4. To select one or more section points, click **Settings**.

   The **Field Report Section Point Settings** dialog box appears. Use this dialog box to select the desired section points. For more information, see *Selecting section point data by category*.

5. Click **OK** to apply your section point selections and to close the **Field Report Section Point Settings** dialog box.

To generate your report, configure the remaining options on the **Setup** page, which is also in the **Report Field Output** dialog box; then click **Apply**. When you have finished, click **Cancel** to close the dialog box.

Additional information

- *Selecting field output variables*
- *Using tabular report options*

Selecting options and thresholds for free body cut reports

You can create a tabular report of the resultant forces and moments in all active free body cuts in your session. You can activate or suppress individual free body cuts by toggling their **Show** check boxes in the **Free Body Cut Manager**; for more information, see *Displaying, hiding, and highlighting free body cuts*. Abaqus/CAE reports resultant force and moment data with respect to the global coordinate system, regardless of the settings selected in the **Component Resolution** options for free body cuts or for view cuts.

You can generate reports for the current frame or for multiple frames. You can also specify custom threshold values for force data and moment data in the report; forces and moments smaller than these thresholds are reported as zero in the report. Selecting appropriate thresholds enables you to produce cleaner report data; for example, replacing small report values such as `1.234E-17` with `0` makes report data easier to read. The default threshold for both force and moment values is `1E-006`.

1. Locate the options for free body cut reports.

   From the main menu bar, select **Report->Free Body Cut**.

2. Choose the frames from which Abaqus/CAE reads free body cut data.

   - Choose **Specify** to use the current step/frame. To change the current step or frame, click . For more information, see *Selecting the results step and frame*.
   - Choose **All active steps/frames** to use all active steps/frames. Click **Active Steps/Frames** to change the steps or frames from which Abaqus/CAE reads free body cut data. For more information, see *Activating and deactivating steps and frames*.

3. From the **File** options, specify the report file name. For specific instructions, see *Specifying your report file name*.
4. From the **Output Format** options, specify the presentation format for the report data. For specific instructions, see *Controlling report layout, width, format, and coordinate system*.
5. If desired, specify a threshold value for forces and a threshold value for moments from the **Thresholds** options. Abaqus/CAE will report force and moment values smaller than these thresholds as zero.

To generate your report, click **Apply**. When you have finished, click **Cancel** to close the dialog box.

Additional information

- *Selecting field output variables*
- *Using tabular report options*

Specifying your report file name

Abaqus/CAE writes your tabular data report to the file name of your choice. If you choose to write your report to an existing file, you can further specify whether the new information should be appended to the current file contents or whether the file should be overwritten. The default is to append the new information.

1. Locate the **File** options.

   ### For a report of X–Y data or field output:

   From the main menu bar, select**Report->XY** or **Report->Field Output**; then click the **Setup** tab in the dialog box that appears. The **File** options are at the top of the page.

   ### For a report of free body cuts:

   From the main menu bar, select**Report->Free Body Cut**. The **File** options are at the top of the page.

   ### For a report of probe values:

   From the main menu bar, select**Tools->Query**, then click **Probe values** in the dialog box that appears. The **Probe Values** dialog box appears.

   Move the cursor to probe the model or *X–Y* plot in the current viewport, then click mouse button 1 to store values of interest in the dialog box. When you are finished, click **Write to File**. The **Report Probe Values** dialog box appears; the **File** options are at the top of the dialog.

2. To select a file name using the standard file browser, click **Select**.

   The **File Selection** dialog box appears. Use the dialog to filter and browse existing files. For more information on using this dialog box, see *Using file selection dialog boxes*. When you are finished, click **OK** to close the dialog box.

3. Type into the **Name** field the name of the file to which your report is to be written.
4. Toggle **Append to file** to append this report to the current contents (if any) of the file you have specified. When **Append to file** is off, existing file contents will be overwritten.

To generate your report, configure the remaining options in the dialog box; then click **Apply** (for *X–Y*, field output, or free body cuts) or **OK** (for probe values reports). When you have finished, click **Cancel** to close the dialog box.

Additional information

• *Using tabular report options*

Controlling report layout, width, format, and coordinate system

Options are available to format the report layout for ease of reading and exporting.

For tabular reports of *X–Y* data, field output, or probe values you can limit the width of the table; for example, to the number of characters your printer can support.

An *X–Y* data report can include one or multiple *X–Y* data objects. Similarly, a field output report can include one or multiple variables. For both types of reports, if you include multiple items, you can choose to present each item in its own table or to combine items into a single table. If you combine multiple items into a single table, additional columns of data are formed and the width of the table increases.

To combine *X–Y* data objects into a single table, Abaqus/CAE aligns the *X*-values of the data objects. If any data objects do not have matching *X*-values, you can choose to have Abaqus/CAE compute the missing points by interpolation and extrapolation. To learn more about interpolation and extrapolation, see *Understanding X–Y data interpolation and extrapolation*.

For field output reports Abaqus/CAE creates a separate table (of a single variable or of combined variables, according to your specification) for every region in the current display group. A region is a portion of your model that has compatible materials, section properties, and element types. Abaqus/CAE identifies the region associated with each table in the report. (For more information on display groups, see *Using display groups to display subsets of your model*; for more information on regions, see *Understanding result value averaging*.)

For field output and free body cuts Abaqus/CAE enables you to generate report output in either annotated format or in comma-separated value (CSV) format. In annotated format, results are presented so that they can be read easily; in CSV format, results are intended to be exported and read in spreadsheet applications.

You can also report data from free body cuts in the global coordinate system or in the local coordinate systems for which they were defined.

1. Locate the **Output Format** options.

For a report of X–Y data or field output:

From the main menu bar, select**Report->XY** or **Report->Field Output**; then click the **Setup** tab in the dialog box that appears. The **Output Format** options are in the center of the page.

For a report of free body cuts:

From the main menu bar, select**Report->Free Body Cut**. The **Output Format** options are in the center of the page.

For a report of probe values:

From the main menu bar, select**Tools->Query**, then click **Probe values** in the dialog box that appears. The **Probe Values** dialog box appears.

Move the cursor to probe the model or *X–Y* plot in the current viewport, then click mouse button 1 to store values of interest in the dialog box. When you are finished, click **Write to File**. The **Report Probe Values** dialog box appears; the **Output Format** options are in the center of the dialog.

2. For *X–Y* data reports, select the **Layout** option of your choice:

- Select **Single table for all *X–Y* data** to combine all the selected data objects into a single table.

  Toggle **Interpolate between X values (if necessary)** to have Abaqus compute missing points. When this option is toggled off, missing points (if any) appear as “No Value” in the table.

- Select **Separate table for each *X–Y* data** to have each of the selected data objects appear in its own table.

3. For field output reports, select the format of your choice:

   - Select **Annotated format** to include the data such as step/frame and output position at the beginning of the report. Field output is written only under steps/frames where it is available.

     Toggle **Separate table for each field output variable** to have each of the selected output variables appear in its own table.
   - Select **Comma-separated values (CSV)** to generate a report that includes a single header containing all the selected field output variables and combines the field values from all regions and instances into a single table. If any of the selected field output is not available in a particular step/frame, an entry of **NoValue** appears in the table column corresponding to that field.

     When you select this format, the options to use separate tables for each field output variable, to specify the page width, to include column totals, and to include a summary of the minimum and maximum values are unavailable.
   - To include information about the local coordinate system at each value, if applicable, toggle **Element orientations** in the **Data** options area. Coordinate system columns, if specified, might not adhere to the page width.

4. For *X–Y* data reports or field output reports, select the **Page width (characters)** option of your choice:

   - Select **No limit** to allow an unlimited table width.
   - Select **Specify** to limit the table's width. Then, in the **Specify** text field, enter the maximum number of characters that can appear along the width of the table.

5. For free body cut reports, perform the following:

   - Select either **Normal annotated format** or **Comma-separated values (CSV)** as the report format.
   - Select either **Global CSYS** or **Local CSYS** as the coordinate system for the free body cuts.

To generate your report, configure the remaining options in the dialog box; then click **Apply** (for *X–Y*, field output, or free body cut reports) or **OK** (for probe values reports). When you have finished, click **Cancel** to close the dialog box.

Additional information

• *Using tabular report options*
• *Formatting report values*
• *Understanding X–Y data interpolation and extrapolation*

Sorting field output data

For tabular field output reports you can choose to sort all of the data in the table according to the values in any single column of the table and you can choose to sort in either ascending or descending order.

You control which columns Abaqus/CAE includes in the table using the **Variable** options in the **Report Field Output** dialog box. (For more information, see *Selecting field output variables*.) The table has one column for each field output variable you have selected, and additional columns to identify the origin of the field output; for example, if your table includes unique nodal quantities Abaqus/CAE provides a **Node Label** (node number) column.

Negative element labels are used in the reports to distinguish internal elements created by Abaqus/CAE from elements that you created while defining the model. If your report includes internal elements and you choose to sort by element labels, these elements will be grouped at the top or bottom of your report.

For information on sorting the data in a tabular report of probe values, see *Entering tabular data*.

1. Locate the field output report sorting options.

   From the main menu bar, select **Report->Field Output**; then click the **Setup** tab in the dialog box that appears. The **Sort by** options are in the middle of the page.
2. Click the **Sort by** arrow to reveal the list of column choices.
3. Select the column to sort by from the list.
4. Click either **Ascending** or **Descending** to choose the order of the sort.

To generate your report, configure the remaining options in the dialog box; then click **Apply**. When you have finished, click **Cancel** to close the dialog box.

Additional information

- *Using tabular report options*

Formatting report values

You can specify the number of significant digits (for *X–Y* data reports, field output reports, and probe value reports) or the total number of decimal places (for free body cut reports) to present in your tabular data report. For *X–Y* data reports, field output reports, and probe value reports, the default number of significant digits is 6; for free body cut reports, the default number of decimal places is 3. More digits give greater precision but take more space and increase the width of the tables; the number of significant digits or decimal places used determines the width of each column in the table. In addition, you can select one of the following number formats for your data values:

Automatic

Very large values and very small values are expressed in scientific format. All remaining values are expressed with no exponent and using the specified number of significant digits. This format is available for *X–Y* data reports, field output reports, and probe value reports.

Engineering

Values greater than or equal to 1000 (or values less than or equal to 0.001) are expressed as a number ranging from 1 to 999 that is multiplied by 10 to the *n*th power, where *n* is a product of 3 (for example, `20.5E+03` or `17.76E+06`). All remaining values are expressed using the specified number of significant digits.

Fixed

All values are expressed without using exponent values. When you select this format, the number 501,000 is displayed in the legend as `501000.00`. This number format is available only for free body cut reports, and your legend values may be displayed differently if you change the **Decimal places** option.

Scientific

All values are expressed as a number between 1 and 10 that is multiplied by an appropriate power of 10 (for example, `2.05E+04` or `1.776E+07`).

The default format is **Engineering** for *X–Y* data reports, field output reports, and probe value reports and **Scientific** for free body cut reports.

1. Locate the **Output Format** options.

For a report of X–Y data or field output:

From the main menu bar, select**Report->XY** or **Report->Field Output**; then click the **Setup** tab in the dialog box that appears. The **Output Format** options are in the center of the page.

For a report of free body cuts:

From the main menu bar, select**Report->Free Body Cut**. The **Output Format** options are in the center of the page.

For a report of probe values:

From the main menu bar, select**Tools->Query**, then click **Probe values** in the dialog box that appears. The **Probe Values** dialog box appears.

Move the cursor to probe the model or *X–Y* plot in the current viewport, then click mouse button 1 to store values of interest in the dialog box. When you are finished, click **Write to File**. The

Report Probe Values dialog box appears; the **Output Format** options are in the center of the dialog.

2. Specify the precision level for numerical values in the report:

   - For *X*–*Y*, field output, or probe value reports, specify this value in the **Number of significant digits** text field.
   - For free body cut reports, enter this value in the **Decimal places** text field.

   You can also click the arrows next to the applicable field until the desired number appears.

3. Click the **Number Format** button, and select the number format of your choice from the list that appears.

To generate your report, configure the remaining options in the dialog box; then click **Apply** (for *X*–*Y*, field output, or free body cut reports) or **OK** (for probe values reports). When you have finished, click **Cancel** to close the dialog box.

Additional information

• *Using tabular report options*

Reporting data values, minimums, maximums, and totals

You have the option to include minimum and maximum value summaries or column totals in reports.

For tabular reports of *X–Y* data or field output, you can include or suppress *X–Y* data or field output values, column minimum and maximum value summaries, and column totals. By default, Abaqus/CAE includes only the actual data values in reports of *X–Y* data. In reports of field output values, Abaqus/CAE includes by default the data values as well as column summaries and totals.

For tabular reports of probe values, Abaqus/CAE always includes the actual data values in the report. You can include or suppress column minimum and maximum value summaries and column totals for any columns in which such values would be meaningful.

1. Locate the **Data** or **Data Values** options.

For a report of X–Y data or field output:

From the main menu bar, select**Report->XY** or **Report->Field Output**; then click the **Setup** tab in the dialog box that appears. The **Data** options are at the bottom of the page.

For a report of probe values:

From the main menu bar, select**Tools->Query**, then click **Probe values** in the dialog box that appears. The **Probe Values** dialog box appears.

Move the cursor to probe the model or *X–Y* plot in the current viewport, then click mouse button 1 to store values of interest in the dialog box. When you are finished, click **Write to File**. The **Report Probe Values** dialog box appears; the **Data Values** options are at the bottom of the dialog box.

2. For *X–Y* data reports or field output reports, you must choose one or more of the following items to include in your report. If you generate field output reports in comma-separated value (CSV) format, the options to include column totals and to include a summary of the minimum and maximum values are unavailable.
   - Toggle **XY data** or **Field output** to include the actual *X–Y* data or field output values, respectively. Toggling this option off results in a report that consists of only the column total or min/max data you request.
   - Toggle **Column totals** to include totals for each column.
   - Toggle **Column min/max** to include a summary of the minimum and maximum value occurring in each column.

To generate your report, configure the remaining options in the dialog box; then click **Apply** (for *X–Y* reports or field output reports) or **OK** (for probe values reports). When you have finished, click **Cancel** to close the dialog box.

Additional information

• *Using tabular report options*

Customizing plot display

This chapter explains how to customize the appearance of your plots by selecting various plot state–dependent and plot state–independent options.

Using display groups to display subsets of your model and *Overlaying multiple plots* describe additional ways to customize the display of your model in the viewport.

In this section:

- *Selecting plot display options*
- *Customizing render style, translucency, and fill color*
- *Customizing element and surface edges*
- *Customizing model shape*
- *Customizing model labels*
- *Displaying multiple plot states*
- *Displaying element and surface normals*
- *Customizing the appearance of display bodies*
- *Customizing camera movement*
- *Controlling the display of model entities*
- *Controlling the display of constraints in the Visualization module*
- *Customizing general model display*

Selecting plot display options

You can customize how your model appears in undeformed, deformed, contour, symbol, and material orientation plots.
For the undeformed and deformed plot states, all of the customization options applied to the model shape are plot state–independent. That is, Abaqus/CAE applies the customizations to all undeformed and deformed plots, including those that also display contours, symbols, or material orientations. The plot state–independent options govern the render style and fill color; element and surface edges; element colors; the appearance of model labels, node symbols, and display bodies; the movement of the camera; the display of various model entities; the smoothness of curved edges; the color of elements with no results; and model sweeping and extrusion. Use the **Options** menu in the main menu bar to choose from these plot state–independent customization options.

Select **Tools->Color Code** from the main menu bar to color individual elements. Select **Options->Display Body** from the main menu bar to customize the appearance of all display bodies in your model. Select **View->View Options** from the main menu bar to customize the movement of the camera. To choose from the remaining plot state–independent options, select **View->ODB Display Options** from the main menu bar. If you choose to superimpose the deformed model shape on the undeformed shape for the same plot state, select **Options->Superimpose** from the main menu bar to customize the undeformed shape independently from the deformed shape. Like the other plot state–independent customizations, these plot options are applied to superimposed plots in all plot states.

Note:

Displaying model labels and/or symbols in the viewport can increase the amount of time needed to refresh the display for plots and animations.

In addition to the plot state–independent customization options, you can select plot state–dependent options for the contour, symbol, and material orientation plot states. The plot state–dependent options are unique to each plot type. For example, you can customize the contour color spectrum, the size and style of symbols, and the display of material orientation triad axes. If a similar customization such as the color of model edges in the common and contour plot options can be made using both independent and dependent plot options, the plot state–dependent option overrides the independent option.

In this section:

- *Saving customizations for use in subsequent sessions*
- *Available customization options*

Saving customizations for use in subsequent sessions

By default, plot display customizations persist for the current session only, but you can save customizations to a file if you want to apply them to subsequent sessions. Abaqus/CAE offers the following methods to retain plot display customizations:

Saving customizations to the display options file

Select **File->Save Display Options** from the main menu bar to save all your plot state–dependent and plot state–independent customization options as display options. Display options are stored in a file called `abaqus_2026.gpr`, and Abaqus/CAE loads the settings in this file automatically upon startup as the new default settings throughout your session. For plot state customization, saving your display options to a file enables you to store settings such as the render style, the visibility of prescribed conditions and the various types of datum geometry, and the display of mesh, element, and node labels.

For more information, see *Saving your display options settings*.

Saving customizations to an XML file, model database, or output database

Select **File->Save Session Objects** from the main menu bar to save selected plot state–dependent and plot state–independent customization options to an XML file, the model database, or an output database. When you use this method, you can save all the customization options or you can save just the customization options related to one or more plot states. For example, you can save customizations you make in the common plot options and in the contour plot options to a file.

If you save customizations to a model database or an output database, those settings are used when you open the file. When you load customizations from an XML file, these customizations become the new settings for your session. You can load settings from a file by selecting **File->Load Session Objects**.

For more information, see *Managing session objects and session options*.

Available customization options

Many options are available to customize how your model appears in undeformed, deformed, contour, symbol, and material orientation plots.

Abaqus/CAE provides the following customization options:

Render style

Render style is the style in which Abaqus/CAE displays your model. Render style is a plot state–independent option; that is, you set it once for all undeformed, deformed, contour, symbol, and material orientation plots. However, you can set a different value of render style for use with the undeformed shape in a superimposed plot. Render style choices include wireframe, filled, hidden, and lightsource-shaded. For more information, see *Customizing render style, translucency, and fill color*.

Element and surface edge style and visibility

Edge style is the line style and thickness of element and surface edges; edge visibility is the extent to which Abaqus/CAE displays these edges. Edge style and visibility options are plot state–independent, but you can set them differently for use with the undeformed shape in a superimposed plot. For more information, see *Customizing element and surface edges*.

Element and surface edge color

You can control the overall color of element and surface edges using the plot state–independent **Color & Style** options. In addition, you can customize the edge color of individual elements and surfaces using the plot state–independent **Color Code** dialog box. By default, the color code selections override the overall colors. For more information on overall edge coloring, see *Selecting overall element and surface edge color*. To learn more about individual item edge coloring, see *Customizing the display color of individual objects*. Individual item edge coloring applies only to wireframe and hidden render style plots.

Element face and surface fill color

You can control the overall fill color of element faces and surfaces using the plot state–independent **Color & Style** options. In addition, you can customize the face color of individual elements using the plot state–independent **Color Code** dialog box. By default, the color code selections override the overall colors. For more information on overall fill color, see *Selecting overall fill color*. To learn more about individual item color filling, see *Customizing the display color of individual objects*. Individual item fill coloring applies only to filled and shaded render style plots.

Model labels and node symbols

You can change the visibility and customize the color and font of element, node, and face labels and the color and style of node symbols. All these options are plot state–independent. For more information, see *Customizing model labels*.

Element and surface normals

You can choose to display arrows representing the element or surface normals in the model. The arrows are visible in all plot states, and you can control the arrow size, color, and arrowhead style. For more information, see *Displaying element and surface normals*.

Display body appearance

You can customize the render style; edge visibility, color, and style; fill color; scaling; and translucency for all display bodies in your model. These options are plot state–independent when applied to display bodies. For more information, see *Customizing the appearance of display bodies*.

Camera movement

You can select a coordinate system and match the motion of that coordinate system with the camera. You can also make the camera follow the rotation of the selected coordinate system. If you are using the camera in movie mode, you can also position the camera in the model at the origin of the coordinate system. For more information, see *Customizing camera movement*.

Entity display

You can control the display of symbols representing various model entities, including boundary conditions, connectors, coordinate systems, and point elements. Entity display options are plot state–independent. For more information, see *Controlling the display of model entities*.

Constraints display

You can control the display of analysis constraints that were applied in the Interaction module; for example, tie constraints or kinematic coupling constraints. For more information, see *Controlling the display of constraints in the Visualization module*.

General model display options

Abaqus/CAE offers several other plot state–independent general model display options. These options include:

- **Sweep/Extrude** to control the three-dimensional display of two-dimensional models. For more information, see *Sweeping and extruding your model*.
- **Mirror/Pattern** to simulate the display of a complete model when only a representative portion of the model was analyzed. For more information, see *Using mirrors and patterns to display your results*.
- **Curved Lines & Faces** to control how quadratic and cubic element edges and faces are displayed. For more information, see *Refining curved edges and faces*.
- **Elements with No Results** to control the color of elements having no results (for example, rigid surfaces) in contour plots. For more information, see *Coloring elements with no results*.
- **Idealizations** to control the display of beam profiles, shell thickness, and thermal fluid pipe elements. For more information, see *Controlling beam profile display for postprocessing* and *Controlling shell thickness display for postprocessing*, and *Controlling the display of thermal fluid pipe elements*.
- **Model Change** to control the visibility of components deactivated by model change interactions. For more information, see *Viewing removed elements*.

Customizing render style, translucency, and fill color

This section explains how to customize the render style, translucency, and fill color of your model.

In this section:

- *Choosing a render style*
- *Customizing translucency*
- *Selecting overall fill color*

Choosing a render style

Render style is the style in which Abaqus/CAE displays your model. Render style is plot state–independent; that is, you set it once for all undeformed, deformed, contour, symbol, and material orientation plots.

You can also set a second render style that Abaqus/CAE will apply to the undeformed shape when the deformed shape is superimposed on it.  Possible render styles are **Wireframe**, **Hidden**, **Filled**, and **Shaded**; these styles are shown in *Figure 1*. An explanation of these choices follows.

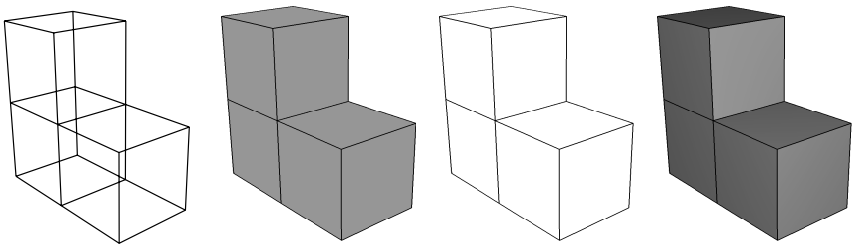

Figure 1: Model showing render style options. From left to right: the wireframe, filled, hidden, and lightsource-shaded render styles.

Wireframe

Displays model edges; both interior and exterior edges are potentially visible. Wireframe plots produce a frame-like visual effect in which model faces are not displayed.

Filled

Displays model faces “painted” in a uniform color. Filled plots produce a solid rather than frame-like appearance in which only exterior faces are visible.

Hidden

Displays a wireframe plot in which edges obscured by the model are not visible. Hidden plots produce a solid rather than frame-like appearance.

Shaded

Displays a filled plot in which a light source appears to be directed at the model. Shaded plots produce a highly three-dimensional visual effect.

1. Locate the common or superimposed **Render Style** options. The common render style always applies to the deformed shape; it applies to the undeformed shape when it is plotted individually in any plot state (undeformed, contour, symbol, or material orientation). When the undeformed shape is plotted with the deformed shape, the superimpose render style applies.

   From the main menu bar, select **Options->Common** or **Superimpose**; then click the **Basic** tab in the dialog box that appears. The **Render Style** options become available.

2. From the **Render Style** list, select the render style that you want.

   Tip: You can also select the render style for the current plot state (excluding display bodies and the undeformed shape when it is superimposed) by clicking the wireframe , hidden , filled , or shaded  icons located in the Render Style toolbar.

   Note:

   Symbol and material orientation plots in the shaded, filled, and hidden render styles are easier to view if you activate *translucency*.

3. Click **Apply** to implement your changes.

   The render style changes to reflect your specification.

   By default, your changes are saved for the duration of the session and will affect all subsequent plots in the current viewport and in any new viewports created from the current viewport. If you want to retain the changes you applied for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

Additional information

- *Customizing translucency*
- *Choosing a render style*

Customizing translucency

Translucency options control the degree of transparency of your model, and they apply to plots in all render styles except wireframe. Translucency is plot state–independent; that is, you set it once for all undeformed, deformed, contour, symbol, and material orientation plots. You can also set the translucency that Abaqus/CAE will apply to the undeformed shape when the deformed shape is superimposed on it.

For shaded symbol and material orientation plots, symbol plot arrows and material orientation triads located in the interior of the model are easier to view if you turn on translucency.

1. Locate the common or superimposed **Translucency** options. The common translucency setting always applies to the deformed shape; it applies to the undeformed shape when it is plotted individually in any plot state (undeformed, deformed, contour, symbol, or material orientation). When the undeformed shape is plotted with the deformed shape, the superimpose translucency style applies.

   From the main menu bar, select **Options->Common** or **Superimpose**. Click the **Other** tab in the dialog box that appears; then click the **Translucency** tab. The **Translucency** options appear.

2. Toggle on **Apply translucency** to activate the translucency options.
3. Choose the percentage of translucency.

   Drag the slider to the percentage of translucency that you want. A value of .00 indicates transparent plotting; 1.00 indicates opaque plotting. The default translucency is .30.

4. Click **Apply** to implement your changes.

   The translucency changes to reflect your specifications.

   By default, your changes are saved for the duration of the session and will affect all subsequent plots in the current viewport and in any new viewports created from the current viewport. If you want to retain the changes you applied for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

Additional information

- *Customizing render style, translucency, and fill color*
- *Coloring elements with no results*

Selecting overall fill color

Fill color is the color in which Abaqus/CAE displays your model faces. This color is plot state–independent; that is, you set it once for all undeformed, deformed, symbol, and material orientation plots. You can also set the fill color that Abaqus/CAE will apply to the undeformed shape when the deformed shape is superimposed on it. Fill color applies to filled and lightsource-shaded *render style* plots only; it is not applicable to contour plots.

You can choose one display color for your entire model, or you can optionally override this display color for selected items, such as particular elements. For example, you can display your model in green, with a group of elements shown in red. For more information on individual item coloring, see *Customizing the display color of individual objects*.

1. Locate the common or superimposed fill color options. The common fill color always applies to the deformed shape; it applies to the undeformed shape when it is plotted individually in any plot state (undeformed, deformed, symbol, or material orientation). When the undeformed shape is plotted with the deformed shape, the superimpose fill color applies.

   From the main menu bar, select **Options->Common** or **Superimpose**; then click the **Color & Style** tab in the dialog box that appears.

   The **Fill color in filled/shaded plots** options are in the center of the **Color & Style** page.

2. Choose the fill color:

   a. Click the **Fill color in filled/shaded plots** color sample .

      Abaqus/CAE displays the **Select Color** dialog box.

   b. Use one of the methods in the **Select Color** dialog box to select a new color. For more information, see *Customizing colors*.

   c. Click **OK** to close the **Select Color** dialog box.

      The color sample changes to the selected color. The new color does not appear in the viewport until you click **OK** or **Apply** in the **Plot Options** dialog box.

3. Toggle **Allow color code selections to override options in this dialog** off to display all elements in the fill color specified above. Toggle it on to override this color using individual item color selections. The default is on. For more information, see *Customizing the display color of individual objects*.

4. Click **Apply** to implement your changes.

   The fill color changes to reflect your specifications.

   By default, your changes are saved for the duration of the session and will affect all subsequent plots in the current viewport and in any new viewports created from the current viewport. If you want to retain the changes you applied for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

Customizing element and surface edges

This section explains how to customize the appearance of element and surface edges in your model.

In this section:

- *Controlling element and surface edge visibility*
- *Defining model feature edges*
- *Selecting overall element and surface edge color*
- *Customizing element and surface edge style*

Controlling element and surface edge visibility

You can control the extent to which Abaqus/CAE displays element and surface edges. Edge visibility is plot state–independent; that is, you set it once for all undeformed, deformed, symbol, and material orientation plots. You can also set the edge visibility that Abaqus/CAE will apply to the undeformed shape when the deformed shape is superimposed on it. The following choices are available to control edge display: **All edges**, **Exterior edges**, **Feature edges**, **Free edges**, and **No edges**. The first four options are shown in *Figure 1*.

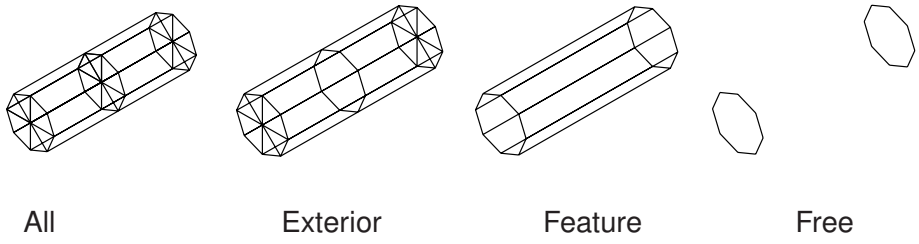

Figure 1: Model showing edge display options.

Note:

If your output database includes both homogeneous solid elements and either composite solid elements or continuum shell elements, Abaqus/CAE displays a free edge or a feature edge at the boundary between the homogeneous solid geometry and the composite geometry or continuum shell geometry.

1. Locate the common or superimposed **Visible Edges** options. The common visible edges setting always applies to the deformed shape; it applies to the undeformed shape when it is plotted individually in any plot state (undeformed, deformed, contour, symbol, or material orientation). When the undeformed shape is plotted with the deformed shape, the superimpose visible edges setting applies.

   From the main menu bar, select **Options->Common** or **Superimpose**; then click the **Basic** tab in the dialog box that appears. The **Visible Edges** options are on the right side of the **Basic** page.

2. To choose the element and surface edges you want to display, click one of the following:

All edges

Displays all element and surface edges. To see element edges on the interior of the model, you must also set the *render style* to wireframe.

Exterior edges

Displays only edges on the exterior of the model.

Feature edges

Displays only edges on the exterior of the model that are calculated to be feature edges. Feature edges lie between elements that have normals that differ by more than the “feature angle.” The feature angle is set in the **View->ODB Display Options->General** dialog box; for more information, see *Defining model feature edges*.

Free edges

Displays only edges that belong to a single element. Free edge display is particularly useful for locating potential holes or cracks in your mesh.

No edges

Suppresses the display of all edges. This choice is available only for plots in the *filled or shaded* render styles.

Note:

When elements are duplicated (i.e., share all the same corner nodes), Abaqus/CAE will not display the element edges in a free or feature edge plot.

3. Click **Apply** to implement your changes.

   The edge visibility changes according to your specification.

   Your changes are saved for the duration of the session and will affect all subsequent plots in the current viewport and in any new viewports created from the current viewport.

   By default, your changes are saved for the duration of the session and will affect all subsequent plots in the current viewport and in any new viewports created from the current viewport. If you want to retain the changes you applied for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

Additional information

- *Defining model feature edges*
- *Selecting overall element and surface edge color*
- *Customizing element and surface edge style*
- *Controlling edge visibility*

Defining model feature edges

The common and superimposed plot options determine which model edges appear in all plot states. When you specify that only feature edges are to be visible, Abaqus/CAE determines which edges meet this criteria. Feature edges lie between elements having normals that differ by more than the “feature angle.”You can customize the feature angle. Larger angles will reduce the number of feature edges; conversely, smaller angles will cause more edges to be visible. The default is 20°. The setting of the feature angle applies to all plot states. However, all segment edges are drawn for analytical rigid surfaces regardless of the feature angle setting.

In *Figure 1* the plot on the left shows feature edges when the feature angle is set to 0°, the plot in the middle shows feature edges on the same model but with the feature angle set to 15°, and the plot on the right shows the model with the feature angle set to 30°.

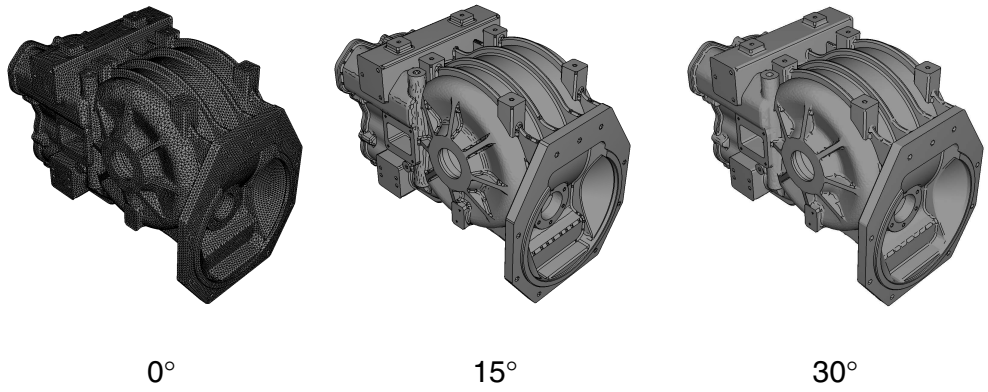

Figure 1: Plots showing feature angles of 0°, 15°, and 30°.

1. Locate the **Feature Angle** options.

   From the main menu bar, select **View->ODB Display Options**. Click the **General** tab in the dialog box that appears. The **Feature Angle** options are at the bottom of the **General** page.
2. Drag the **Feature Angle** slider to the desired feature angle.
3. Click **Apply** to implement your changes.

   Feature edges for all plot states change to reflect your feature angle specification. By default, your feature angle specification is saved for the duration of the session. If you want to retain this change for subsequent sessions, save it to a file. For more information, see *Saving customizations for use in subsequent sessions*.

Additional information

- *Controlling element and surface edge visibility*
- *Defining mesh feature edges*

Selecting overall element and surface edge color

You can customize the color in which Abaqus/CAE displays element and surface edges. With the exception of contour plots, edge color is plot state–independent; that is, you set it once for all undeformed, deformed, symbol, and material orientation plots. You can choose a different edge color for certain *render styles*, and you can set the edge color that Abaqus/CAE will apply to the undeformed shape when the deformed shape is superimposed on it. For contour plots you can choose a different edge color for certain *contour types*.

You can choose one display color for your entire model, or you can optionally override this display color for selected items, such as particular elements. For example, you can display your model in green, with a group of elements shown in red. For more information on individual item coloring, see *Customizing the display color of individual objects*.

1. Locate the edge color options (common, superimposed, or contour) that you want to customize.

   - For all plots except superimposed and contour plots:

     From the main menu bar, select**Options->Common**; then click the **Color & Style** tab in the dialog box that appears.

     The **Color** options are at the top of the **Color & Style** page.

   - For contour plots:

     From the main menu bar, select**Options->Contour**; then click the **Color & Style** tab in the dialog box that appears. Click the **Model Edges** tab.

   - For the undeformed shape in a superimposed plot:

     From the main menu bar, select**Options->Superimpose**; then click the **Color & Style** tab in the dialog box that appears.

     The **Color** options are at the top of the **Color & Style** page.

2. Choose the color of the element and surface edges for wireframe and hidden render style plots and line-type contours. (For all of these plots Abaqus/CAE does not display model faces.)

   a. Click the color sample , which is labeled either **Edges in wireframe/hidden plots** or **In line plots**.

      Abaqus/CAE displays the **Select Color** dialog box.

   b. Use one of the methods in the **Select Color** dialog box to select a new color. For more information, see *Customizing colors*.

   c. Click **OK** to close the **Select Color** dialog box.

      The color sample changes to the selected color. The new color does not appear in the viewport until you click **OK** or **Apply** in the **Plot Options** dialog box.

3. Choose the color of the element and surface edges for filled and shaded render style plots and banded- and quilt-type contour plots. (For all of these plots Abaqus/CAE displays model faces.)

   a. Click the color sample , which is labeled either **Edges in filled/shaded plots** or **In banded/quilt plots**.

      Abaqus/CAE displays the **Select Color** dialog box.

   b. Use one of the methods in the **Select Color** dialog box to select a new color. For more information, see *Customizing colors*.

   c. Click **OK** to close the **Select Color** dialog box.

      The color sample changes to the selected color. The new color does not appear in the viewport until you click **OK** or **Apply** in the **Plot Options** dialog box.

4. Toggle **Allow color code selections to override options in this dialog** off to display all edges in the color specified above. Toggle it on to override this color using color code selections. The default is on. This option is not available for contour plots.
5. Click **Apply** to implement your changes.

   The edge color changes according to your specification. If you specify an edge color for wireframe, hidden, or line plots that is the same color as the viewport background, Abaqus/CAE draws the edges in a contrasting color so that your plot will not disappear. Edges drawn in the viewport background color in filled or shaded plots may obscure the corresponding model faces if you zoom out or if the faces are so small that the edges begin to overlap.

   By default, your changes are saved for the duration of the session and will affect all subsequent plots in the current viewport and in any new viewports created from the current viewport. If you want to retain the changes you applied for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

Additional information

- *Controlling element and surface edge visibility*
- *Customizing element and surface edge style*
- *Choosing background colors*

Customizing element and surface edge style

You can customize the style and thickness in which Abaqus/CAE displays element and surface edges.

For example, *Figure 1* shows a plot with default element edges on the left and customized edges on the right. Edge style options are plot state–independent; that is, you set them once for all undeformed, deformed, symbol, and material orientation plots. You can also set the edge style options that Abaqus/CAE will apply to the undeformed shape when the deformed shape is superimposed on it.

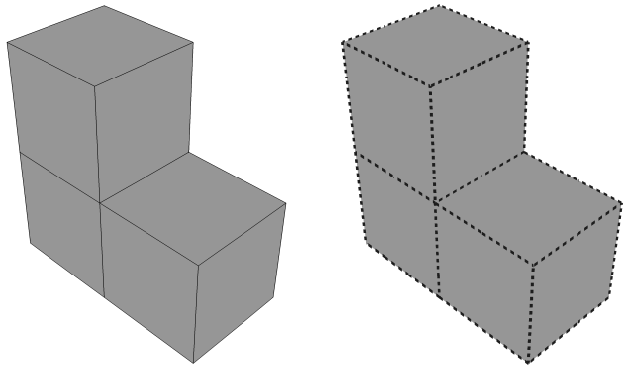

Figure 1: Models showing default and customized element edges.

1. Locate the common or superimposed **Edge Attributes** options. The common edge attributes always apply to the deformed shape; they apply to the undeformed shape when it is plotted individually in any plot state (undeformed, deformed, contour, symbol, or material orientation). When the undeformed shape is plotted with the deformed shape, the superimpose edge attributes apply.

   From the main menu bar, select **Options->Common** or **Superimpose**. Click the **Other** tab in the dialog box that appears; then click the **Color & Style** tab in the dialog box that appears.

   The **Edge Attributes** options are at the bottom of the **Color & Style** page.

2. Choose the style of the element and surface edges:
   a. Click the **Style** button to reveal the edge style options.
   b. Click the edge style you want.

      The specified edge style appears on the **Style** button.

3. Choose the thickness of the element and surface edges:
   a. Click the **Thickness** button to reveal the edge thickness options.
   b. Click the edge thickness you want.

      The specified edge thickness appears on the **Thickness** button.

4. Click **Apply** to implement your changes.

   The element and surface edge style changes according to your specification.

   By default, your changes are saved for the duration of the session and will affect all subsequent plots in the current viewport and in any new viewports created from the current viewport. If you want to retain the changes you applied for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

Additional information

- *Controlling element and surface edge visibility*
- *Selecting overall element and surface edge color*

Customizing model shape

This section explains how to customize the shape of your model.

In this section:

- *Scaling deformations*
- *Scaling coordinates and shrinking the model*

Scaling deformations

Deformations are the values of a deformed field output variable; for example, displacement or velocity. Abaqus/CAE computes the deformed shape by applying the deformations to the undeformed nodal coordinates. You can scale the deformations to magnify, reduce, or otherwise distort the deformed model shape. For example, *Figure 1* displays a deformed shape contour plot on the left and the same plot with the deformation magnified 15 times on the right.

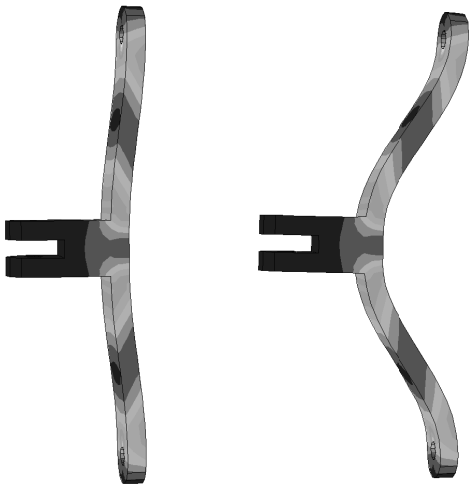

Figure 1: Contour plots showing default and magnified deformation values.

Deformation scaling is plot state–independent; that is, you set it once for the deformed shape in all deformed, contour, symbol, and material orientation plots. The default scaling is a uniform factor of 1.00 for large-displacement analyses. For small-deformation analyses—for example, a perturbation analysis—Abaqus/CAE scales the deformation such that the maximum deformation is 10% of the largest model dimension.

1. From the main menu bar, select **Options->Common**. Click the **Basic** tab in the dialog box that appears. The **Deformation Scale Factor** options are in the lower left corner of the **Basic** page.
2. Choose one of the following scale factor options:
   - Click **Auto-compute** to request that Abaqus automatically compute and uniformly apply a single scale factor to all *X*-, *Y*-, and *Z*-components of deformation values.
   - Click **Uniform** to specify and uniformly apply a single scale factor to all *X*-, *Y*-, and *Z*-components of deformation values.

     When **Uniform** is on, a **Value** specification box becomes available. Click the **Value** box, and enter your scale factor.
   - Click **Nonuniform** to specify individual scale factors to be applied to the *X*-, *Y*-, and *Z*-components of deformation values.

     When **Nonuniform** is on, **X**-, **Y**-, and **Z**-component scale factor specification boxes become available. For each component you want to scale, click the component (**X**, **Y**, or **Z**) scale factor box and enter your scale factor.
3. Click **Apply** to implement your changes.

   The deformed shape changes according to your specification. The *state block*, if active, changes to show the current deformation scale factors.

Your changes are saved for the duration of the session and will affect all subsequent deformed shape plots.

By default, your changes are saved for the duration of the session and will affect all subsequent deformed shape plots. If you want to retain the changes you applied for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

Additional information

• *Scaling coordinates and shrinking the model*

Scaling coordinates and shrinking the model

You can magnify, reduce, or otherwise distort the shape of your model by scaling, and you can shrink each element about its centroid. Scaling modifies all nodal coordinates in each of the *X*-, *Y*-, and *Z*-directions. Shrinking reduces each element in size uniformly about its centroid. For example, the elements shown in *Figure 1* have been shrunk by a factor of 0.40.

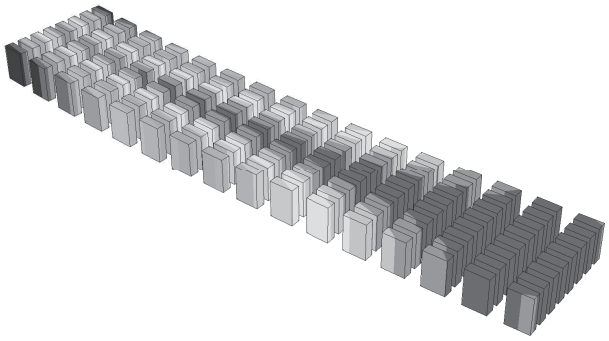

Figure 1: Elements showing the effect of shrinking.

Scaling and shrinking options are plot state–independent; that is, you set them once for all undeformed, deformed, contour, symbol, and material orientation plots. You can also set the scaling and shrinking options that Abaqus/CAE will apply to the undeformed shape when the deformed shape is superimposed on it.

1. Locate the common or superimposed **Scaling** options. The common scaling options always apply to the deformed shape; they apply to the undeformed shape when it is plotted individually in any plot state (undeformed, deformed, contour, symbol, or material orientation). When the undeformed shape is plotted with the deformed shape, the superimpose scaling options apply.

   From the main menu bar, select **Options->Common** or **Superimpose**; then click the **Other** tab in the dialog box that appears. Click the **Scaling** tab; the **Scaling** options appear.

2. Toggle **Shrink elements** to request or suppress shrinking each element about its centroid.
   a. When **Shrink elements** is on, the shrink **Factor** slider becomes available.
   b. Drag the **Factor** slider to the desired shrink factor.

      A value of 0.00 indicates no shrinking. A value of 0.90 shrinks all elements to dots.

3. Toggle **Scale coordinates** to request or suppress model scaling by nodal coordinate *X*-, *Y*-, and *Z*-directions.
   a. When **Scale coordinates** is on, scale factors become available. Click the **X**, **Y**, and **Z** boxes to enter scale factors for the *X*, *Y*, and *Z* nodal coordinates, respectively.

4. Click **Apply** to implement your changes.

   The model display changes according to your specification.

   By default, your changes are saved for the duration of the session and will affect all subsequent plots in the current viewport and in any new viewports created from the current viewport. If you want to retain the changes you applied for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

Additional information

• *Scaling deformations*

Customizing model labels

This section explains how to customize the appearance of element labels, face labels, node labels, and node symbols for undeformed, deformed, contour, symbol, and material orientation plots.

In this section:

- *Setting the label font*
- *Customizing element labels*
- *Customizing face labels*
- *Customizing node labels*
- *Customizing node symbols*
- *Displaying nodal-averaged orientations*

Setting the label font

Abaqus/CAE uses a single font to display all element, face, and node labels. You can set the properties (family, size, boldness, italics) of this font for all plot states, and you can set them separately for use with the undeformed shape in a superimposed plot.

1. Locate the common or superimposed label font options. The common font options always apply to the deformed shape; they apply to the undeformed shape when it is plotted individually in any plot state (undeformed, deformed, contour, symbol, or material orientation). When the undeformed shape is plotted with the deformed shape, the superimpose label font options apply.

   From the main menu bar, select **Options->Common** or **Superimpose**; then click the **Labels** tab in the dialog box that appears. The font options are at the top of the **Labels** page.

2. Click **Set Font for All Model Labels**.

   The **Select Font** dialog box appears.

3. Use the **Select Font** dialog box to set the font properties that you want.
4. When you have set the desired font properties, click **OK**.

   The **Select Font** dialog box closes.

5. Click **Apply** to implement your changes.

   The element, face, and node labels change according to your specification.

   By default, your changes are saved for the duration of the session and will affect all subsequent plots in the current viewport and in any new viewports created from the current viewport. If you want to retain the changes you applied for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

Additional information

- *Customizing element labels*
- *Customizing face labels*
- *Customizing node labels*

Customizing element labels

Element labels are numeric labels (element numbers) that identify each element. For example, the elements are labeled in *Figure 1*.

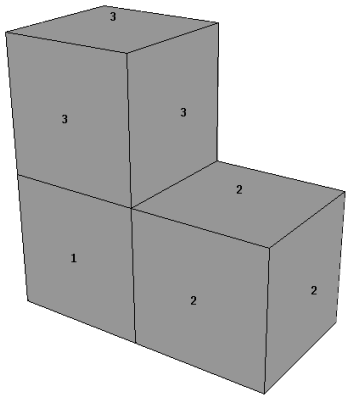

Figure 1: Model showing element labels.

Element labels are plot state–independent; that is, you set them once for all undeformed, deformed, contour, symbol, and material orientation plots. You can also set the element labels that Abaqus/CAE will display on the undeformed shape when the deformed shape is superimposed on it. Toggle **Show element labels** to display or suppress element labels and to choose their color.

1. Locate the common or superimposed element label options. The common element label options always apply to the deformed shape; they apply to the undeformed shape when it is plotted individually in any plot state (undeformed, deformed, contour, symbol, or material orientation). When the undeformed shape is plotted with the deformed shape, the superimpose element label options apply.

   From the main menu bar, select **Options->Common** or **Superimpose**; then click the **Labels** tab in the dialog box that appears.

2. Toggle **Show element labels** to display or suppress numeric element labels.

   When **Show element labels** is on, the element label color options become available.

3. Choose the color of the element labels:

   a. Click the color sample .

      Abaqus/CAE displays the **Select Color** dialog box.

   b. Use one of the methods in the **Select Color** dialog box to select a new color. For more information, see *Customizing colors*.

   c. Click **OK** to close the **Select Color** dialog box.

      The color sample changes to the selected color

4. Click **Apply** to implement your changes.

   The labels change according to your specification.

   By default, your changes are saved for the duration of the session and will affect all subsequent plots in the current viewport and in any new viewports created from the current viewport. If you want to

retain the changes you applied for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

Additional information

• *Setting the label font*

Customizing face labels

Face labels identify the order of faces within each element. For example, the faces are labeled in *Figure 1*.

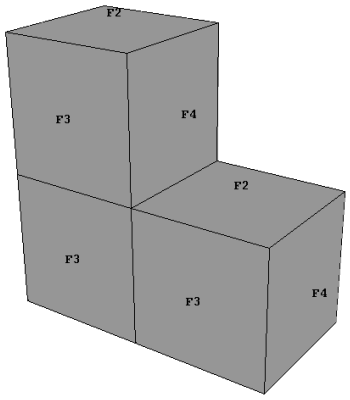

Figure 1: Model showing face labels.

Face labels are plot state–independent; that is, you set them once for all undeformed, deformed, contour, symbol, and material orientation plots. You can also set the face labels that Abaqus/CAE will display on the undeformed shape when the deformed shape is superimposed on it. Toggle **Show face labels** to display or suppress element labels and to choose their color.

1. Locate the common or superimposed face label options. The common face label options always apply to the deformed shape; they apply to the undeformed shape when it is plotted individually in any plot state (undeformed, deformed, contour, symbol, or material orientation). When the undeformed shape is plotted with the deformed shape, the superimpose face label options apply.

   From the main menu bar, select **Options->Common** or **Superimpose**; then click the **Labels** tab in the dialog box that appears.

2. Toggle **Show face labels** to display or suppress numeric face labels.

   When **Show face labels** is on, the face label color options become available.

3. Choose the color of the face labels:

   a. Click the color sample .

      Abaqus/CAE displays the **Select Color** dialog box.

   b. Use one of the methods in the **Select Color** dialog box to select a new color. For more information, see *Customizing colors*.

   c. Click **OK** to close the **Select Color** dialog box.

      The color sample changes to the selected color.

4. Click **Apply** to implement your changes.

   The labels change according to your specification.

   By default, your changes are saved for the duration of the session and will affect all subsequent plots in the current viewport and in any new viewports created from the current viewport. If you want to

retain the changes you applied for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

Additional information

• *Setting the label font*

Customizing node labels

Node labels are numeric labels (node numbers) identifying each node. For example, the nodes are labeled in *Figure 1*.

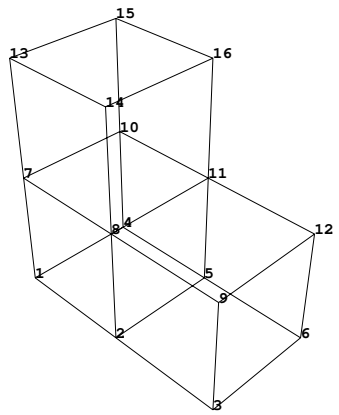

Figure 1: Model showing node labels.

Node labels are plot state–independent; that is, you set them once for all undeformed, deformed, contour, symbol, and material orientation plots. You can also set the node labels that Abaqus/CAE will display on the undeformed shape when the deformed shape is superimposed on it. Toggle **Show node labels** to display or suppress node labels and to choose their color.

1. Locate the common or superimposed node label options. The common node label options always apply to the deformed shape; they apply to the undeformed shape when it is plotted individually in any plot state (undeformed, deformed, contour, symbol, or material orientation). When the undeformed shape is plotted with the deformed shape, the superimpose node label options apply.

   From the main menu bar, select **Options->Common** or **Superimpose**; then click the **Labels** tab in the dialog box that appears.

2. Toggle **Show node labels** to display or suppress numeric node labels.

   When **Show node labels** is on, the node label color options become available.

3. Choose the color of the node labels:

   a. Click the color sample .

      Abaqus/CAE displays the **Select Color** dialog box.

   b. Use one of the methods in the **Select Color** dialog box to select a new color. For more information, see *Customizing colors*.

   c. Click **OK** to close the **Select Color** dialog box.

      The color sample changes to the selected color.

4. Click **Apply** to implement your changes.

   The labels change according to your specification.

   By default, your changes are saved for the duration of the session and will affect all subsequent plots in the current viewport and in any new viewports created from the current viewport. If you want to

retain the changes you applied for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

Additional information

• *Setting the label font*

Customizing node symbols

Node symbols (circles, squares, triangles, etc.) identify the location of each node. For example, filled circles are used to symbolize the nodes shown in *Figure 1*.

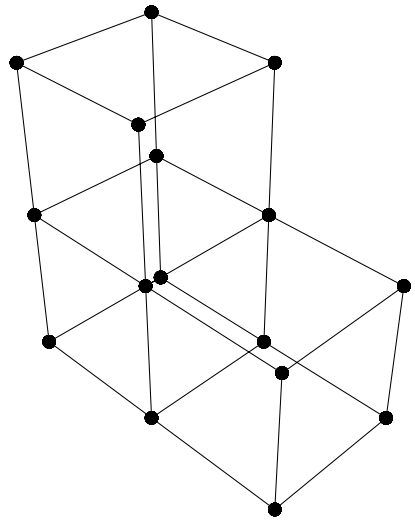

Figure 1: Model showing node symbols.

Node symbols are plot state–independent; that is, you set them once for all undeformed, deformed, contour, symbol, and material orientation plots. You can also set the node symbols that Abaqus/CAE will display on the undeformed shape when the deformed shape is superimposed on it. Toggle **Show node symbols** to display or suppress node labels and to choose their color.

1. Locate the common or superimposed node symbol options. The common node symbol options always apply to the deformed shape; they apply to the undeformed shape when it is plotted individually in any plot state (undeformed, deformed, contour, symbol, or material orientation). When the undeformed shape is plotted with the deformed shape, the superimpose node symbol options apply.

   From the main menu bar, select **Options->Common** or **Superimpose**; then click the **Labels** tab in the dialog box that appears.

2. Toggle **Show node symbols** to display or suppress node symbols.

   When **Show node symbols** is on, the node symbol color, type, and size options become available.

3. Choose the color of the node symbols:

   a. Click the color sample .

      Abaqus/CAE displays the **Select Color** dialog box.

   b. Use one of the methods in the **Select Color** dialog box to select a new color. For more information, see *Customizing colors*.

   c. Click **OK** to close the **Select Color** dialog box.

      The color sample changes to the selected color. The new color does not appear in the viewport until you click **OK** or **Apply** in the **Plot Options** dialog box.

4. Choose the type (circle, square, triangle, etc.) of the node symbols:

   a. Click the **Symbol** button to reveal the node symbol type options.

b. Click the symbol type you want.

The specified symbol type appears on the **Symbol** button.

5. Choose the size of the node symbols:

a. Click the **Size** button to reveal the node symbol size options.

b. Click **Small**, **Medium**, or **Large**.

The specified symbol size appears on the **Size** button.

6. Click **Apply** to implement your changes.

The symbols change according to your specification.

By default, your changes are saved for the duration of the session and will affect all subsequent plots in the current viewport and in any new viewports created from the current viewport. If you want to retain the changes you applied for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

Additional information

• *Customizing node labels*

Displaying nodal-averaged orientations

For line- and banded-type contour plots, element results are extrapolated and conditionally averaged from the element centroids or integration points to the nodes to create the plots. You can use the **Result Options** dialog box to control how Abaqus/CAE applies averaging to a model. One option allows you to compute invariants (scalars) and extract components after averaging the results at each node; when you choose to compute the results in this order, Abaqus/CAE applies the vector or tensor orientation from one of the adjacent elements as the orientation for each node. Under the **Other** tab of the **Contour Plot Options** dialog box, toggle **Show nodal-averaged vector/tensor orientations when computing scalars after averaging** to display or suppress the averaged orientations on the contour plot. When this option is enabled, Abaqus/CAE draws a triad at each node indicating the nodal-averaged orientation for the plotted vector or tensor. By default, the 1-axis appears in teal, the 2-axis appears in yellow, and the 3-axis appears in red. You can use the same procedures described in *Customizing material orientation plot triads*, to customize the appearance of these triads.

If you choose to compute scalars prior to averaging the results at the nodes, orientations are not averaged and do not appear in your contour plot.

Additional information

- *Selecting result options*

Displaying multiple plot states

In addition to superimposing the undeformed and deformed shape for a single plot state such as contour plots, you can choose to display multiple plot states in a viewport.

By toggling on **Allow Multiple Plot States**  in the toolbox, you can choose any combination of the undeformed and deformed plot shapes with contours, symbols, and material orientations for the selected step and frame of the current output database. Abaqus/CAE displays the deformed plots using the **Common Plot Options** and the undeformed plots using the **Superimposed Plot Options** in combination with the other plot state–independent and dependent options for each plot state.

If you toggle off **Allow Multiple Plot States**, Abaqus/CAE uses the following order in combination with the last plot states that were displayed to select the single plot state to display:

- Undeformed
- Deformed
- Contours
- Symbols
- Material Orientations

For example, if you display contours and material orientations, Abaqus/CAE retains the contour plot when you toggle off **Allow Multiple Plot States**. This is the same order that the plot states are listed in the **Plot** menu and displayed in the toolbox.

To display more complex plot combinations, you must use an **Overlay Plot**. Overlay plots allow you to display animations or *X*–*Y* plots along with the stationary plot states listed above. You can also use overlay plots to plot results from multiple steps, frames, or output databases. For more information, see *Overlaying multiple plots*.

Additional information

- *Using common plot options*
- *Superimposing deformed and undeformed model plots*

Displaying element and surface normals

When you create an undeformed or deformed plot, you can choose to display arrows in the plot that indicate the directions of the element or surface normals. You can display normal directions for beams, pipes, frame elements, contact surfaces, membranes, rigid elements, rigid surfaces, shells, three-dimensional solids, and trusses. (For information about normal directions for a particular type of element or surface, see *Abaqus Elements Guide*.)

1. Locate the common or superimposed normals options. The common normals options apply to the undeformed and the deformed shape when they are plotted individually. The superimpose normals options apply to the undeformed shape when it is plotted with the deformed shape.

   From the main menu bar, select **Options->Common** or **Superimpose**; then click the **Normals** tab in the dialog box that appears.

2. Toggle on **Show normals**.

   The **Normals** options become available.

3. Toggle on **On elements** to display the normals on elements in your model or **On surfaces** to display the normals on surfaces in your model.
4. In the area of the dialog box labeled **Colors**, select the colors in which you want the different types of normals to appear.
5. In the area of the dialog box labeled **Style**:
   a. Click the arrow next to the **Length** field, and select the arrow length of your choice. The default selection is **Medium**.
   b. Click the arrow next to the **Line Thickness** field, and select the arrow thickness of your choice.
   c. Click the arrow next to the **Arrowhead** field, and select the arrowhead style of your choice.
6. Click **Apply** to implement your changes.

   Arrows appear in the viewport that indicate the normal directions of the elements or surfaces in the model. In general, the arrows appear at the centroid of exterior element faces.

Customizing the appearance of display bodies

A display body is a part instance that does not take part in the analysis but is visible during postprocessing. You can customize the appearance of such part instances in your model using the **Display Body Options** in the Visualization module. The options available for display bodies are similar to those available for all of the plot states in Abaqus/CAE: render style; edge visibility, color, and style; fill color; scaling; and translucency can all be customized. Similar to the common plot options, display body options are plot state–independent; i.e., the options applied to display bodies are reflected in all plot states. Display body options apply to all display bodies in your model; to customize the appearance of individual display bodies, you can create display groups based on part instances (see *Creating or editing a display group*). Individual item coloring can also be applied to individual display body part instances to override the edge and/or fill colors specified as general display body options; see *Color coding geometry and mesh elements* for more information.

To locate the display body options, select **Options->Display Body** from the main menu bar. Click the following tabs to customize the appearance of all display bodies in the current viewport:

- **Basic**: Choose render style (*Choosing a render style*) and edge visibility (*Controlling element and surface edge visibility*).

  Note:

  The render style icons located in the Render Style toolbar do not apply to display bodies in any plot state. In addition, by default, only free edges are shown for display bodies while all exterior edges are shown for other model components.

- **Color & Style**: Control model edge color (*Selecting overall element and surface edge color*), model edge style (*Customizing element and surface edge style*), and model fill color (*Selecting overall fill color*).
- **Other**: The **Other** page contains the following tabs:
  - **Scaling**: Control model scaling and shrinking (*Scaling coordinates and shrinking the model*).
  - **Translucency**: Control shaded render style translucency (*Customizing translucency*).

Additional information

- *Defining display body constraints*
- *Display bodies*

Customizing camera movement

You can customize two groups of camera options in your model by using the **View Options** in the Visualization module, as shown in *Figure 1*.

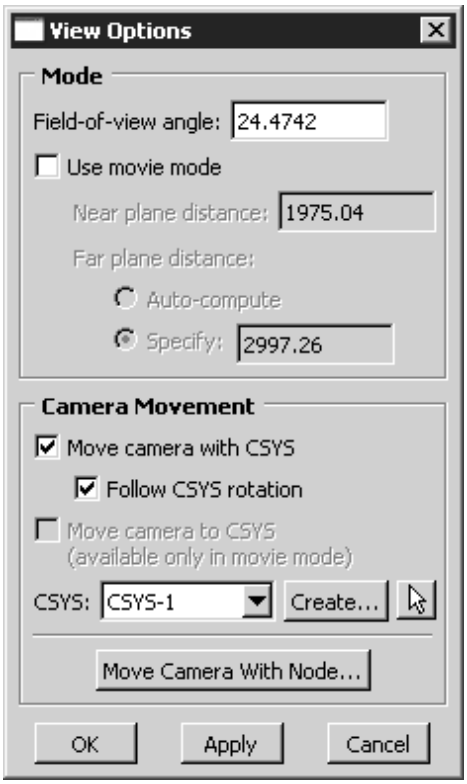

Figure 1: The View Options dialog box.

The **Mode** options are available in all Abaqus/CAE modules except the Sketch module; the **Mode** options are discussed in *Manipulating the view and controlling perspective* and are saved only for the current session. The **Camera Movement** options are available only in the Visualization module. They control the position and movement of the camera with respect to a selected local coordinate system. You can save the settings of the **Camera Movement** options by selecting **File->Save Options** from the main menu bar.

To locate the view options, select **View->View Options** from the main menu bar. To use the **Camera Movement** options, you must first toggle on **Move camera with CSYS**, then select a local coordinate system using one of the following methods:

- Select a coordinate system from the list provided in the dialog box,
- Click **Create** to create a new local coordinate system,
- Click  to pick a local coordinate system from the viewport, or
- Click **Move Camera With Node** or use the  button in the context bar to create a rectangular coordinate system following a single node.

Note:

To reset the camera to follow the global coordinate system, either toggle off **Move camera with CSYS** or click the  button in the context bar.

You can select from the following camera movement options:

Move camera with CSYS

Select this option to fix the origin of the selected coordinate system in the viewport. If you create an animation or change the ODB frame, Abaqus/CAE moves all objects in the viewport relative to the position of the selected local coordinate system. If the selected local coordinate system is not a moving coordinate system, you will not observe any difference from the default settings that fix the camera to the (stationary) global coordinate system.

If you select **Move camera with CSYS**, it is recommended that you pause any animation in the current viewport before attempting to manipulate the view.

Follow CSYS rotation

Select this option to fix both the position and the rotation of the local coordinate system in the viewport. All model rotations are transformed so that the model appears to rotate about the selected coordinate system. This option is available only when **Move camera with CSYS** is toggled on.

Move camera to CSYS

This option is available only when **Use movie mode** and **Move camera with CSYS** are toggled on. **Use movie mode** allows the camera to move into and through the model instead of viewing the model from a distance (for more information, see *Camera modes and view terminology*). When you apply **Move camera to CSYS**, the camera moves to the origin of the selected coordinate system. Abaqus/CAE toggles this option off immediately after you click **Apply** in the **View Options** dialog box to avoid conflicts with the view manipulation tools, some of which also reposition the camera.

Note: When you apply **Move camera to CSYS**, Abaqus/CAE may display a blank view in the viewport. The most common cause for this blank view is the **Near plane distance** setting; apply a smaller **Near plane distance** to view portions of the model that are close to the camera.

Warning: If you pan, rotate, or magnify the view in the Visualization module, it is recommended that you first pause any animations in the viewport. Since animations and view manipulations both affect the view, their instructions to Abaqus/CAE may conflict with each other and create undesirable results.

Additional information

- *Understanding camera modes and view options*
- *Creating coordinate systems during postprocessing*

Controlling the display of model entities

The **Entity Display** options in the **ODB Display Options** dialog box allow you to control the display of symbols. The displayed symbols represent the following entities in your model:

- boundary conditions applied during the analysis,
- connectors used in the model (the highlighting of endpoints, the display of local orientation axes associated with each connector, and the display of connector type labels can be controlled individually),
- coordinate systems written to the current output database or created in the Visualization module during the current session, and
- point elements, including reference points, mass and inertia elements, springs and dashpots, spot welds and distributing coupling (DCOUP*) elements, tracer particles, continuum particle elements, discrete particle elements, and rendering of particle element edges.

Model entity display is plot state–independent. Abaqus/CAE displays model entity symbols for the current *step and frame* of your output database. You can customize the appearance of the model entity symbols in the Visualization module only by changing their size.

For information on the symbols representing boundary conditions, see *Understanding symbols that represent prescribed conditions*; for information on the symbols representing connectors, see *Understanding symbols that represent interactions, constraints, and connectors*. For information on controlling the display of these entities in assembly-related modules, see *Controlling the display of attributes*.

Tip: You can also control the display of connectors using display groups; each connector is listed as an element set. See *Creating or editing a display group* for more information on display groups.

The render particle element edges option allows the display of symbols for particle element edges. You can use Wireframe, Hidden, and Filled render style options for particle elements.

Only session coordinate systems and reference points are displayed by default. The display of model entities can affect performance significantly. To maximize the performance of Abaqus/CAE, be selective about the entities you choose to display.

1. From the main menu bar, select **View->ODB Display Options**. Click the **Entity Display** tab in the dialog box that appears.

   The entity display options become available.

2. Toggle the entities that you want to display. Only the entities that you select (if they have been defined for the current model) will appear in the viewport.
3. If desired, drag the **Symbol size** slider left or right to modify the size of the symbols in the viewport.
4. Click **Apply** to implement your changes.

   The plot in the current viewport changes to reflect your specification.

   By default, your changes are saved for the duration of the session and will affect all subsequent plots in the current viewport and in any new viewports created from the current viewport. If you want to retain the changes you applied for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

- *Understanding connectors*
- *Creating coordinate systems during postprocessing*

- *Why are datum coordinate systems so important?*

Controlling the display of constraints in the Visualization module

In the Visualization module you can selectively control the display of analysis constraints using display groups and the **ODB Display Options** dialog box. These controls are useful when debugging models that contain large numbers of constraints. By turning the display of some constraints on and off, you can more easily understand complex models.

There are two levels of controls for showing or hiding constraints:

- You must first add the desired constraints to a display group for them to be visible in the viewport. You can create and edit display groups to include or exclude different constraints. See *Creating or editing a display group*, for more information about display groups.
- Different types of constraints can be selected or hidden in the **Constraints** tab of the **ODB Display Options** dialog box. From the main menu bar, select**View->ODB Display Options** to access these options.

The following types of constraints can be displayed or hidden:

- tie constraints
- rigid body constraints (ties and pins only)
- shell-to-solid couplings
- distributing couplings
- kinematic couplings
- multi-point constraints

Note:

These types of constraints are created in the Interaction module, not the Assembly module. See *Understanding constraints* for more information.

Table 1 shows how each type of constraint is displayed by Abaqus/CAE.

Table 1: How constraints are shown in the viewport.

Constraint type	Display in viewport
Tie	Spidering of red lines drawn between the nodes on the main and secondary surfaces of the constraint.
Rigid body	The rigid body regions (elements, nodes, or surfaces) are highlighted in the viewport.
Shell-to-solid coupling	Spidering of yellow lines drawn between the nodes on the shell edge and the solid face.
Distributing coupling	Spidering of orange lines drawn between the control point and the coupling points (nodes) in the constraint region.
Kinematic coupling	Spidering of purple lines drawn between the control point and the coupling points (nodes) in the constraint region.
Multi-point constraint (Abaqus/Explicit only)	The nodes comprising the multi-point constraint are connected with yellow lines.

You can change the default colors of the constraint spider lines in the **Color Code** dialog box. For more information, see *Coloring constraints in the Visualization module*.

Additional information

Customizing general model display

This section explains several of the general model display options.

In this section:

- *Sweeping and extruding your model*
- *Using mirrors and patterns to display your results*
- *Refining curved edges and faces*
- *Coloring elements with no results*
- *Controlling beam profile display for postprocessing*
- *Controlling shell thickness display for postprocessing*
- *Controlling the display of thermal fluid pipe elements*
- *Viewing removed elements*

Sweeping and extruding your model

You can display axisymmetric models as planar, two-dimensional shapes or "sweep" the models through a specified angle, producing a three-dimensional visual effect.
Similarly, you can view just the modeled sector of a cyclic symmetric structure or "sweep" the sector to see a specified portion of the entire model. (For more information on cyclic symmetric structures, see *Analysis of Models that Exhibit Cyclic Symmetry*.) In addition, you can view two-dimensional models (or three-dimensional cylindrical rigid surfaces) as planar or extrude them to a specified depth, producing a three-dimensional visual effect. Sweeping and extruding are particularly useful for displaying contour plots of two-dimensional elements and contact surfaces.

Axisymmetric analytical rigid surfaces can be rotated about an axis (swept), as can the following elements: ACAX*n*, CAX*n*, CAXA*n*, CGAX*n*, DCAX*n*, DCCAX*n*, DSAX*n*, FAX*n*, MAX*n*, MGAX*n*, RAX*n*, SAX*n*, and SAXA*n*. Models that contain three-dimensional axisymmetric analytical rigid surfaces or CAXA elements are swept by default (the default start angle, end angle, and number of sectors vary depending on the model type). If the model contains both analytical rigid surfaces and CAXA elements, only the CAXA elements are swept by default. When you display boundary conditions for swept axisymmetric elements, symbols appear on only the original nodes and not on the swept nodes.

Cyclic symmetric models are not swept by default. When you display contours on a swept cyclic symmetric model, only nodal quantities can be contoured on the swept sectors; scalar, vector, and tensor quantities at integration points can be contoured only on the original sector.

You can extrude analytical rigid surfaces and all of the planar, two-dimensional solid elements in the Abaqus library along the *Z*-direction. For a list of these elements, see *Two-Dimensional Solid Element Library*.

Figure 1 shows an axisymmetric planar model in a planar view (left) and the same model with an axisymmetric sweep angle of 90° and 10 sweep sectors (right).

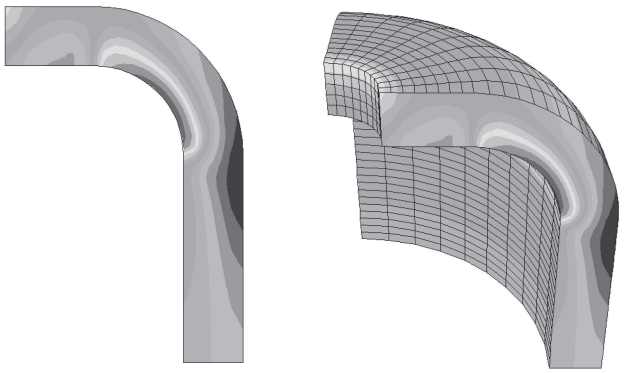

Figure 1: Axisymmetric model with planar and swept display.

Figure 2 shows the original modeled sector of a cyclic symmetric fan (left) and sectors 1–4 of the swept model (right).

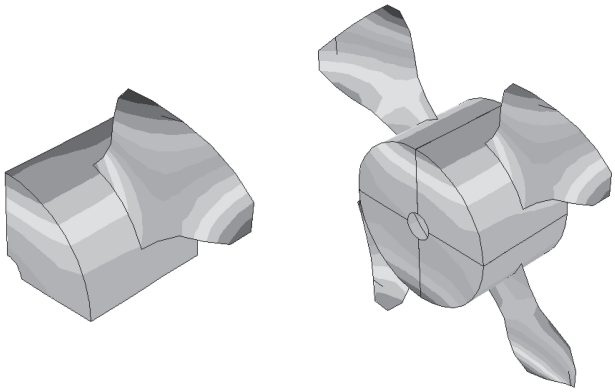

Figure 2: Cyclic symmetric model: single sector and swept view of multiple sectors.

Figure 3 shows a two-dimensional planar model in a planar view (left) and the same model displayed with an extrusion depth of 0.1 (right).

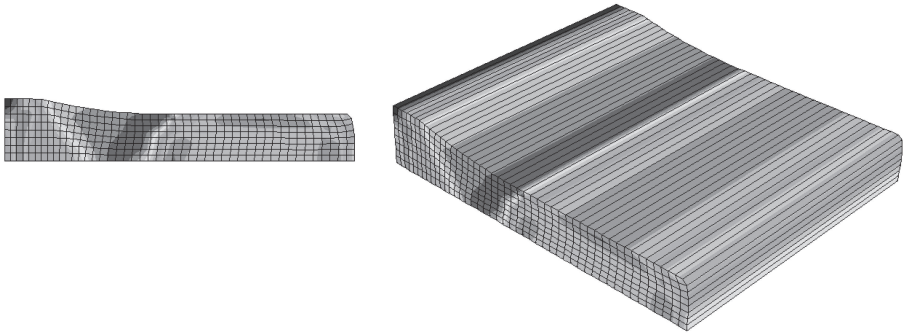

Figure 3: Two-dimensional model with planar and extruded display.

Additional information

- *Refining curved edges and faces*

Sweep elements in your axisymmetric model

1. Locate the **General Sweep** options.

   From the main menu bar, select **View->ODB Display Options**. Click the **Sweep/Extrude** tab in the dialog box that appears. The **General Sweep** options are in the upper portion of the page.

   Note:

   If there are no elements or analytical rigid surfaces in your model that can be swept, the **General Sweep** options will not be available.

2. Toggle **Sweep elements**.
3. Specify the sweep angle by typing a number (in degrees) in the **Sweep from** field (the default is 0°) and a number (in degrees) in the **To** field (the default is 180° for all models).

   Abaqus/CAE sweeps the two-dimensional model counterclockwise about the axis of rotation from the first specified angle to the second.

4. Specify the number of segments to use along the circumferential direction when sweeping by typing a positive integer in the **Number of segments** field or by clicking on the arrows next to the field. The default number of segments used varies depending on the model type.

   The angle between the segments is updated automatically in the dialog box. As you increase the number of segments, curves in the model appear smoother (the angle between them decreases). However, a smaller number of segments plots faster.

5. Click **Apply** to implement your changes.

   Your sweep specifications are reflected in all plot states and, by default, they are saved for the duration of the session. If you want to retain the changes you applied for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

   If a contour plot is displayed, the contours appear on all swept faces.

   If a symbol plot is displayed, the model is swept as specified, but the symbols appear only on the original planar model faces.

Sweep analytical rigid surfaces in your axisymmetric model

1. Locate the **General Sweep** options.

   From the main menu bar, select **View->ODB Display Options**. Click the **Sweep/Extrude** tab in the dialog box that appears. The **General Sweep** options are in the upper portion of the page.

   Note:

   If there are no elements or analytical rigid surfaces in your model that can be swept, the **General Sweep** options will not be available.

2. Toggle on **Sweep analytical rigid surfaces** if it is not currently active.
3. Specify the sweep angle by typing a number (in degrees) in the **Sweep from** field and a number (in degrees) in the **To** field (the default value is 180° when you first open an axisymmetric model and 360° when you first open a three-dimensional model).

   Abaqus/CAE sweeps the analytical rigid surface counterclockwise about the axis of rotation from the first specified angle to the second.

4. Specify the number of segments to use along the circumferential direction when sweeping analytical rigid surfaces by typing a positive integer in the **Number of segments** field or by clicking on the arrows next to the field. By default, Abaqus/CAE uses 10 segments for axisymmetric models and 20 segments for three-dimensional models.

   The angle between the segments is updated automatically in the dialog box. As you increase the number of segments, curves in the model appear smoother (the angle between them decreases). However, a smaller number of segments plots faster.

5. Click **Apply** to implement your changes.

   Your sweep specifications are reflected in all plot states and are saved for the duration of the session. If you want to retain the changes you applied for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

Sweep your cyclic symmetric model

1. Locate the **Sector Sweep** options.

   From the main menu bar, select **View->ODB Display Options**. Click the **Sweep/Extrude** tab in the dialog box that appears. The **Sector Sweep** options are in the center portion of the page.

Note:

If there are no cyclic symmetry elements in your model, the **Sector Sweep** options will not be available.

2. Toggle **Sweep cyclic symmetry sectors**.
3. Click the arrow next to the **Sector selection** field to choose from the following available sweep methods:

By Number

This is the default sweep method. The total number of sectors in the model is given in the dialog box. You can specify which of these sectors should be displayed by typing positive integers between 1 and the total number of sectors (delimited by commas) in the **Sectors** field. The sectors are numbered counterclockwise from the original sector.

Abaqus/CAE displays only the specified sectors (whether or not they are adjacent).

By Angle

The sector angle (the angle between each sector) is given in the dialog box. You can specify the sweep angle in increments of the sector angle by typing a number (in degrees) in the **Sweep from** field (the default is 0°) and a number (in degrees) in the **To** field (the default is the sector angle). Both numbers should be divisible by the sector angle.

Tip: You can also use the arrows next to the text fields to specify the angles.

Abaqus/CAE sweeps the two-dimensional model about the axis of rotation by the number of degrees you specify. If you enter a sweep angle that is not divisible by the sector angle, Abaqus/CAE rounds up to the next number that is.

All Sectors

If you choose this sweep method, all sectors will be displayed; in other words, the model will be swept 360° about the axis of rotation.

4. Click **Apply** to implement your changes.

   Your sweep specifications are reflected in all plot states and are saved for the duration of the session. If you want to retain the changes you applied for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

   If a contour plot is displayed, the contours of nodal quantities appear on all swept faces; contours of scalar, vector, and tensor quantities at integration points appear only on the original sector.

   If a symbol plot is displayed, the model is swept as specified, but the symbols appear only on the original planar model faces.

Extrude elements in your model

1. Locate the **Extrude** options.

   From the main menu bar, select **View->ODB Display Options**. Click the **Sweep/Extrude** tab in the dialog box that appears. The **Extrude** options are in the lower portion of the page.

Note:

If there are no elements in your model that can be extruded, the **Extrude** options will not be available.

2. Toggle **Extrude elements**.

   When **Extrude elements** is on, the **Depth** option becomes available.

3. Specify the depth of the extrusion by typing a positive number (in model units) in the **Depth** field. The default depth is 1.0.

   Abaqus/CAE extends your model the specified number of units in the negative z-direction.

   Use the view manipulation rotation tool to view the extruded model in three dimensions.

4. Click **Apply** to implement your changes.

   Your extrude specifications are reflected in all plot states and are saved for the duration of the session. If you want to retain the changes you applied for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

   If a contour plot is displayed, the contours appear on all extruded faces.

   If a symbol plot is displayed, the model is extruded as specified, but the symbols appear only on the original planar model faces.

Extrude analytical rigid surfaces in your model

1. Locate the **Extrude** options.

   From the main menu bar, select **View->ODB Display Options**. Click the **Sweep/Extrude** tab in the dialog box that appears. The **Extrude** options are in the lower portion of the page.

Note:

If there are no elements or analytical rigid surfaces in your model that can be extruded, the **Extrude** options will not be available.

2. Toggle on **Extrude analytical rigid surfaces** if it is not currently active.

   When **Extrude analytical rigid surfaces** is on, the **Depth** options become available.

3. Select a depth for the extrusion.

   You can either accept the default depth by selecting **Auto-compute**, or you can specify a custom depth by typing a positive number (in model units) in the **Specify** field. The default extrusion depth for analytical rigid surfaces is the maximum value that does not stretch the bounding box.

   Abaqus/CAE extends your model the specified number of units in the negative z-direction.

   Use the view manipulation rotation tool to view the extruded model in three dimensions.

4. Click **Apply** to implement your changes.

   Your extrude specifications are reflected in all plot states and are saved for the duration of the session. If you want to retain the changes you applied for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

Using mirrors and patterns to display your results

In the Sketch module you can use mirrors and patterns to copy a common feature and complete the sketch of a feature. Similarly, in the Visualization module you can copy analysis results representing a repetitive portion of a model to visualize results for the entire model.
To mirror results, you can select the coordinate system and up to three mirrors corresponding to the principal planes of the selected system. To pattern results, you can select the coordinate system and apply a rectangular or circular pattern. You can apply mirrors, rectangular patterns, and circular patterns in conjunction; and you can select their order of application to produce the desired view.

Note:

There are no restrictions to prevent copied results from obscuring portions of the original data or other copies in the viewport.

Mirrors and patterns are a visualization aid only. Any numerical representation of the results, such as the contour legend, indicates only the portion of the model that was analyzed. Use great care in selecting your model and the mirror and pattern settings so that the displayed results will accurately simulate the complete model.

Figure 1 shows one quarter of a plastic fastener as it was modeled for analysis (left) and the same model mirrored about two symmetry planes to display the complete fastener (right). (The rigid hole is a swept profile and, thus, appears complete prior to mirroring the fastener.)

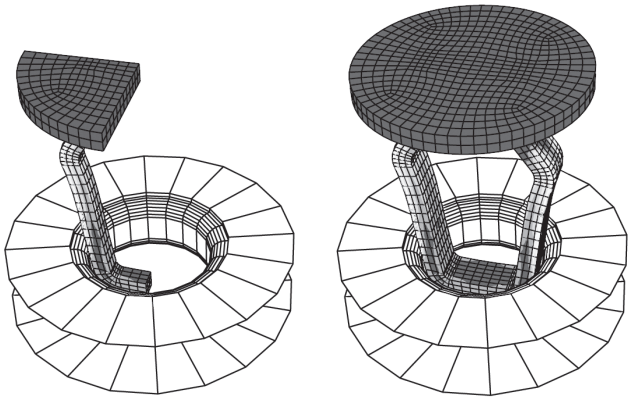

Figure 1: Quarter-symmetry model (left) and complete fastener display (right).

Figure 2 shows a rectangular pattern of completed fasteners.

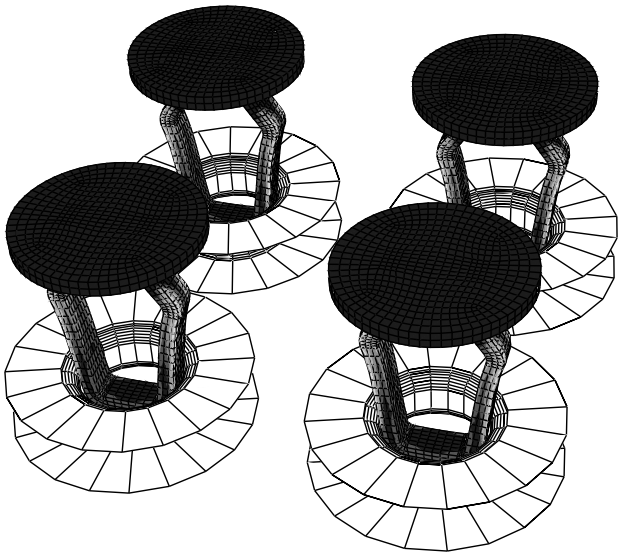

Figure 2: A rectangular pattern of fasteners.

Additional information

- *Sweeping and extruding your model*
- *Refining curved edges and faces*

Mirror your model

1. Locate the **Mirror** options.

   From the main menu bar, select **View->ODB Display Options**. Click the **Mirror/Pattern** tab in the dialog box that appears. The **Mirror** options are in the upper portion of the page.

2. Accept the default global coordinate system, or select a coordinate system from the **Mirror CSYS** list.

   You can select any coordinate system that exists in the output database. If a suitable coordinate system does not already exist, you can create a new coordinate system using one of the methods described in *Creating coordinate systems during postprocessing*.

3. Toggle on the mirror planes that you want Abaqus/CAE to use to copy the model results.
4. Toggle on **Mirror display bodies** if you also want Abaqus/CAE to copy display bodies.
5. If you apply mirrors in conjunction with rectangular or circular patterns, select the **Order of Operations** that Abaqus/CAE will use to create the copies.
6. Click **Apply** to implement your changes.

   Your specifications are reflected in all plot states and are saved for the duration of the session. If you want to retain the changes you applied for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

   If a contour plot is displayed, the contours appear on all faces.

   If a symbol or material orientation plot is displayed, the symbols or material orientations appear only on the original model faces.

Pattern your model

1. Locate the **Pattern** options.

   From the main menu bar, select **View->ODB Display Options**. Click the **Mirror/Pattern** tab in the dialog box that appears. The **Pattern** options are in the middle of the page.

2. Accept the default global coordinate system, or select a coordinate system from the **Pattern CSYS** list.

   You can select any coordinate system that exists in the output database. If a suitable coordinate system does not already exist, you can create a new coordinate system using one of the methods described in *Creating coordinate systems during postprocessing*.

3. Edit the rectangular and circular pattern parameters as follows:

   - Rectangular pattern

     - Enter the **Number** of results that you want to display in the *X*-, *Y*-, and *Z*-directions of the selected coordinate system.
     - Enter the **Offset** distance, in model units, between copies for each direction.

       To place the copies adjacent to each other, the offset in each direction must be the same as the model dimension in that direction.

       Tip: If you do not know the model dimensions, use the query tool  to determine the distance between the first and last model nodes in the desired direction. (For more information, see *Understanding the Query toolset in the Visualization module*.)

   - Circular pattern

     - Select the axis of rotation.
     - Enter the **Number** of results that you want to display around the selected axis.
     - If desired, edit the **Total angle**Abaqus/CAE will use to position the copies.

       Abaqus/CAE places the original result at 0°. All subsequent copies are positioned according to the **Total angle** divided by the **Number** of copies.

4. If you use both rectangular and circular patterns or if you use a pattern in conjunction with mirrors, select the **Order of Operations** that Abaqus/CAE will use to create the copies.
5. Click **Apply** to implement your changes.

   Your specifications are reflected in all plot states and are saved for the duration of the session. If you want to retain the changes you applied for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

   If a contour plot is displayed, the contours appear on all faces.

   If a symbol or material orientation plot is displayed, the symbols or material orientations appear only on the original model faces.

Refining curved edges and faces

If your model contains quadratic elements, cubic elements, 2-node spring elements, or analytical rigid surfaces having curved segments, you can control the refinement with which Abaqus/CAE displays these curved model components. Similarly, if your model contains 2-node dashpot elements, you can control the refinement of the symbol used to represent those elements. Click the **General** tab in the **ODB Display Options** dialog box to choose a refinement level between extra coarse and extra fine for the display of curved edges and faces. When you select **Extra Coarse** refinement, Abaqus/CAE displays curved elements using straight lines; midside nodes have no effect on the shape displayed for these elements. **Extra Coarse** refinement will treat springs and dashpots as straight lines. For example, in *Figure 1* the **Extra Coarse** refinement level was used to create the undeformed plot on the left, and the **Extra Fine** refinement level was used to produce an undeformed plot of the same model on the right.

Note:

As the refinement level increases, the display performance will decrease. The **Medium** setting should produce acceptable results for most models.

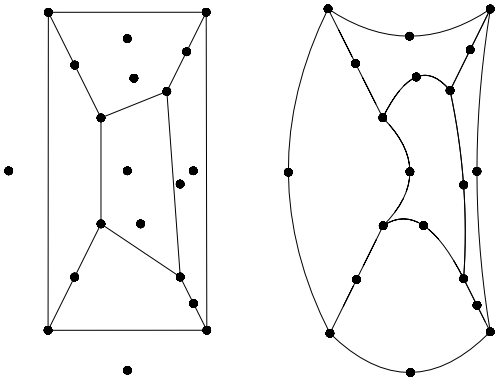

Figure 1: Model plotted with different refinement levels (extra coarse and extra fine).

1. Locate the **Curved Lines & Faces** options.

   From the main menu bar, select **View->ODB Display Options**. Click the **General** tab in the dialog box that appears. The **Curved Lines & Faces** options are at the top of the **General** page.
2. Click the **Refinement level** button to reveal the refinement options.
3. In the refinement list, click the level you want. Extra fine produces the smoothest curves but may slow plotting; conversely, coarse refinement gives a rough appearance but plots most quickly.

   The refinement level you specify appears on the **Refinement Level** button.
4. Click **Apply** to implement your changes.

   Curved edges and faces for all plot states change to reflect your refinement specification, which is saved for the duration of the session. If you want to retain the changes you applied for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

Additional information

- *Sweeping and extruding your model*

Coloring elements with no results

To produce a contour plot, Abaqus/CAE reads results for the variable and frame you specify from the output database. Results for a particular variable and frame may not be available or may not be applicable for one or more elements included in the plot. You can specify the display color for elements that have no results. The default color is white.

For example, the contour plot in *Figure 1* shows the von Mises stress generated when a blank sheet is deformed using a die and punch (the punch is not shown in the figure). In this case the color gray was selected for elements with no results. The die elements appear gray because the die is a rigid surface for which no stress results exist.

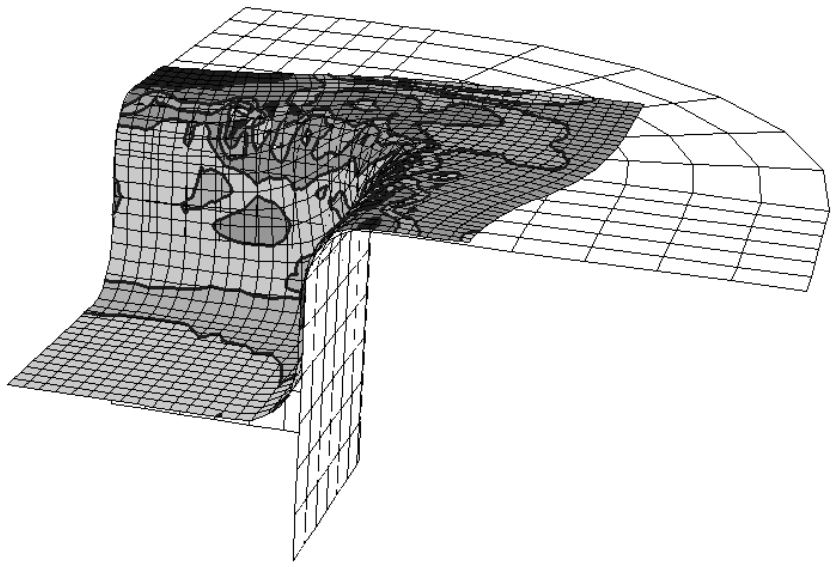

Figure 1: Contour plot of blank and die.

1. Locate the **Elements with No Results** options.

   From the main menu bar, select **View->ODB Display Options**. Click the **General** tab in the dialog box that appears. The **Elements with No Results** options are in the center of the **General** page.

2. Click the color sample .

   Abaqus/CAE displays the **Select Color** dialog box.

3. Use one of the methods in the **Select Color** dialog box to select a new color. For more information, see *Customizing colors*.

4. Click **OK** to close the **Select Color** dialog box.

   The color sample changes to the selected color.

5. Click **Apply** to implement your changes.

   Elements with no results in contour plots (including display bodies) change to reflect your coloring specification, which is saved for the duration of the session. If you want to retain the changes you applied for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

Additional information

- *Producing a contour plot*

• *Customizing render style, translucency, and fill color*

Controlling beam profile display for postprocessing

Beam rendering is available in the Visualization module for undeformed, deformed, and contour plots only. For deformed plots Abaqus/CAE scales the displacement components of the deformation based on the deformed field output variable but does not scale the twisting of the beam profile using the rotational components of the deformation when you change the deformation scale factor.

You can view a realistic display of the beam profile for results data by selecting **View->ODB Display Options** in the Visualization module.

The rendering of beam profiles requires the presence of beam orientation data in the output database. Beam normals are written to the output database automatically for all the steps that include field output. For analyses that include geometric nonlinearity, you can display beam profiles during postprocessing only if nodal output is requested in the model. For more information, see *Using a Beam Section Integrated during the Analysis to Define the Section Behavior*.

Abaqus/CAE does not render the tapering of beam profiles along their length. If your model includes tapered beam sections, Abaqus/CAE renders these beams using the beam's starting profile along its entire length. For more information about tapered beams, see *Creating beam sections*.

Beam elements that have BRADIUS values are rendered using circular beam profiles with the radius coming from the BRADIUS field in the output database.

Displaying beam profiles is useful for checking that the correct profile has been assigned to a particular region and that the assigned beam orientation results in the expected orientation of the profile. For example, *Figure 1* shows the box beam profiles displayed on the light-service crane described in *Example: cargo crane*.

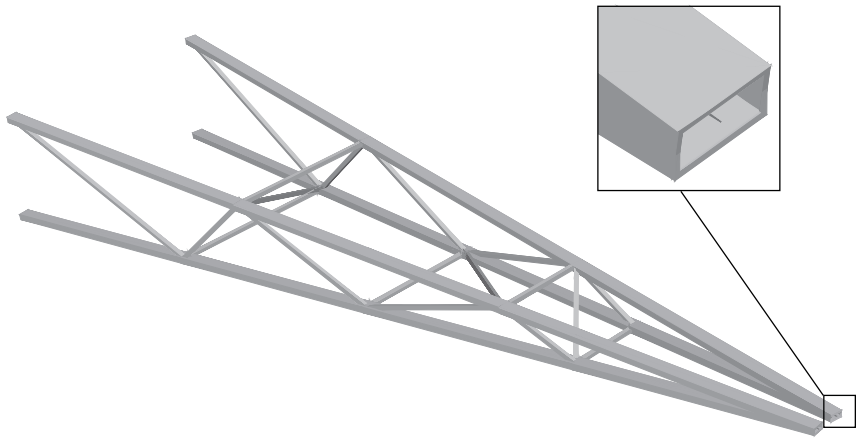

Figure 1: The cargo crane example with beam profiles displayed.

Note:

If your results include quadratic beam elements, Abaqus/CAE does not consider the midside nodes in those elements when the beam profiles are rendered.

If you assign a general beam section to a wire, Abaqus/CAE displays the beam profile as an ellipse with a cross-sectional area and moments of inertia (I_{11} and I_{22}) that match the values you specified. If you assign a truss section to a wire, Abaqus/CAE displays the truss profile as a circle with a cross-sectional area that matches the value you specified.

Abaqus/CAE renders beam profiles according to the current settings for color coding and translucency. When these settings change, the color and translucency of the beam profiles change as well. When beam profiles are displayed, Abaqus/CAE disables scaling and shrinking of the model.

1. Locate the **Render beam profiles** option.

   From the main menu bar, select **View->ODB Display Options**. In the dialog box that appears, click the **General** tab.
2. From the bottom of the dialog box, toggle on **Render beam profiles** to display beam profiles.
3. If desired, apply a **Scale factor** to the beam profiles to increase or decrease their size. The default value is 1.
4. + Click **OK** to implement your changes and to close the dialog box.

   Abaqus/CAE displays the profile of the beam section with the appropriate dimensions and in the correct orientation. By default, your changes are saved for the duration of the session. If you want to retain the changes you applied for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

Additional information

- *Producing a contour plot of linear beam section stresses*
- *Controlling beam profile display*

Controlling shell thickness display for postprocessing

Rendering of shell thickness is available in the Visualization module for all plot states.

If you use shell elements to model relatively thin components in your analysis, you can use the **View->ODB Display Options** to view the actual thickness of these shell elements in your model during postprocessing.

For deformed and contour plots Abaqus/CAE scales the displacement components of the deformation but does not scale the rotational components of the deformation when you change the deformation scale factor. For contour plots Abaqus/CAE applies colors based on your selection of active section point locations. If the top section point or bottom section point is currently active, Abaqus/CAE displays the contour for that section point throughout the shell thickness; if both top and bottom section points are currently active, Abaqus/CAE creates a linear contour gradient from the top values to the bottom values through the shell thickness.

Displaying shell thickness after a sizing optimization allows you to view the resulting change in shell thickness across the design area of your structure as the optimization progresses.

Abaqus/CAE determines shell thickness for postprocessing using the shell thickness definition specified for the model in its undeformed state. If your model undergoes large deformations or large rotations during the analysis, shell thickness might not display well in the deformed plot state.

Displaying shell thickness enables you to examine the thickness of shell geometry relative to the rest of the model. You can apply a scale factor to reduce or increase the display of shell thickness for your session. *Figure 1* shows the effect of scale factor changes to a model.

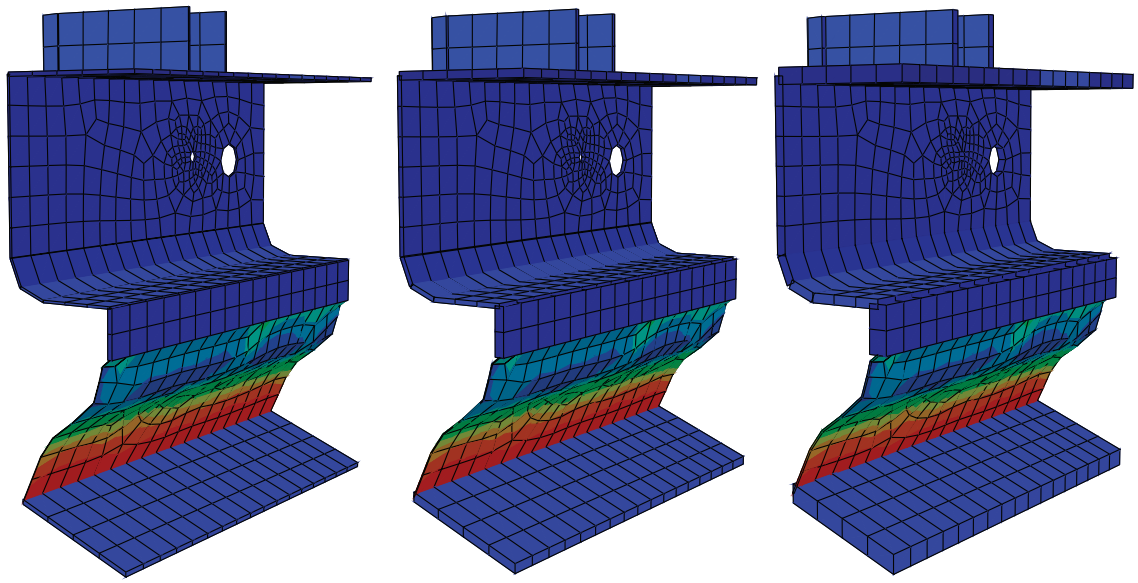

Figure 1: From left to right: shell thickness scale factor settings of 0.5, 1 (default), and 2.

Abaqus/CAE renders shell thickness for three-dimensional shell elements only; thickness is not displayed for axisymmetric shell elements, such as SAX1 elements. When shell thickness is displayed, Abaqus/CAE also renders the edges of shell geometry unless a view cut is displayed in the viewport. Abaqus/CAE renders shell thickness according to the current settings for color coding and translucency. When these settings change, the color and translucency of the shell thickness change as well.

1. Locate the **Render shell thickness** option.

   From the main menu bar, select **View->ODB Display Options**. In the dialog box that appears, click the **General** tab.

2. From the bottom of the dialog box, toggle on **Render shell thickness** to display shell thicknesses for the shell sections in your model.
3. If desired, apply a **Scale factor** to the shell thicknesses to increase or decrease their thickness. The default value is 1, which produces a realistic rendering of the shell thickness settings.
4. + Click **OK** to implement your changes and to close the dialog box.

   Abaqus/CAE displays the shell sections in the selected part or assembly with the appropriate thickness. By default, your changes are saved for the duration of the session. If you want to retain the changes you applied for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

Additional information

• *Controlling shell thickness display*

Controlling the display of thermal fluid pipe elements

Rendering of thermal fluid pipe elements is available in the Visualization module for undeformed, deformed, and contour plots only.
There is no deformation associated with thermal fluid pipe elements; the deformed and undeformed plots are the same.

If you use thermal fluid pipe elements to model the flow of a liquid through a pipe in your analysis, you can use the **View->ODB Display Options** to visualize the fluid pipe along with the fluid pressure, fluid temperature, and wall temperature contours. To clearly visualize the contours and plot shapes, you should create a display group that contains only the thermal fluid pipe elements.

When you select the regions individually, Abaqus/CAE renders the fluid region as a solid cylinder and the inner wall and outer wall as thin hollow cylinders. If you choose to render both the inner wall and outer wall, a thick-walled cylinder is displayed. Temperature variation across the wall is visible on the end caps. When you render multiple regions, only the outermost region is visible on the surface of the cylinder; all the selected regions are rendered at the end caps. *Figure 1* shows the nodal temperature (NT11) on the inner wall and outer wall of a fluid pipe.

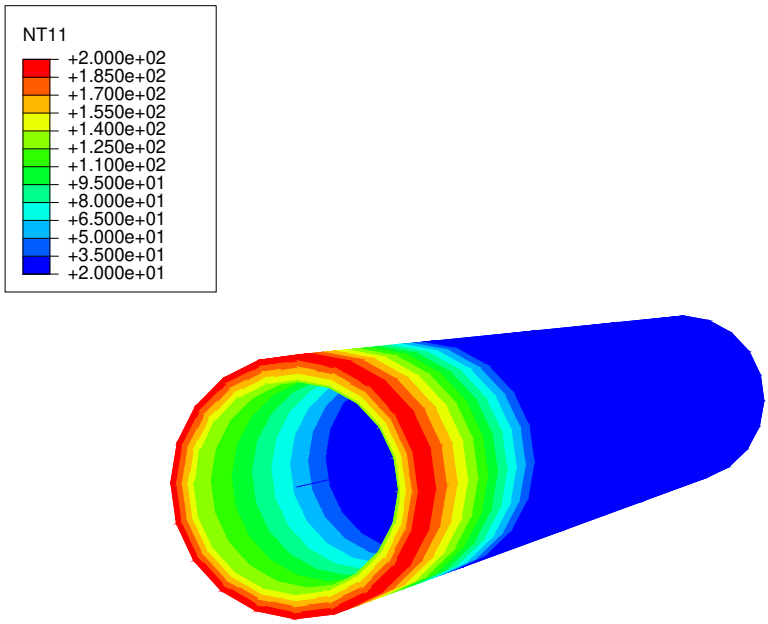

Figure 1: Rendering of fluid pipe thermal elements.

Abaqus/CAE renders thermal fluid pipe elements according to the current settings for color coding and translucency. When these settings change, the color and translucency of the thermal fluid pipe elements change as well. When thermal fluid pipe elements are displayed, Abaqus/CAE disables scaling and shrinking of the model.

1. Locate the **Fluid pipe thermal elements** option.

   From the main menu bar, select **View->ODB Display Options**. In the dialog box that appears, click the **General** tab.

2. From the bottom of the dialog box, toggle on **Fluid pipe thermal elements** to render the thermal fluid pipe elements in your model.
3. Toggle the following regions that you want to render:

   - **Fluid region**

- **Inner wall**
- **Outer wall**

4. If desired, apply a **Scale factor** to the radius of each of the selected regions to increase or decrease its thickness. The default value is 1.
5. + Click **OK** to implement your changes and to close the dialog box.

   Abaqus/CAE displays the thermal fluid pipe elements in the selected part or assembly. By default, your changes are saved for the duration of the session. If you want to retain the changes you applied for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

Additional information

• *Selecting plot display options*

Viewing removed elements

You can create model change interactions that deactivate selected components of the model (geometry, elements, skins, and stringers). Skins, geometry, and elements can be removed from the viewport for model change interactions on model geometry. Skins, stringers, and elements can be removed from the viewport for model change interactions on an orphan mesh. You can control the visibility of these removed components from the **ODB Display Options** dialog box.

The behavior of the viewport depends on the status of the visibility toggle and on the plot state. Elements deactivated in a model change interaction can be removed from the viewport for all plot states. When the option to remove deactivated elements in the viewport is toggled off, the deactivated elements are colored gray in the contour plot but remain unchanged for all other plot states. If the option to display beam profiles is toggled off, Abaqus/CAE will not remove deactivated elements with beam profiles from the viewport, regardless of the status of the removed element toggle.

1. From the main menu bar, select **View->ODB Display Options**. Click the **General** tab in the dialog box that appears. The **Model Change** display option is at the bottom of the **General** page.
2. Toggle on **Account for deactivated elements** from the viewport.
3. Click **OK** to implement your changes and to close the dialog box.

Additional information

• *Defining a model change interaction*

Customizing viewport annotations

The viewport annotations generated by Abaqus/CAE consist of the legend, the title block, the state block, the 3D compass, and the view triad; they are provided to help you identify and interpret the contents of your plot. In addition, you can add customized text and arrow annotations to a viewport (for more information, see *Managing viewports on the canvas*). You can use the **Viewport Annotation Options** to toggle all viewport annotations on and off, and you can also customize the appearance of the annotations generated by Abaqus/CAE.

For information on the 3D compass, see *The 3D compass*. For information on the view triad, see *Customizing the view triad*.

In this section:

- *Customizing the legend*
- *Customizing the title block*
- *Customizing the state block*
- *Using viewport annotation options*

Customizing the legend

The legend is a key to help you interpret your plots. For example, a contour plot legend shows the values that each contour color represents; a symbol plot legend shows the values that each vector color represents. The *X*–*Y* plot legend refers to each curve by label and shows the curve's style.

Figure 1 shows a contour plot legend and a symbol plot legend.

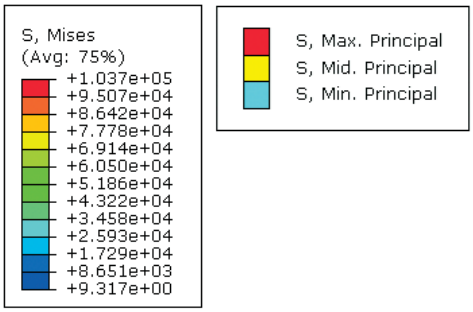

Figure 1: Contour plot legend and symbol plot legend.

You can display or suppress legends for all plot states, and you can customize the following:

- the position of the legend,
- the font and color of the legend text,
- the appearance of a box outlining the legend,
- whether minimum and maximum plot values are shown,
- the appearance of the legend background (the rectangular area behind the legend),
- the formatting of the numbers displayed for the digit values, and
- the number of digits displayed for the legend values.

You cannot directly specify the size of the legend. However, by varying the size of the text font or the number of digits in the legend values, you can increase or decrease the legend's size.

The content of the legend depends on the plot type and on plot state–specific options such as the number of contour intervals. For more information on contour plot legend content, see *Understanding contour plotting*.

This section describes how to customize the legend for all plot states except *X*–*Y* plots. To customize the *X*–*Y* plot legend, see *Customizing the X–Y plot legend*.

1. Locate the **Legend** options.

   From the main menu bar, select **Viewport->Viewport Annotation Options**.

2. To display or suppress legends for all plot states except *X*–*Y* plots, toggle **Show legend** in the **General** tab.

   When **Show legend** is on, legend options become available.

3. Click the **Legend** tab. The basic legend options are at the top of the **Legend** page.
4. To display or suppress a box outlining the legend, toggle **Show bounding box**. This “bounding box” visually separates the legend from the underlying plot.
5. To display or suppress the minimum and maximum values associated with contour plots, toggle **Show min/max values**.
6. Establish the position of the upper left corner of the legend.

To control the *X*- or *Y*-position, click the **% Viewport X** or **% Viewport Y** boxes, respectively. Enter the positions you want as a percentage of the total width of the current viewport.

7. Customize the legend text font.
   a. Click **Set Font**.
      The **Select Font** dialog box appears.
   b. Use the **Select Font** dialog box to choose the font characteristics you want. For more information, see *Customizing fonts*.
   c. When you are done, click **OK** to implement your changes and to close the **Select Font** dialog box.
8. Choose the color of the legend text.
   a. Click the color sample .
      Abaqus/CAE displays the **Select Color** dialog box.
   b. Use one of the methods in the dialog box to select a new color. For more information, see *Customizing colors*.
   c. Click **OK** to close the **Select Color** dialog box.
      The color sample changes to the selected color.
9. To customize the background, click one of the following:
   - **Match viewport** to match the background to the viewport color.
   - **Transparent** to eliminate the background and show only the text.
   - **Other color** to reveal other background color options.

   If you selected **Other color**:
   a. Click the color sample .
      Abaqus/CAE displays the **Select Color** dialog box.
   b. Use one of the methods in the **Select Color** dialog box to select a new color. For more information, see *Customizing colors*.
   c. Click **OK** to close the **Select Color** dialog box.
      The color sample changes to the selected color.
10. To change the format of the legend values, click the **Format** arrow and select one of the following formats:
   - Select **Scientific** to display legend values in scientific notation, which expresses legend values as a decimal value between 1 and 10 multiplied by a power of 10. When you select this format for the number `501,000`, the value appears in the legend as `5.01e5`.
   - Select **Fixed** to display legend values without using exponent values. When you select this format, the number `501,000` is displayed in the legend as `501000.00`.
   - Select **Engineering** to select engineering notation, which expresses values in a similar format to scientific notation but allows exponent values that are multiples of three only. When you select this format, the number `501,000` is displayed in the legend as `501E3`.

Note:

All three of these examples are displayed with two decimal places. Your legend values may be displayed differently if you change the **Decimal places** option.

11. To choose the number of digits shown in legend values, click the **Decimal places** arrow. For legend values in scientific or fixed format, the **Decimal places** option controls the number of digits to the right of the decimal point. For legend values in engineering format, this option controls the number of significant digits to the left of the exponent value. For all formats, larger **Decimal places** values require more display space.

The specified number of digits appears in the **Decimal places** box.

12. Click **Apply** to implement your changes.

In the current viewport, legends for all plots change to reflect your specifications, which are saved for the duration of the session.

Customizing the title block

The title block contains text identifying the model and results shown in the current plot. This text indicates:

- The name of the output database (from the name of the analysis job).
- The description of the model.
- The product name (usually Abaqus/Standard or Abaqus/Explicit) and release used to generate the output database.
- The date the output database was last modified.

You can display or suppress the title block for all plot states, and you can display or suppress the appearance of a box bounding the title block. In addition, you can control the position, text font, and text color of the title block and the appearance of the title block background. You cannot directly specify the size of the title block. However, by varying the size of the text font, you can increase or decrease the title block's size. The content of the title block is fixed and cannot be customized.

1. Locate the **Title Block** options.

   From the main menu bar, select **Viewport->Viewport Annotation Options**.
2. To display or suppress title blocks for all plot states, toggle **Show title block** in the **General** tab.

   When **Show title block** is on, the title block options become available.
3. Click the **Title Block** tab. The basic title block options are at the top of the **Title Block** page.
4. To display or suppress a box outlining the title block, toggle **Show bounding box**. This “bounding box” visually separates the title block from the underlying plot.
5. Establish the position of the upper left corner of the title block.

   To control the *X*- or *Y*-position, click the **% Viewport X** or **% Viewport Y** boxes, respectively. Enter the positions you want as a percentage of the total width of the current viewport.
6. Customize the title block text font.
   a. Click **Set Font**.

      The **Select Font** dialog box appears.
   b. Use the **Select Font** dialog box to choose the font characteristics you want. For more information, see *Customizing fonts*.
   c. When you are done, click **OK** to implement your changes and to close the **Select Font** dialog box.
7. Choose the color of the title block text.
   a. Click the color sample .

      Abaqus/CAE displays the **Select Color** dialog box.
   b. Use one of the methods in the dialog box to select a new color. For more information, see *Customizing colors*.
   c. Click **OK** to close the **Select Color** dialog box.

      The color sample changes to the selected color.
8. To customize the background, click one of the following:

   - **Match viewport** to match the background to the viewport color.
   - **Transparent** to eliminate the background and show only the text.
   - **Other color** to reveal other background color options.

   If you selected **Other color**:

a. Click the color sample .

Abaqus/CAE displays the **Select Color** dialog box.

b. Use one of the methods in the **Select Color** dialog box to select a new color. For more information, see *Customizing colors*.

c. Click **OK** to close the **Select Color** dialog box.

The color sample changes to the selected color.

9. Click **Apply** to implement your changes.

In the current viewport, title blocks for all plots change to reflect your specifications, which are saved for the duration of the session.

Customizing the state block

The state block contains text identifying the analysis results associated with the current plot. This information includes step, frame, results variables, deformation magnification factor, eigenmode, and eigenvalue, as applicable.

You can display or suppress the state block for all plot states, and you can display or suppress the appearance of a box bounding the state block. In addition, you can control the position, text font, and text color of the state block and the appearance of the state block background. You cannot directly specify the size of the state block. However, by varying the size of the text font, you can increase or decrease the state block's size. The content of the state block is fixed and cannot be customized.

1. Locate the **State Block** options.

   From the main menu bar, select **Viewport->Viewport Annotation Options**.

2. To display or suppress state blocks for all plot states, toggle **Show state block** in the **General** tab.

   When **Show state block** is on, state block options become available.

3. Click the **State Block** tab. The basic state block options are at the top of the **State Block** page.
4. To display or suppress a box outlining the state block, toggle **Show bounding box**. This “bounding box” visually separates the state block from the underlying plot.
5. Establish the position of the upper left corner of the state block.

   To control the *X*- or *Y*-position, click the **% Viewport X** or **% Viewport Y** boxes, respectively. Enter the positions you want as a percentage of the total width of the current viewport.

6. Customize the state block text font.
   a. Click **Set Font**.

      The **Select Font** dialog box appears.

   b. Use the **Select Font** dialog box to choose the font characteristics you want. For more information, see *Customizing fonts*.
   c. When you are done, click **OK** to implement your changes and to close the **Select Font** dialog box.

7. Choose the color of the state block text.
   a. Click the color sample .

      Abaqus/CAE displays the **Select Color** dialog box.

   b. Use one of the methods in the dialog box to select a new color. For more information, see *Customizing colors*.
   c. Click **OK** to close the **Select Color** dialog box.

      The color sample changes to the selected color.

8. To customize the background, click one of the following:

   - **Match viewport** to match the background to the viewport color.
   - **Transparent** to eliminate the background and show only the text.
   - **Other color** to reveal other background color options.

   If you selected **Other color**:

   a. Click the color sample .

      Abaqus/CAE displays the **Select Color** dialog box.

   b. Use one of the methods in the **Select Color** dialog box to select a new color. For more information, see *Customizing colors*.
   c. Click **OK** to close the **Select Color** dialog box.

The color sample changes to the selected color.

9. Click **Apply** to implement your changes.

   In the current viewport, state blocks for all plots change to reflect your specifications, which are saved for the duration of the session.

Using viewport annotation options

Use the viewport annotation options to customize the legend, the title block, the state block, the 3D compass, and the view triad for all plot states. In addition, the viewport annotation options control the display of arrow and text annotations.

1. From the main menu bar, select **Viewport->Viewport Annotation Options**.

   The **Viewport Annotation Options** dialog box appears. It contains the following tabs:

   - **General**: Control the display of all viewport annotations—those generated by Abaqus/CAE and any arrow and text annotations that you created.
   - **Triad**: Control the appearance and position of the view triad.
   - **Legend**: Control the appearance and position of the legend and whether minimum and maximum values are shown.
   - **Title Block**: Control the appearance and position of the title block.
   - **State Block**: Control the appearance and position of the state block.

2. Use the **General** tab to control the display of viewport annotations for all plots in the current viewport. You can display all viewport annotations in the current viewport by clicking **Set all on**, or you can hide all viewport annotations in the current viewport by clicking **Set all off**.
3. Use the remaining tabs in the dialog box to customize the viewport annotations generated by Abaqus/CAE. To create and customize arrow and text annotations, see *Working with viewport arrow and text annotations*.

Additional information

- *What are arrow and text annotations?*
- *Customizing the 3D compass*
- *Customizing the view triad*
- *Customizing the legend*
- *Customizing the title block*
- *Customizing the state block*

Using toolsets

This part describes how to use each of the toolsets in Abaqus/CAE, except those in the Visualization module. Toolsets in the Visualization module are discussed in *Viewing results*.

In this section:

- *The Amplitude toolset*
- *The Analytical Field toolset*
- *The Attachment toolset*
- *The CAD Connection toolset*
- *The Customize toolset*
- *The Datum toolset*
- *The Discrete Field toolset*
- *The Edit Mesh toolset*
- *The Feature Manipulation toolset*
- *The Filter toolset*
- *The Free Body toolset*
- *The Options toolset*
- *The Geometry Edit toolset*
- *The Partition toolset*
- *The Query toolset*
- *The Reference Point toolset*
- *The Set and Surface toolsets*
- *The Stream toolset*
- *The Virtual Topology toolset*

The Amplitude toolset

Amplitudes allow you to specify arbitrary time or frequency variations of load, displacement, and some interaction attributes throughout a step using step time or throughout an analysis using total time. The Amplitude toolset allows you to create and manage amplitudes.

In this section:

- *Understanding the role of the Amplitude toolset*
- *Understanding the amplitude editors*
- *Selecting an amplitude type to define*
- *Using tabular data to define an amplitude curve*
- *Using equally spaced data to define an amplitude curve*
- *Using periodic data to define an amplitude curve*
- *Using modulated data to define an amplitude curve*
- *Using exponential decay data to define an amplitude curve*
- *Defining a solution-dependent amplitude curve*
- *Using smooth step data to define an amplitude curve*
- *Defining a spectrum*
- *Defining a user-defined amplitude curve*
- *Defining a PSD definition*

Understanding the role of the Amplitude toolset

The Amplitude toolset allows you to create any type of amplitude that is supported by Abaqus/Standard or Abaqus/Explicit.
Amplitudes created in the Amplitude toolset always involve relative data, while amplitudes defined directly in the input file can involve either relative or absolute data. (For more information, see “Specifying relative or absolute data” in *Amplitude Curves*.) You can also use the Amplitude toolset to define a spectrum to be used in a response spectrum analysis.

Select **Tools->Amplitude->Create** from the main menu to create a new amplitude definition; select **Edit** from the same menu to make changes to an existing definition. Either command opens the amplitude editor, which allows you to select the options and provide the data needed to define your amplitude.

You can also plot amplitude data in much the same way that you can plot *X*–*Y* data. For more information about using the **Amplitude Plotter** plug-in, see *Plotting amplitude data*.

Additional information

- *Amplitude Curves*
- *Response Spectrum Analysis*

Understanding the amplitude editors

You create amplitudes by entering data in the amplitude editor; you can type the data in using the keyboard or you can read it in from a file. (For more information, see *Entering tabular data*.)

The top panel of the editor displays the name of the amplitude and the amplitude type. The format of the rest of the editor depends on the type of amplitude you are creating. For example, the editor for creating a periodic amplitude is shown in *Figure 1*.

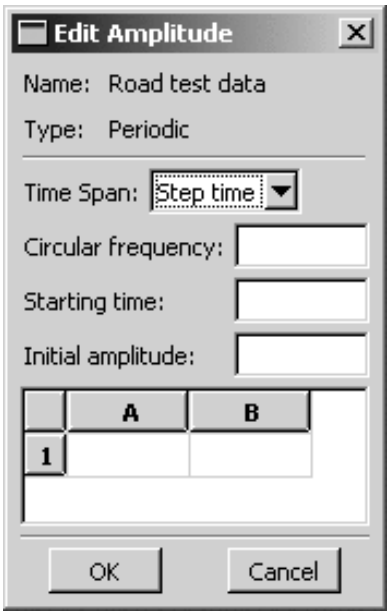

Figure 1: The amplitude editor.

Additional information

- *Amplitude Curves*
- *Response Spectrum Analysis*
- *Entering tabular data*

Selecting an amplitude type to define

Select **Tools->Amplitude->Create** from the main menu bar to create an amplitude. For detailed information on amplitudes, see *Amplitude Curves* and *Specifying a Spectrum*.

1. From the main menu bar, select **Tools->Amplitude->Create**.

   Tip: You can also create an amplitude by clicking mouse button 3 on the **Amplitudes** container in the Model Tree or by clicking **Create** in the **Amplitude Manager**.

   The **Create Amplitude** dialog box appears.

2. In the **Name** field, enter a name for the amplitude. For information on naming objects, see *Using basic dialog box components*.
3. Choose the **Type** of amplitude that you want to create:

   - Choose **Tabular** to define the amplitude curve as a table of values at convenient points on the time scale. Abaqus interpolates linearly between these values, as needed. For more information, see *Defining Tabular Data*.
   - Choose **Equally spaced** to give a list of amplitude values at fixed time intervals beginning at a specified value of time. Abaqus interpolates linearly between each time interval. For more information, see *Defining Equally Spaced Data*.
   - Choose **Periodic** to define the amplitude, a, as a Fourier series:

     $$a = A_0 + \sum_{n=1}^{N} \left[A_n \cos n\omega \left(t - t_0 \right) + B_n \sin n\omega \left(t - t_0 \right) \right] \text{ for } t \geq t_0,$$
     $$a = A_0 \quad \text{for } t < t_0,$$

     where t_0, N, ω, A_0, A_n, and B_n, $n = 1, 2 \ldots N$, are user-defined constants. For more information, see *Defining Periodic Data*.
   - Choose **Modulated** to define the amplitude, a, as

     $$a = A_0 + A \sin \omega_1 \left(t - t_0 \right) \sin \omega_2 \left(t - t_0 \right) \quad \text{for } t > t_0,$$
     $$a = A_0 \quad \text{for } t \leq t_0,$$

     where A_0, A, t_0, ω_1, and ω_2 are user-defined constants. For more information, see *Defining Modulated Data*.
   - Choose **Decay** to define the amplitude, a, as

     $$a = A_0 + A \exp \left(- \left(t - t_0 \right) / t_d \right) \quad \text{for } t \geq t_0,$$
     $$a = A_0 \quad \text{for } t < t_0,$$

     where A_0, A, t_0, and t_d are user-defined constants. For more information, see *Defining Exponential Decay*.
   - Choose **Solution dependent** to calculate amplitude values based on a solution-dependent variable. For more information, see *Defining a Solution-Dependent Amplitude for Superplastic Forming Analysis*.
   - Choose **Smooth step** to define the amplitude, a, between two consecutive data points (t_i, A_i) and (t_{i+1}, A_{i+1}) as

$$a = A_i \quad + \quad (A_{i+1} - A_i)\,\xi^3\left(10 - 15\xi + 6\xi^2\right) \quad \text{for } t_i \le t \le t_{i+1},$$

where $\xi = (t - t_i) / (t_{i+1} - t_i)$. For more information, see *Defining Smooth Step Data*.

- Choose **Actuator** to import the current value of an actuator amplitude at any given time from a co-simulation with a logical modeling program. For more information, see *Defining an Actuator Amplitude via Co-Simulation*. No additional data is required to define the amplitude curve.
- Choose **Spectrum** to define a spectrum to be used in a response spectrum analysis. For more information, see *Specifying a Spectrum*.
- Choose **User** to define the amplitude curve in user subroutine *UAMP* (Abaqus/Standard) or *VUAMP* (Abaqus/Explicit). For more information, see *Defining an Amplitude via a User Subroutine*.
- Choose **PSD definition** to define a frequency function that defines the frequency dependence of the random loading in a random response analysis step. This amplitude curve represents the power spectral density function for the random noise source. The PSD amplitude can be referenced in the correlation definition of a base motion boundary condition in a random response step. For more information, see *Defining the Frequency Functions*.

4. Click **Continue**.

   The **Edit Amplitude** dialog box appears in which you can enter all of the data necessary to define the amplitude curve. See the following sections for detailed instructions:

   - *Using tabular data to define an amplitude curve*
   - *Using equally spaced data to define an amplitude curve*
   - *Using periodic data to define an amplitude curve*
   - *Using modulated data to define an amplitude curve*
   - *Using exponential decay data to define an amplitude curve*
   - *Defining a solution-dependent amplitude curve*
   - *Using smooth step data to define an amplitude curve*
   - *Defining a spectrum*
   - *Defining a user-defined amplitude curve*
   - *Defining a PSD definition*

Additional information

- *Amplitude Curves*
- *Understanding the amplitude editors*
- *Entering tabular data*

Using tabular data to define an amplitude curve

Use the tabular definition method to define the amplitude curve as a table of values at convenient points on the time scale. Abaqus interpolates linearly between these values, as needed. For more information, see *Defining Tabular Data*.

1. Display the **Edit Amplitude** dialog box as described in *Selecting an amplitude type to define*.
2. Click the arrow to the right of the **Time span** field, and specify how you want to define the amplitude as a function of time:
   - Select **Step time** for time that is measured from the beginning of each step.
   - Select **Total time** for total time accumulated over all non-perturbation analysis steps.
3. Indicate how you want to define **Smoothing**:
   - Choose **Use solver default** to accept a default value of 0.25 in Abaqus/Standard and 0.0 in Abaqus/Explicit.
   - Choose **Specify** to enter a value for the smoothing parameter in the adjacent field. A value of 0.05 is suggested for amplitude definitions that contain large time intervals to avoid severe deviation from the specified definition.

   The **Smoothing** parameter is the fraction of the time interval before and after each time point during which the piecewise linear time variation is replaced by a smooth quadratic time variation. This parameter is applicable only when time derivatives are needed (for displacement or velocity boundary conditions in a direct integration dynamic analysis) and is ignored for all other uses of this option.
4. Display the **Amplitude Data** tabbed page, and enter the tabular data. For detailed information on how to enter data, see *Entering tabular data*.
5. If desired, display the **Baseline Correction** tabbed page.

   When you use an amplitude definition to define an acceleration history in the time domain (a seismic record of an earthquake, for example), the integration of the acceleration record through time may result in a relatively large displacement at the end of the event. This behavior typically occurs because of instrumentation errors or a sampling frequency that is not sufficient to capture the actual acceleration history. In Abaqus/Standard it is possible to compensate for it by using "baseline correction." For more information, see *Baseline Correction in Abaqus/Standard*.
6. Click the arrow to the right of the **Correction** field, and select one of the following options:
   - Select **None** for no baseline correction.
   - Select **Single interval** to treat the entire time of the amplitude definition as a single correction interval.
   - Select **Multiple intervals** to treat the entire time of the amplitude definition as multiple correction intervals. If you select this option, enter the time points defining the different correction intervals (i.e. in the first row enter the time point defining the end of the first correction interval and the beginning of the section correction interval; in the second row enter the time point defining the end of the second correction interval and the beginning of the third correction interval, etc.).
7. Click **OK** to save your amplitude definition and to close the **Edit Amplitude** dialog box.

Using equally spaced data to define an amplitude curve

Use the equally spaced definition method to provide a list of amplitude values at fixed time intervals beginning at a specified value of time. Abaqus interpolates linearly between each time interval. For more information, see *Defining Equally Spaced Data*.

1. Display the **Edit Amplitude** dialog box as described in *Selecting an amplitude type to define*.
2. Click the arrow to the right of the **Time span** field, and specify how you want to define the amplitude as a function of time:
   - Select **Step time** for time that is measured from the beginning of each step.
   - Select **Total time** for total time accumulated over all non-perturbation analysis steps.
3. Indicate how you want to define **Smoothing**:
   - Choose **Use solver default** to accept a default value of 0.25 in Abaqus/Standard and 0.0 in Abaqus/Explicit.
   - Choose **Specify** to enter a value for the smoothing parameter in the adjacent field. A value of 0.05 is suggested for amplitude definitions that contain large time intervals to avoid severe deviation from the specified definition.

   The **Smoothing** parameter is the fraction of the time interval before and after each time point during which the piecewise linear time variation is replaced by a smooth quadratic time variation. This parameter is applicable only when time derivatives are needed (for displacement or velocity boundary conditions in a direct integration dynamic analysis) and is ignored for all other uses of this option.
4. Display the **Amplitude Data** tabbed page.
5. In the **Fixed interval** field, enter the fixed time or frequency interval at which you will provide the amplitude data.
6. In the first row of the **Time/Frequency** column in the data table, enter the time (or lowest frequency) at which you will enter the first amplitude.
7. Enter the **Amplitude** values for each time or frequency. For detailed information on how to enter data, see *Entering tabular data*.
8. If desired, display the **Baseline Correction** tabbed page.

   When you use an amplitude definition to define an acceleration history in the time domain (a seismic record of an earthquake, for example), the integration of the acceleration record through time may result in a relatively large displacement at the end of the event. This behavior typically occurs because of instrumentation errors or a sampling frequency that is not sufficient to capture the actual acceleration history. In Abaqus/Standard it is possible to compensate for it by using "baseline correction." For more information, see *Baseline Correction in Abaqus/Standard*.
9. Click the arrow to the right of the **Correction** field, and select one of the following options:
   - Select **None** for no baseline correction.
   - Select **Single interval** to treat the entire time of the amplitude definition as a single correction interval.
   - Select **Multiple intervals** to treat the entire time of the amplitude definition as multiple correction intervals. If you select this option, enter the time points defining the different correction intervals (i.e. in the first row enter the time point defining the end of the first correction interval and the beginning of the section correction interval; in the second row enter the time point defining the end of the second correction interval and the beginning of the third correction interval, etc.).
10. Click **OK** to save your amplitude definition and to close the **Edit Amplitude** dialog box.

Using periodic data to define an amplitude curve

Select **Periodic** to define the amplitude, a, as a Fourier series:

$$a = A_0 + \sum_{n=1}^{N} [A_n \cos n\omega (t - t_0) + B_n \sin n\omega (t - t_0)] \text{ for } t \geq t_0,$$

$$a = A_0 \quad \text{for } t < t_0,$$

where t_0, N, ω, A_0, A_n, and B_n, $n = 1, 2 \ldots N$, are user-defined constants. For more information, see *Defining Periodic Data*.

1. Display the **Edit Amplitude** dialog box as described in *Selecting an amplitude type to define*.
2. Click the arrow to the right of the **Time span** field, and specify how you want to define the amplitude as a function of time:
   - Select **Step time** for time that is measured from the beginning of each step.
   - Select **Total time** for total time accumulated over all non-perturbation analysis steps.
3. In the **Circular frequency** field, enter ω, the circular frequency, in radians per time.
4. In the **Starting time** field, enter t_0.
5. In the **Initial amplitude** field, enter A_0, the constant term in the Fourier series.
6. In the data table, enter values for **A**, the coefficient of the cosine terms, and **B**, the coefficient of the sine terms. For detailed information on how to enter data, see *Entering tabular data*.
7. Click **OK** to save your amplitude definition and to close the **Edit Amplitude** dialog box.

Using modulated data to define an amplitude curve

Use the modulated definition method to define the amplitude, a, as

$$a = A_0 + A \sin \omega_1 (t - t_0) \sin \omega_2 (t - t_0) \quad \text{for } t > t_0,$$
$$a = A_0 \quad \text{for } t \le t_0,$$

where A_0, A, t_0, ω_1, and ω_2 are user-defined constants. For more information, see *Defining Modulated Data*.

1. Display the **Edit Amplitude** dialog box as described in *Selecting an amplitude type to define*.
2. Click the arrow to the right of the **Time span** field, and specify how you want to define the amplitude as a function of time:
   - Select **Step time** for time that is measured from the beginning of each step.
   - Select **Total time** for total time accumulated over all non-perturbation analysis steps.
3. In the **Initial amplitude** field, enter A_0.
4. In the **Amplitude** field, enter A.
5. In the **Starting time** field, enter t_0.
6. In the **Circular frequency 1** field, enter ω_1.
7. In the **Circular frequency 2** field, enter ω_2.
8. Click **OK** to save your amplitude definition and to close the **Edit Amplitude** dialog box.

Using exponential decay data to define an amplitude curve

Use the exponential decay definition method to define the amplitude, *a*, as

$$a = A_0 + A\exp\left(-\left(t - t_0\right)/t_d\right) \quad \text{for } t \geq t_0,$$
$$a = A_0 \quad \text{for } t < t_0,$$

where A_0, A, t_0, and t_d are user-defined constants. For more information, see *Defining Exponential Decay*.

1. Display the **Edit Amplitude** dialog box as described in *Selecting an amplitude type to define*.
2. Click the arrow to the right of the **Time span** field, and specify how you want to define the amplitude as a function of time:
   - Select **Step time** for time that is measured from the beginning of each step.
   - Select **Total time** for total time accumulated over all non-perturbation analysis steps.
3. In the **Initial amplitude** field, enter A_0.
4. In the **Amplitude** field, enter *A*.
5. In the **Starting time** field, enter the start time of the exponential function, t_0.
6. In the **Decay time** field, enter the decay time of the exponential function, t_d.
7. Click **OK** to save your amplitude definition and to close the **Edit Amplitude** dialog box.

Defining a solution-dependent amplitude curve

Use the solution-dependent definition method to calculate amplitude values based on a solution-dependent variable. For more information, see *Defining a Solution-Dependent Amplitude for Superplastic Forming Analysis*.

1. Display the **Edit Amplitude** dialog box as described in *Selecting an amplitude type to define*.
2. Click the arrow to the right of the **Time span** field, and specify how you want to define the amplitude as a function of time:
   - Select **Step time** for time that is measured from the beginning of each step.
   - Select **Total time** for total time accumulated over all non-perturbation analysis steps.
3. In the **Initial amplitude** field, enter the initial amplitude value. The amplitude starts with the initial value and is then modified based on the progress of the solution.
4. In the **Min amplitude** field, enter the minimum amplitude value.
5. In the **Max amplitude** field, enter the maximum amplitude value. The maximum value is typically the controlling mechanism used to end the analysis.
6. Click **OK** to save your amplitude definition and to close the **Edit Amplitude** dialog box.

Using smooth step data to define an amplitude curve

Use the smooth step definition method to define the amplitude, a, between two consecutive data points (t_i, A_i) and (t_{i+1}, A_{i+1}) as

$$a = A_i \quad + \quad (A_{i+1} - A_i)\,\xi^3\left(10 - 15\xi + 6\xi^2\right) \quad \text{for } t_i \le t \le t_{i+1},$$

where $\xi = (t - t_i) / (t_{i+1} - t_i)$. This definition is intended to ramp up or down smoothly from one amplitude value to another. For more information, see *Defining Smooth Step Data*.

1. Display the **Edit Amplitude** dialog box as described in *Selecting an amplitude type to define*.
2. Click the arrow to the right of the **Time span** field, and specify how you want to define the amplitude as a function of time:
   - Select **Step time** for time that is measured from the beginning of each step.
   - Select **Total time** for total time accumulated over all non-perturbation analysis steps.
3. In the data table, enter the tabular data. For detailed information on how to enter data, see *Entering tabular data*.
4. Click **OK** to save your amplitude definition and to close the **Edit Amplitude** dialog box.

Defining a spectrum

Use the spectrum method to define a spectrum to be used in a response spectrum analysis. For more information, see *Specifying a Spectrum*.

1. Display the **Edit Amplitude** dialog box as described in *Selecting an amplitude type to define*.
2. Click the arrow to the right of the **Specification units** field, and specify the units in which you want to define the spectrum.
   - Select **Displacement**, **Velocity**, or **Acceleration** to define the spectrum in displacement units, velocity units, or acceleration units, respectively.
   - Select **Gravity** to specify an acceleration spectrum in *g*-units.
3. If you selected **Gravity**, enter the value of the acceleration of gravity.
4. In the data table, enter the **Magnitude** (magnitude of the spectrum), **Frequency** (frequency, in cycles per time, at which this magnitude is used), and **Damping** (associated damping, given as a ratio of critical damping) values. For detailed information on how to enter data, see *Entering tabular data*.
5. Click **OK** to save your amplitude definition and to close the **Edit Amplitude** dialog box.

Defining a user-defined amplitude curve

Use the user definition method to define the amplitude curve in user subroutine *UAMP* (Abaqus/Standard) or *VUAMP* (Abaqus/Explicit). For more information, see *Defining an Amplitude via a User Subroutine*.

1. Display the **Edit Amplitude** dialog box as described in *Selecting an amplitude type to define*.
2. In the **Number of variables** field, enter the number of solution-dependent state variables that must be stored with this amplitude definition.
3. Define the amplitude in user subroutine *UAMP* (for Abaqus/Standard) or *VUAMP* (for Abaqus/Explicit). See the following sections for more information:
   - *Specifying general job settings*
   - *UAMP*
   - *VUAMP*
4. Click **OK** to save your amplitude definition and to close the **Edit Amplitude** dialog box.

Defining a PSD definition

Use the PSD definition method to define the frequency dependence of the random loading in a random response analysis step. For more information, see *Defining the Frequency Functions*.

1. Display the **Edit Amplitude** dialog box as described in *Selecting an amplitude type to define*.
2. Click the arrow to the right of the **Specification units** field, and specify the units in which you want to define the curve.
   - Select **Power** to define the frequency function directly in power units.
   - Select **Decibel** to define the frequency function in decibel units.
   - Select **Gravity (base motion)** if the frequency function will be used to define a base motion in *g*-units. If you choose these units, you must define the acceleration of gravity.
3. If you selected **Decibel** units, enter a value for the **Reference power**.
4. If you selected **Gravity** units, enter a value for the **Reference gravity**.
5. In the data table, enter or import the data values for the function:
   - **Real** and **Imaginary** parts of the function, in decibels or in units^2 per frequency.
   - **Frequency**, in cycles/time, or frequency band number (for **Decibel** units).

   For detailed information on how to enter data, see *Entering tabular data*
6. Toggle on **Specify data in an external user subroutine** if you will provide the PSD function in user subroutine *UPSD*.
7. Click **OK** to save your amplitude definition and to close the **Edit Amplitude** dialog box.

The Analytical Field toolset

Abaqus/CAE provides two types of analytical fields: expression fields and mapped fields.
You can use analytical fields to define spatially varying values for selected properties, loads, interactions, and predefined fields, such as the variation of a pressure over a region in a pressure load. The Analytical Field toolset allows you to create and manage analytical fields in the Property module, Interaction module, or Load module.

In this section:

- *Using the Analytical Field toolset*
- *Using analytical expression fields*
- *Using analytical mapped fields*
- *Displaying symbols for interactions and prescribed conditions that use analytical fields*
- *Displaying symbols to visualize mapping source data*
- *Creating expression fields*
- *Creating mapped fields*

Using the Analytical Field toolset

The Analytical Field toolset allows you to create and manage analytical fields. Analytical fields defined using mathematical expressions are called expression fields. Analytical fields defined using an external data source, such as point cloud data, are called mapped fields. Analytical fields indicate points in space using coordinates of the global coordinate system or of a local coordinate system.

Select **Tools->Analytical Field->Create** from the main menu bar in the Property module, Interaction module, or Load module to create a new analytical field. Select **Edit** from the same menu to change an existing analytical field.

Using analytical expression fields

Analytical expression fields define analytical functions—special types of mathematical functions.

You can use expression fields in many prescribed conditions to define spatially varying parameters. For more information, see the following sections:

- *Using the interaction editors*
- *Using the load editors*
- *Using the boundary condition editors*
- *Using the predefined field editors*

In this section:

- *Building valid expressions*
- *Operations and functions in expressions*
- *Evaluating expression fields*

Building valid expressions

Expression fields describe the variation of a parameter for selected interactions and prescribed conditions (such as a pressure magnitude) at a point in space. You create an expression field by building a mathematical expression in the expression field editor. To locate the expression field editor, select **Tools->Analytical Field->Create** from the main menu bar.

Expression fields indicate points in space using coordinates of the global coordinate system or of a local coordinate system. In the expression field editor, these coordinates are listed as **Parameter Names**. By default, the expression is built using the coordinates of the global coordinate system (**X**, **Y**, and **Z** parameter names). The parameter names that are available depend on the type of coordinate system that you select, as shown in *Table 1*. For cylindrical and spherical coordinate systems, the values for **Th** and **P** are evaluated in radians in the range from $-\pi$ to π.

Table 1: Relationship between coordinate system types and parameter names in the expression field editor.

Coordinate system type	Parameter	Parameter names
Rectangular or Global (default)	*X*-, *Y*-, and *Z*-axes	**X**, **Y**, **Z**
Cylindrical	*R*-, θ-, and *Z*-axes	**R**, **Th**, **Z**
Spherical	*R*-, θ-, and ϕ-axes	**R**, **Th**, **P**

An expression is composed using one or more parameter names and one or more operators. You can build the mathematical expression in the expression window of the editor by selecting the parameter names and operators from lists or by typing the parameter names and operators directly into the expression window. Parameter names and operators are case sensitive. Expressions use the syntax required by Python; entries containing errors will generate standard Python errors. See *Operations and functions in expressions* for information on supported operators.

The following examples demonstrate valid expressions.

Example 1

To define a spatial variation with linear distance along a face, type:

```
4.5 * X + 2.75
```

in the expression window of the editor. `X` is the parameter name representing the distance along the face.

Example 2

To define a more complex spatial variation in a cylindrical coordinate system, type:

```
R + sin(Th*pi/2)
```

in the expression window of the editor.

For detailed information, see *Creating expression fields*.

Operations and functions in expressions

This section lists the operations and functions available in the expression field editor.

Arguments to trigonometric functions are assumed to be in radians in the range from $-\pi$ to π. Proper inline Python statements returning a value, including functions in the math module such as those listed, can be used.

For more information, see the documentation for the math module accessible from the official Python home page (*http://www.python.org*). Select **Help->About Abaqus** from the main menu bar to obtain the Python version used by Abaqus/CAE.

Mathematical operations:

+	Add
–	Subtract
*****	Multiply
/	Divide
%	Return the remainder of integer division.
1/A	Return the reciprocal of **A**.
ceil(A)	Return the ceiling of **A**, the smallest integer value greater than or equal to **A**.
fabs(A)	Return the absolute value.
floor(A)	Return the floor of **A**, the largest integer value less than or equal to **A**.
fmod(A,B)	Return fmod(**A**, **B**), as defined by the platform C library. The intent of the C standard is that fmod(**A**, **B**) be exactly (mathematically; to infinite precision) equal to **A** – *n* * **B** for some integer *n* such that the result has the same sign as **A** and magnitude less than abs(**B**).
frexp(A)[]	Return the mantissa and exponent of **A** as the pair (*m*, *e*). *m* is a float and *e* is an integer such that **A** = *m* * 2 ** *e* exactly. Use the brackets to specify the index of the return value to use in the expression evaluation.
modf(A)[]	Return the fractional and integer parts of **A**. Use the brackets to specify the index of the return value to use in the expression evaluation.

Trigonometric functions:

acos(A)	Return the arccosine.
asin(A)	Return the arcsine.
atan(A)	Return the arctangent.
cos(A)	Return the cosine.
cosh(A)	Return the hyperbolic cosine.
hypot(A,B)	Return the Euclidean norm, sqrt(**A***A + **B***B). This is the length of the vector from the origin to point (**A**, **B**).
sin(A)	Return the sine.
sinh(A)	Return the hyperbolic sine.
tan(A)	Return the tangent.
tanh(A)	Return the hyperbolic tangent.

Power and logarithmic functions:

exp(A)	Return the natural exponential to the power **A**, e^{A}.
ldexp(A,B)	Return **A** * (2^{B}).
log(A)	Return the natural logarithm.
log10(A)	Return the base 10 logarithm.
pow(A,B)	Raise a variable to a power.
sqrt(A)	Return the square root.

Constants:

pi	Mathematical constant .
e	Mathematical constant *e*.

Additional information

- *Building valid expressions*
- *Creating expression fields*

Evaluating expression fields

If you specify an expression field for an interaction or prescribed condition, Abaqus/CAE must evaluate the expression field as the first step in determining the values to submit for the analysis. Expressions are evaluated as Python input; entries containing errors will generate standard Python errors. For cylindrical and spherical coordinate systems, the values for **Th** and **P** are evaluated in radians in the range from $-\pi$ to π. Abaqus/CAE evaluates the expression field when the input file is written.

Abaqus/CAE evaluates the expression field at different locations on the model depending on the type of region that you selected when you created the interaction or prescribed condition. *Table 1* indicates the locations on the model that Abaqus/CAE uses for evaluation of the expression field.

Table 1: Expression field evaluation locations.

Region type	Location of expression field evaluation
Node or vertex	At the node or vertex
Edge	At the midpoint of the edge of each element
Surface or face	Centroid of each element face contained in the region
Cell	Centroid of the element

Next, Abaqus/CAE multiplies the magnitude that you specify for the spatially varying parameter, such as a pressure magnitude, by the evaluated expression at each element or node to determine the final values that are submitted to the analysis. The expression field is applied to magnitudes in the interaction or prescribed condition, including the real and imaginary parts of complex magnitudes. Beam and shell gradient values, such as gradients in temperature, are not affected by the expression field. During the analysis, Abaqus applies any amplitude that you have specified for the interaction or prescribed condition.

Analytical field and datum coordinate system

In Abaqus/CAE, when an analytical field uses a local coordinate system, the field is evaluated based on the transformations with respect to the assembly global coordinate system. The instance assembly transformations are evaluated if the analytical field is created in the Load module and an instance level datum coordinate system (for example, Part-1-1.Datum-1) is selected. The instance assembly transformations are not evaluated if the analytical field is created in the Property module and a part-level datum coordinate system (for example, Datum-1) is selected.

Using analytical mapped fields

Analytical mapped fields allow you to define spatially varying parameter values from an external data source.

In this section:

- *About analytical mapped fields*
- *Point cloud data file formats for mapping*
- *Coordinate system for point cloud mapped fields*
- *Mesh-to-mesh mapping from an output database file*
- *Supported elements for mapping*

About analytical mapped fields

In Abaqus/CAE a mapped field is used to provide the values of selected loads, interactions, properties, etc., at different points in space.
For example, you can define a spatially varying shell thickness or pressure load by providing the thickness or pressure values at different coordinates. Parameter values can be read in from a point cloud data file generated by a third-party CAE application or from an Abaqus output database (`.odb`) file.

Mapped fields allow you to import discrete and discontinuous parameter data and apply them to your Abaqus/CAE model. Abaqus/CAE applies the values to the current model, mapping the input *X*-, *Y*-, and *Z*-coordinates to locations in the model. Abaqus/CAE maps the source data onto the target model, and Abaqus computes the distributed parameter values to be used during the analysis. The parameter values are also called field values, or field data; for example, pressure values at different points on a surface.

When you create a mapped field from point cloud data, you can assign a local coordinate system to the source data region to simplify the three-dimensional definition of points in space. The local coordinate system can be rectangular, cylindrical, or spherical. For example, with a rectangular coordinate system, the *X*-, *Y*-, and *Z*-coordinates are interpreted in that local coordinate system.

Only scalar data values can be used in mapped fields. Each field data value is mapped from the source to the target region as a scalar value. The Abaqus/CAE mapping algorithm is purely geometric, with no physical considerations such as conservative mapping.

Mapped fields can be used to define the properties and attributes shown in *Table 1*.

Table 1: Attributes and properties that support mapped fields.

Category	Attribute/Property
Loads	Body concentration flux
	Body heat flux
	Pressure
	Surface concentration flux
	Surface heat flux
	Surface pore fluid flow
Boundary conditions	Acoustic pressure
	Electrical potential
	Normalized concentration
	Mass flow
	Pore pressure
	Temperature
Predefined fields	Nodal temperature
	Pore pressure
	Saturation
	Void ratio
Interactions	Concentrated film condition
	Surface film condition
	Surface radiation
Other	Density (material density distributions)

Category	Attribute/Property
	Shell thicknesses (element distribution or nodal distribution in shell sections)

The magnitude you specify in the property, load, predefined field, or interaction is used as a multiplier for the mapped field data values. You can also scale the source data coordinates; for example, to account for a mismatch of units (i.e., meters to millimeters).

When you apply a load, interaction, or predefined field using a mapped field, you can display symbols in the viewport to visualize the locations and magnitudes of the field values. However, you must mesh the model first to be able to see these symbols.

Abaqus/CAE provides a set of mapping tolerance controls that allow you to adjust how far source data points may lie from the target points. Depending on how far away each source point is from the nearest node on the meshed model target, Abaqus/CAE must decide whether to use or discard each source point.

Output request frequency time points are not supported in mapped fields.

Note: When a mapped field is used to apply a pressure load, you must request output for the field output variable P to be able to visualize the mapped pressure values in the Visualization module. The output variable name P is automatically changed to PDLOAD during the analysis; see *Abaqus/Standard Output Variable Identifiers*, or *Abaqus/Explicit Output Variable Identifiers*.

Point cloud data file formats for mapping

Point cloud data files must be plain text files in one of two formats: **XYZ** or **Grid**.
A point cloud data file in **XYZ** format must contain the desired field values at a set of coordinates. For a rectangular coordinate system, the points must be given by *X*-, *Y*-, and *Z*-coordinates. If you use a cylindrical or spherical local coordinate system, the appropriate coordinates must be used. The **Grid** format contains field values at points in a three-dimensional grid. Abaqus/CAE interpolates to fill in any missing field values in your grid data files.

In this section:

- *XYZ format*
- *Grid format*

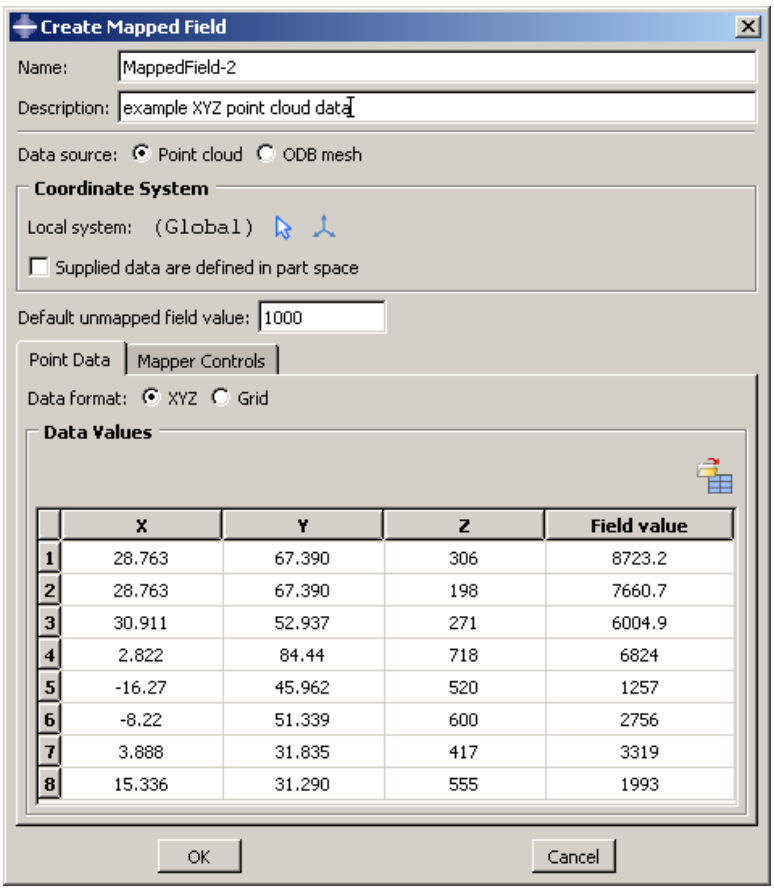
XYZ format

A point cloud data file in **XYZ** format must contain rows of data. For a rectangular coordinate system, each row must consist of *X*-, *Y*-, and *Z*-coordinates followed by the field value at that point. The values in each row can be separated by any combination of spaces, tabs, or commas; each space, tab, or comma is considered a single field delimiter. Comma-separated values (CSV), shown in the following example, is a commonly used format:

```
X1,Y1,Z1,value
X2,Y2,Z2,value
X3,Y3,Z3,value
etc.
```

If you use a cylindrical or spherical local coordinate system, the appropriate coordinates must be given in the data file; see *Coordinate system for point cloud mapped fields*.

Figure 1 shows an example of point cloud data in **XYZ** format that have been imported into the **Edit Mapped Field** dialog box.



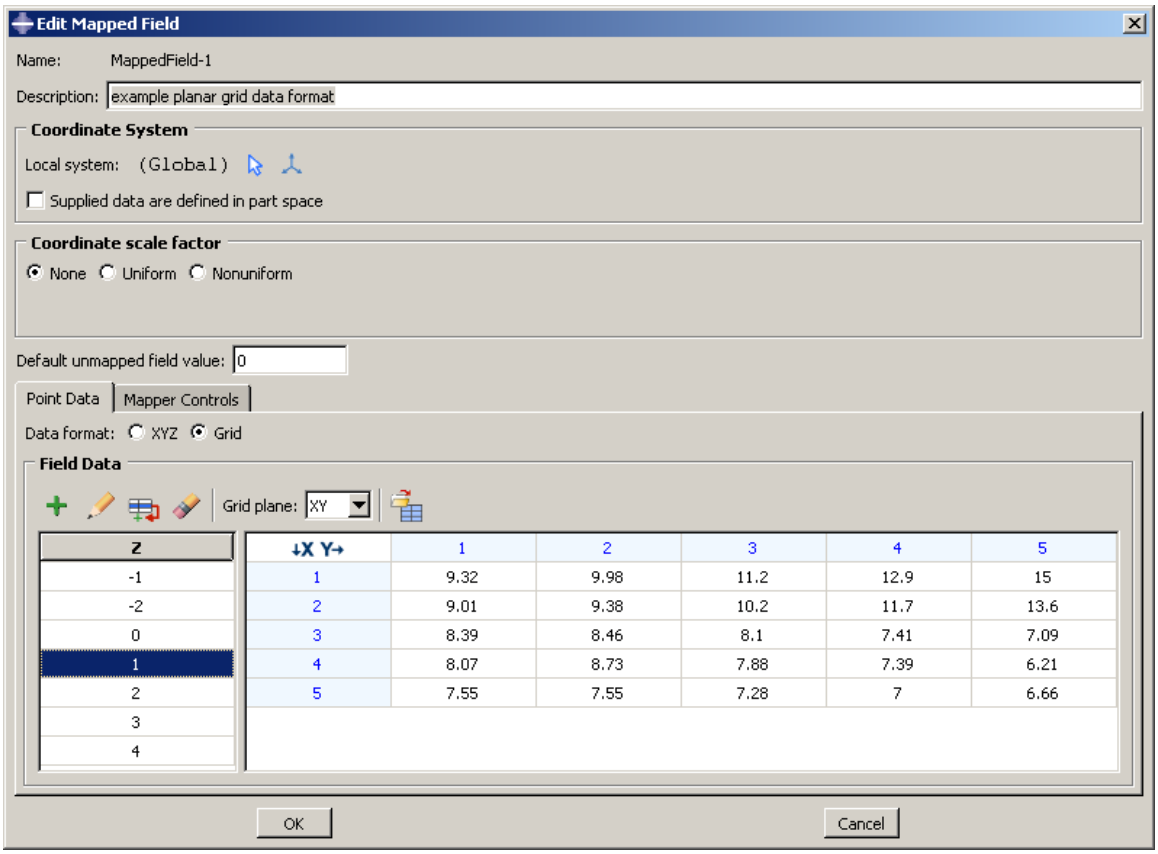


Figure 1: Point cloud data in XYZ format.

Grid format

A point cloud data file in **Grid** format defines the field values at points in a three-dimensional grid. For a rectangular coordinate system, this is a planar or cubic grid. *Figure 1* shows a simple example of point cloud data in **Grid** format that have been imported into the **Edit Mapped Field** dialog box.

Z	↓X Y→	1	2	3	4	5
-1	1	9.32	9.98	11.2	12.9	15
-2	2	9.01	9.38	10.2	11.7	13.6
0	3	8.39	8.46	8.1	7.41	7.09
1	4	8.07	8.73	7.88	7.39	6.21
2	5	7.55	7.55	7.28	7	6.66
3						
4						

Figure 1: Point cloud data in Grid format.

Grid data consist of a set of files, each containing a single plane. For example, you could have one file for the *Z*=3 plane. This file would contain a grid of *X*- and *Y*-coordinates and the field value at each point; for example:

```
a,  -2,     -1,     0,      1,      2
-2, 0.146, 0.141, 0.139, 0.137, 0.131
-1, 0.141, 0.121, 0.116, 0.111, 0.100
 0, 0.139, 0.116, 0.105, 0.101, 0.094
 1, 0.133, 0.129, 0.122, 0.114, 0.107
 2, 0.128, 0.120, 0.111, 0.102, 0.090
```

The *X*-coordinates appear in the first (left) column in this file, and the *Y*-coordinates are in the first (top) row, starting in the second position. The first position contains a dummy value that is ignored by Abaqus/CAE when you import the file into the data table in the **Create Mapped Field** dialog box. In the example file above, the dummy value is the character `a`; you can use any value in this position since it will be ignored.

The values in each row of a grid data file can be separated by any combination of spaces, tabs, or commas; each space, tab, or comma is considered a single field delimiter.

Your complete set of grid data files must include one file for each plane; for example, the *X*–*Y* planes at *Z*=0, *Z*=1, *Z*=2, *Z*=3. The *Y*–*Z*, *X*–*Z*, *Y*–*X*, *Z*–*Y*, and *Z*–*X* planes can also be used. You choose between the different grid planes in the **Create Mapped Field** dialog box.

If your grid data files have any missing field values, Abaqus/CAE interpolates to fill in the missing points; you do not need to fill in these missing values in the **Create Mapped Field** dialog box.

If you use a cylindrical or spherical local coordinate system, the appropriate coordinates must be given in the grid data files; see *Coordinate system for point cloud mapped fields*.

Coordinate system for point cloud mapped fields

Mapped fields indicate points in space using coordinates of the global coordinate system or a local coordinate system. For a point cloud data source, different coordinate systems can be involved when the mapped data coordinates are interpreted and applied to the property, load, predefined field, or interaction. When analytical field values (point cloud data in grid format) referring to a cylindrical or spherical coordinate system are used to map a field variable, Abaqus/CAE converts the values in the cylindrical or spherical coordinate system into corresponding discrete values in the Cartesian coordinate system.

Source data local coordinate system

The three-dimensional coordinates and field values are all defined in the local coordinate system. You can specify the coordinate system to use in the **Create Mapped Field** dialog box. This is an assembly-level (not part-level) coordinate system.

If you use a rectangular coordinate system (default), Abaqus/CAE uses *X*-, *Y*-, and *Z*-coordinates to interpret the source data points. If you specify a cylindrical or spherical coordinate system, Abaqus/CAE interprets the coordinates as shown in *Table 1*. The columns shown in the data table of the **Create Mapped Field** dialog box depend on the type of local coordinate system that you choose. For cylindrical and spherical coordinate systems, the values for **Th** and **P** are entered in degrees and during the analysis are converted to radians in the range from $-\pi$ to π.

Table 1: Coordinate system types and coordinate names for mapped fields.

Coordinate system type	Coordinates	Columns shown in data table
Rectangular or Global (default)	*X*-, *Y*-, and *Z*-axes	**X**, **Y**, **Z**
Cylindrical	*R*-, θ-, and *Z*-axes	**R**, **Th**, **Z**
Spherical	*R*-, θ-, and ϕ-axes	**R**, **Th**, **P**

Source data defined in part space

You can choose this option by toggling on **Supplied data are defined in part space** in the **Create Mapped Field** dialog box. The source data and its local coordinate system are both interpreted in the part-level coordinate system of the target model region.

Mesh-to-mesh mapping from an output database file

When the data source is an Abaqus output database (`.odb`) file, the field output variable values must be displayed in a viewport. This technique is called mesh-to-mesh mapping. The field output variable values can be located at nodes, element centroids, or integration points. In this type of mapping the geometric region of the source data is the mesh connectivity data such as element faces or element sets.

To select the exact source data you want to use, open the desired output database file and display the undeformed contour plot in the Visualization module. You can also use the deformed plot, but the data are still mapped from the undeformed mesh. Choose the field output variable and the step and frame of the analysis for the value you want to map. When you create the new mapped field in your target model in the model database (`.cae`) file, you specify the displayed viewport as the data source. The current state of the viewport is taken as a snapshot of the set of values to be mapped onto the target model; namely, the specific field output variable displayed at a specific step and frame of the analysis.

As an example, you might use mesh-to-mesh mapping in the following workflow:

1. Set up and run a thermal analysis in Abaqus to generate an output database containing nodal temperatures (output variable NT).
2. Open the output database (`.odb`) file in the Visualization module, and display output variable NT at Step-3, Frame 0 of the analysis.
3. Open the model database (`.cae`) file containing your main target model. Select **Tools->Analytical Field->Create** from the main menu bar in the Load module to create a mapped field from the nodal temperature values. In the **Create Mapped Field** dialog box, select the viewport containing the output database as the source data.
4. Mesh (or remesh) your main model.
5. Create a temperature predefined field, and select the mapped analytical field to define the temperature distribution. Abaqus/CAE maps the source data points and their associated temperatures onto points in the target model.
6. Set up and run the subsequent analysis.

The source data on the output database mesh can be located at nodes, integration points, or whole elements. Dissimilar meshes are supported.

The current settings in the selected viewport are used in the mapping. These settings are as follows:

- Primary field output variable
- Step/increment
- Averaging options selected in the **Result Options** dialog box
- Section points (top or bottom)
- Etc.

The following viewport settings are not supported for mesh-to-mesh mapping:

- Display groups
- Transformations
- Averaging by element sets or display groups in the **Result Options** dialog box
- Element face data
- User data in the current session (but data saved in the output database file is supported)

When you create a mapped field from output database data and close the **Create Mapped field** dialog box, the source data are saved to the mapped field object, but the viewport itself is not saved. Any changes made in the viewport after creating the mapped field are not reflected in the mapping data. After you have created a mapped field using

mesh-to-mesh mapping, you cannot edit the source data mesh specifications; you can edit an existing mapped field only to change the default field value or mapper control options.

Volumetric mesh-to-mesh mapping can be performed only with nodal temperatures and material densities. When the mapping target is a mesh-based nodal region, you must specify whether the target is a surface or a volumetric region. Abaqus/CAE uses different mapping algorithms for a surface versus a volumetric region.

Supported elements for mapping

Mapped fields can be used only in models in which supported element types are used in the mesh.
The most commonly used elements are supported, including shells.

Supported element classes are listed below, according to the topology of the representative element type: shape, number of nodes, and number of integration points. Any similar element with the same topology is supported for mapping.
The supported representative elements are as follows:

- S3, S4, S4R, S8R, STRI65
- C3D4, C3D6, C3D8, C3D8R, C3D10, C3D15, C3D20, C3D20R
- CPE3, CPE4, CPE6, CPE8
- CAX3, CAX4, CAX6, CAX8

The following classes of elements are not supported and cannot be used in a target model mesh or output database source mesh:

- Surface elements
- Rigid elements
- Analytical rigid surface elements
- Cohesive elements
- Composite solid elements
- Continuum shell elements

Displaying symbols for interactions and prescribed conditions that use analytical fields

When you apply an interaction or a prescribed condition to a region, you can display symbols in the viewport that represent the interaction or prescribed condition.

By default, the symbols for interactions and prescribed conditions that use analytical field distributions are scaled based on the calculated value. For symbols other than arrows, a plus sign (+) or a minus sign (−) is displayed inside each symbol to indicate whether the magnitude of the interaction or prescribed condition is positive or negative at that location. You can turn off the symbol scaling using the **Attribute** display options in the **Assembly Display Options** dialog box. For more information, see *Controlling the display of attributes*.

Abaqus/CAE displays scaled-down symbols for interactions and prescribed conditions when an analytical field evaluates to zero for a portion of its region. These scaled-down symbols are noticeably smaller than the default symbol size. For more information, see *Understanding prescribed condition symbol type, color, and size*.

In this section:

- *Expression field display symbol details*
- *Mapped field display symbol details*

Expression field display symbol details

The points used for symbol display on meshes coincide with the locations where the expression field is evaluated during the analysis. On geometry, when the symbols appear equally spaced along an edge or over the face of a model, Abaqus/CAE selects a random set of points to use for symbol display. The points selected for symbol display may or may not coincide with the locations where the expression field is evaluated.

In some cases the expression field cannot be evaluated at a given point due to an error; for example, division by zero. When this situation occurs, a message appears in the message area indicating that an error occurred while evaluating the expression field. As a visual cue to indicate that there is an error, the symbols displayed in the viewport are no longer scaled, even though the setting to scale symbols based on the expression field value is turned on. You can attempt to eliminate the evaluation error by changing the symbol density settings, which prompts Abaqus/CAE to select a different set of points to use for symbol display. For more information on changing the symbol density settings, see *Controlling the display of attributes*.

Mapped field display symbol details

To be able to see the symbols representing a mapped field, you must first mesh your model before applying the load, interaction, or predefined field.

The points used for symbol display on mapped fields are the native or orphan mesh nodes or elements that will be used in the analysis. If a native mesh is not present, the symbols will be displayed unscaled. In addition, if the mapping fails due to an error (for example, unsupported element types or incorrect tolerances), the symbols will also be displayed unscaled.

In these cases a message appears in the message area indicating an error in the evaluation. As a visual cue to indicate that there is an error, the symbols displayed in the viewport are no longer scaled and are displayed at the points they would be when scaling is turned off. You can try to fix the mapping by remeshing or by changing the symbol density settings, which prompts Abaqus/CAE to select a different set of points to use for symbol display. For more information on changing the symbol density settings, see *Controlling the display of attributes*.

Displaying symbols to visualize mapping source data

You can plot your mapping source data separately from the load, interaction, or predefined field where it is applied. Plotting of source data is supported only for analytical mapped fields created from point cloud data in **XYZ** format.

1. From the Model Tree, expand the **Fields** container and the **Analytical Fields** container to display the mapped field object.
2. Click mouse button 3 on the mapped field object, and select **Plot source data** from the menu that appears.

The displayed symbols represent the locations and relative magnitudes (field values) of the source data points. The magnitudes are color coded using a rainbow color spectrum from red (for the maximum value) to blue (for the minimum value), as shown in *Figure 1*.

Figure 1: Color coding used for visualizing mapping source data.

Creating expression fields

Select **Tools->Analytical Field->Create** from the main menu bar in the Property module, Interaction module, or Load module to create an analytical field using an expression. Analytical fields defined using mathematical expressions are referred to as expression fields.

1. Open the **Create Expression Field** dialog box using one of the following methods:
   - From the main menu bar, select **Tools->Analytical Field->Create**.

     Tip: You can also click **Create** in the **Analytical Field Manager**.

   - From the interaction editor in the Interaction module, click $f(x)$ next to the **Definition** or **Emissivity distribution** field.
   - From the load, boundary condition, or predefined field editor in the Load module, click $f(x)$ next to the **Distribution** field.
2. Choose **Expression field** as the **Type**, and click **Continue**.
3. In the **Name** text field, enter a name for the expression field. For information on naming objects, see *Using basic dialog box components*.
4. In the **Description** text field, enter a description for the expression field.
5. If you want to change the local coordinate system for the expression field, click **Edit** and use one of the following methods:
   - Select an existing datum coordinate system in the viewport.
   - Select an existing datum coordinate system by name.
     1. From the prompt area, click **Datum CSYS List** to display a list of datum coordinate systems.
     2. Select a name from the list, and click **OK**.
   - Click **Use Global CSYS** from the prompt area to revert to the global coordinate system.
6. Build your expression in the expression window of the editor using a combination of the following procedures:
   - Select a parameter name from the list on the left side of the editor. The parameter names that are available depend on the type of coordinate system that you select:
     - **Rectangular**: **X**, **Y**, and **Z** are the values on the *X*-, *Y*-, and *Z*-axes, respectively.
     - **Cylindrical**: **R**, **Th**, and **Z** are the values on the *R*-, θ-, and *Z*-axes, respectively.
     - **Spherical**: **R**, **Th**, and **P** are the values on the *R*-, θ-, and ϕ-axes, respectively.

     The parameter name appears in the expression window.
   - Select an operation, function, or constant from the **Operators** list on the right side of the editor. For more information, see *Operations and functions in expressions*.

     The selected operation, function, or constant appears in the expression window.
   - Use standard mouse and keyboard editing techniques in the expression window to position the cursor and configure your expression. Parameter names and operators are case sensitive.
   - Adjust *the syntax of your expression* if necessary; parentheses may be needed.

- Click **Clear Expression** to clear the entire expression in the expression window.

7. Click **OK** to create the expression field and to exit the editor.

Additional information

- *Using the interaction editors*
- *Using the load editors*
- *Using the boundary condition editors*
- *Using the predefined field editors*
- *The Analytical Field toolset*

Creating mapped fields

Select **Tools->Analytical Field->Create** from the main menu bar in the Property module, Interaction module, or Load module to create an analytical mapped field.
Analytical fields defined from an external data source are referred to as mapped fields. The external data source can be either point cloud data files or an Abaqus output database (`.odb`) file. See *Using analytical mapped fields* for an overview of mapped fields.

In this section:

- *Creating mapped fields from point cloud data*
- *Creating mapped fields from output database mesh data*
- *Search controls for mapped fields*

Creating mapped fields from point cloud data

You can create a mapped field by reading parameter values in from a point cloud data file generated by a third-party CAE application. Before creating a mapped field using the procedure below, you must have your point cloud data files prepared and ready to import.

1. Open the **Create Mapped Field** dialog box using one of the following methods:
   - From the main menu bar, select **Tools->Analytical Field->Create**.

     Tip: You can also click **Create** in the **Analytical Field Manager**.

   - From the interaction editor in the Interaction module, click $f(x)$ next to the **Definition** or **Emissivity distribution** field.
   - From the load or predefined field editor in the Load module, click $f(x)$ next to the **Distribution** field.
2. Choose **Mapped field** as the **Type**, and click **Continue**.
3. In the **Name** text field, enter a name for the mapped field. For information on naming objects, see *Using basic dialog box components*. In the **Description** text field, enter a description for the mapped field.
4. Choose **Point cloud** as the **Data source** to import point cloud data files that you have generated from another CAE application. These files must contain your field values and coordinates in either **XYZ** format or **Grid** format, as described in *Point cloud data file formats for mapping*.
5. For a point cloud data source you can optionally assign a local coordinate system to the source data region to simplify the three-dimensional definition of points in space. Click and use one of the following methods:
   - Select an existing datum coordinate system in the viewport.
   - Select an existing datum coordinate system by name.
     1. From the prompt area, click **Datum CSYS List** to display a list of datum coordinate systems.
     2. Select a name from the list, and click **OK**.
   - Click **Use Global CSYS** from the prompt area to revert to the global coordinate system.

   Click to create a new datum coordinate system.

   When you assign a local coordinate system, the source data coordinates will be defined in that coordinate system, which is an assembly-level (not part-level) coordinate system. See *Coordinate system for point cloud mapped fields*, for more information.
6. If desired, toggle on **Supplied data are defined in part space** to indicate that the source data and its local coordinate system are both defined in the part-level coordinate system of the target model region.
7. If desired, choose one of the following to enter a **Scale factor** and to scale the source data coordinates; for example, to account for a mismatch of units (i.e., meters to millimeters):
   - Choose **Uniform**, and enter a single scale factor.
   - Choose **Nonuniform**, and enter a scale factor for the *X*-, *Y*-, and *Z*-coordinates.

8. Enter a value for **Default unmapped field value**, or accept the default of zero. Abaqus/CAE assigns this value at any target points for which it cannot find a source point from which to map. See *Search controls for mapped fields*.
9. On the **Point Data** tabbed page, choose one of the following as the data format:
   - Choose **XYZ** if your data file contains rectangular *X*-, *Y*-, and *Z*-coordinates with corresponding field values. See *XYZ format*, for details about this format. Click  to browse and select your data file to import. For more information about reading data from a file, see *Entering tabular data*.

     If your local coordinate system is cylindrical or spherical rather than rectangular, Abaqus/CAE expects your data file to contain the appropriate coordinate types. See *Coordinate system for point cloud mapped fields*.
   - Choose **Grid** if your data files contain field values defined in a three-dimensional grid of points. See *Grid format*, for details about this format.

     In the **Field Data** table, specify the planes and then import the field values as follows:

     1. Select the grid plane in which your data are organized, such as **XY**, **YZ**, **XZ**, **YX**, **ZY**, or **ZX** for a rectangular coordinate system.
     2. Click  to add a plane in the left frame. Enter the plane height, click **OK**, and enter the field values in the table or click  to import from a file. For example, add a plane at *Z*=2 and then import the field values at various *X*- and *Y*-coordinates within this plane.
     3. Repeat for other plane heights within the same grid plane; for example, at *Z*=3, *Z*=4, etc.

     You can use the following editing tools in the **Data Values** table:

	**Add Plane**
	**Edit Plane**
	**Copy Plane**
	**Delete Plane**

     For more information about reading data from a file, see *Entering tabular data*.

10. On the **Mapper Controls** tabbed page, you can adjust the search tolerance parameters. See *Search controls for mapped fields*.
11. Click **OK** to create the mapped field and to close the dialog box.

When you later apply a load, interaction, or predefined field using a mapped field, you can display symbols in the viewport to visualize the locations and magnitudes of the field values. However, you must mesh the model first to be able to see these symbols.

Additional information

- *Using the interaction editors*
- *Using the load editors*
- *Using the boundary condition editors*

- *The Analytical Field toolset*

Creating mapped fields from output database mesh data

You can create a mapped field by reading parameter values in from an Abaqus output database (`.odb`) file. When the mapping data source is an Abaqus output database, the field values must be displayed in a contour plot in the Visualization module. See *Mesh-to-mesh mapping from an output database file*, for an overview of mesh-to-mesh mapping.

1. When creating a mapped field from an output database, you must have two files open and displayed simultaneously in separate viewports:
   - the model database (`.cae`) file containing your main target model for the mapping, and
   - the output database (`.odb`) file containing field output variable data from a previous analysis run on the same (or similar) model.
2. Select the source data you want to use.
   a. In the Visualization module, open the output database file that contains the source data.
   b. Display the undeformed contour plot in a viewport. You can also use the deformed plot, but the data are still read from the undeformed mesh.
   c. Choose the field output variable for the values you want to map, at a specific step and frame of the analysis. See *Producing a contour plot*, for details about contour plots.
3. In the model database containing the main (target) model, open the **Create Mapped Field** dialog box using one of the following methods:
   - From the main menu bar, select **Tools->Analytical Field->Create**.

     Tip: You can also click **Create** in the **Analytical Field Manager**.

   - From the interaction editor in the Interaction module, click $f(x)$ next to the **Definition** or **Emissivity distribution** field.
   - From the load, boundary condition, or predefined field editor in the Load module, click $f(x)$ next to the **Distribution** field.
4. Choose **Mapped field** as the **Type**, and click **Continue**.
5. In the **Name** text field, enter a name for the mapped field. For information on naming objects, see *Using basic dialog box components*. In the **Description** text field, enter a description for the mapped field.
6. Choose **ODB mesh** as the **Data source**.
7. If desired, choose one of the following to enter a **Scale factor** and to scale the source data coordinates; for example, to account for a mismatch of units (i.e., meters to millimeters):
   - Choose **Uniform**, and enter a single scale factor.
   - Choose **Nonuniform**, and enter a scale factor for the *X*-, *Y*-, and *Z*-coordinates.
8. Enter a value for **Default unmapped field value**, or accept the default of zero. Abaqus/CAE assigns this value at any target points for which it cannot find a source point from which to map. See *Search controls for mapped fields*.
9. On the **ODB Mesh Data** tabbed page, select the **Viewport to map** from the list of open viewports.

Abaqus/CAE uses the current plot state of the selected viewport as the set of values to be mapped onto the target model in your model database (`.cae`) file; namely, the specific field output variable displayed at a specific step and frame of the analysis.

10. On the **Mapper Controls** tabbed page, you can adjust the search tolerance parameters. See *Search controls for mapped fields*.
11. Click **OK** to create the mapped field and to close the dialog box.

After you have created a mapped field using mesh-to-mesh mapping, you cannot edit the source data mesh specifications; you can edit an existing mapped field only to change the default field value or the mapper controls.

When you later apply a load, interaction, or predefined field using a mapped field, you can display symbols in the viewport to visualize the locations and magnitudes of the field values. However, you must mesh the model first to be able to see these symbols.

Additional information

- *Using the interaction editors*
- *Using the load editors*
- *Using the boundary condition editors*
- *The Analytical Field toolset*

Search controls for mapped fields

On the **Mapper Controls** tabbed page of the **Create Mapped Field** dialog box, you can adjust the search tolerance parameters. The search controls are slightly different for point cloud data sources versus output database mesh sources.

Abaqus/CAE attempts to map all of your source data points and their associated field values onto points in the target model. Depending on how far away each source point lies from the nearest node on the meshed model target, Abaqus/CAE must decide whether to use or discard each source point. These decisions are based on the search tolerance distance values you choose on the **Mapper Controls** tabbed page.

Search controls for point cloud mapped fields

The positive and negative normal tolerance values define how far away a source data point can lie from the exterior surface of the target model. The target model surface is interpolated in the undeformed finite element model. By default, each source data point must lie within a distance calculated by multiplying the average element characteristic size in the target model by 0.05. This distance is measured along the positive normal vector of the target surface (see *Figure 1*).

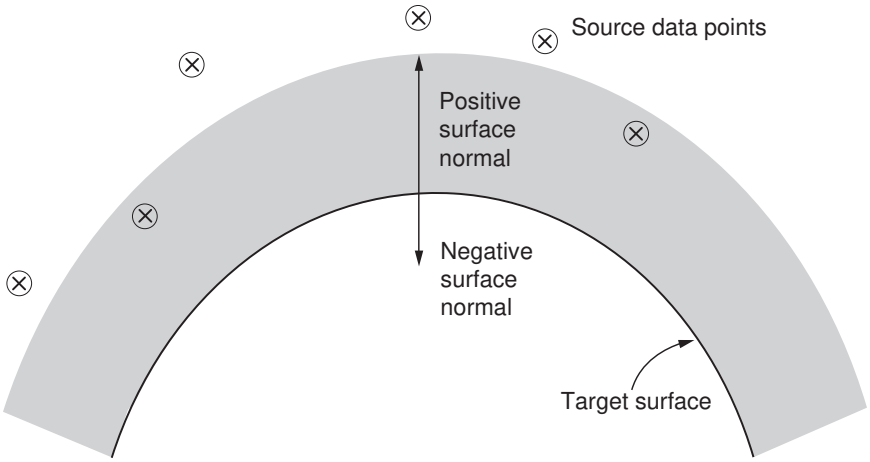

Figure 1: Positive normal search distance.

You can change the tolerance distance values to control which source data points will be included or ignored. You can define the tolerance values as a relative fraction of the average element size in the meshed model or as an absolute distance measured in the length units being used in your model.

For any target points at which Abaqus/CAE cannot map a source point, it will substitute the **Default unmapped field value** entered in the **Create Mapped Field** dialog box. The default is zero. The default field value is applied for both point cloud data sources and output database mesh sources.

For a point cloud data source, the following options and search tolerance values are available on the **Mapper Controls** tabbed page:

Tolerance type

If you choose **Relative** (default), the tolerance values are interpreted as a fraction (not percentage) of the average element characteristic size in the meshed model. If you choose **Absolute**, the tolerance values are taken as exact distances measured in the length units used in your model.

Positive normal search distance tolerance

Any source points within this distance, as measured along the positive normal vector of the underlying geometry of the target surface, are mapped and included in the analysis (see *Figure 1*). This tolerance applies only to

surface (not volumetric) target mapping. The default is 0.05 of the average element characteristic size in the meshed model.

Negative normal search distance tolerance

Any source points within this distance, as measured along the negative normal vector of the underlying geometry of the target surface, are mapped and included in the analysis. This tolerance applies only to surface (not volumetric) target mapping. The default is 0.15 of the average element characteristic size in the meshed model.

Neighborhood search distance tolerance

Any source data points that lie outside the neighborhood search tolerance are ignored and are not used in the analysis. This tolerance applies to both surface and volumetric target mapping.

Abaqus/CAE uses a distance weighting algorithm to interpolate the field data values on the meshed target model. Abaqus/CAE always tries to interpolate the source values on the target. If Abaqus/CAE finds any points for which interpolation is not possible, a distance weighting algorithm is used that will take nodes within the neighborhood search distance. Distance weighting does not consider any other existing tolerances (positive/negative normal search tolerances or boundary search tolerance). You can deactivate distance weighting by using a very small neighborhood search distance, in which case Abaqus/CAE applies the **Default unmapped field value** at these nodes.

Abaqus/CAE makes three passes when attempting to map source points onto target points. Abaqus/CAE:

1. Tries to interpolate field values on the target. The neighborhood search tolerance is ignored on the first pass.
2. Uses the distance weighting algorithm to take source points within the neighborhood search tolerance.
3. For any target points that remain unmapped, Abaqus/CAE applies the **Default unmapped field value**.

Search controls for output database fields

The normal tolerance value defines how far away a source data point can lie from the exterior surface of the target model. By default, each source data point must lie within a distance calculated by multiplying the average element characteristic size in the target model by 0.05. This distance is measured along the normal vector of the target surface. The tolerance values are interpreted as a fraction (not percentage) of the average element characteristic size in the meshed model

You can change the default tolerance values to determine which source data points will be included or discarded.

For any target points at which Abaqus/CAE cannot map a source point, it will substitute the **Default unmapped field value** entered in the **Create Mapped Field** dialog box. The default is zero. The default field value is applied for both point cloud data sources and output database mesh sources.

For an output database source, the following options and search tolerance values are available on the **Mapper Controls** tabbed page:

Normal search distance tolerance

Any source points within this distance, as measured along the positive normal vector of the underlying geometry of the target surface, are mapped and included in the analysis. This tolerance applies to both surface and volumetric target mapping. The default is 0.05 of the average element characteristic size in the meshed model.

Boundary search distance tolerance

This tolerance specifies the in-plane distance within which a source data point must lie, outside the region of the elements of the meshed target model (see *Figure 2*). Increasing this tolerance from the default of 0.01 (of the

average element size) effectively allows you to expand each target element face for the purpose of mapping. Increasing this tolerance may be helpful when the source data are a coarser mesh than the target model mesh.

The field values are interpolated when they are mapped onto the target model. The boundary search tolerance applies to both surface mapping and volumetric mapping.

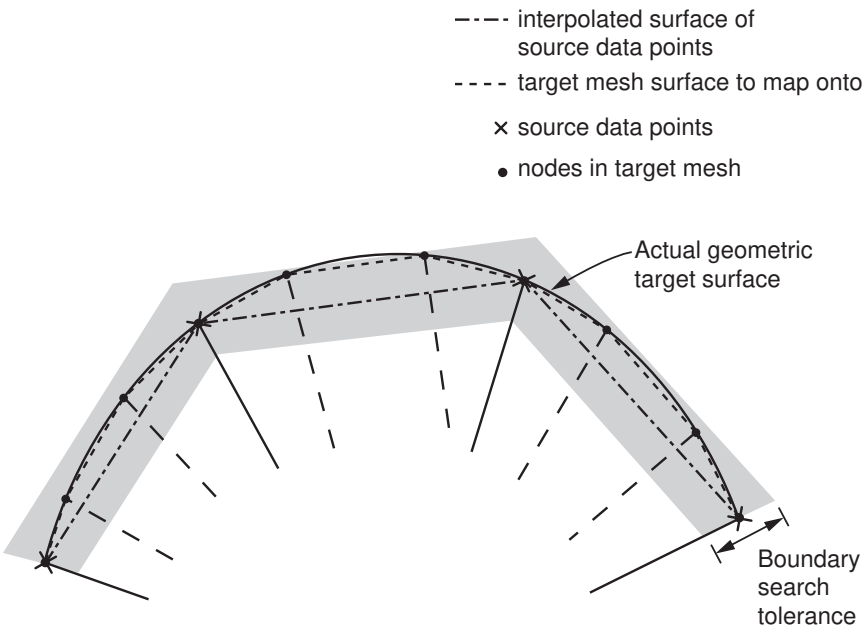

Figure 2: Boundary search distance.

Volume-to-surface mapping control

The **Mapper Controls** tabbed page of the **Create Mapped Field** dialog box includes the **Mapping algorithm for target surface** option, which lets you choose **Surface** or **Volumetric** mapping.

Your target region must be one of three types: a volume, a surface, or a set of nodes in a mesh. If the target is a volume, Abaqus/CAE always performs volumetric mapping. However, if the target is a surface or a set of nodes, you must choose the algorithm that you want Abaqus/CAE to use to apply the source data. Choosing **Surface** causes Abaqus/CAE to use a surface projection algorithm in which it projects the source data to target surface centroids or nodes. Choosing **Volumetric** causes Abaqus/CAE to use a volumetric interpolation algorithm in which it interpolates the source data to target element centroids or nodes. The distinction between the two algorithms only affects how field values from a source volume are applied to a target surface.

For the purpose of the mapping algorithm, a target surface or volume is defined in the context of either a geometric model or a mesh in Abaqus/CAE:

- a volume in a geometric model is a three-dimensional cell
- a volume in a mesh consists of elements
- a surface in a three-dimensional geometric model is a geometric face
- a “surface” in a mesh consists of element faces

Your choice of surface versus volumetric algorithm also applies when you are mapping onto nodes and the target nodes are defined by a node set (mesh-based). However, if the target nodes are defined from model geometry, Abaqus/CAE always uses surface mapping for geometric faces and uses volumetric mapping for geometric cells.

The target region is where you apply the load, interaction, boundary condition, or predefined field in your main model. If you apply the same mapped field source in two different attributes, they may have different behaviors if the target region type is different.

Volume-to-surface control for point cloud data sources

Table 1 describes the cases in which Abaqus/CAE performs volumetric or surface mapping for a point cloud data source and when you must choose between the two.

Table 1: Volumetric vs. surface mapping cases for a point cloud data source.

Point cloud data source	Target region type		
	Geometric cell (3D elements or nodes)	Shell or surface/faces[1]	Node set
Point cloud data	Volumetric	Volumetric or surface	Volumetric or surface
[1] For the purpose of the mapping algorithm, a surface can be a face of a three-dimensional element.			

Volume-to-surface control for output database sources

Table 2 describes the cases in which Abaqus/CAE performs volumetric or surface mapping for an output database source and when you must choose between the two.

Table 2: Volumetric vs. surface mapping cases for an output database source.

Output database source	Target region type		
	Geometric cell (3D elements or nodes)	Shell or surface/faces[1]	Node set
Nodal data	Volumetric	Volumetric or surface	Volumetric or surface
Element-based data[2]	Volumetric	Volumetric or surface	Volumetric or surface
Surface-based data	N/A (error)	Surface	Surface
[1] For the purpose of the mapping algorithm, a surface can be a face of a three-dimensional element.			
[2] Output database averaging controls in the Visualization module affect the continuity of element-based source data.			

If the target region is a shell or surface, the volumetric algorithm interpolates field values from an entire source volume (in the output database) onto the target surface region. Alternatively, the surface algorithm projects only the field values from the surface of the source volume onto the target surface region.

The surface algorithm projects output database source data onto target surface centroids or nodes when the target surface can reference three-dimensional element faces. The volumetric algorithm interpolates source data onto target element centroids or nodes.

The Attachment toolset

The Attachment toolset allows you to create attachment points and attachment lines that can be used to define fasteners and other components in your model.
The Attachment toolset is available in the Part, Property, Assembly, and Interaction modules. This chapter describes the Attachment toolset and editing features created using the toolset.

In this section:

- *Understanding attachment points and lines*
- *Understanding the projection methods*
- *Creating attachment points by picking or reading from a file*
- *Creating attachment points by choosing a direction and a spacing*
- *Creating patterns of attachment points based on edges*
- *Creating attachment lines by projecting points*
- *Editing attachment points and lines*
- *Removing attachment points and lines*

Understanding attachment points and lines

You use the Attachment toolset to add attachment points and lines to your model. You use attachment points to define point-based fasteners, inertia, springs, dashpots, loads or boundary conditions, or connector points for a connector definition in your model; and you use attachment lines to define discrete fasteners. Fasteners model point-to-point connections (such as spot welds, rivets, and bolts) and are described in *About fasteners*. You can create attachment points on the assembly or on a part. You can create attachment lines on only the assembly.

You can use the Attachment toolset to create attachment points and lines by selecting **Tools->Attachment** from the main menu bar and selecting one of the available menu options. In the Interaction module you can use the tools in the module toolbox to create attachment points and lines. The three attachment point tools are also available from the Property module and Part module toolboxes. The Attachment toolset provides the following tools for creating attachment points:

Create attachment points by picking or reading from a file

This tool allows you to create attachment points by picking each point from the viewport or reading the coordinates of the points from a file. For detailed instructions, see *Creating attachment points by picking or reading from a file*.

Create attachment points by choosing a direction and a spacing

This tool allows you to create attachment points by defining a line and specifying the number of points along the line or specifying the spacing of the points along the line. For detailed instructions, see *Creating attachment points by choosing a direction and a spacing*.

Create attachment points by choosing edges and offsets

This tool allows you to create simple patterns of attachment points on edges, on faces, or along directions by selecting a single edge or connected edges and then defining pattern parameters. For detailed instructions, see *Creating patterns of attachment points based on edges*.

If desired, you can move the points to a specified face, as described in *Understanding the projection methods*.

The Attachment toolset provides the following tool for creating attachment lines:

Create attachment lines by projecting points

This tool allows you to create attachment lines by specifying points and then projecting them through multiple faces. Attachment lines connect one or more faces. You can create attachment lines only on the assembly; you cannot create attachment lines on a part. Creating attachment lines is a three-step process:

1. Select the points to project.
2. Project the points onto a source face along the normal to the surface or along a specified direction.
3. From the intersection of the projected points with the source face, project the attachment lines to the target faces along the normal to the source face for a specified distance.

For detailed instructions, see *Creating attachment lines by projecting points*.

Attachment points and lines are features, and they regenerate when you change the model; for example, after you add a cut feature. The regeneration may affect the projection of attachment points and lines and change the total number

of fastening points and lines created by the attachment feature. In addition, the sets that contain attachments may be affected by the regeneration. Therefore, you should determine that your attachment points and lines are behaving as expected after you change the model. You should also check that any prescribed conditions that you have applied to your attachment points and lines, such as loads and boundary conditions, have not changed.

Understanding the projection methods

The Attachment toolset provides three tools for creating attachment points. The tools provide convenient methods for producing points, such as following an edge, reading the coordinates of each point from a file, or spacing points along a line. However, in some cases it may be easier to define the attachment points in one location and project the points onto a desired face. Therefore, Abaqus/CAE provides projection options as a method of positioning attachment points on a face.

The Attachment toolset provides the following techniques to create attachment points by projecting points onto the desired face:

- Project each point to its closest face.
- Choose the start point and end point of a projection vector. Abaqus/CAE projects each point along the vector and creates an attachment point where it first intersects with a face.

Figure 1 illustrates the two techniques for projecting points onto a selected face.

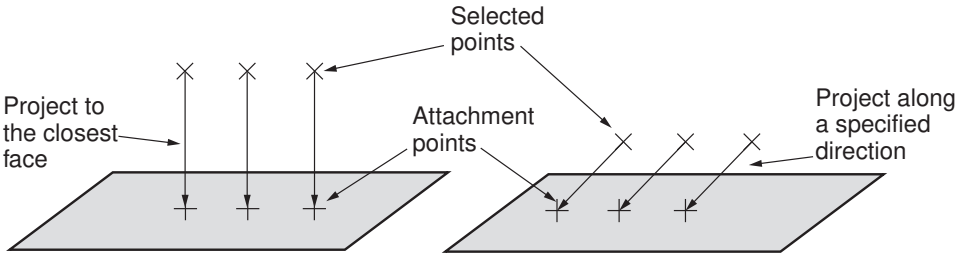

Figure 1: Projecting points onto a selected face.

For more information about how fasteners use attachment points, see *About fasteners*.

Additional information

- *Understanding attachment points and lines*
- *About fasteners*

Creating attachment points by picking or reading from a file

You can position attachment points by picking each point from the viewport or by reading the coordinates of the points from a file. If desired, you can create the attachment points by projecting the specified points onto a selected face. You can use attachment points to define the location of point-based fasteners. For more information, see *About fasteners*.

1. From the main menu bar, select **Tools->Attachment->Points From File/By Picking**.

   Abaqus/CAE displays the **Create Attachment Points** dialog box.

   Tip: You can also create attachment points by picking or reading from a file using the tool, located with the attachment tools in the Interaction module toolbox or the Property module toolbox. For a diagram of the attachment tools in the toolbox, see *Understanding attachment points and lines*.

2. From the dialog box, use one of the following methods to enter the coordinates of each attachment point in the table:

   - Select to pick a point from the part or assembly in the viewport. You can select any existing point from the part, including vertices, datum points, interesting points, reference points, and orphan mesh nodes. You can also enter the *X*-, *Y*-, and *Z*-coordinates of the point in the text field that appears in the prompt area.
   - Click to read an ASCII file containing the *X*-, *Y*-, and *Z*-coordinates of each point.
   - Click to delete the selected row from the table.

   For more information, see *Entering tabular data*.

   If the attachment points are created on a part, the coordinates you provide are relative to the part's coordinate system. If the attachment points are created on the assembly, the coordinates are relative to the assembly's global coordinate system.

3. To project the specified points onto a selected face, display the **Projection** tabbed page, and do the following:

   a. Toggle on **Project onto faces**.

   b. Click , and select the faces onto which the points will be projected. The faces can be planar or nonplanar.

   c. Select the method for projecting the points.

      - Choose **Proximity** to allow Abaqus/CAE to draw a vector from each point to the closest point on the selected faces.
      - Choose **Direction** to define the vector along which to project the points. Click to choose the **Start point** and **End point** of the vector.

   For more information, see *Understanding the projection methods*.

4. By default, Abaqus/CAE creates a set that will contain the attachment points. If desired, you can modify the set name. Toggle off **Create set with name** if you do not want to create a set containing the attachment points.
5. Click **OK** to create the attachment points.

Abaqus/CAE displays the attachment points. You cannot modify attachment points; you must delete the points and create new points.

Additional information

- *Understanding attachment points and lines*
- *About fasteners*

Creating attachment points by choosing a direction and a spacing

You can position attachment points by choosing a start point and a direction and by specifying the spacing of the points. If desired, you can create the attachment points by projecting the specified points onto a selected face. You can use attachment points to define the location of point-based fasteners. For more information, see *About fasteners*.

1. From the main menu bar, select **Tools->Attachment->Points Along Direction**.

   Tip: You can also create attachment points by choosing a direction and a spacing using the  tool, located with the attachment tools in the Interaction module toolbox or the Property module toolbox. For a diagram of the attachment tools in the toolbox, see *Understanding attachment points and lines*.

2. From the current viewport, select a point representing the starting point. You can also enter the *X*-, *Y*-, and *Z*-coordinates of the point in the text field that appears in the prompt area.

   Abaqus/CAE displays the **Create Attachment Points Along Direction** dialog box.

3. From the dialog box, use either of the following methods to select a method for specifying the direction along which the points will be created:

   - Choose **End point** and click  to select a point specifying the end point of the direction vector.
   - Choose **Straight line** and click  to select a straight line specifying the direction vector.

4. Do either of the following to specify the spacing of the points along the direction vector:

   - Choose **Number of points between start and end points**, and enter the desired number of points. (This option is available only when you select an end point to specify the direction vector.)
   - Choose **Spacing**, and enter the distance between each attachment point.

     Do either of the following to specify the number of points to create:

     - Choose **Number of points along direction**, and enter the desired number of points. The attachment points can extend beyond the end point of the direction vector. Click  to reverse the direction vector.
     - Choose **Auto-fit points between start and end points** to allow Abaqus/CAE to determine the number of points that can be created between the start and end points with the specified spacing.

5. By default, Abaqus/CAE creates additional attachment points at both ends of the direction vector. If desired, toggle off **At start point** and/or **At end point** to prevent Abaqus/CAE from creating the additional points.
6. To project the specified points onto a selected face, display the **Projection** tabbed page, and do the following:
   a. Toggle on **Project onto faces**.
   b. Click , and select the faces onto which the points will be projected. The faces can be planar or nonplanar.
   c. Select the method for projecting the points.

- Choose **Proximity** to allow Abaqus/CAE to draw a vector from each point to the closest point on the selected faces.

- Choose **Direction** to define the vector along which to project the points. Click  to choose the **Start point** and **End point** of the vector.

For more information, see *Understanding the projection methods*.

7. By default, Abaqus/CAE creates a set that will contain the attachment points. If desired, you can modify the set name. Toggle off **Create set with name** if you do not want to create a set containing the attachment points.
8. Click **OK** to create the attachment points.

   Abaqus/CAE displays the attachment points. For information on editing attachment points, see *Editing attachment points created by choosing a direction and a spacing*.

Additional information

- *Understanding attachment points and lines*
- *About fasteners*

Creating patterns of attachment points based on edges

You can position attachment points in a simple pattern along a single edge or connected edges. You can then position the points in a pattern of rows on an adjacent face or along a specified direction. If desired, you can project the specified points onto a selected face. You can use the attachment points to define the location of point-based fasteners. For more information, see *About fasteners*.

1. From the main menu bar, select **Tools->Attachment->Points Offset From Edges**.

   Tip: You can also create attachment points by choosing edges and offsets using the  tool, located with the attachment tools in the Property module or Interaction module toolbox. For more information on the attachment tools in the toolbox, see *Understanding attachment points and lines*.

2. From the current viewport, select the edges on which to assign the attachment points. You can select multiple edges as long as the edges are connected and do not branch. You can click **Sets** from the right side of the prompt area to use a previously defined set.

   If the edge selection forms a closed loop, select the starting vertex for point generation from the viewport.

   A red arrow appears to indicate the direction of point generation from the start point.

3. In the prompt area, click **Flip** to reverse the direction of point generation, if necessary, and click **Yes**.

   Abaqus/CAE displays the **Create Attachment Points Offset From Edges** dialog box.

4. From the dialog box, specify the points along the edges.

   - Select **by number** to define the number of attachment points along the edge selection. Abaqus/CAE automatically spaces the points along the edges.

     1. Enter the number of points along the edges.
     2. Enter the desired offset of the first attachment point from the start point.
     3. Enter the desired offset of the last attachment point from the end point.

   - Select **by spacing** to define the distance between the attachment points.

     1. Enter the spacing between the points.
     2. Enter the desired offset of the first attachment point from the start point.
     3. Specify the number of points along the edges, or select **Auto-fit** to have Abaqus/CAE determine the number of attachment points. If you specify the number of points, Abaqus/CAE will create only the points between the start point and the end point; any points extending past the end point will not be created.

5. If desired, define the pattern of rows of the attachment points by specifying the following:

   - Enter the number of rows in the pattern. The default value of 1 creates a single row of attachment points.
   - Enter a value for spacing to define the distance between the rows of the pattern.
   - Enter the offset distance of the first row of the pattern from the edges. The default value of 0 will create the first row of the pattern on the edges.

- Select **Orthogonal to faces** as the offset method, and click  to select an adjacent face on which to position the pattern.
- Select **Along direction** as the offset method, and click  to specify the start and end points of the direction vector.

6. To project the specified points onto a selected face, display the **Projection** tabbed page and do the following:
   a. Toggle on **Project onto faces**.
   b. Click , and select the faces onto which the points will be projected. The faces can be planar or nonplanar.
   c. Select the method for projecting the points.
      - Choose **Proximity** to allow Abaqus/CAE to draw a vector from each point to the closest point on the selected faces.
      - Choose **Direction** to define the vector along which to project the points. Click  to choose the **Start point** and **End point** of the vector.

   For more information, see *Understanding the projection methods*.
7. By default, Abaqus/CAE creates a set that contains the attachment points. If desired, you can modify the set name. Toggle off **Create set with name** if you do not want to create a set containing the attachment points.
8. Click **OK** to create the attachment points.

   Abaqus/CAE displays the attachment points. For information on editing attachment points, see *Editing attachment points created by a pattern based on edges*.

Additional information

- *Understanding attachment points and lines*
- *About fasteners*

Creating attachment lines by projecting points

Positioning attachment lines is a three-step process:

1. Select the points to project.
2. Project the points onto a source face along a specified direction.
3. From the intersection of the projected points with the source face, project the attachment lines to the target faces along the normal to the source face for a specified distance or to a specified number of target faces.

You can use attachment lines to define the location of discrete fasteners. For more information, see *About fasteners*.

1. From the main menu bar, select **Tools->Attachment->Lines by Projecting Points**.

   Tip: You can also create attachment lines by projecting points using the  tool, located with the attachment tools in the Interaction module toolbox. For a diagram of the attachment tools in the toolbox, see *Understanding attachment points and lines*.

2. From the current viewport, select the points to project and click **Done** in the prompt area. You can select vertices, reference points, or attachment points.
3. From the current viewport, select the source faces onto which the points will be projected and click **Done** in the prompt area. An attachment line starts where the direction vector intersects a source surface.
4. From the current viewport, select the target faces that will be intersected by the attachment lines, and click **Done** in the prompt area. Attachment lines are drawn from the start point normal to the source face and end at the furthermost target face.

   Abaqus/CAE displays the **Create Attachment Lines By Projecting Points** dialog box. If desired, you can use the dialog box to edit the points and the source and target faces.

5. From the dialog box, select the method for projecting the points:

   - Choose **Proximity** to allow Abaqus/CAE to draw a vector from each point to the closest point on the selected faces.
   - Choose **Direction** to define the vector along which to project the points. Click  to choose the **Start point** and **End point** of the vector.

6. To change the target faces, display the **Target** tabbed page, and do the following:
   a. Abaqus/CAE displays an arrow indicating the direction in which the points on the source faces will be projected to the target faces. Click  to reverse the direction of the arrow.
   b. Select the method for determining the length of the projection vector:
      - Choose **Maximum projections along direction**, and enter the maximum number of target faces to be intersected by the attachment lines.
      - Choose **Maximum length of projection vector**, and enter the maximum length of the attachment lines.

7. By default, Abaqus/CAE creates a set that will contain the end points of the attachment lines. If desired, you can modify the set name. Toggle off **Create set with name** if you do not want to create a set containing the end points.
8. Click **OK** to create the attachment lines.

Abaqus/CAE displays the attachment lines. For information on editing attachment lines, see *Editing attachment lines created by projecting points*.

Additional information

- *Understanding attachment points and lines*
- *About fasteners*

Editing attachment points and lines

You can edit several parameters for attachment points created by choosing a direction and spacing, attachment points created in patterns along or offset from edges, and attachment lines created by projecting points.
You cannot edit attachment points created by picking or reading from a file. Attachment features created in the Part module or Property module can be edited only from those two modules; attachment features created in the Assembly module or Interaction module can be edited only from those two modules. By default, Abaqus/CAE regenerates the model when the edit procedure is finished.

In this section:

- *Editing attachment points created by choosing a direction and a spacing*
- *Editing attachment points created by a pattern based on edges*
- *Editing attachment lines created by projecting points*

Editing attachment points created by choosing a direction and a spacing

You can edit attachment points created by choosing a direction and a spacing.

1. From the main menu bar, select **Feature->Edit**.

    **Tip:** You can also edit a feature by clicking the  tool located in the module toolbox.

2. Select the attachment point feature to modify. You can select the feature either directly from the current viewport or from the Model Tree.

   The **Edit Attachment Points Along Direction Feature** dialog box appears.

3. Select the method for specifying the spacing of the points along the direction vector:

   - Choose **Number of points between start and end points**, and enter the desired number of points. (This option is available only when you select an end point to specify the direction vector.)
   - Choose **Spacing**, and enter the distance between each attachment point.

     Do either of the following to specify the number of points to create:

     - Choose **Number of points along direction**, and enter the desired number of points. The attachment points can extend beyond the end point of the direction vector.
     - Choose **Auto-fit points between start and end points** to allow Abaqus/CAE to determine the number of points that can be created between the start and end points with the specified spacing. (This option is available only when you select an end point to specify the direction vector.)

4. Toggle **At start point** and/or **At end point** to add or remove attachment points at the start and end points. The **At end point** option is available only when you have selected an end point to specify the direction vector.
5. If desired, toggle **Regenerate on OK** to control the model regeneration when the edit procedure is finished.

Additional information

- *Understanding attachment points and lines*
- *About fasteners*

Editing attachment points created by a pattern based on edges

You can edit attachment points created by a pattern based on edges.

1. From the main menu bar, select **Feature->Edit**.

   Tip: You can also edit a feature by clicking the tool located in the module toolbox.

2. Select the attachment point feature to modify. You can select the feature either directly from the current viewport or from the Model Tree.

   The **Edit Attachment Points Offset From Edges Feature** dialog box appears.

3. Do either of the following to specify the points along the edges:

   - Select **by number** to define the number of attachment points along the edge selection. Abaqus/CAE automatically spaces the points along the edges.

     1. Enter the number of points along the edges.
     2. Enter the desired offset of the first attachment point from the start point.
     3. Enter the desired offset of the last attachment point from the end point.

   - Select **by spacing** to define the distance between the attachment points.

     1. Enter the spacing between the points.
     2. Enter the desired offset of the first attachment point from the start point.
     3. Specify the number of points along the edges, or select **Auto-fit** to have Abaqus/CAE determine the number of attachment points. If you specify the number of points, Abaqus/CAE will create only the points between the start point and the end point; any points extending past the end point will not be created.

4. If desired, define the pattern of rows of the attachment points by specifying the following:

   - Enter the number of rows in the pattern. A value of 1 creates a single row of attachment points.
   - Enter a value for spacing to define the distance between the rows of the pattern.
   - Enter the offset distance of the first row of the pattern from the edges. A value of 0 creates the first row of the pattern on the edges.

5. If desired, toggle **Regenerate on OK** to control the model regeneration when the edit procedure is finished.

Additional information

- *Understanding attachment points and lines*
- *About fasteners*

Editing attachment lines created by projecting points

You can edit attachment lines created by projecting points.

1. From the main menu bar, select **Feature->Edit**.

    **Tip:** You can also edit a feature by clicking the  tool located in the module toolbox.

2. Select the attachment line feature to modify. You can select the feature either directly from the current viewport or from the Model Tree.

   The **Edit Attachment Lines Feature** dialog box appears.

3. Select the method for determining the length of the projection vector.

   - Choose **Maximum projections along direction**, and enter the maximum number of target faces to be intersected by the attachment lines.
   - Choose **Maximum length of projection vector**, and enter the maximum length of the attachment lines.

4. If desired, toggle **Regenerate on OK** to control the model regeneration when the edit procedure is finished.

Additional information

- *Understanding attachment points and lines*
- *About fasteners*

Removing attachment points and lines

You can remove attachment points and lines from your model. The removed attachment points or lines appear in the Model Tree as a **Remove Attachments** feature in the **Features** container under the part or assembly, depending on the module in which the attachment points or lines were created. You can suppress or delete the **Remove Attachments** feature to restore the removed attachment points or lines. Attachment points created in the Part module or Property module can be removed only from these two modules; attachment points and lines created in the Assembly module or Interaction module can be removed only from these two modules.

1. From the main menu bar, select **Tools->Attachment->Remove attachments**.
2. From the current viewport, select the attachment points or lines to remove. You can click **Sets** from the right side of the prompt area to remove a previously defined set.
3. If you are in the Part module or Property module, click **Done** in the prompt area to indicate that you have finished selecting attachment points to remove.

   The selected attachment points are removed from the model and a **Remove Attachments** feature is created in the Model Tree under the part.
4. If you are in the Interaction module or Assembly module, do the following:
   a. In the prompt area, click **Done** to indicate that you have finished selecting attachment points or lines to remove.
   b. In the dialog box that appears, do one of the following:
      - Click **Yes** to continue and remove the selected attachment points or lines from the model.

        A **Remove Attachments** feature is created in the Model Tree under the assembly.
      - Click **No** to return to the viewport to modify the selected attachment points or lines to remove.
      - Click **Cancel** to exit the procedure without removing any attachment points or lines.
5. If desired, select additional attachment features to remove.
6. Click mouse button 2 to exit the remove attachments procedure.

Additional information

• *Understanding attachment points and lines*
• *About fasteners*

The CAD Connection toolset

The CAD Connection toolset is used by the optional add-on associative interfaces for Abaqus/CAE to create a connection from Abaqus/CAE to another CAD system.
You can use the CAD system to modify a model or to change its position, and you can use the established connection to update the model quickly in Abaqus/CAE. You can also modify some geometric features in Abaqus/CAE and use the CAD connection to update the original CAD system model.

In this section:

- *Creating a CAD connection*
- *Updating geometry parameters in an imported model*

Creating a CAD connection

You can use the CAD Connection toolset to create a connection from Abaqus/CAE to another CAD system running an associative interface plug-in.

You can use the connection to export the model from the CAD system to the Assembly module in Abaqus/CAE. You can also use the connection to export certain geometry modifications from an imported model in Abaqus/CAE back to the CAD system (see *Updating geometry parameters in an imported model*). Associative interface plug-ins are available for the following CAD systems:

- CATIA V6
- CATIA V5
- SOLIDWORKS
- Creo Parametric
- NX (Unigraphics)

Figure 1 shows concurrent CATIA V5 and Abaqus/CAE sessions and illustrates the communication between the applications.

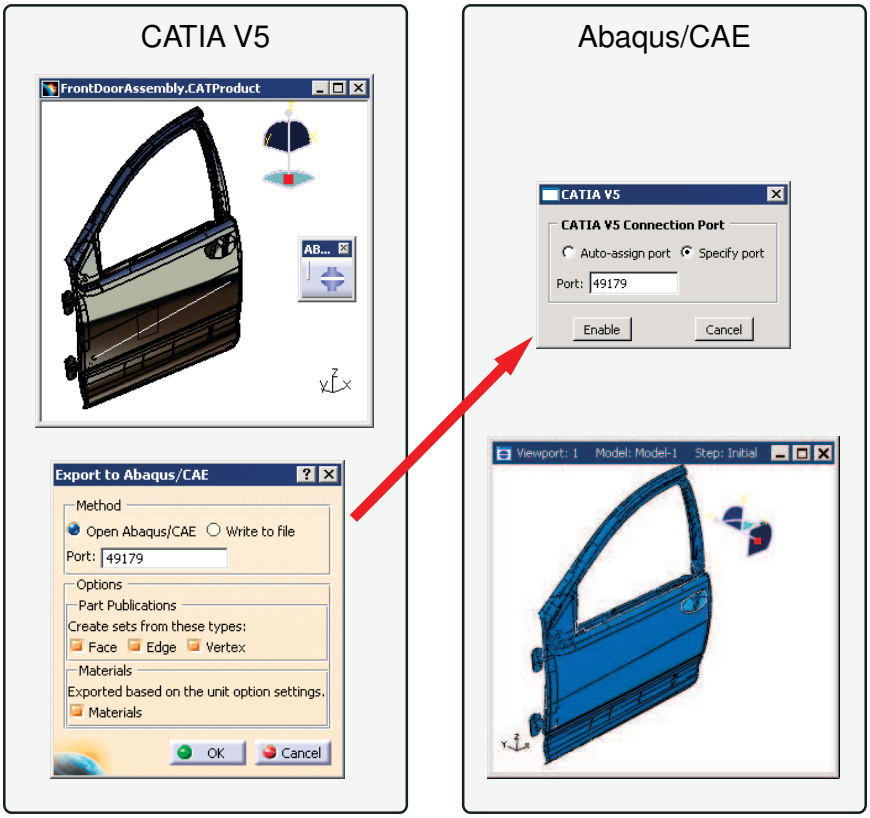

Figure 1: Associative import using the CATIA V5 Associative Interface.

Using a CAD connection to transfer a model from a CAD system running an associative interface plug-in to Abaqus/CAE is called associative import. For further information about the individual associative interface plug-ins, including the CAD packages that support associative import along with the supported version numbers, see the following resources:

- SIMULIA Installation Guide
- *https://www.3ds.com/products-services/simulia/products/abaqus/add-ons/cad-associative-interfaces*
- Dassault Systèmes Knowledge Base at *http://support.3ds.com/knowledge-base/*

1. From the main menu bar in the Assembly module, select **Tools->CAD Interfaces->*CAD System***. ***CAD System*** is the name of the CAD system to which you are connecting; you can establish connections with CATIA V6, CATIA V5, SOLIDWORKS, NX, and Creo Parametric.
2. From the dialog box that appears, do one of the following:

Auto-assign port

Choose **Auto-assign port**, and click **Enable** to open a port from Abaqus/CAE.

Abaqus/CAE displays the port number that it assigned in the message area. When you export a model from the CAD system, the data are transferred through this connection port number.

Specify port

Choose **Specify port**, and enter a port number to specify a port. The number must be between 1025 and 65535. If you are reopening a connection, you can use the port number displayed by Abaqus/CAE when it first assigned the port.

Disable port

If a connection has already been enabled, you can click **Disable** from the dialog box to disable the connection.

3. After you have used the CAD Connection toolset to create a connection from Abaqus/CAE to another CAD system running an associative interface plug-in, you can do the following to export the assembly to the Abaqus/CAE session:

CATIA V6

CATIA V6R2013x or earlier

Select **Tools->Associative Export->Export to Abaqus/CAE** from the main menu bar.

CATIA V6R2014 or later

Select **Share->Export->Associative Export->Export to Abaqus/CAE**.

More detailed instructions are available in the SIMULIA Associative Interface for Abaqus/CAE User's Guide; this guide is available after you install the SIMULIA Associative Interface for Abaqus/CAE app.

CATIA V5

Select **Abaqus->Export to Abaqus/CAE** from the CATIA V5 main menu bar. In the **Export to Abaqus/CAE** dialog box that appears, select **Open Abaqus/CAE**, and click **OK**. More detailed instructions are available in the CATIA V5 Associative Interface User's Guide; you can find information about this guide in the Dassault Systèmes Knowledge Base at *http://support.3ds.com/knowledge-base/*.

SOLIDWORKS

Select **Abaqus->Export to Abaqus/CAE** from the SOLIDWORKS main menu bar. In the **Export to Abaqus/CAE** dialog box that appears, toggle on **Open in Abaqus/CAE**, and click the green check mark. More detailed instructions are available in the SOLIDWORKS Associative

Interface User's Guide; you can find information about this guide in the Dassault Systèmes Knowledge Base at *http://support.3ds.com/knowledge-base/*.

Creo Parametric

Select **Abaqus->Open in CAE** from the Creo Parametric main menu bar. More detailed instructions are available in the Abaqus Associative Interface for Creo Parametric User's Guide; you can find information about this guide in the Dassault Systèmes Knowledge Base at *http://support.3ds.com/knowledge-base/*.

NX

Select **Abaqus->Open in /CAE** from the NX main menu bar. More detailed instructions are available in the Abaqus/CAE Associative Interface for NX User's Guide; you can download this guide from the Elysium, Inc. website.

For more information on associative import, see *What can I do with the associative interfaces?*.

Updating geometry parameters in an imported model

The parameter update capability allows a bidirectional associative import, in which you modify the dimensions of geometric features in a model that has been imported into Abaqus/CAE, then propagate the new dimensions back to the model files from the original CAD system. This bidirectional import feature is currently available only with the CATIA V5 Associative Interface, the CATIA V6 Associative Interface, and the Abaqus Associative Interface for Creo Parametric.

To use the parameter update capability, you must first use the CAD system (CATIA V5, CATIA V6, or Creo Parametric) to indicate which model dimensions can be modified within Abaqus/CAE. The modifiable dimensions must be defined in terms of feature-level parameters, which are imported into Abaqus/CAE along with the model. For example, a parameter might be associated with the radius of a hole in the model; modifying the value of that parameter also modifies the radius of the hole. Each parameter name must begin with the string `ABQ_` to be imported into Abaqus/CAE. In addition, to avoid overwriting an existing parameter with the same name, each parameter name must be unique.

The CATIA V5 Associative Interface, the CATIA V6 Associative Interface, and the Abaqus Associative Interface for Creo Parametric use a special parameters (`.par_abq`) file to pass parameters to Abaqus/CAE. For more information about defining modifiable parameters in an imported CATIA V5, CATIA V6, or Creo Parametric model, refer to the CATIA V5 Associative Interface, the CATIA V6, or the Abaqus Associative Interface for Creo Parametric User's Guides. These guides are available from the Dassault Systèmes Knowledge Base at *http://support.3ds.com/knowledge-base/*.

You can use the **CAD Parameters** dialog box in Abaqus/CAE to assign new values to the imported parameters. When you change a parameter value, the associated geometry feature is regenerated both in the Abaqus/CAE model and in the saved CAD model. This dialog box also enables you to keep the CAD software running in the background after you make a change to CAD parameters. Having the CAD software running in the background improves performance for bidirectional parameter update, but this option occupies a license for your CAD software for the remainder of your session.

1. Do either of the following:
   - Import a model from CATIA V5 using the CATIA V5 Associative Interface.
   - Import a model from CATIA V6 using the CATIA V6 Associative Interface.
   - Import a model from Creo Parametric using the Abaqus Associative Interface for Creo Parametric.
2. Open the **CAD Parameters** dialog box:
   - In the Part module, select **Tools->CAD Parameters**.
   - In the Assembly module, select **Tools->CAD Interfaces->CAD Parameters**.

   The **CAD Parameters** dialog box displays all the parameters that can be modified.
3. If you are importing parameters from CATIA V5 or Creo Parametric, click on a parameter name to highlight the portion of the model that is impacted by that parameter in the viewport.
4. To modify a parameter value, click the appropriate cell in the **Value** column, and enter a new value.
5. If you are importing parameters from Creo Parametric, you can toggle on **Keep CAD software running in the background after parameter update**. This option improves performance if you perform bidirectional import or make additional updates.
6. When you have changed all the necessary parameter values, do one of the following:
   - Click **Update** to regenerate the model in Abaqus/CAE based on the new parameter values. The geometry in the saved Creo Parametric part (`.prt`) files is updated as well. The original model must not be open in Creo Parametric when you perform the update.

- Click mouse button 3, and select **Write to File** to create an updated parameters file without updating the model geometry. This file can be used to manually update parameters using the Abaqus Scripting Interface. For more information about the parameters file, refer to the Abaqus Associative Interface for Creo Parametric User's Guide.
- Click **Defaults** to reset all the parameters in the **CAD Parameters** table to the values in the current Abaqus/CAE model.

Additional information

• *What can I do with the associative interfaces?*
• *Creating a CAD connection*

The Customize toolset

The Customize toolset allows you to change the behavior and appearance of some aspects of Abaqus/CAE.

In this section:

- *Configuring the visibility of toolbars*
- *Configuring keyboard shortcuts*
- *Custom toolbars*
- *Configuring icons in custom toolbars*
- *Using the Customize toolset*

Configuring the visibility of toolbars

Using the Customize toolset, you can remove individual toolbars from the Abaqus/CAE display. Hiding toolbars that you use infrequently reduces clutter on the screen. You can always access the functionality in a hidden toolbar using an alternate method (such as the main menu bar, module-specific toolboxes, or keyboard shortcuts).

There are three ways to change the visibility of a toolbar:

Closing a floating toolbar

You can hide a floating toolbar by clicking the “X” in the toolbar's title bar. For an explanation of floating versus docked toolbars, see *Components of the toolbars*.

To resume the display of a floating toolbar, you must use one of the techniques described below.

Using the main menu bar

To hide a visible toolbar, select **View->Toolbars->*Toolbar Name*** from the main menu bar. Use the same procedure to resume the display of a hidden toolbar. Toolbars that are currently being displayed have a check mark next to their names in the menu listing.

Using the Customize dialog box

Using the **Customize** dialog box, you can change the visibility of multiple toolbars at once. Open the **Customize** dialog box by selecting **Tools->Customize** from the main menu bar. On the **Toolbars** tabbed page, toggle off any toolbars you want to hide; toggle on any toolbars you want to make visible.

Configuring keyboard shortcuts

You can use the Customize toolset to edit default keyboard shortcuts, to add new shortcuts for other functions in Abaqus/CAE, and to display a list of all currently defined shortcuts.
A keyboard shortcut is a single keystroke or combination of keys that you can use to launch a function in Abaqus/CAE; for example, **[Ctrl] + `S`** saves the current model.

Several keyboard shortcuts are defined by default for common functions. Select **Tools->Customize** from the main menu bar; display the **Functions** tabbed page of the dialog box that appears to access the **Keyboard** editor.

Tip: Keyboard shortcuts are active only when their function is allowed in the current module and only when the application's focus is not in the Model Tree, Results Tree, message area, or command line interface. If a shortcut does not appear to work, confirm that the function is allowed in the current module or shift focus to the viewport by clicking the viewport title bar.

Abaqus/CAE allows the following keys and key combinations to be specified as keyboard shortcuts:

- Any function key except the `F1` key,
- **[Alt] + [Shift] + `any key`**, or
- **[Ctrl] + `any key`** (except **[Ctrl] + `A`**, which is limited to the select all option in a selection procedure). You can also add **[Alt]** or **[Shift]** to any keyboard shortcut that includes the **[Ctrl]** key.

However, not all keys are eligible for inclusion in a keyboard combination; you cannot specify a keyboard combination that includes a function key or a key from the alphanumeric keypad.

• *Filtering your selection based on the type of object*

Custom toolbars

The Customize toolset allows you to create custom toolbars containing shortcuts to most of the defined functions in Abaqus/CAE. A custom toolbar can be used to collect commonly used tools in a single location, create tools for functions that do not have an existing shortcut, or provide easily accessible controls for a common procedure (for example, the create part, instance part, and mesh part functions could all be part of the same toolbar). Custom toolbars are visible in all modules. If a tool acts as a shortcut to a module-specific function, Abaqus/CAE automatically switches to the appropriate module when that tool is invoked.

The contents and locations of custom toolbars are saved between sessions.

To create a custom toolbar, select **Tools->Customize** from the main menu bar. For detailed instructions on the creation of custom toolbars, see *Creating and modifying custom toolbars*.

Configuring icons in custom toolbars

You can change the default icon that is assigned to tools in custom toolbars. If you create a tool that does not have a default icon assignment, you can assign a new icon to that tool. If a tool appears in more than one custom toolbar, the icon assignment for that tool applies in all custom toolbars. The icons in default Abaqus/CAE toolbars and toolboxes cannot be changed and are not affected by custom icon assignments.

To change or add an icon assignment, select **Tools->Customize** from the main menu bar. On the **Functions** tabbed page of the dialog box that appears, select a tool's function and click **Select** to assign a new icon to that tool.

When assigning an icon, you can select from any of the icons currently used in Abaqus/CAE. You can also import user icons. User icons must be in one of the following formats: bitmap (`.bmp`), GIF (`.gif`), PNG (`.png`), or XPM (`.xpm`). Icon images should be sized appropriately—the standard size for toolbar icons in Abaqus/CAE is 24 × 24 pixels. You cannot scale the size with which user icons are displayed in Abaqus/CAE; if you increase the icon size scale factor (as described in *Scaling the size of icons*), only the Abaqus/CAE icons will increase in size.

Abaqus/CAE creates a directory named `abaqus_icons` in your home directory to store imported user icon images. If you delete an image file from this directory, Abaqus/CAE reverts to the default icon assignment for any tools that use the deleted image file.

The same icon can be assigned to multiple tools. To distinguish the functions of tools using the same icon, place the cursor over a tool for a moment; a small box, or “tooltip,” containing a description of the tool's function will appear.

Using the Customize toolset

All of the functionality of the Customize toolset is accessible through the **Customize** dialog box. Select **Tools**->**Customize** or **View**->**Toolbars**->**Customize** from the main menu bar in any module to open the **Customize** dialog box.

This section explains how to use the features of the **Customize** dialog box.

In this section:

- *Hiding toolbars*
- *Creating, modifying, and removing keyboard shortcuts*
- *Displaying existing keyboard shortcuts*
- *Creating and modifying custom toolbars*
- *Changing icon assignments*
- *Restoring toolbars to their default settings*

Hiding toolbars

Select **Tools->Customize** from the main menu bar to set the visibility of toolbars in Abaqus/CAE. For other methods of hiding toolbars, see *Configuring the visibility of toolbars*.

1. From the main menu bar in any module, select **Tools->Customize**.

   The **Customize** dialog box appears.
2. On the **Toolbars** tabbed page, toggle on the name of any toolbar you want to display; toggle off the name of any toolbar you want to hide.
3. When you have set the visibility for all toolbars as desired, click **Dismiss** to close the **Customize** dialog box.

Additional information

- *Components of the toolbars*
- *Configuring the visibility of toolbars*
- *Using the Customize toolset*

Creating, modifying, and removing keyboard shortcuts

You can assign keyboard shortcuts to particular functions in Abaqus/CAE.
For information on acceptable keystroke combinations, see *Configuring keyboard shortcuts*.

1. From the main menu bar in any module, select **Tools->Customize**.
2. From the **Customize** dialog box that opens, click the **Functions** tab.
3. From the **Module/Toolset** list, select the Abaqus/CAE module or toolset to which your function belongs.

   Abaqus/CAE populates the **Functions** list with the available functions in the selected module or toolset.
4. Select the function for which you want to create, modify, or remove a keyboard shortcut.
5. Perform one of the following steps:

To create or modify a keyboard shortcut:

Enter the function key or key combination that you want to use, then click **Assign**.

The new keyboard shortcut appears in the **Current shortcut** field.

To remove a keyboard shortcut:

Click **Remove**.

Abaqus/CAE deletes the keyboard shortcut assignment and clears the **Current shortcut** field.

Additional information

- *Configuring keyboard shortcuts*
- *Using the Customize toolset*

Displaying existing keyboard shortcuts

The **Shortcut Listing** dialog box displays a listing of all keyboard shortcuts currently assigned in Abaqus/CAE and the functions to which they map.

1. From the main menu bar in any module, select **Tools->Customize**.
2. From the **Customize** dialog box that opens, click the **Functions** tab.
3. To display a list of existing keyboard shortcuts, click **Show all assignments**.

   From the **Shortcut Listing** dialog box that appears, you can review all currently defined keyboard shortcuts.

Additional information

- *Configuring keyboard shortcuts*
- *Creating, modifying, and removing keyboard shortcuts*
- *Using the Customize toolset*

Creating and modifying custom toolbars

You can create new toolbars, change the contents of existing custom toolbars, rename custom toolbars, or delete custom toolbars.
Select **Tools->Customize** to edit custom toolbars in Abaqus/CAE.

Additional information

- *Components of the toolbars*
- *Custom toolbars*
- *Using the Customize toolset*

Create or modify a custom toolbar

1. From the main menu bar in any module, select **Tools->Customize**.
   The **Customize** dialog box appears.
2. To create a new custom toolbar:
   a. On the **Toolbars** tabbed page, click **Create**.
   b. In the dialog box that appears, enter a **Name** for the new toolbar, and click **OK**.
   Abaqus/CAE creates an empty floating toolbar in the main window.
3. Display the **Functions** tabbed page.
4. From the **Module/Toolset** list, select the Abaqus/CAE module or toolset to which your desired function belongs.
   In a custom toolbar, you should use the render style **Functions** available when **Visualization Display Options** is selected in the **Module/Toolset** list instead of those available for **View Manipulation**.
   Abaqus/CAE populates the **Functions** list with the available functions in the selected module or toolset.
5. In the **Functions** list, locate the function that you want to add to the toolbar. Click and drag the function over a custom toolbar; the cursor changes to a plus symbol . Release the mouse button to add the function to the toolbar.
   You can drag functions onto new or existing custom toolbars.
6. If desired, add or modify the icon assignment for the selected function. See *Changing icon assignments*, for details.
7. To remove a function from a custom toolbar, click the icon on the toolbar and drag it off the toolbar; the cursor changes to a minus symbol . Release the mouse button to delete the icon from the toolbar.

   Note:

   You can remove icons from a custom toolbar at any time using this procedure. The **Customize** dialog box does not need to be open.

8. Repeat Steps 4 to 7 until the toolbar contains all of the desired functions.
9. Click **Dismiss** to close the **Customize** dialog box.

Rename a custom toolbar

1. From the main menu bar in any module, select **Tools->Customize**.
   The **Customize** dialog box appears.

2. Display the **Toolbars** tabbed page.
3. Select the toolbar whose name you want to change, and click **Rename**.
4. In the dialog box that appears, enter a new name for the toolbar and click **OK**.
5. Click **Dismiss** to close the **Customize** dialog box.

Delete a custom toolbar

1. From the main menu bar in any module, select **Tools->Customize**.
   The **Customize** dialog box appears.
2. Display the **Toolbars** tabbed page.
3. Select the name of the toolbar that you want to delete, and click **Delete**.
4. Click **Dismiss** to close the **Customize** dialog box.

Changing icon assignments

Select **Tools->Customize** to change the icon that is associated with a particular tool or function on a custom toolbar.

1. From the main menu bar in any module, select **Tools->Customize**.

   The **Customize** dialog box appears.
2. Display the **Functions** tabbed page.
3. From the **Module/Toolset** list, select the Abaqus/CAE module or toolset to which your desired function belongs.

   Abaqus/CAE populates the **Functions** list with the available functions in the selected module or toolset.
4. From the **Functions** list, select the function whose icon you want to change.
5. In the **Icon** field at the bottom right of the dialog box, click **Select**.

   The **Select Icon** dialog box appears.
6. To use an existing Abaqus/CAE icon, select the icon image from the display on the **Abaqus Icons** tabbed page and click **OK**.

   Abaqus/CAE updates the icon for the selected function in all custom toolbars.
7. To use a custom icon:
   a. Display the **User Icons** tabbed page.
   b. To remove a custom icon from the selection display on the **User Icons** tabbed page, select the icon image and click **Delete**.
   c. If the icon you want to use is in the display, skip to step "e."

      If the icon you want is not in the display, click **Import** to import the icon image.
   d. In the **Select an Icon** dialog box that appears, select an image file to use as an icon. See *Configuring icons in custom toolbars*, for information on acceptable icon image files. For information on using the **Select an Icon** dialog box, see *Using file selection dialog boxes*.
   e. Select the icon image from the display on the **User Icons** tabbed page, and click **OK**.

      Abaqus/CAE updates the icon for the selected function in all custom toolbars.

      Note:

      You cannot modify the icons in default Abaqus/CAE toolbars and toolboxes. Nondefault icon assignments apply only to tools in custom toolbars.
8. Click **Dismiss** to close the **Customize** dialog box.

Additional information

- *Custom toolbars*
- *Configuring icons in custom toolbars*
- *Using the Customize toolset*

Restoring toolbars to their default settings

The **Reset** button in the **Customize** dialog box restores all of the toolbars to their original settings. Resetting the toolbars:

- returns all default Abaqus/CAE toolbars to their original visibility settings;
- relocates all default Abaqus/CAE toolbars to their original positions below the main menu bar; and
- deletes all custom toolbars.

These setting do not take effect immediately; you must restart Abaqus/CAE to see the changes. Any changes you make to the toolbar settings between clicking the **Reset** button and restarting Abaqus/CAE will not be saved.

1. From the main menu bar in any module, select **Tools->Customize**.
   The **Customize** dialog box appears.
2. On the **Toolbars** tabbed page, click **Reset**.
3. Restart Abaqus/CAE.

Additional information

• *Components of the toolbars*
• *Using the Customize toolset*

The Datum toolset

A datum is a construction aid that helps you progress through the modeling process when the model itself does not contain the desired geometry. You use the Datum toolset to create these construction aids.
This section explains how you use the Datum toolset to create and position datum points, axes, planes, and coordinate systems.

In this section:

- *Understanding the role of datum geometry*
- *Using the Datum toolset*
- *Why are datum coordinate systems so important?*
- *Understanding a datum as a feature*
- *Datum creation techniques*
- *Creating datum points*
- *Creating datum axes*
- *Creating datum planes*
- *Creating datum coordinate systems*

Understanding the role of datum geometry

As you proceed through the modeling process, you may find that you need a particular piece of geometry, such as a vertex or an edge, that does not exist in your model. You can use the Datum toolset to create the required piece of geometry, which is called a datum.

You can create a datum point, a datum axis, a datum plane, or a datum coordinate system.

- When prompted to select a point, you can select a point from a part, a datum point, or the origin of a datum coordinate system.
- When prompted to select an edge, you can select an edge from a part, a datum axis, or one of the axes of a datum coordinate system.
- When prompted to select a face, you can select a face from a part or a datum plane.
- When prompted to select a coordinate system, you must select a datum coordinate system.

An example of how you might use a datum plane as a sketching plane involves the part shown in *Figure 1*.

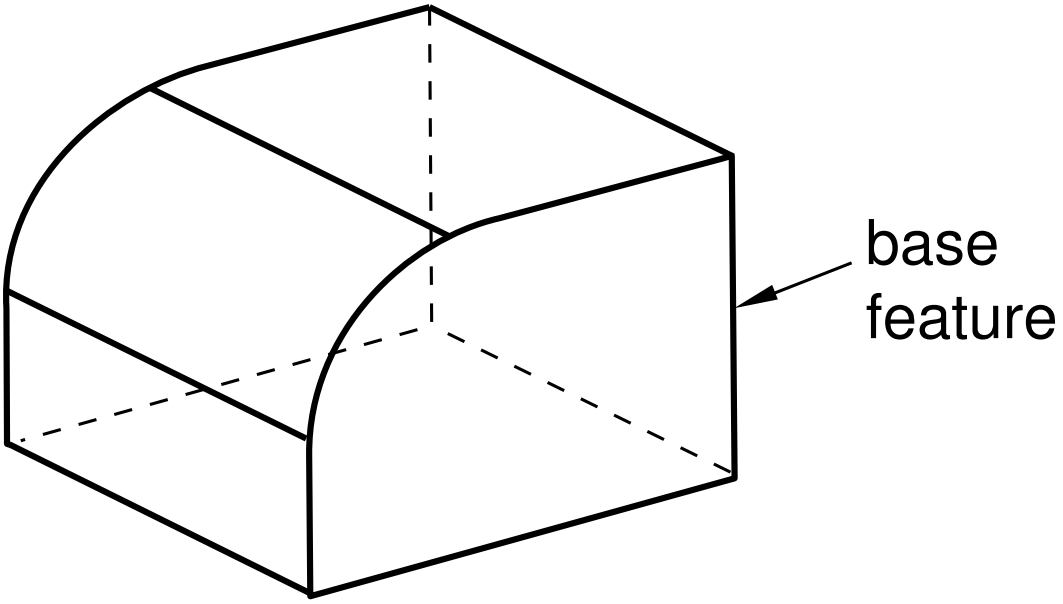

Figure 1: Creating a sketch plane.

To extrude a blind cut into the curved surface, you need to sketch the profile on a plane that is tangent to the curved surface. The desired plane does not exist, but you can create one with the Datum toolset and sketch on the resulting plane. The datum plane and the resulting cut feature are shown in *Figure 2*.

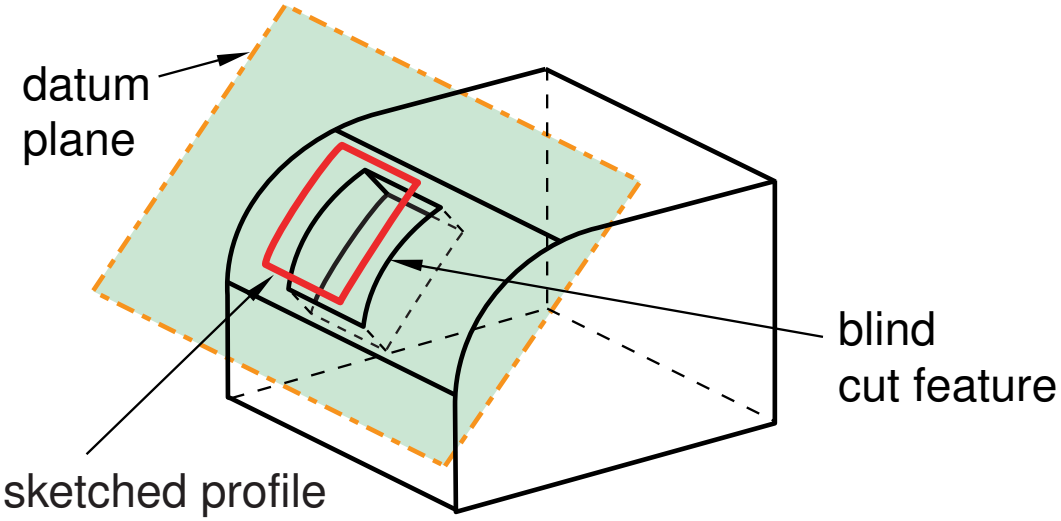

Figure 2: The resulting feature.

Abaqus/CAE does not generate meshes on datum geometry, and datum geometry has no effect on the analysis of your model; it is simply a convenience to help you construct complex geometry. You should use the Partition toolset if you want to add geometry to the model itself, such as a vertex along an edge or a plane through a cell.

You create a datum by defining it with respect to existing geometry (such as vertices, planes, and edges) or to other datum geometry. You can create a datum on a part in the Part or Property module or on an assembly in other modules. For example, you can define a datum axis that passes through two selected points of a part in the Part module, and you can use the axis to align instances of the part in the Assembly module. You can create a datum as a dependent or independent feature; and, like all features, it can be edited, deleted, suppressed, and resumed. A dependent datum is regenerated when the assembly or part is regenerated. You can also use display groups to show or hide datum geometry in a viewport.

Additional information

- *Understanding a datum as a feature*
- *Using display groups to display subsets of your model*

Using the Datum toolset

You can access the Datum toolset in any module from the main menu bar or from the module toolbox.

Select **Tools->Datum** from the main menu bar to display the **Create Datum** dialog box, and choose the type of datum to create—point, axis, plane, or coordinate system (CSYS)—from the **Type** options at the top of the dialog box. The **Method** list changes to reflect the datum you create. Select the desired datum tool from the **Method** list, and follow the prompts in the prompt area to create the datum.

You can also access the Datum toolset from the module toolbox; *Figure 1* shows the hidden icons for all the datum tools in the module toolboxes.

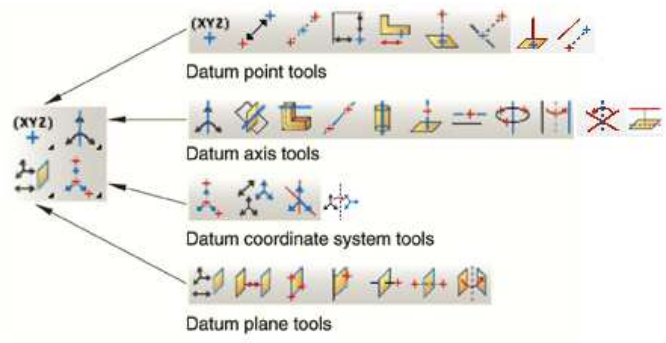

Figure 1: The datum tools.

To see a brief tooltip containing a definition of each datum tool, hold the mouse over the tool for a moment. For information on using toolboxes and selecting hidden icons, see *Using toolboxes and toolbars that contain hidden icons*.

- *Datum creation techniques*
- *Using the Datum toolset in the Part module*
- *Using datum geometry in the Assembly module*
- *Controlling datum display*

Why are datum coordinate systems so important?

Datum coordinate systems are used throughout Abaqus/CAE; for example, to define material and connector orientations; to define the orientation of a coupling constraint, an inertia relief load, and boundary conditions; and to position and align part instances.

In addition, you can select the origin of a datum coordinate system when prompted to select a point, and you can select an axis of a datum coordinate system when prompted to select an edge.

Abaqus/CAE provides three methods for creating a datum coordinate system:

- Three points
- Offset from coordinate system
- Two lines

For more information, see *Methods for creating a datum coordinate system*. In contrast with other types of datums, you can name a datum coordinate system while you create it. As with all datums, you can use the Model Tree to rename a datum coordinate system.

Additional information

- *Understanding a datum as a feature*

Understanding a datum as a feature

A datum is a useful construction aid in the feature-based modeling process and is a feature itself. As a result, you can use the Feature Manipulation toolset to delete, suppress, and resume a datum.

By default, a datum is created as a dependent feature; however, you can choose to make a datum independent when you create it. For an independent datum, no parent-child relationship exists between the datum and any feature used to create it. Once created, a datum cannot be changed from dependent to independent or vice versa. Abaqus/CAE regenerates a dependent datum along with the part or assembly, taking into account any changes to underlying geometry. If you suppress or delete the parent feature of a dependent datum, the datum is also suppressed or deleted.

You can edit any numerical parameters that define a datum; for example, the *X*-, *Y*-, and *Z*-coordinates used to define a datum point. However, a datum is always defined by the same underlying geometry you selected when you created it; if you need to define the datum using different geometry, you must delete the datum and create a new one.

You can create a datum on a part in the Part or Property module or on an assembly in other modules. If you create a dependent datum on a part, the datum moves along with an instance of the part in the Assembly module. If you create a dependent datum on the assembly by selecting entities from a part instance, the datum moves along with the instance in the Assembly module. However, if you create a datum on the assembly by entering coordinates in the prompt area, the datum remains fixed when the instance moves.

When you modify a feature, you should be aware of any parent-child relationships between your dependent datum and the modified feature. For example, consider *Figure 1*, which shows a dependent datum axis passing through the midpoint of two arcs. The midpoints of the arcs that define the location of the datum axis are parents of the datum axis.

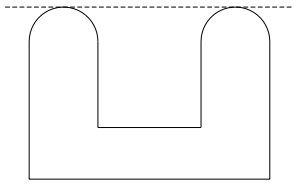

Figure 1: The original datum axis between two midpoints.

If you modify the part, Abaqus/CAE regenerates the datum axis so that it still passes through the two midpoints, as shown in *Figure 2*.

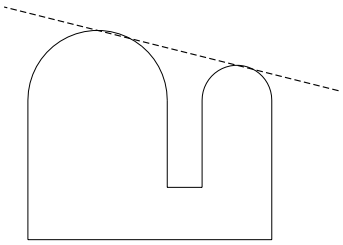

Figure 2: The datum axis after the part is modified.

Additional information

• *The Feature Manipulation toolset*

Datum creation techniques

This section provides an overview of the methods for creating each type of datum.

In this section:

- *Methods for creating a datum point*
- *Methods for creating a datum axis*
- *Methods for creating a datum plane*
- *Methods for creating a datum coordinate system*

Methods for creating a datum point

When you choose **Point** from the **Create Datum** dialog box, the **Method** list displays the methods for creating a datum point.

The following methods are available:

(XYZ) Enter coordinates

Enter the *X*-, *Y*-, and *Z*-coordinates of the datum point, as shown in *Figure 1*. For detailed instructions, see *Creating a datum point by entering its coordinates*.

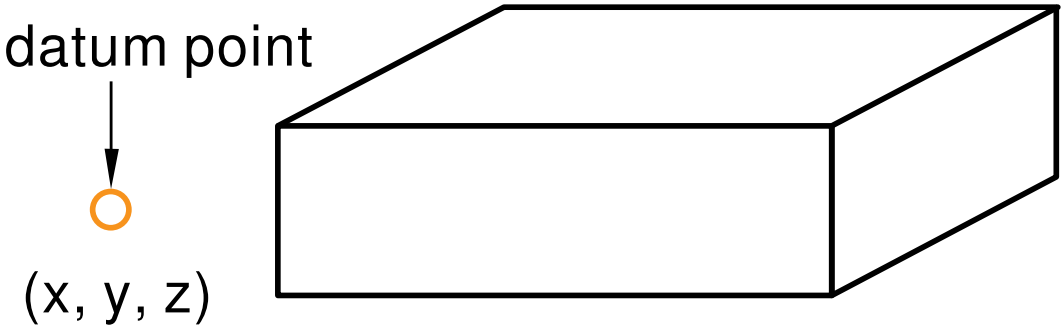

Figure 1: Creating a datum point by entering coordinates.

Offset from point

Enter the location of the datum point in the form of the *X*-, *Y*-, and *Z*-coordinates of an offset from a selected point, as shown in *Figure 2*. For detailed instructions, see *Creating a datum point at an offset from a selected point*.

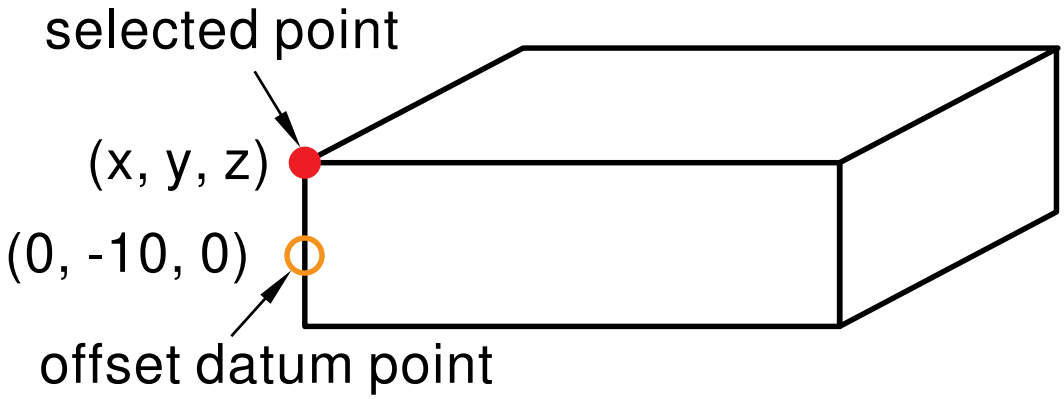

Figure 2: Creating a datum point by offsetting from a point.

Midway between 2 points

Select two points on the model; Abaqus/CAE creates the datum point midway between the two selected points, as shown in *Figure 3*. For detailed instructions, see *Creating a datum point midway between two points*.

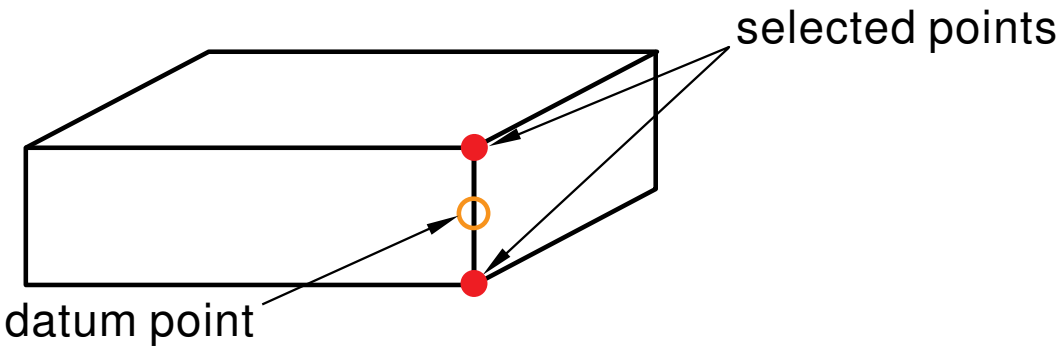

Figure 3: Creating a datum point by selecting two end points.

Offset from 2 edges

Select two edges on the model; and enter the distance from the datum point to each edge, as shown in *Figure 4*. For detailed instructions, see *Creating a datum point at a specified distance from two edges*.

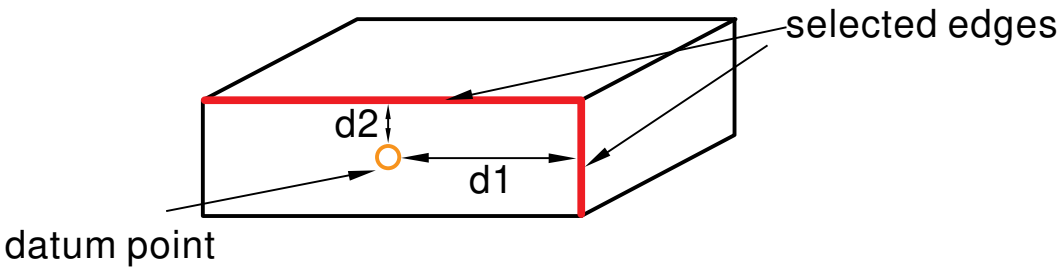

Figure 4: Positioning a datum point a specified distance from two edges.

Enter parameter

Select an edge on the model, and enter the location of the datum point in the form of a parameter value that represents a percentage of the edge length. An arrow along the edge indicates the direction of increasing parameter value from the start vertex (corresponding to an edge parameter value of zero) to the end vertex (corresponding to a value of one), as shown in *Figure 5*. For detailed instructions, see *Creating a datum point by entering an edge parameter*.

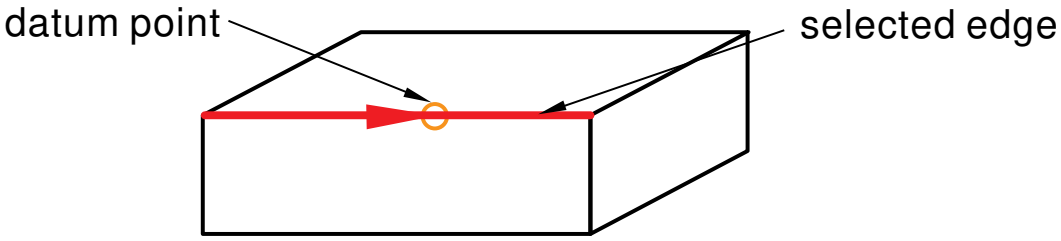

Figure 5: Positioning a datum point a specified distance along an edge.

Project point on face/plane

Select a point and a face or plane on which to project the point. Abaqus/CAE creates the datum point where the face or plane intersects a line that is normal to it and passing through the selected point, as shown in *Figure 6*. The datum point also marks the shortest distance between the selected point and the selected face or plane. For detailed instructions, see *Creating a datum point by projecting a point on a face or plane*.

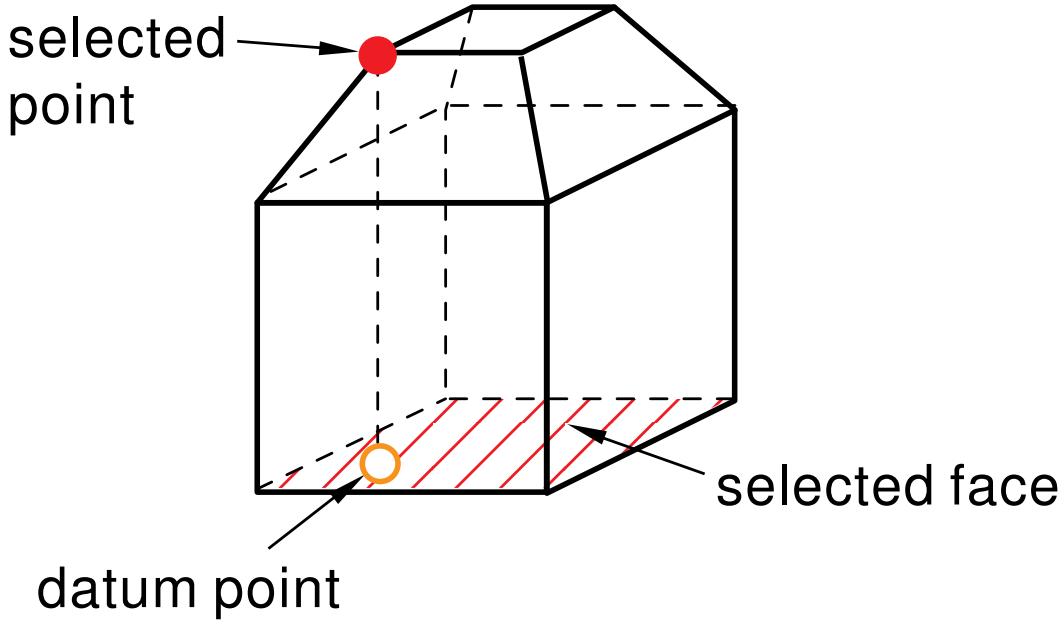

Figure 6: Creating a datum point by projecting a point onto a face.

Project point on edge/datum axis

Select a point on the model and an edge or datum axis on which to project the point. Abaqus/CAE creates the datum point where the edge or datum axis intersects a line that is normal to it and passing through the selected point, as shown in *Figure 7*. The datum point also marks the shortest distance between the selected point and the selected edge or datum axis. For detailed instructions, see *Creating a datum point by projecting a point on an edge or datum axis*.

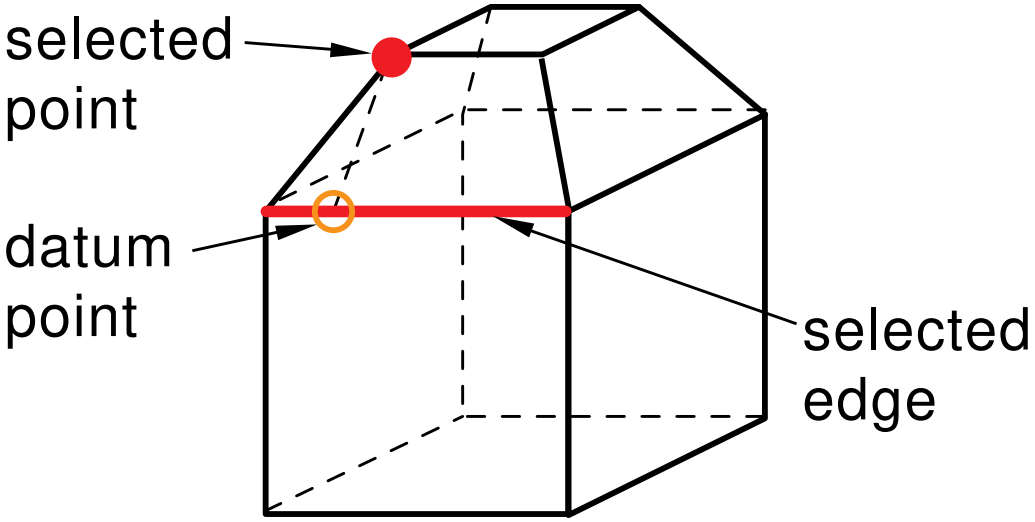

Figure 7: Creating a datum point by projecting a point onto an edge.

Intersection of line and plane

Select a linear edge or datum axis and a planar face or datum plane on the model. Abaqus/CAE creates the datum point at the location where the line intersects with the plane, as shown in *Figure 8*. For detailed instructions, see *Creating a datum point by intersecting a line and a plane*.

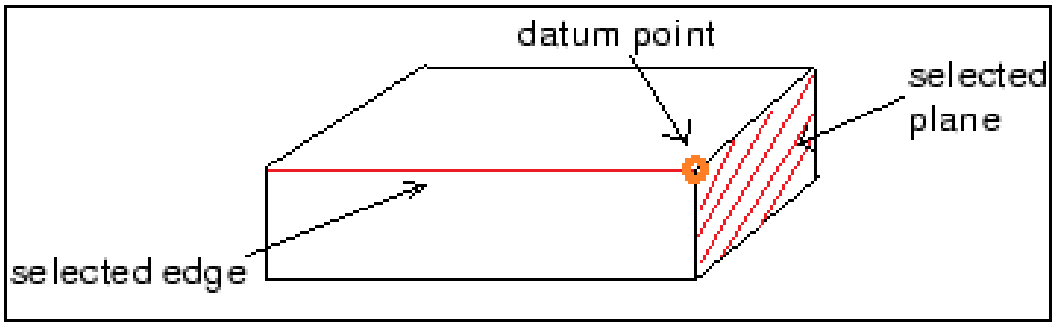

Figure 8: Creating a datum point by intersecting a line and a plane.

Offset from point in a direction

Select a point on the model to offset; select a linear edge or datum axis on the model to act as the offset direction, and enter the offset distance. Abaqus/CAE creates the datum point by offsetting the point in the given direction, by the given distance, as shown in *Figure 9*. For detailed instructions, see *Creating a datum point by offsetting a point along a direction*.

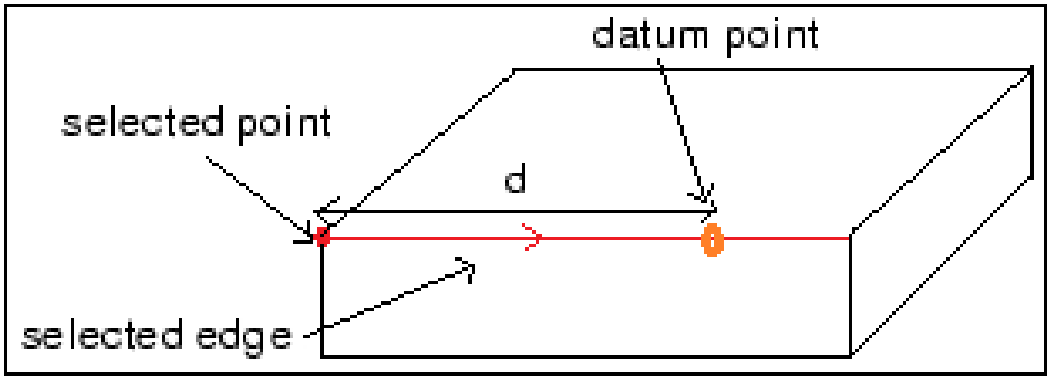

Figure 9: Creating a datum point by offsetting a point along a direction.

Additional information

- *Creating datum points*
- *Controlling datum display*

Methods for creating a datum axis

When you choose **Axis** from the **Create Datum** dialog box, the **Method** list displays the methods for creating a datum axis.

The following methods are available:

Principal axis

Select one of the three principal axes with which the datum axis must be colinear, as shown in *Figure 1*. For detailed instructions, see *Creating a datum axis along a principal axis*.

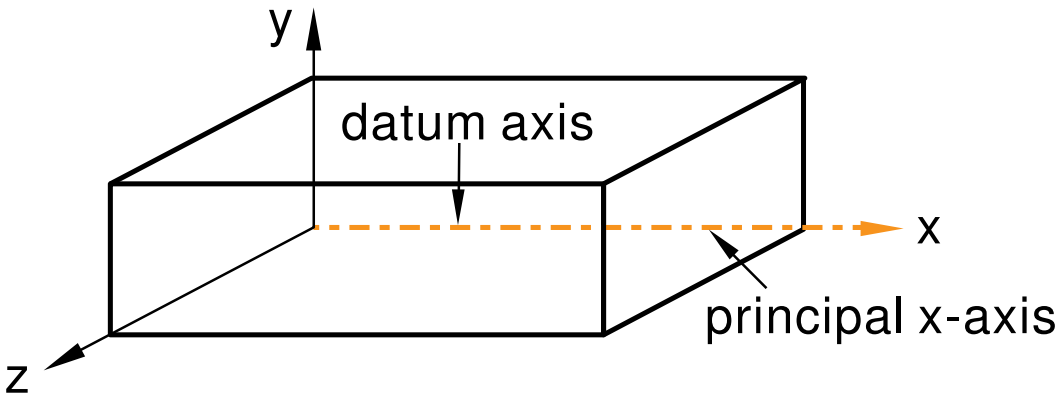

Figure 1: Defining a datum axis as one of the three principal axes.

Intersection of 2 planes

Select two non-parallel planar surfaces. Abaqus/CAE creates the datum axis where the two planes (or extensions of the two planes) intersect, as shown in *Figure 2*. For detailed instructions, see *Creating a datum axis along the intersection of two planes*.

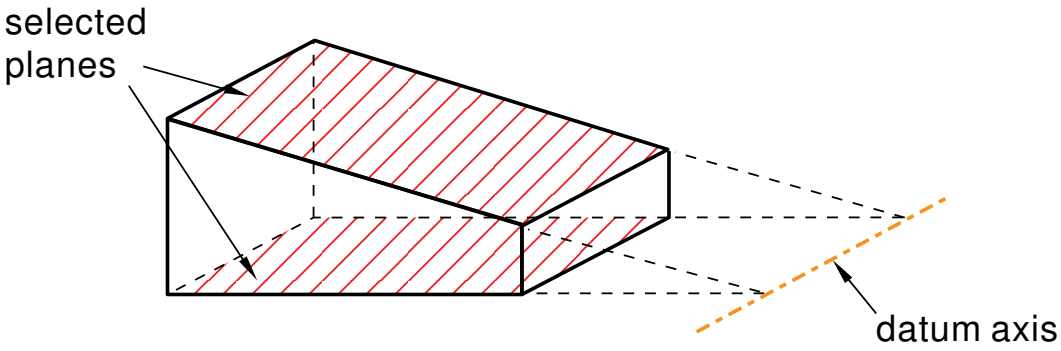

Figure 2: Defining a datum axis as the intersection of two planes.

Straight edge

Select a straight edge on the model with which the datum axis must be colinear, as shown in *Figure 3*. For detailed instructions, see *Creating a datum axis along a straight edge*.

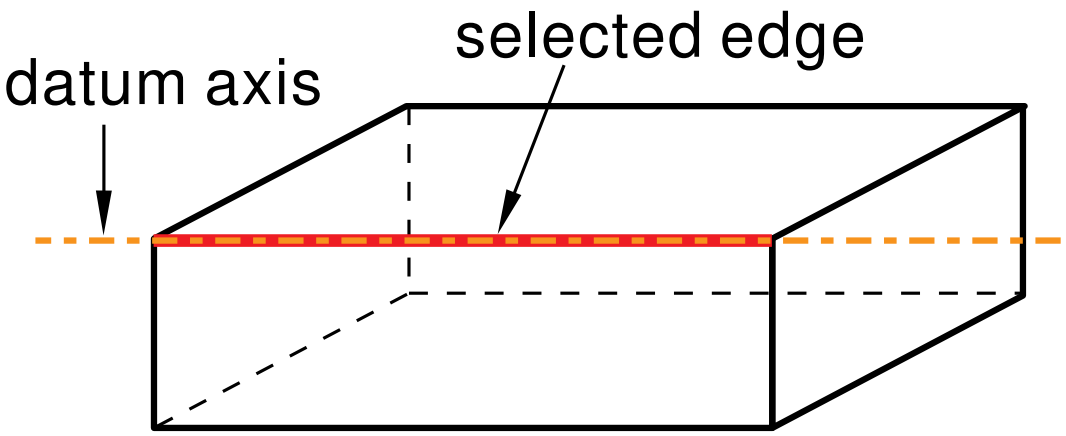

Figure 3: Defining a datum axis as a straight edge on the model.

2 points

Select any two points on the model through which the datum axis must pass, as shown in *Figure 4*. For detailed instructions, see *Creating a datum axis through two points*.

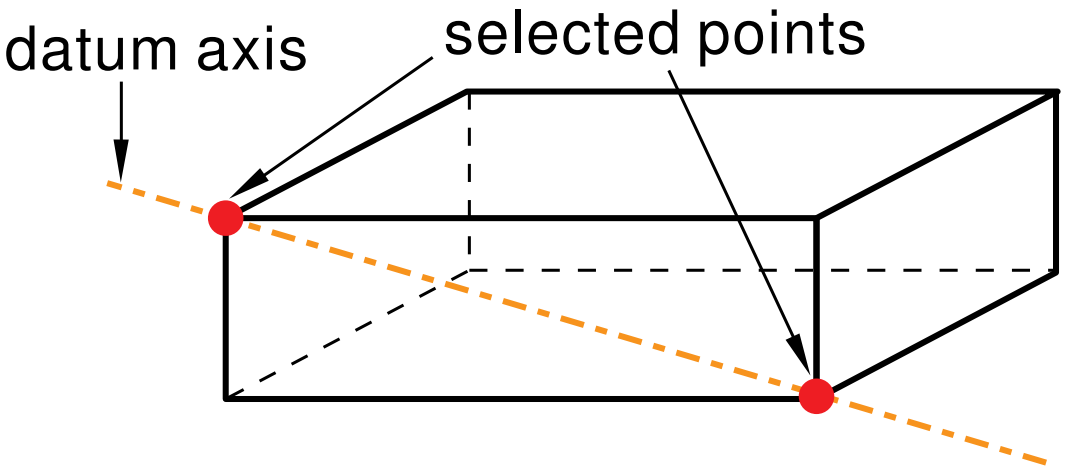

Figure 4: Defining a datum axis by selecting two points.

Axis of cylinder

Select a cylindrical face on the model. Abaqus/CAE creates a datum axis that lies along the axis of the cylindrical face, as shown in *Figure 5*. For detailed instructions, see *Creating a datum axis along the axis of a cylinder*.

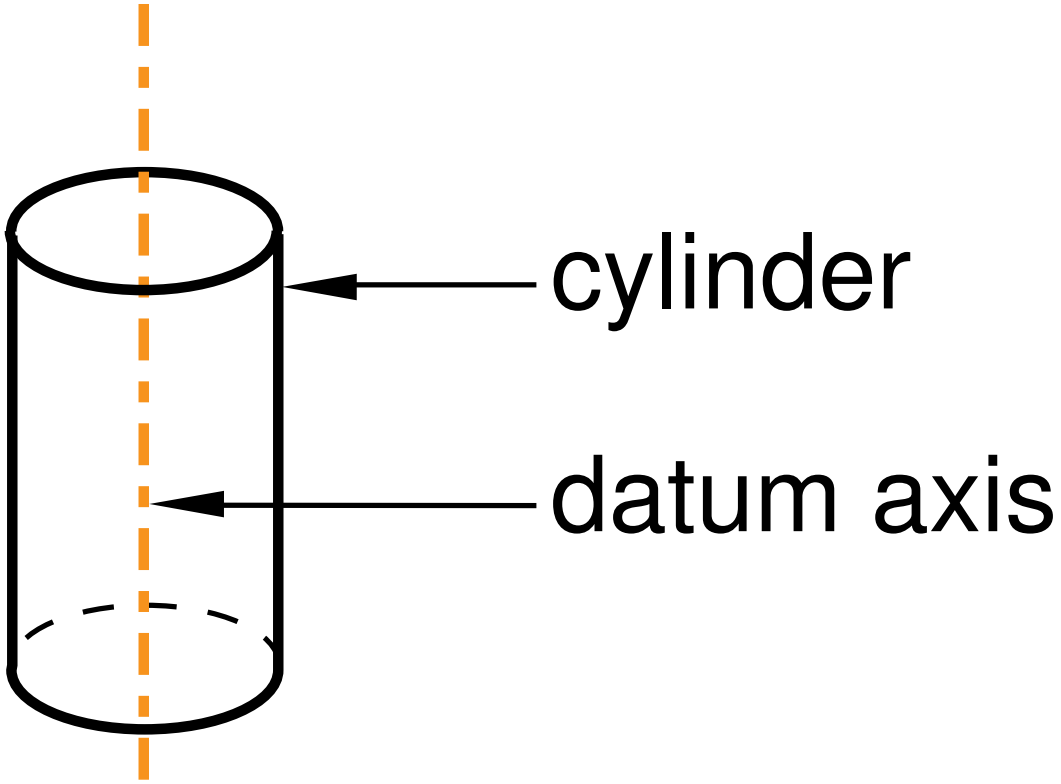

Figure 5: Defining a datum axis as the axis of a cylinder.

Normal to plane, thru point

Select a plane and a point that is not on the plane. Abaqus/CAE creates a datum axis that is normal to the plane and passes through the point, as shown in *Figure 6*. For detailed instructions, see *Creating a datum axis normal to a plane and passing through a point*.

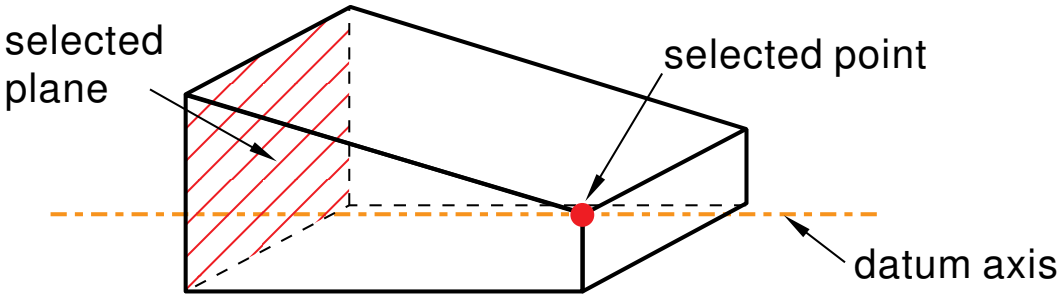

Figure 6: Defining a datum axis by selecting a point and a plane.

Parallel to line, thru point

Select an edge of the model and a point outside the edge. Abaqus/CAE creates a datum axis that is parallel to the edge and passes through the point, as shown in *Figure 7*. For detailed instructions, see *Creating a datum axis parallel to a line and passing through a point*.

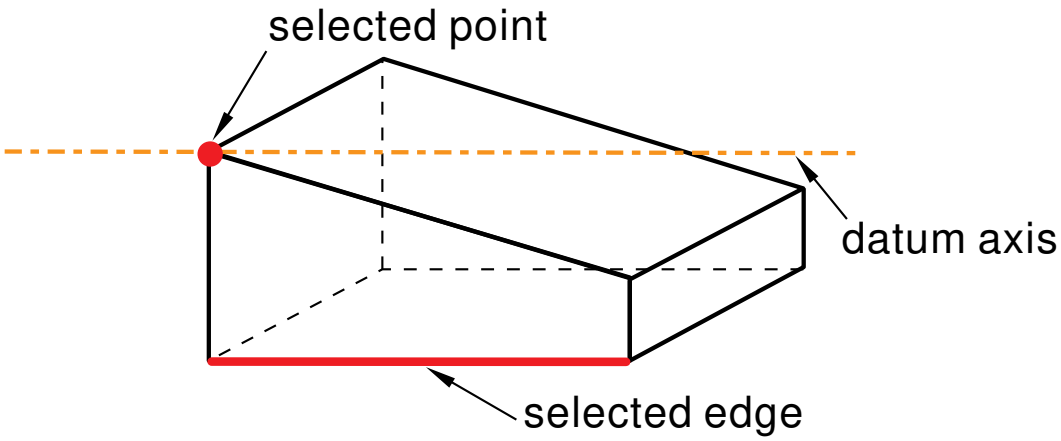

Figure 7: Defining a datum axis by selecting a point and an edge.

3 points on circle

Select three points on the model that define a circle. Abaqus/CAE creates a datum axis along the axis of the circle, as shown in *Figure 8*. For detailed instructions, see *Creating a datum axis running along the axis of a circle defined by three points*.

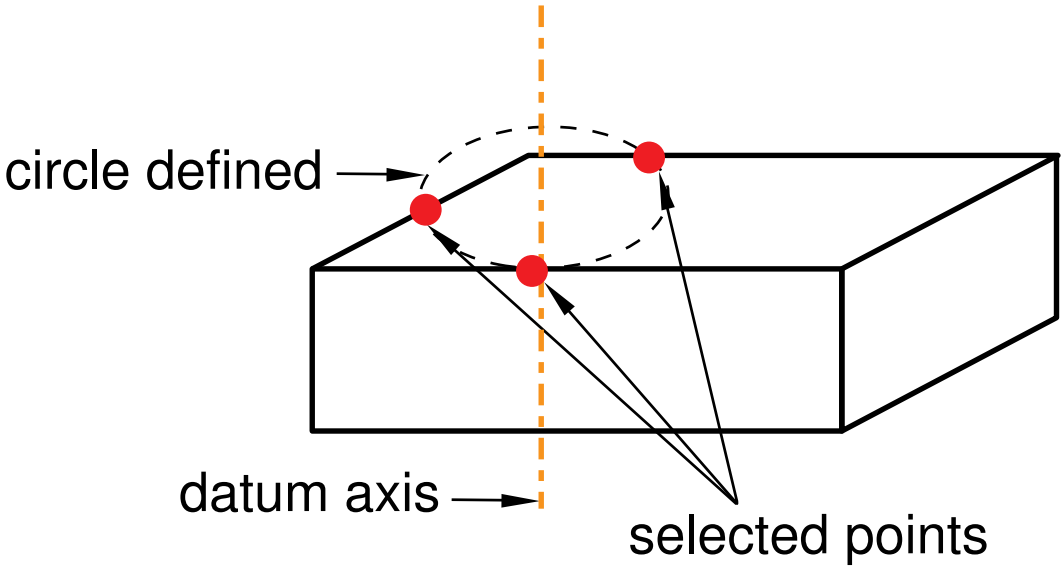

Figure 8: Defining a datum axis as the axis of a circle.

Rotate from line

Select an edge and an axis of rotation, and specify the angle through which the edge will be rotated. Abaqus/CAE creates a datum axis by rotating the edge about the axis through the specified angle, as shown in *Figure 9*. For detailed instructions, see *Creating a datum axis by rotating an existing edge through a specified angle*.

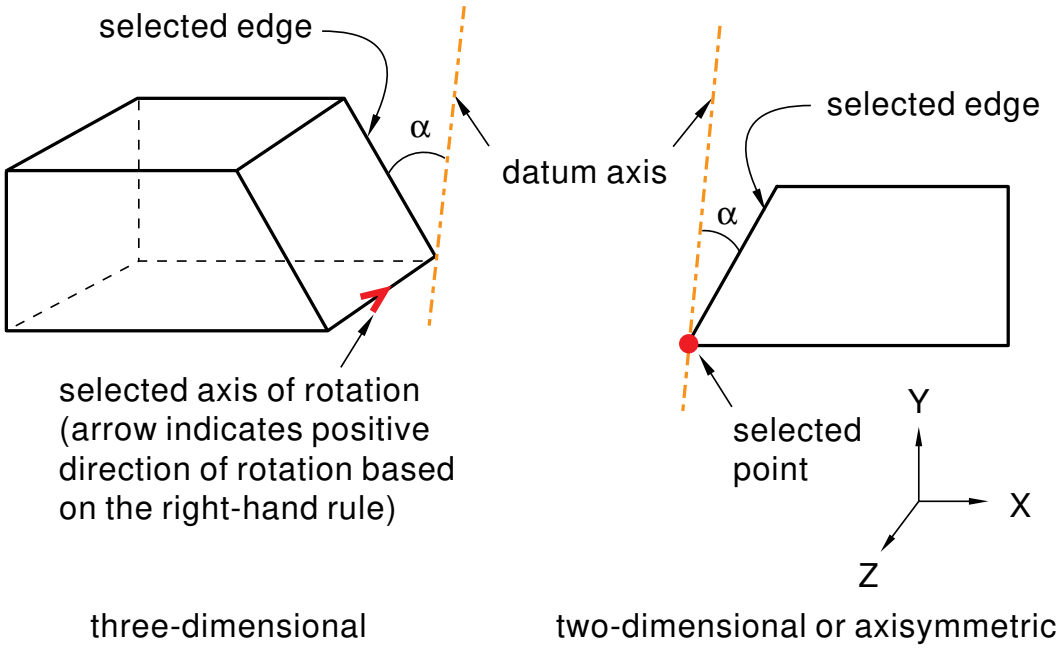

Figure 9: Defining a datum axis by rotating an edge through a specified angle.

Cross product of 2 lines

Select two non-parallel linear edges or datum axes on the model. Abaqus/CAE creates a datum axis orthogonal to the plane formed by both lines, as shown in *Figure 10*. For detailed instructions, see *Creating a datum axis by taking the cross product of two lines*.

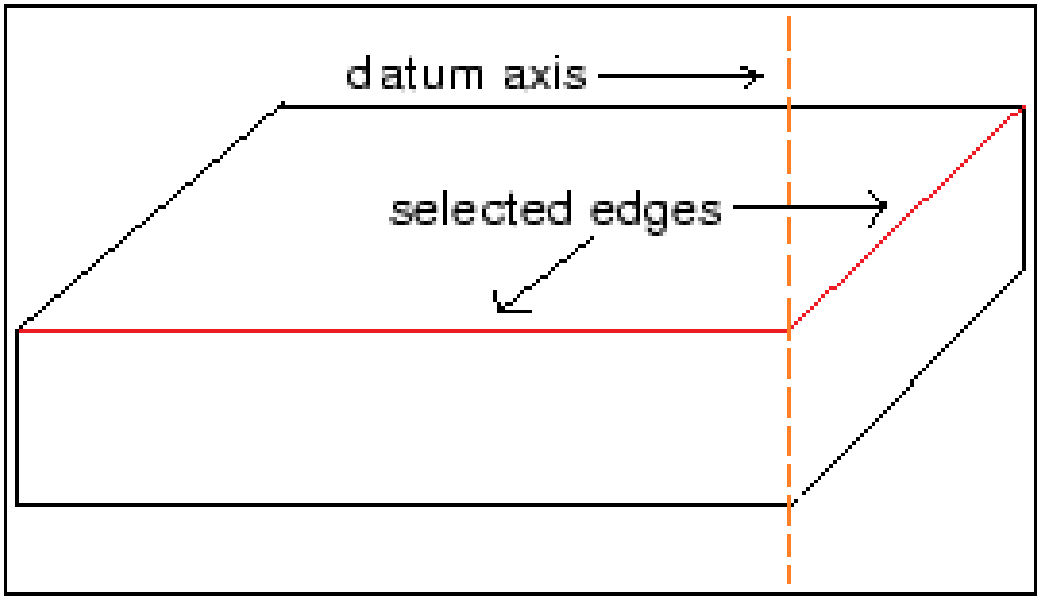

Figure 10: Defining a datum axis by selecting two lines.

Project line on plane

Select a linear edge or datum axis and a planar face or datum plane on the model. Abaqus/CAE creates a datum axis by projecting the line onto the plane, as shown in *Figure 11*. For detailed instructions, see *Creating a datum axis by projecting a line on a plane*.

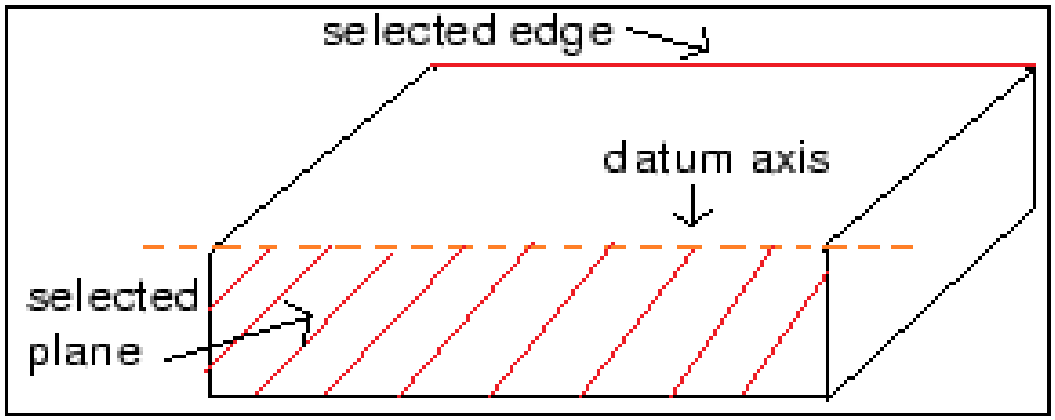

Figure 11: Defining a datum axis by projecting a line on a plane.

Additional information

- *Creating datum axes*
- *Controlling datum display*

Methods for creating a datum plane

When you choose **Plane** from the **Create Datum** dialog box, the **Method** list displays the methods for creating a datum plane.

The following methods are available:

Offset from principal plane

Select one of the three principal planes; and provide the location of the datum plane in the form of an offset from the selected plane, as shown in *Figure 1*. A positive value indicates an offset in the positive direction along the axis normal to the selected plane; for example, along the *X*-axis normal to the *Y*–*Z* plane. For detailed instructions, see *Creating a datum plane offset from a principal plane*.

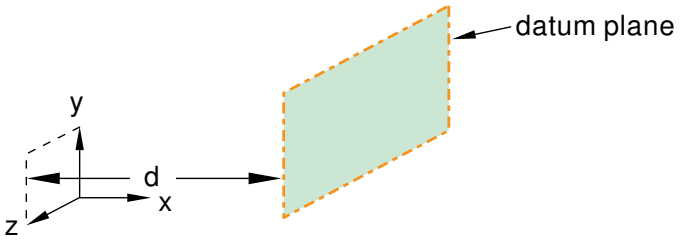

Figure 1: Creating a datum plane by offsetting from one of the three principal planes.

Offset from plane

Select any plane on the model; and provide the location of the datum plane by specifying the direction of the normal and an offset from the selected plane along the normal, as shown in *Figure 2*. You can specify the offset by entering a value or selecting a point. For detailed instructions, see *Creating a datum plane at an offset from a selected plane*.

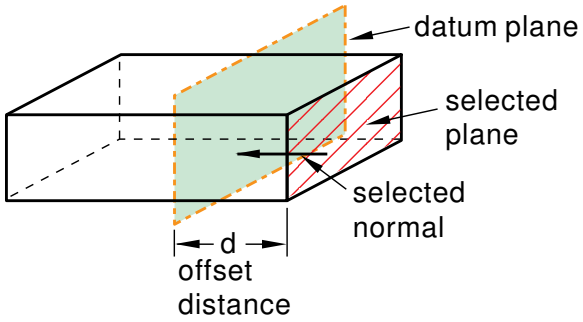

Figure 2: Creating a datum plane by offsetting from any plane.

3 points

Select three points through which the datum plane must pass, as shown in *Figure 3*. For detailed instructions, see *Creating a datum plane passing through three points*.

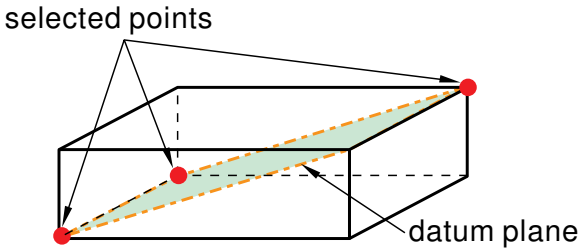

Figure 3: Creating a datum plane by selecting three points.

Line and point

Select an edge and a point through which the datum plane must pass, as shown in *Figure 4*. For detailed instructions, see *Creating a datum plane through a line and a point*.

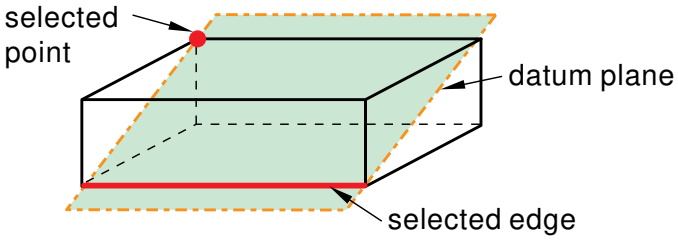

Figure 4: Creating a datum plane by selecting a point and an edge.

Point and normal

Select a point and an edge; the datum plane passes through the point and is normal to the selected edge, as shown in *Figure 5*. For detailed instructions, see *Creating a datum plane passing through a point and normal to an edge*.

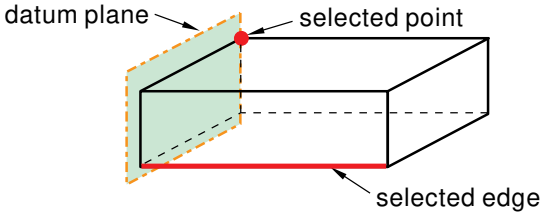

Figure 5: Creating a datum plane by selecting a point and a normal edge.

Midway between 2 points

Select two points. Abaqus/CAE creates a datum plane midway between the two selected points and normal to the line connecting them, as shown in *Figure 6*. For detailed instructions, see *Create a datum plane midway between two points and normal to the line connecting the two points*.

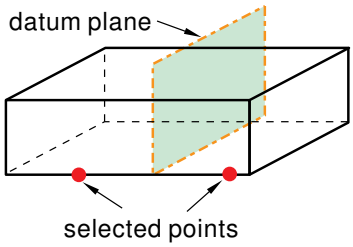

Figure 6: Positioning a datum plane midway between two points.

Rotate from plane

Select a face and an axis of rotation, and specify the angle through which the face will be rotated. Abaqus/CAE creates a datum plane by rotating the face about the axis through the specified angle, as shown in *Figure 7*. For detailed instructions, see *Creating a datum plane by rotating an existing face through a specified angle*.

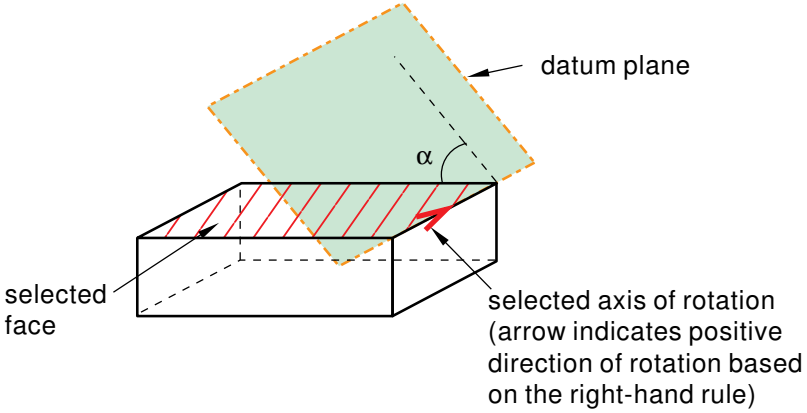

Figure 7: Defining a datum plane by rotating a face through a specified angle.

Additional information

- *Creating datum planes*

Methods for creating a datum coordinate system

When you choose **CSYS** from the **Create Datum** dialog box, the **Method** list displays the methods for creating a datum coordinate system.

Datum coordinates systems are used throughout Abaqus/CAE; for example, to define material orientations and to define connector orientations. To help you keep track of your datum coordinate systems, you can name the systems when you create them, and the name appears alongside their entry in the Model Tree.

The following methods are available:

3 points

Define a rectangular, cylindrical, or spherical coordinate system by selecting the origin and, optionally, two additional points. In the case of a rectangular system, the second point defines the *X*-axis, and the *X*–*Y* plane passes through the second and third points, as shown in *Figure 1*. This is the most versatile tool for creating a datum coordinate system, and you should use it when possible. For detailed instructions, see *Creating a datum coordinate system defined by three points*.

Figure 1: Positioning a rectangular datum coordinate system by selecting the origin and two points.

Offset from CSYS

Select a coordinate system; and provide the location of the rectangular, cylindrical, or spherical datum coordinate system by specifying an offset, as shown by the example involving a rectangular system in *Figure 2*. You can specify the offset by entering a value or by selecting a point. For detailed instructions, see *Creating a datum coordinate system at an offset from another coordinate system*.

Figure 2: Positioning a rectangular datum coordinate system by offsetting from another coordinate system.

2 lines

Select two edges that define the rectangular, cylindrical, or spherical coordinate system. In the case of a rectangular system, the first edge defines the *X*-axis and the *X*–*Y* plane passes through the second edge, as shown in *Figure 3*. For detailed instructions, see *Creating a datum coordinate system defined by two lines*.

Figure 3: Positioning a rectangular datum coordinate system by selecting two edges.

Rotate from CSYS

Select a coordinate system and an axis of rotation, and specify the angle through which the datum coordinate system will be rotated to create a rectangular, cylindrical, or spherical datum coordinate system, as shown by the example involving a rectangular system in *Figure 4*. For detailed instructions, see *Creating a datum coordinate system by rotating another coordinate system*.

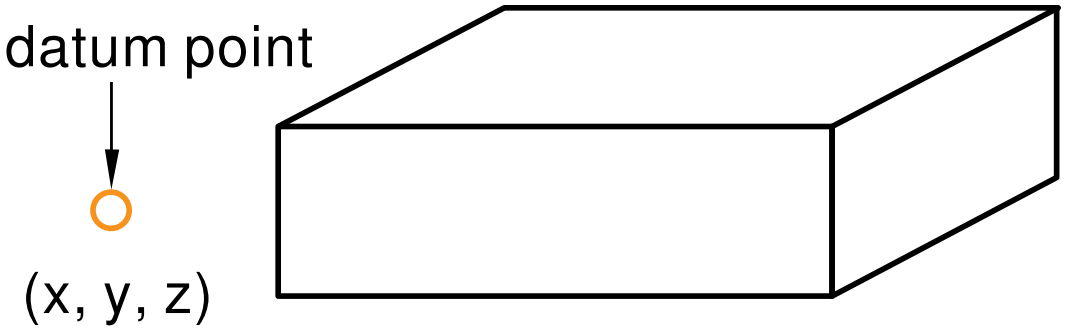
Figure 4: Positioning a rectangular datum coordinate system by rotating from another coordinate system.

Additional information

- *Creating datum planes*
- *Controlling datum display*

Creating datum points

This section describes the tools that you can use to create a datum point.



In this section:

- *Creating a datum point by entering its coordinates*
- *Creating a datum point at an offset from a selected point*
- *Creating a datum point midway between two points*
- *Creating a datum point at a specified distance from two edges*
- *Creating a datum point by entering an edge parameter*
- *Creating a datum point by projecting a point on a face or plane*
- *Creating a datum point by projecting a point on an edge or datum axis*
- *Creating a datum point by intersecting a line and a plane*
- *Creating a datum point by offsetting a point along a direction*

Creating a datum point by entering its coordinates

You can position a datum point by entering its *X*-, *Y*-, and *Z*-coordinates.

The figure below shows an example of creating a datum point by entering its coordinates.

1. From the main menu bar, select **Tools**->**Datum**.

   The **Create Datum** dialog box appears. The dialog box outlines the types of datum geometry you can create.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also create a datum point using the (XYZ) tool, located in the module toolbox. For a diagram of the datum tools in the toolbox, see *Using the Datum toolset*.

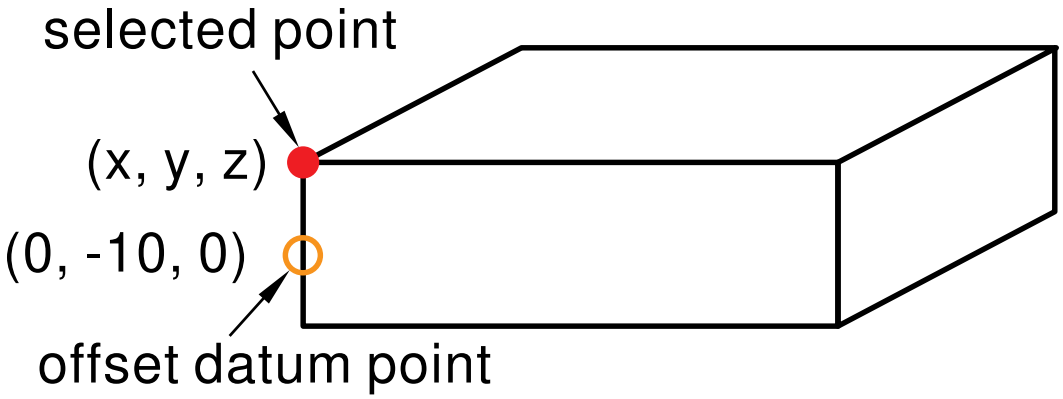
2. From the list of types at the top of the dialog box, choose **Point**.

   The **Method** list indicates the methods you can use to create a datum point.

3. From the **Method** list, select **Enter coordinates**.
4. In the text field that appears in the prompt area, enter the *X*-, *Y*-, and *Z*-coordinates of the datum point you want to create. If the datum is associated with the assembly, the coordinates you provide are relative to the assembly's global coordinate system. If the datum is associated with a part, the coordinates are relative to the part's coordinate system. If you are unsure of the location or orientation of the part's coordinate system, first create a default coordinate system at the origin of the part. For more information, see *Creating a datum coordinate system defined by three points*.

   The datum point appears. You can modify the coordinates of the datum point by selecting **Feature**->**Edit** from the main menu bar and selecting the datum.

5. You can select a local coordinate system before entering the coordinates. The datum point will get created relative to the selected coordinate system.



Additional information

- *Methods for creating a datum point*
- *Datum creation techniques*
- *Controlling datum display*

Creating a datum point at an offset from a selected point

You can position a datum point by selecting a point on the model and entering the *X*-, *Y*-, and *Z*-coordinates of an offset from the point.

The figure below shows an example of creating a datum point at an offset from a selected point.

1. From the main menu bar, select **Tools->Datum**.

   The **Create Datum** dialog box appears. The dialog box outlines the types of datum geometry you can create.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

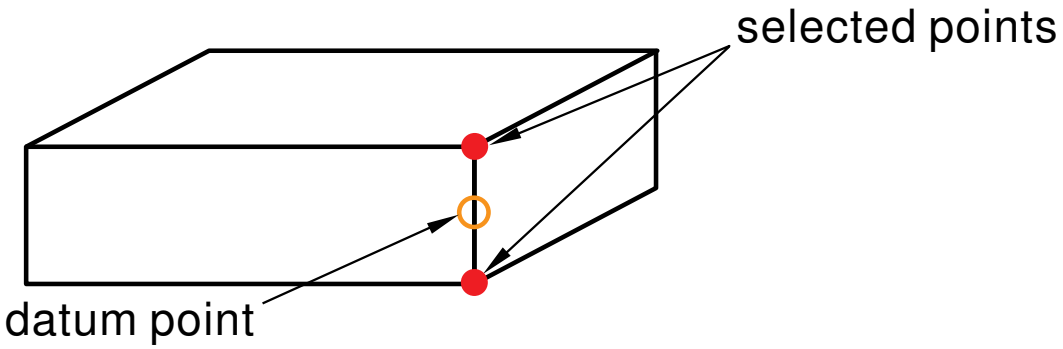
   Tip: You can also create a datum point using the tool, located in the module toolbox. For a diagram of the datum tools in the toolbox, see *Using the Datum toolset*.

2. From the list of types at the top of the dialog box, choose **Point**.

   The **Method** list indicates the methods you can use to create a datum point.

3. From the **Method** list, select **Offset from point**.
4. If desired, select **Make Independent** from the prompt area to create the datum as an independent feature.
5. From the part or assembly in the current viewport, select a point.
6. In the text field that appears in the prompt area, enter the *X*-, *Y*-, and *Z*-coordinates of the offset from the selected point.

   The datum point appears. You can modify the coordinates of the offset by selecting **Feature->Edit** from the main menu bar and selecting the datum.



Additional information

- *Methods for creating a datum point*
- *Datum creation techniques*
- *Controlling datum display*

Creating a datum point midway between two points

You can position a datum point by selecting two points on the model; Abaqus/CAE creates the datum point midway between the two selected points.

The figure below shows an example of creating a datum point midway between two points.

1. From the main menu bar, select **Tools->Datum**.

   The **Create Datum** dialog box appears. The dialog box outlines the types of datum geometry you can create.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

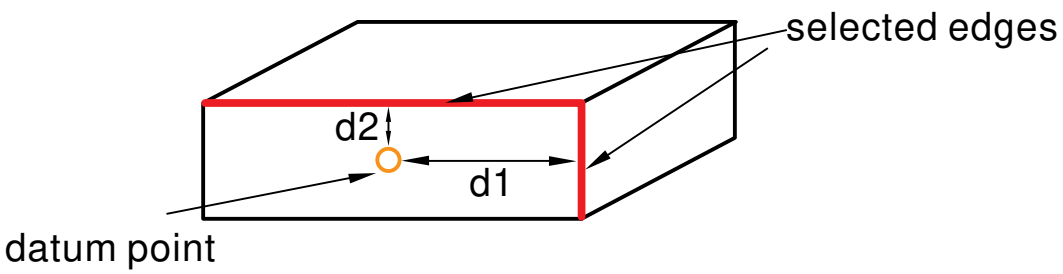
   Tip: You can also create a datum point using the tool, located in the module toolbox. For a diagram of the datum tools in the toolbox, see *Using the Datum toolset*.

2. From the list of types at the top of the dialog box, choose **Point**.

   The **Method** list indicates the methods you can use to create a datum point.

3. From the **Method** list, select **Midway between 2 points**.
4. If desired, select **Make Independent** from the prompt area to create the datum as an independent feature.
5. From the part or assembly in the current viewport, select two points.

   The datum point appears. You cannot modify a datum point created with this method; you must delete the old point and create a new one.



Additional information

- *Methods for creating a datum point*
- *Datum creation techniques*
- *Controlling datum display*

Creating a datum point at a specified distance from two edges

You can position a datum point by selecting two edges on the model and entering the distance from the datum point to each edge.

The figure below shows an example of creating a datum point at a specified distance from two edges.

1. From the main menu bar, select **Tools->Datum**.

   The **Create Datum** dialog box appears. The dialog box outlines the types of datum geometry you can create.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

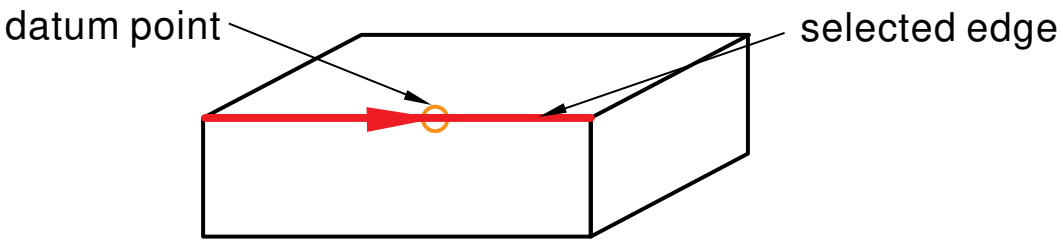
   Tip: You can also create a datum point using the tool, located in the module toolbox. For a diagram of the datum tools in the toolbox, see *Using the Datum toolset*.

2. From the list of types at the top of the dialog box, choose **Point**.

   The **Method** list indicates the methods you can use to create a datum point.

3. From the **Method** list, select **Offset from 2 edges**.
4. If desired, select **Make Independent** from the prompt area to create the datum as an independent feature.
5. From the part or assembly in the current viewport, select the plane on which to create the datum point.
6. Select a straight edge on the specified plane and enter the distance of the datum point from this edge.
7. Select a second straight edge on the plane and enter the distance of the datum point from this edge.

   The datum point appears. You can modify the position of the datum point by selecting **Feature->Edit** from the main menu bar and modifying the distance from the datum to each edge.



Additional information

- *Methods for creating a datum point*
- *Datum creation techniques*
- *Controlling datum display*

Creating a datum point by entering an edge parameter

You can position a datum point by selecting an edge on the model and entering a parameter value that represents a percentage of the edge length.
An arrow along the edge indicates the direction of increasing parameter value from the start vertex (corresponding to an edge parameter value of zero) to the end vertex (corresponding to a value of one.)

The figure below shows an example of creating a datum point by entering an edge parameter.

1. From the main menu bar, select **Tools->Datum**.

   The **Create Datum** dialog box appears. The dialog box outlines the types of datum geometry you can create.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also create a datum point using the tool, located in the module toolbox. For a diagram of the datum tools in the toolbox, see *Using the Datum toolset*.

2. From the list of types at the top of the dialog box, choose **Point**.

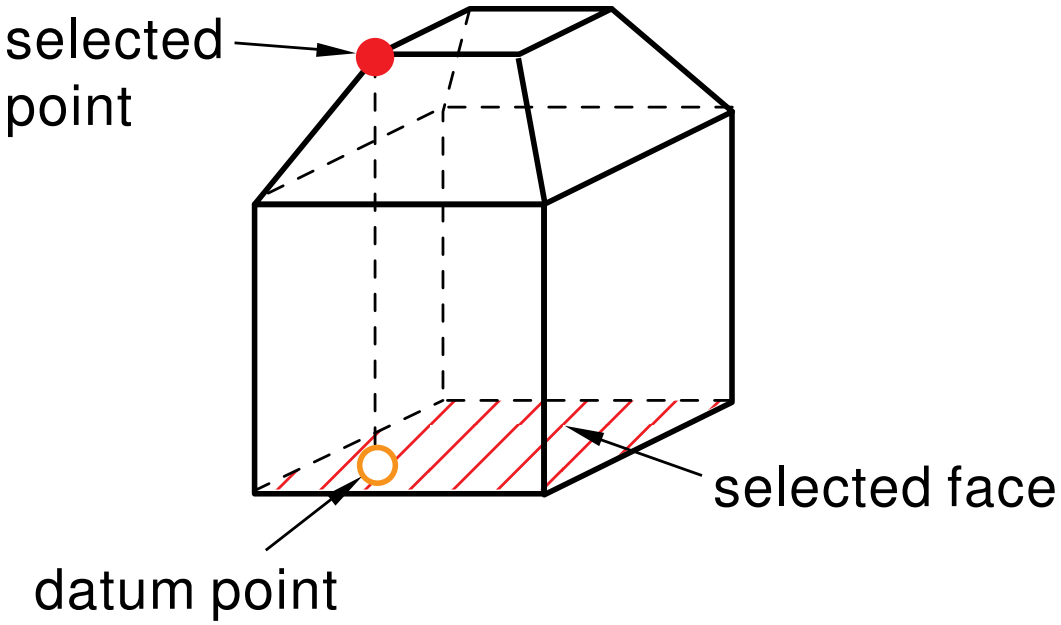
   The **Method** list indicates the methods you can use to create a datum point.

3. From the **Method** list, select **Enter parameter**.
4. If desired, select **Make Independent** from the prompt area to create the datum as an independent feature.
5. From the part or assembly in the current viewport, select the edge on which the datum point will be positioned.

   An arrow appears on the selected edge indicating the direction of increasing parameter value.

6. In the text field in the prompt area, enter the value of the edge parameter.

   The datum point appears. You can modify the position of the datum point by selecting **Feature->Edit** from the main menu bar and modifying the value of the edge parameter.



Additional information

- *Methods for creating a datum point*
- *Datum creation techniques*
- *Controlling datum display*

Creating a datum point by projecting a point on a face or plane

You can position a datum point by selecting a point on the model and a face or plane on which to project the point. Abaqus/CAE creates the datum point where the selected face or plane intersects a line that is normal to it and passes through the selected point.

The figure below shows an example of creating a datum point by projecting a point on a face.

1. From the main menu bar, select **Tools->Datum**.

   The **Create Datum** dialog box appears. The dialog box outlines the types of datum geometry you can create.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

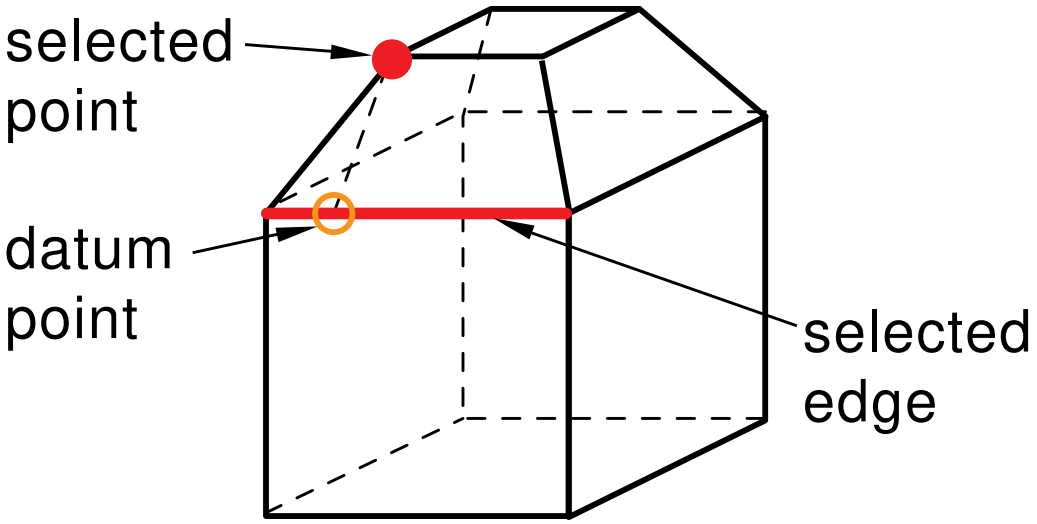
   Tip: You can also create a datum point using the tool, located in the module toolbox. For a diagram of the datum tools in the toolbox, see *Using the Datum toolset*.

2. From the list of types at the top of the dialog box, choose **Point**.

   The **Method** list indicates the methods you can use to create a datum point.

3. From the **Method** list, select **Project point on face/plane**.
4. If desired, select **Make Independent** from the prompt area to create the datum as an independent feature.
5. From the part or assembly in the current viewport, select a point.
6. Select a face or plane on which to project the point. The selection can be a planar face, a nonplanar face, or a datum plane.

The datum point appears. You cannot modify a datum point created with this method; you must delete the old point and create a new one.



Additional information

- *Methods for creating a datum point*
- *Datum creation techniques*
- *Controlling datum display*

Creating a datum point by projecting a point on an edge or datum axis

You can position a datum point by selecting a point on the model and an edge or datum axis on which to project the point.
Abaqus/CAE creates the datum point where the selected edge or datum axis intersects a line that is normal to it and passes through the selected point.

The figure below shows an example of creating a datum point by projecting a point on an edge.

1. From the main menu bar, select **Tools->Datum**.

   The **Create Datum** dialog box appears. The dialog box outlines the types of datum geometry you can create.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

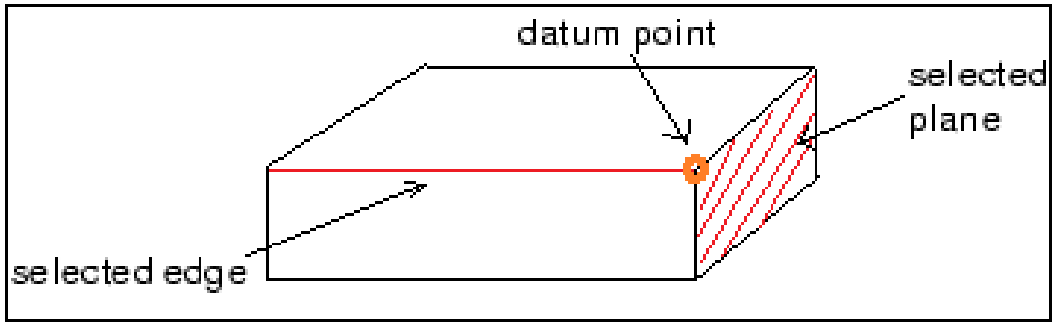
   Tip: You can also create a datum point using the tool, located in the module toolbox. For a diagram of the datum tools in the toolbox, see *Using the Datum toolset*.

2. From the list of types at the top of the dialog box, choose **Point**.

   The **Method** list indicates the methods you can use to create a datum point.

3. From the **Method** list, select **Project point on edge/datum axis**.
4. If desired, select **Make Independent** from the prompt area to create the datum as an independent feature.
5. From the part or assembly in the current viewport, select a point.
6. Select an edge or datum axis on which to project the point.

   The datum point appears. You cannot modify a datum point created with this method; you must delete the old point and create a new one.



Additional information

- *Methods for creating a datum point*
- *Datum creation techniques*
- *Controlling datum display*

Creating a datum point by intersecting a line and a plane

You can position a datum point by selecting a linear edge and a planar face or a datum plane on the model. Abaqus/CAE creates the datum point at the location where the line intersects with the plane.

The figure below shows an example of creating a datum point by intersecting a line and a plane.

1. From the main menu bar, select **Tools->Datum**.

   The **Create Datum** dialog box appears. The dialog box outlines the types of datum geometry you can create.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

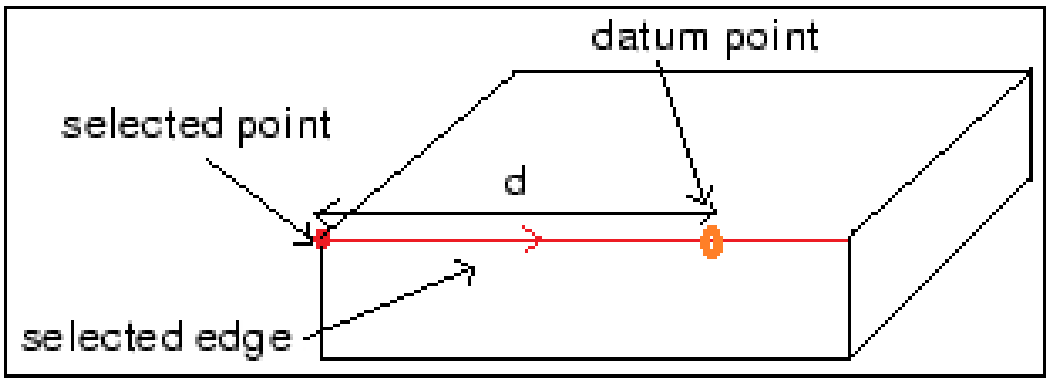
   Tip: You can also create a datum point using the tool, located in the module toolbox. For a diagram of the datum tools in the toolbox, see *Using the Datum toolset*.

2. From the list of types at the top of the dialog box, choose **Point**.

   The **Method** list indicates the methods you can use to create a datum point.

3. From the **Method** list, select **Intersection of line and plane**.
4. If desired, select **Make Independent** from the prompt area to create the datum as an independent feature.
5. From the part or assembly in the current viewport, select a linear edge/datum axis.
6. Select a planar face or a datum plane to intersect the selected line.

   The datum point appears. You cannot modify a datum point created with this method; you must delete the old point and create a new one.



Additional information

- *Methods for creating a datum point*
- *Datum creation techniques*
- *Controlling datum display*

Creating a datum point by offsetting a point along a direction

You can position a datum point by selecting a point on the model, selecting an offset direction, and entering an offset distance.
Abaqus/CAE creates the datum point by offsetting the point in the given direction by the given distance.

The figure below shows an example of creating a datum point by offsetting a point along a direction.

1. From the main menu bar, select **Tools->Datum**.

   The **Create Datum** dialog box appears. The dialog box outlines the types of datum geometry you can create.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also create a datum point using the tool, located in the module toolbox. For a diagram of the datum tools in the toolbox, see *Using the Datum toolset*.

2. From the list of types at the top of the dialog box, choose **Point**.

   The **Method** list indicates the methods you can use to create a datum point.

3. From the **Method** list, select **Offset from point in a direction**.
4. If desired, select **Make Independent** from the prompt area to create the datum as an independent feature.
5. From the part or assembly in the current viewport, select a point.
6. Select a linear edge or datum axis for the direction..

   The datum point appears. You cannot modify a datum point created with this method; you must delete the old point and create a new one.

7. Press **OK**, or flip the direction.
8. In the text field in the prompt area, enter the value of the offset distance.

   The datum point appears. You can modify the position of the datum point by selecting **Feature > Edit** from the main menu bar and modifying the value of the offset distance or flip direction.

Additional information

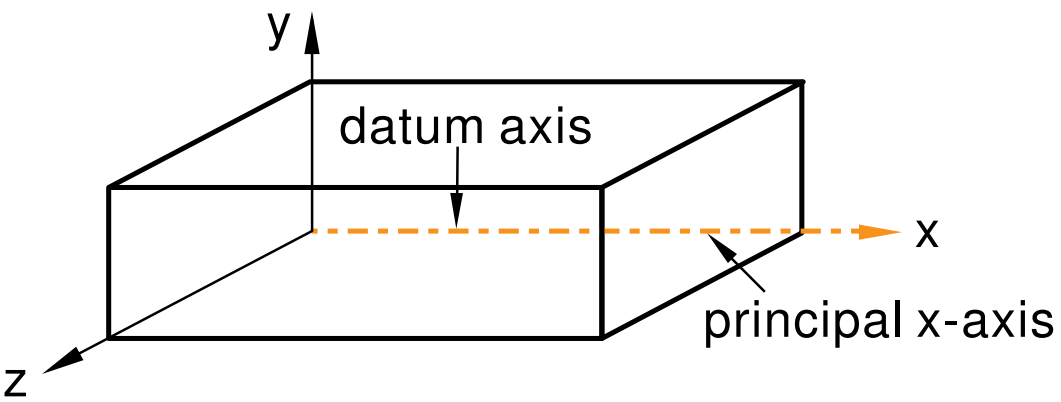
Creating datum axes

This section describes the tools that you can use to create a datum axis.



In this section:

- *Creating a datum axis along a principal axis*
- *Creating a datum axis along the intersection of two planes*
- *Creating a datum axis along a straight edge*
- *Creating a datum axis through two points*
- *Creating a datum axis along the axis of a cylinder*
- *Creating a datum axis normal to a plane and passing through a point*
- *Creating a datum axis parallel to a line and passing through a point*
- *Creating a datum axis running along the axis of a circle defined by three points*
- *Creating a datum axis by rotating an existing edge through a specified angle*
- *Creating a datum axis by taking the cross product of two lines*
- *Creating a datum axis by projecting a line on a plane*

Creating a datum axis along a principal axis

You can position a datum axis by selecting one of the three principal axis to define as the datum axis.

The figure below shows an example of creating a datum axis by selecting a principal axis.

1. From the main menu bar, select **Tools->Datum**.

   The **Create Datum** dialog box appears. The dialog box outlines the types of datum geometry you can create.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

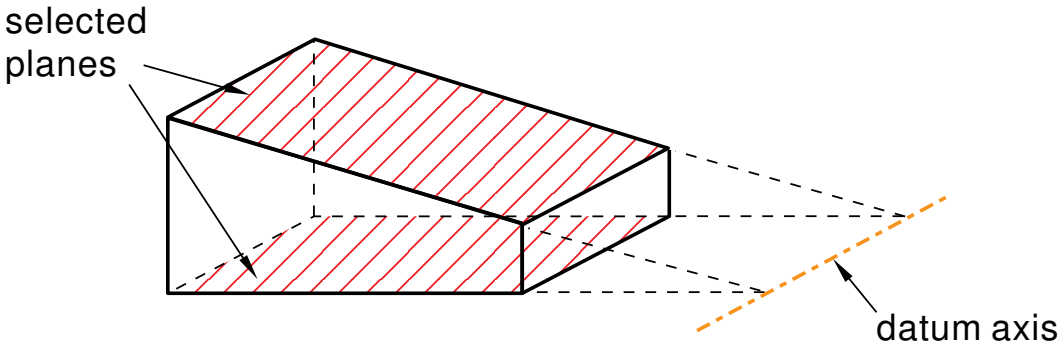
   Tip: You can also create a datum axis using the tool, located in the module toolbox. For a diagram of the datum tools in the toolbox, see *Using the Datum toolset*.

2. From the list of types at the top of the dialog box, choose **Axis**.

   The **Method** list indicates the methods you can use to create a datum axis.

3. From the **Method** list, select **Principal axis**.
4. Select the principal *X*-, *Y*-, or *Z*-axis through which your datum axis must pass.

   The datum axis appears. You cannot modify a datum axis created with this method; you must delete the old axis and create a new one.



Additional information

- *Methods for creating a datum axis*
- *Datum creation techniques*
- *Controlling datum display*

Creating a datum axis along the intersection of two planes

You can position a datum axis by selecting two nonparallel planar surfaces.
Abaqus/CAE creates the datum axis where the two planes, or a projection of the two planes, intersect.

The figure below shows an example of creating a datum axis at the intersection of two planes.

1. From the main menu bar, select **Tools->Datum**.

   The **Create Datum** dialog box appears. The dialog box outlines the types of datum geometry you can create.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

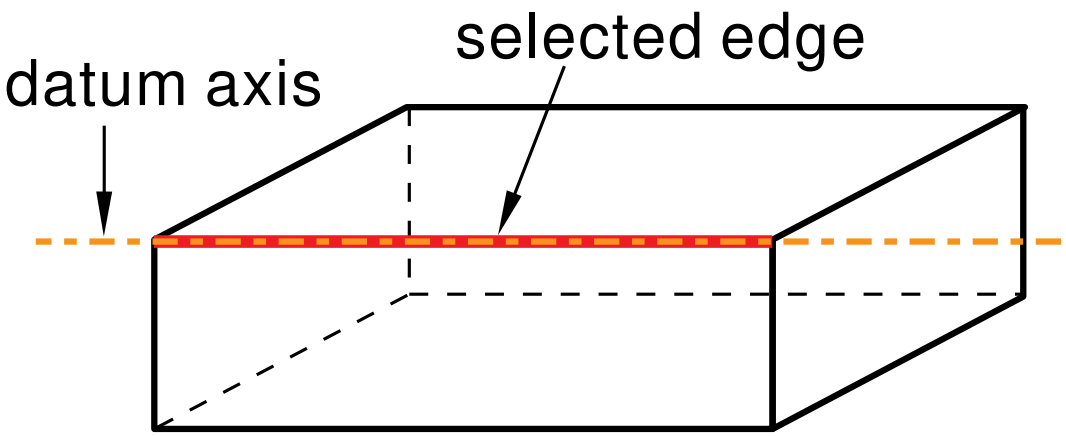
   Tip: You can also create a datum axis using the tool, located in the module toolbox. For a diagram of the datum tools in the toolbox, see *Using the Datum toolset*.

2. From the list of types at the top of the dialog box, choose **Axis**.

   The **Method** list indicates the methods you can use to create a datum axis.

3. From the **Method** list, select **Intersection of 2 planes**.
4. If desired, select **Make Independent** from the prompt area to create the datum as an independent feature.
5. From the part or assembly in the current viewport, select a plane.
6. Select a second plane that is not parallel with the first.

   The datum axis appears. You cannot modify a datum axis created with this method; you must delete the old axis and create a new one.



Additional information

- *Methods for creating a datum axis*
- *Datum creation techniques*
- *Controlling datum display*

Creating a datum axis along a straight edge

You can position a datum axis by selecting a straight edge on the model to define as the datum axis.

The figure below shows an example of creating a datum axis along a straight edge on the model.

1. From the main menu bar, select **Tools->Datum**.

   The **Create Datum** dialog box appears. The dialog box outlines the types of datum geometry you can create.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

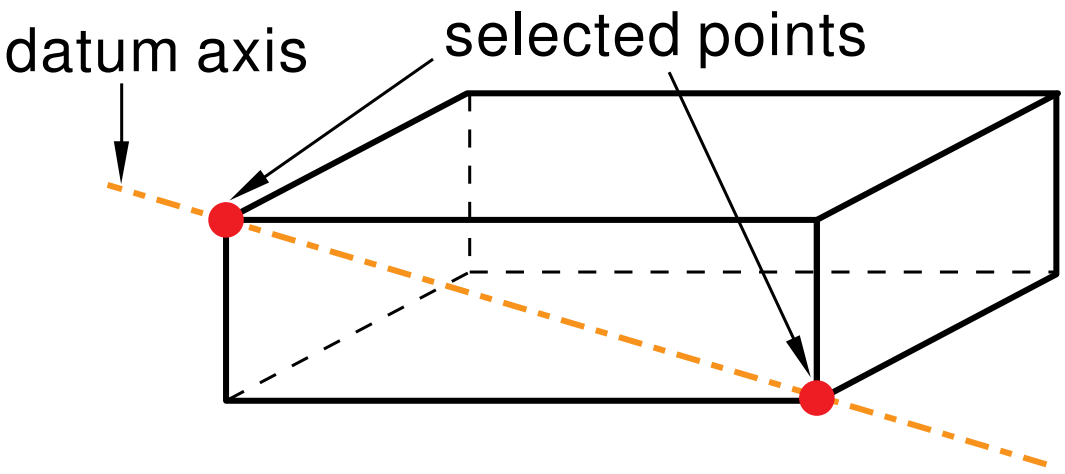
   Tip: You can also create a datum axis using the  tool, located in the module toolbox. For a diagram of the datum tools in the toolbox, see *Using the Datum toolset*.

2. From the list of types at the top of the dialog box, choose **Axis**.

   The **Method** list indicates the methods you can use to create a datum axis.

3. From the **Method** list, select **Straight edge**.
4. If desired, select **Make Independent** from the prompt area to create the datum as an independent feature.
5. From the part or assembly in the current viewport, select a straight edge.

   The datum axis appears. You cannot modify a datum axis created with this method; you must delete the old axis and create a new one.



Additional information

- *Methods for creating a datum axis*
- *Datum creation techniques*
- *Controlling datum display*

Creating a datum axis through two points

You can position a datum axis by selecting any two points on the model through which the datum axis passes.

The figure below shows an example of creating a datum axis through two points.

1. From the main menu bar, select **Tools->Datum**.

   The **Create Datum** dialog box appears. The dialog box outlines the types of datum geometry you can create.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

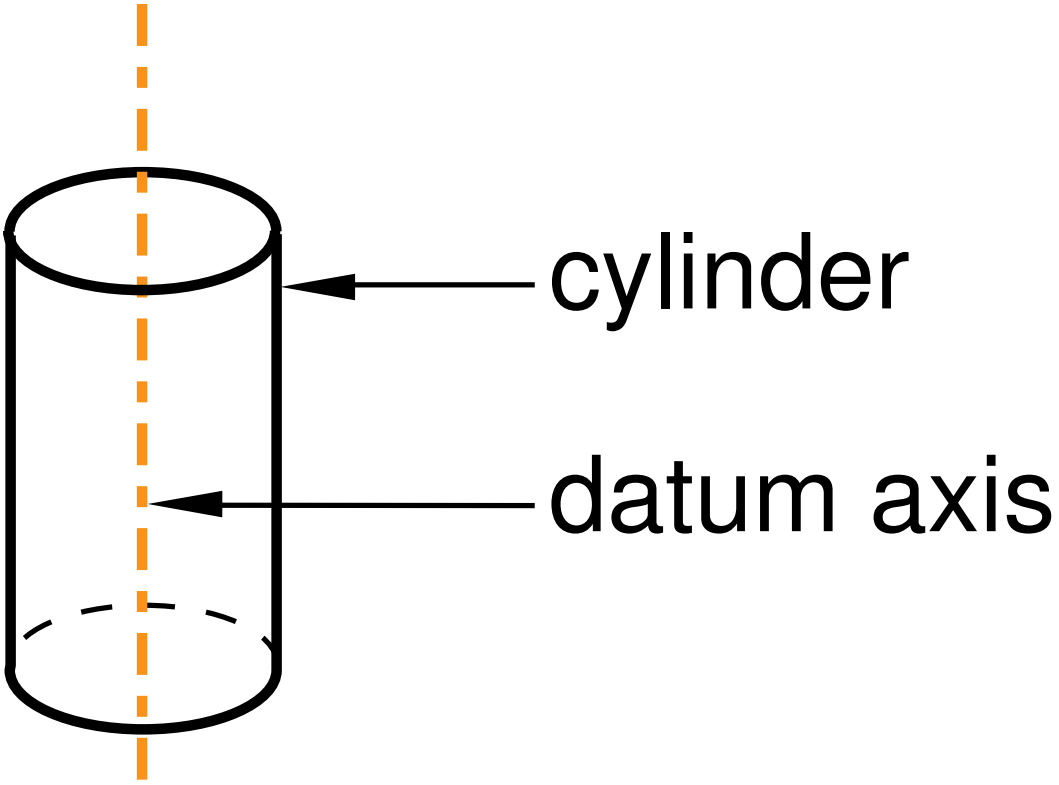
   Tip: You can also create a datum axis using the tool, located in the module toolbox. For a diagram of the datum tools in the toolbox, see *Using the Datum toolset*.

2. From the list of types at the top of the dialog box, choose **Axis**.

   The **Method** list indicates the methods you can use to create a datum axis.

3. From the **Method** list, select **2 points**.
4. If desired, select **Make Independent** from the prompt area to create the datum as an independent feature.
5. From the part or assembly in the current viewport, select two points.

   The datum axis appears. You cannot modify a datum axis created with this method; you must delete the old axis and create a new one.



Additional information

- *Methods for creating a datum axis*
- *Datum creation techniques*
- *Controlling datum display*

Creating a datum axis along the axis of a cylinder

You can position a datum axis by selecting a cylindrical or conical face on the model. Abaqus/CAE creates a datum axis that lies along the axis of the face.

The figure below shows an example of creating a datum axis along the axis of a cylinder.

1. From the main menu bar, select **Tools->Datum**.

   The **Create Datum** dialog box appears. The dialog box outlines the types of datum geometry you can create.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

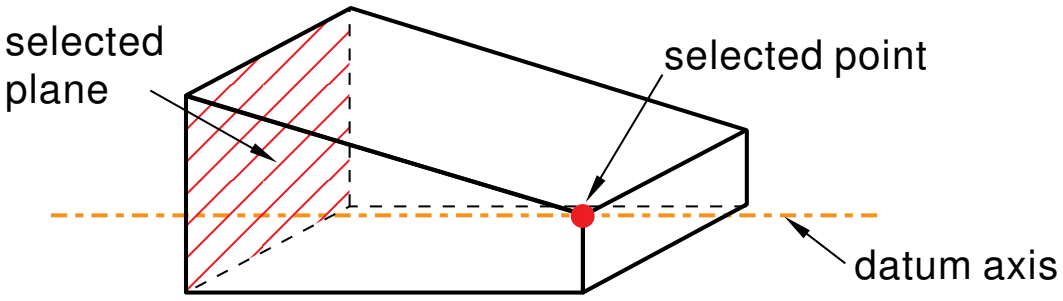
   Tip: You can also create a datum axis using the tool, located in the module toolbox. For a diagram of the datum tools in the toolbox, see *Using the Datum toolset*.

2. From the list of types at the top of the dialog box, choose **Axis**.

   The **Method** list indicates the methods you can use to create a datum axis.

3. From the **Method** list, select **Axis of cylinder**.
4. If desired, select **Make Independent** from the prompt area to create the datum as an independent feature.
5. From the part or assembly in the current viewport, select a a cylindrical or conical face.

The datum axis appears. You cannot modify a datum axis created with this method; you must delete the old axis and create a new one.



Additional information

- *Methods for creating a datum axis*
- *Datum creation techniques*
- *Controlling datum display*

Creating a datum axis normal to a plane and passing through a point

You can position a datum axis by selecting a plane and a point that is not on the plane.
Abaqus/CAE creates a datum axis that is normal to the plane and passes through the point.

The figure below shows an example of creating a datum axis normal to a plane and passing through a point.

1. From the main menu bar, select **Tools->Datum**.

   The **Create Datum** dialog box appears. The dialog box outlines the types of datum geometry you can create.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

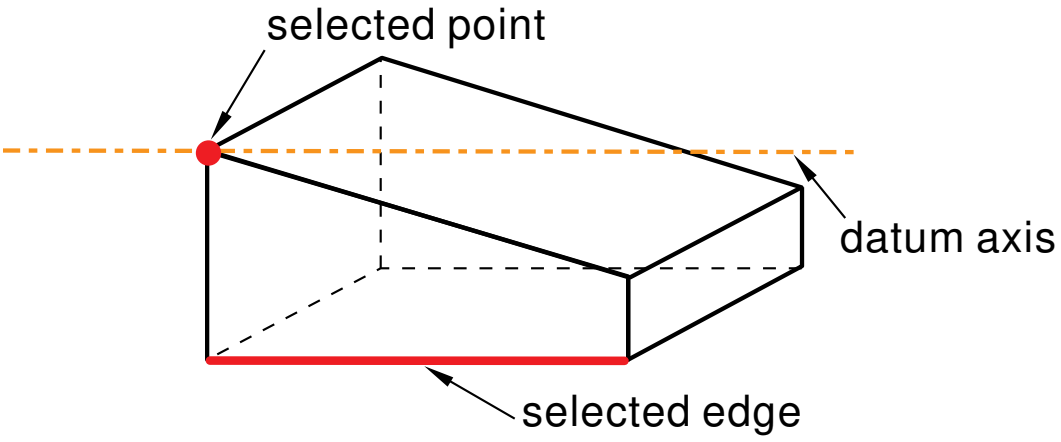
   Tip: You can also create a datum axis using the tool, located in the module toolbox. For a diagram of the datum tools in the toolbox, see *Using the Datum toolset*.

2. From the list of types at the top of the dialog box, choose **Axis**.

   The **Method** list indicates the methods you can use to create a datum axis.

3. From the **Method** list, select **Normal to plane, thru point**.
4. If desired, select **Make Independent** from the prompt area to create the datum as an independent feature.
5. From the part or assembly in the current viewport, select a planar face.
6. From the part or assembly in the current viewport, select a point.

   The datum axis appears. You cannot modify a datum axis created with this method; you must delete the old axis and create a new one.



Additional information

- *Methods for creating a datum axis*
- *Datum creation techniques*
- *Controlling datum display*

Creating a datum axis parallel to a line and passing through a point

You can position a datum axis by selecting an edge of the model and a point outside the edge. Abaqus/CAE creates a datum axis that is parallel to the edge and passes through the point.

The figure below shows an example of creating a datum axis parallel to a line and passing through a point.

1. From the main menu bar, select **Tools->Datum**.

   The **Create Datum** dialog box appears. The dialog box outlines the types of datum geometry you can create.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

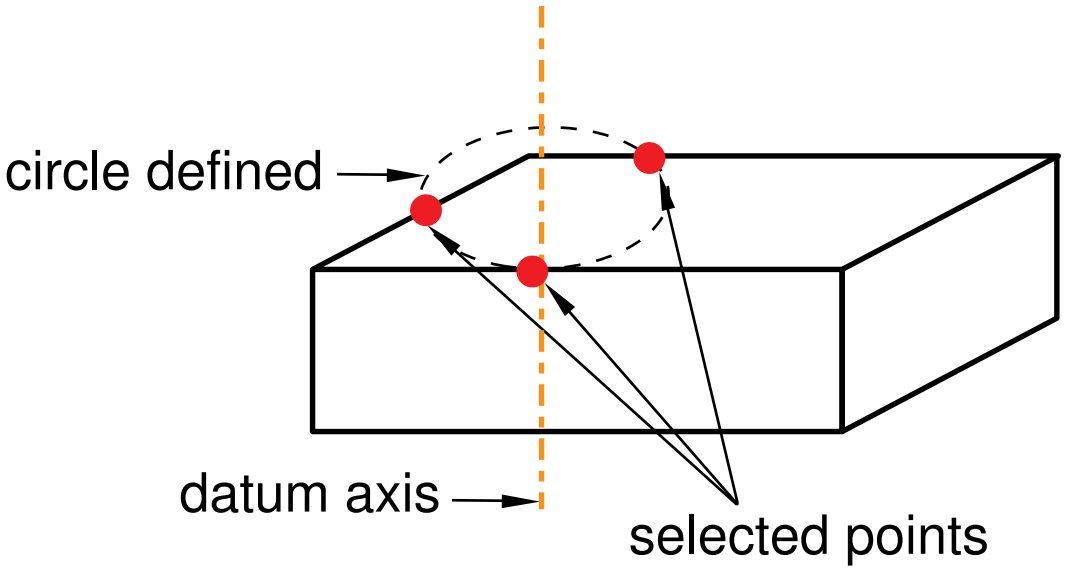
   Tip: You can also create a datum axis using the tool, located in the module toolbox. For a diagram of the datum tools in the toolbox, see *Using the Datum toolset*.

2. From the list of types at the top of the dialog box, choose **Axis**.

   The **Method** list indicates the methods you can use to create a datum axis.

3. From the **Method** list, select **parallel to line, thru point**.
4. If desired, select **Make Independent** from the prompt area to create the datum as an independent feature.
5. From the part or assembly in the current viewport, select an edge.
6. From the part or assembly in the current viewport, select a point.

   The datum axis appears. You cannot modify a datum axis created with this method; you must delete the old axis and create a new one.



Additional information

- *Methods for creating a datum axis*
- *Datum creation techniques*
- *Controlling datum display*

Creating a datum axis running along the axis of a circle defined by three points

You can position a datum axis by selecting three points on the model that define a circle. Abaqus/CAE creates a datum axis along the axis of the circle.

The figure below shows an example of creating a datum axis running along the axis of a circle defined by three points.

1. From the main menu bar, select **Tools->Datum**.

   The **Create Datum** dialog box appears. The dialog box outlines the types of datum geometry you can create.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

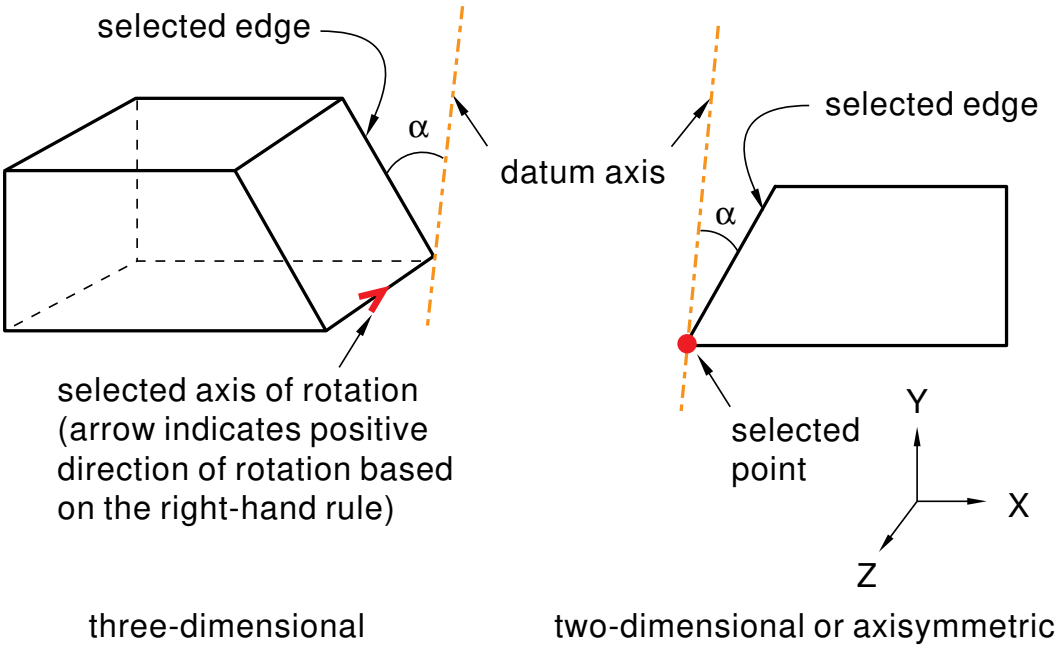
   Tip: You can also create a datum axis using the tool, located in the module toolbox. For a diagram of the datum tools in the toolbox, see *Using the Datum toolset*.

2. From the list of types at the top of the dialog box, choose **Axis**.

   The **Method** list indicates the methods you can use to create a datum axis.

3. From the **Method** list, select **Three points on circle**.
4. If desired, select **Make Independent** from the prompt area to create the datum as an independent feature.
5. From the part or assembly in the current viewport, select three points.

   The datum axis appears.You cannot modify a datum axis created with this method; you must delete the old axis and create a new one.



Additional information

- *Methods for creating a datum axis*
- *Datum creation techniques*
- *Controlling datum display*

Creating a datum axis by rotating an existing edge through a specified angle

You can define a datum axis by rotating a selected edge or datum axis about a selected axis of rotation and through a specified angle.

The figures below show examples of creating a datum axis by rotating an existing edge through a specified angle.

1. From the main menu bar, select **Tools->Datum**.

   The **Create Datum** dialog box appears. The dialog box outlines the types of datum geometry you can create.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also create a datum axis using the tool, located in the module toolbox. For a diagram of the datum tools in the toolbox, see *Using the Datum toolset*.

2. From the list of types at the top of the dialog box, choose **Axis**.

   The **Method** list indicates the methods you can use to create a datum axis.

3. From the **Method** list, select **Rotate from line**.
4. If desired, select **Make Independent** from the prompt area to create the datum as an independent feature.
5. From the part or assembly in the current viewport, select an edge or a datum axis to rotate.
6. The technique for specifying the rotation depends on the modeling space of the part or assembly:

For a two-dimensional or axisymmetric part or assembly:

1. Select a vertex or datum point at the center of rotation. You can also use the text box that appears in the prompt area to enter the precise coordinates of the center of rotation.

2. In the text box in the prompt area, enter the angle of rotation. A positive angle indicates a counterclockwise rotation about the *Z*–axis.

   The datum axis appears.

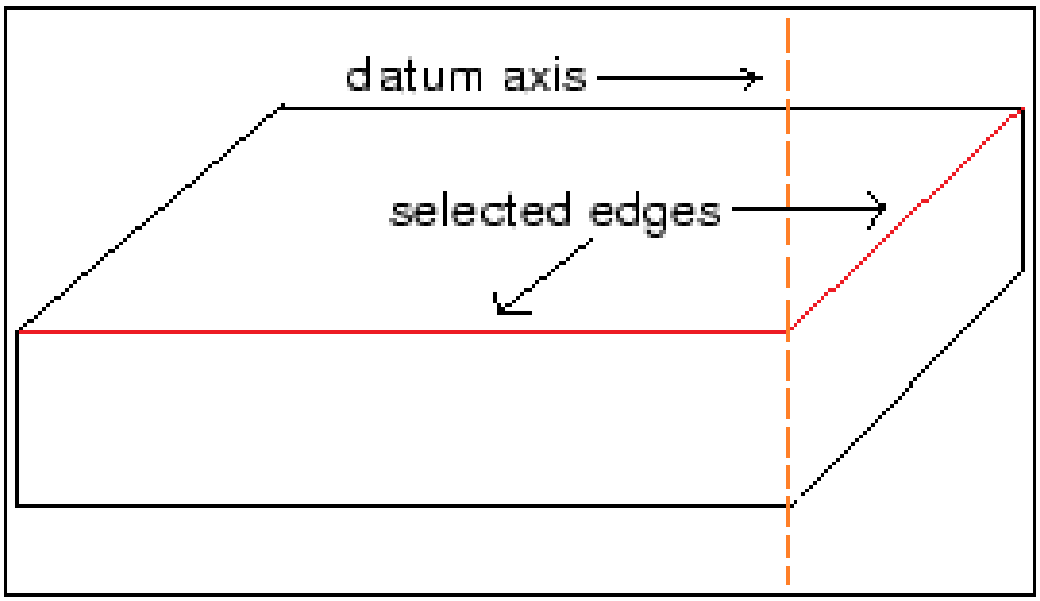
For a three-dimensional part or assembly:

1. Select an edge or a datum axis to represent the axis of rotation.

   Abaqus/CAE displays an arrow along the selected edge indicating the positive direction of rotation using the right-hand rule.
2. In the text box that appears in the prompt area, type the angle of rotation.

   The datum axis appears.

You can modify the angle of rotation by selecting **Feature->Edit** from the main menu bar and selecting the datum axis. If you change the sign of the angle, Abaqus/CAE reverses the direction of rotation.



Additional information

- *Methods for creating a datum axis*
- *Datum creation techniques*
- *Controlling datum display*

Creating a datum axis by taking the cross product of two lines

You can position a datum axis by selecting two non-parallel linear edges or datum axes on the model. Abaqus/CAE creates the datum axis orthogonal to the plane formed by both lines.

The figures below show examples of creating a datum axis by taking the cross product of two lines.

1. From the main menu bar, select **Tools->Datum**.

   The **Create Datum** dialog box appears. The dialog box outlines the types of datum geometry you can create.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also create a datum axis using the tool, located in the module toolbox. For a diagram of the datum tools in the toolbox, see *Using the Datum toolset*.

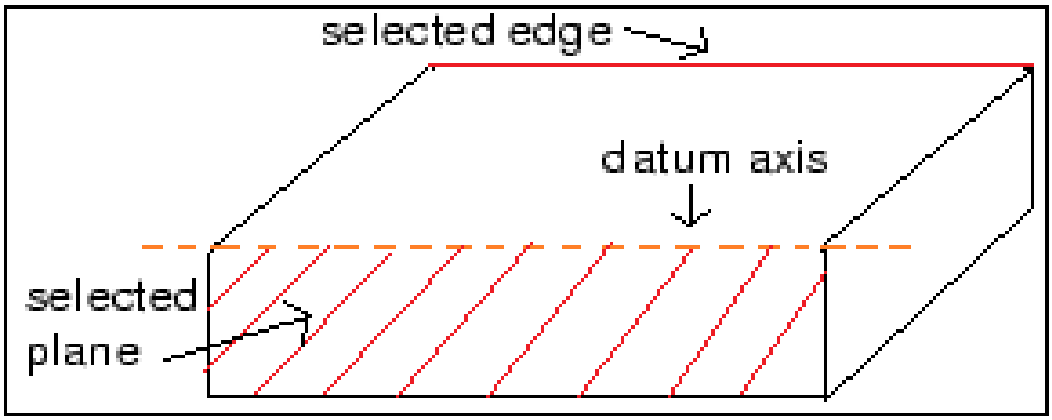
2. From the list of types at the top of the dialog box, choose **Axis**.

   The **Method** list indicates the methods you can use to create a datum axis.

3. From the **Method** list, select **Cross product of 2 lines**.
4. If desired, select **Make Independent** from the prompt area to create the datum as an independent feature.
5. From the part or assembly in the current viewport, select two edges or a datum axes.

   The datum axis appears. You cannot modify a datum axis created with this method; you must delete the old axis and create a new one.

Additional information



- *Methods for creating a datum axis*
- *Datum creation techniques*

- *Controlling datum display*

Creating a datum axis by projecting a line on a plane

You can position a datum axis by selecting a linear edge or datum axis, and a planar face or datum plane on the model. Abaqus/CAE creates the datum axis by projecting the line onto the plane.

The figures below show examples of creating a datum axis by projecting a line on a plane.

1. From the main menu bar, select **Tools->Datum**.

   The **Create Datum** dialog box appears. The dialog box outlines the types of datum geometry you can create.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also create a datum axis using the tool, located in the module toolbox. For a diagram of the datum tools in the toolbox, see *Using the Datum toolset*.

2. From the list of types at the top of the dialog box, choose **Axis**.

   The **Method** list indicates the methods you can use to create a datum axis.

3. From the **Method** list, select **Project line on plane**.
4. If desired, select **Make Independent** from the prompt area to create the datum as an independent feature.
5. From the part or assembly in the current viewport, select a linear edge or a datum axis.
6. From the part or assembly in the current viewport, select a planer face or a datum plane.

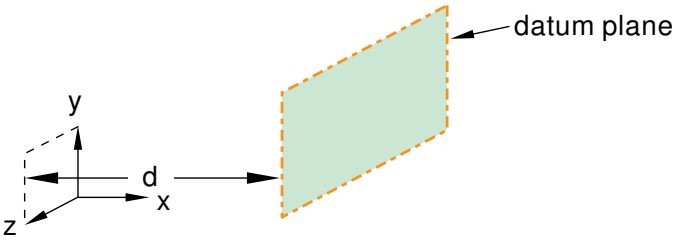
   The datum axis appears. You cannot modify a datum axis created with this method; you must delete the old axis and create a new one.

Additional information

- *Methods for creating a datum axis*
- *Datum creation techniques*
- *Controlling datum display*

Creating datum planes

This section describes the tools that you can use to create a datum plane.



In this section:

- *Creating a datum plane offset from a principal plane*
- *Creating a datum plane at an offset from a selected plane*
- *Creating a datum plane passing through three points*
- *Creating a datum plane through a line and a point*
- *Creating a datum plane passing through a point and normal to an edge*
- *Create a datum plane midway between two points and normal to the line connecting the two points*
- *Creating a datum plane by rotating an existing face through a specified angle*

Creating a datum plane offset from a principal plane

You can position a datum plane by selecting any plane on the model (including another datum plane) and specifying an offset from the selected plane; you can specify the offset by entering a value or selecting a point.

The figure below shows an example of creating a datum plane offset from a principal plane.

1. From the main menu bar, select **Tools->Datum**.

   The **Create Datum** dialog box appears. The dialog box outlines the types of datum geometry you can create.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

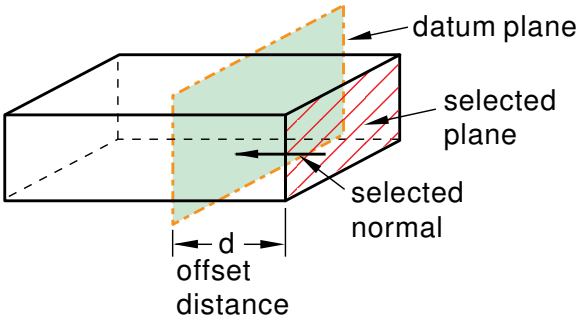
   Tip: You can also create a datum plane using the tool, located in the module toolbox. For a diagram of the datum tools in the toolbox, see *Using the Datum toolset*.

2. From the list of types at the top of the dialog box, choose **Plane**.

   The **Method** list indicates the methods you can use to create a datum plane.

3. From the **Method** list, select **Offset from principal plane**.
4. From the buttons in the prompt area, select the principal plane.
5. In the text field in the prompt area, enter the offset from the selected principal plane. The offset can be positive or negative. A positive value offsets the datum plane along the positive principal axis normal to the selected plane.

   The datum plane appears. You can modify the position of the datum plane by selecting **Feature->Edit** from the main menu bar and modifying the value of the offset.



Additional information

- *Methods for creating a datum plane*
- *Datum creation techniques*
- *Controlling datum display*

Creating a datum plane at an offset from a selected plane

You can position a datum plane by selecting any plane on the model (including another datum plane) and specifying an offset from the selected plane; you can specify the offset by entering a value or selecting a point.

The figure below shows an example of creating a datum plane at an offset from another plane.

1. From the main menu bar, select **Tools->Datum**.

   The **Create Datum** dialog box appears. The dialog box outlines the types of datum geometry you can create.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also create a datum plane using the tool, located in the module toolbox. For a diagram of the datum tools in the toolbox, see *Using the Datum toolset*.

2. From the list of types at the top of the dialog box, choose **Plane**.

   The **Method** list indicates the methods you can use to create a datum plane.

3. From the **Method** list, select **Offset from plane**.
4. If desired, select **Make Independent** from the prompt area to create the datum as an independent feature.
5. From the part or assembly in the current viewport, select a plane.
6. From the buttons in the prompt area, select one of the following:

Enter Value

1. An arrow appears, indicating the offset direction.
2. Click **Flip** to reverse the arrow, if necessary. Click **OK** to accept the indicated offset direction.
3. In the text field in the prompt area, enter the offset from the selected plane. The offset can be positive or negative. A positive value offsets the datum plane in the direction indicated by the arrow.

Select Point

From the part or assembly in the current viewport, select a point to define the offset from the selected plane.

The datum plane appears. You can modify the position of the datum plane by selecting **Feature->Edit** from the main menu bar and modifying the value of the offset.

Creating a datum plane passing through three points

You can position a datum plane by selecting three points through which the datum plane must pass.

The figure below shows an example of creating a datum plane passing through three points.

1. From the main menu bar, select **Tools->Datum**.

   The **Create Datum** dialog box appears. The dialog box outlines the types of datum geometry you can create.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

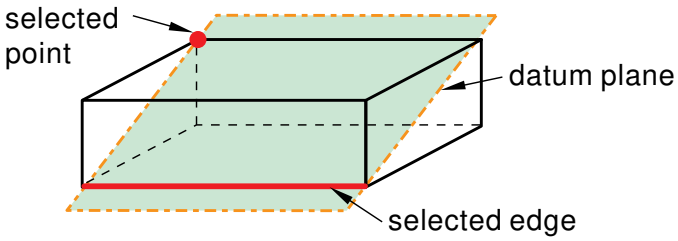
   Tip: You can also create a datum plane using the tool, located in the module toolbox. For a diagram of the datum tools in the toolbox, see *Using the Datum toolset*.

2. From the list of types at the top of the dialog box, choose **Plane**.

   The **Method** list indicates the methods you can use to create a datum plane.

3. From the **Method** list, select **3 points**.
4. If desired, select **Make Independent** from the prompt area to create the datum as an independent feature.
5. From the part or assembly in the current viewport, select three points.

   The datum plane appears. You cannot modify a datum plane created with this method; you must delete the old plane and create a new one.



Additional information

- *Methods for creating a datum plane*
- *Datum creation techniques*
- *Controlling datum display*

Creating a datum plane through a line and a point

You can position a datum plane by selecting an edge and a point through which the datum plane must pass.

The figure below shows an example of creating a datum plane through a line and a point.

1. From the main menu bar, select **Tools->Datum**.

   The **Create Datum** dialog box appears. The dialog box outlines the types of datum geometry you can create.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

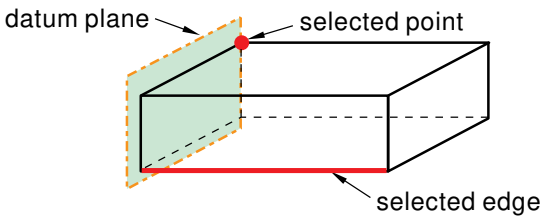
   Tip: You can also create a datum plane using the tool, located in the module toolbox. For a diagram of the datum tools in the toolbox, see *Using the Datum toolset*.

2. From the list of types at the top of the dialog box, choose **Plane**.

   The **Method** list indicates the methods you can use to create a datum plane.

3. From the **Method** list, select **Line and point**.
4. If desired, select **Make Independent** from the prompt area to create the datum as an independent feature.
5. From the part or assembly in the current viewport, select a straight edge.
6. From the part or assembly in the current viewport, select a point.

   The datum plane appears. You cannot modify a datum plane created with this method; you must delete the old plane and create a new one.



Additional information

Creating a datum plane passing through a point and normal to an edge

You can position a datum plane by selecting a point and an edge; the datum plane passes through the point and is normal to the selected edge.

The figure below shows an example of creating a datum plane passing through a point and normal to an edge.

1. From the main menu bar, select **Tools->Datum**.

   The **Create Datum** dialog box appears. The dialog box outlines the types of datum geometry you can create.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

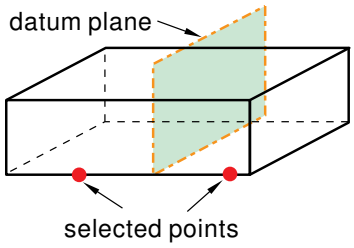
   Tip: You can also create a datum plane using the tool, located in the module toolbox. For a diagram of the datum tools in the toolbox, see *Using the Datum toolset*.

2. From the list of types at the top of the dialog box, choose **Plane**.

   The **Method** list indicates the methods you can use to create a datum plane.

3. From the **Method** list, select **Point and normal**.
4. If desired, select **Make Independent** from the prompt area to create the datum as an independent feature.
5. From the part or assembly in the current viewport, select a point.
6. From the part or assembly in the current viewport, select an edge.

   The datum plane appears. You cannot modify a datum plane created with this method; you must delete the old plane and create a new one.



Additional information

Create a datum plane midway between two points and normal to the line connecting the two points

You can position a datum plane by selecting two points.
Abaqus/CAE creates a datum plane midway between the two selected points and normal to the line connecting them.

The figure below shows an example of creating a datum plane midway between two points and normal to the line connecting the two points.

1. From the main menu bar, select **Tools->Datum**.

   The **Create Datum** dialog box appears. The dialog box outlines the types of datum geometry you can create.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

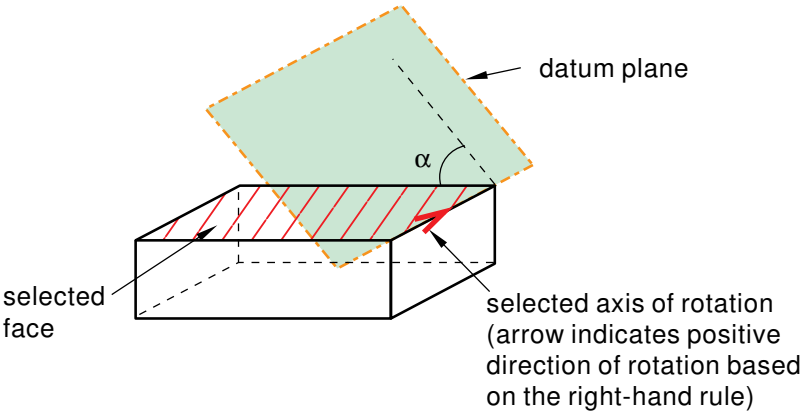
   Tip: You can also create a datum plane using the tool, located in the module toolbox. For a diagram of the datum tools in the toolbox, see *Using the Datum toolset*.

2. From the list of types at the top of the dialog box, choose **Plane**.

   The **Method** list indicates the methods you can use to create a datum plane.

3. From the **Method** list, select **Midway between 2 points**.
4. If desired, select **Make Independent** from the prompt area to create the datum as an independent feature.
5. From the part or assembly in the current viewport, select two points.

   The datum plane appears. You cannot modify a datum plane created with this method; you must delete the old plane and create a new one.



Additional information

- *Datum creation techniques*
- *Controlling datum display*

Creating a datum plane by rotating an existing face through a specified angle

You can define a datum plane by rotating a selected face or datum plane about a selected axis of rotation and through a specified angle.

The figure below shows an example of creating a datum plane by rotating an existing face through a specified angle.

1. From the main menu bar, select **Tools->Datum**.

   The **Create Datum** dialog box appears. The dialog box outlines the types of datum geometry you can create.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also create a datum plane using the tool, located in the module toolbox. For a diagram of the datum tools in the toolbox, see *Using the Datum toolset*.

2. From the list of types at the top of the dialog box, choose **Plane**.

   The **Method** list indicates the methods you can use to create a datum plane.

3. From the **Method** list, select **Rotate from plane**.
4. If desired, select **Make Independent** from the prompt area to create the datum as an independent feature.
5. From the part or assembly in the current viewport, select a face or a datum plane to rotate.
6. Select any edge or a datum axis to represent the axis of rotation. The edge or datum axis you select for the axis of rotation does not have to be coplanar with the face or datum plane you selected to rotate.

   Abaqus/CAE displays an arrow along the selected edge indicating the positive direction of rotation using the right-hand rule.

7. In the text box that appears in the prompt area, type the angle of rotation.

   The datum plane appears. You can modify the angle of rotation by selecting **Feature->Edit** from the main menu bar and selecting the datum plane. If you change the sign of the angle, Abaqus/CAE reverses the direction of rotation.

Creating datum coordinate systems

This section describes the tools that you can use to create a datum coordinate system.

In this section:

- *Creating a datum coordinate system defined by three points*
- *Creating a datum coordinate system at an offset from another coordinate system*
- *Creating a datum coordinate system defined by two lines*
- *Creating a datum coordinate system by rotating another coordinate system*

Creating a datum coordinate system defined by three points

You can position a rectangular, cylindrical, or spherical datum coordinate system by selecting a point defining the origin, a point on the *X*- or *R*-axis, or a point in the *X*–*Y* or *R*–θ plane.

The figure below shows an example of creating a rectangular datum coordinate system defined by three points.

When Abaqus/CAE prompts you to select a point, you can select the origin of a datum coordinate system. When Abaqus/CAE prompts you to select an edge, you can select one of the axes of a datum coordinate system.

1. From the main menu bar, select **Tools->Datum**.

   The **Create Datum** dialog box appears. The dialog box outlines the types of datum geometry you can create.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also create a datum coordinate system using the tool, located in the module toolbox. For a diagram of the datum tools in the toolbox, see *Using the Datum toolset*.

2. From the list of types at the top of the dialog box, choose **CSYS**.

   The **Method** list indicates the methods you can use to create a datum coordinate system.

3. From the **Method** list, select **3 points**.

   Abaqus/CAE displays the **Create Datum CSYS** dialog box.

4. From the dialog box, enter the name of the datum coordinate system.

   To help keep track of your datum coordinate systems, Abaqus/CAE displays its name in the Model Tree. In addition, you can use the Model Tree to rename the datum coordinate system.

5. From the dialog box, select one of the following datum coordinate systems:

   - **Rectangular**: The *X*-, *Y*-, and *Z*-axes are aligned with the 1-, 2-, and 3-global axes, respectively.
   - **Cylindrical**: The *R*-, θ-, and *Z*-axes are aligned with the 1-, 2-, and 3-global axes, respectively.
   - **Spherical**: The *R*-, θ-, and ϕ-axes are aligned with the 1-, 2-, and 3-global axes, respectively.

6. From the **Create Datum CSYS** dialog box, click **Continue**.

   Abaqus/CAE displays a default datum coordinate system. The origin of the datum coordinate system is located at the origin of the part or assembly. In addition, the axes of the default datum coordinate system are aligned with the coordinate system of the part or assembly.

7. If desired, select **Make Independent** from the prompt area to create the datum as an independent feature.

8. To create a datum coordinate system at a different location or with a different orientation, do the following:

   a. From the part or assembly in the current viewport, select a point that will define the origin of the datum coordinate system or enter the coordinates of the origin.

      Abaqus/CAE displays a temporary datum coordinate system at the selected point. The axes of the datum coordinate system are aligned with the axes of the global coordinate system.

b. From the prompt area, press **[Enter]** in the text field to accept the default orientation of the temporary datum coordinate system or select (or enter the coordinates of) a point that will lie on the *X*- or *R*-axis.

Abaqus/CAE recalculates the orientation of the temporary datum coordinate system.

c. From the prompt area, press **[Enter]** in the text field to accept the new orientation of the temporary datum coordinate system or select (or enter the coordinates of) a point that will lie on the *X*–*Y* or *R*–θ plane.

Abaqus/CAE creates the datum coordinate system. You cannot move or rotate a datum coordinate system.

Additional information

- *Methods for creating a datum coordinate system*
- *Datum creation techniques*
- *Controlling datum display*

Creating a datum coordinate system at an offset from another coordinate system

You can position a rectangular, cylindrical, or spherical datum coordinate system by selecting a coordinate system and specifying an offset; you can specify the offset by entering a value or selecting a point.

The figure below shows an example of creating a rectangular datum coordinate system at an offset from the default coordinate system.

When Abaqus/CAE prompts you to select a point, you can select the origin of a datum coordinate system. When Abaqus/CAE prompts you to select an edge, you can select one of the axes of a datum coordinate system.

1. From the main menu bar, select **Tools->Datum**.

   The **Create Datum** dialog box appears. The dialog box outlines the types of datum geometry you can create.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also create a datum coordinate system using the  tool, located in the module toolbox. For a diagram of the datum tools in the toolbox, see *Using the Datum toolset*.

2. From the list of types at the top of the dialog box, choose **CSYS**.

   The **Method** list indicates the methods you can use to create a datum coordinate system.

3. From the **Method** list, select **Offset from CSYS**.

   Abaqus/CAE displays the **Create Datum CSYS** dialog box.

4. From the dialog box, enter the name of the datum coordinate system.

   To help keep track of your datum coordinate systems, Abaqus/CAE displays its name in the Model Tree. In addition, you can use the Model Tree to rename the datum coordinate system.

5. From the dialog box, select one of the following datum coordinate systems:

   - **Rectangular**: The *X*-, *Y*-, and *Z*-axes are aligned with the 1-, 2-, and 3-global axes, respectively.
   - **Cylindrical**: The *R*-, θ-, and *Z*-axes are aligned with the 1-, 2-, and 3-global axes, respectively.
   - **Spherical**: The *R*-, θ-, and ϕ-axes are aligned with the 1-, 2-, and 3-global axes, respectively.

6. From the **Create Datum CSYS** dialog box, click **Continue**.
7. If desired, select **Make Independent** from the prompt area to create the datum as an independent feature.
8. From the current viewport, select a datum coordinate system.
9. From the buttons in the prompt area, select one of the following:

Enter Value

In the text field in the prompt area, enter the *X*-, *Y*-, and *Z*-coordinates of the offset from the selected default coordinate system.

Select Point

From the part or assembly in the current viewport, select a point to define the offset from the selected default coordinate system.

The datum coordinate system appears. You cannot move or rotate a datum coordinate system.

Additional information

- *Methods for creating a datum coordinate system*
- *Datum creation techniques*
- *Controlling datum display*

Creating a datum coordinate system defined by two lines

You can position a rectangular, cylindrical, or spherical datum coordinate system by selecting two edges that define it.

The first edge defines the *X*- or *R*-axis, and the *X*–*Y* or *R*-θ-plane passes through the second.

The figure below shows an example of creating a rectangular datum coordinate system defined by two lines.

When Abaqus/CAE prompts you to select an edge, you can select one of the axes of a datum coordinate system.

1. From the main menu bar, select **Tools->Datum**.

   The **Create Datum** dialog box appears. The dialog box outlines the types of datum geometry you can create.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also create a datum coordinate system using the  tool, located in the module toolbox. For a diagram of the datum tools in the toolbox, see *Using the Datum toolset*.

2. From the list of types at the top of the dialog box, choose **CSYS**.

   The **Method** list indicates the methods you can use to create a datum coordinate system.

3. From the **Method** list, select **2 lines**.

   Abaqus/CAE displays the **Create Datum CSYS** dialog box.

4. From the dialog box, enter the name of the datum coordinate system.

   To help keep track of your datum coordinate systems, Abaqus/CAE displays its name in the Model Tree. In addition, you can use the Model Tree to rename the datum coordinate system.

5. From the dialog box, select one of the following datum coordinate systems:

   - **Rectangular**: The *X*-, *Y*-, and *Z*-axes are aligned with the 1-, 2-, and 3-global axes, respectively.
   - **Cylindrical**: The *R*-, θ-, and *Z*-axes are aligned with the 1-, 2-, and 3-global axes, respectively.
   - **Spherical**: The *R*-, θ-, and ϕ-axes are aligned with the 1-, 2-, and 3-global axes, respectively.

6. From the **Create Datum CSYS** dialog box, click **Continue**.
7. If desired, select **Make Independent** from the prompt area to create the datum as an independent feature.
8. From the part or assembly in the current viewport, select a straight edge that will define the *X*- or *R*-axis of the datum coordinate system.
9. Select a straight edge that will lie in the *X*–*Y* or *R*–θ-plane.

   The datum coordinate system appears. You cannot move or rotate a datum coordinate system.

Additional information

- *Methods for creating a datum coordinate system*
- *Datum creation techniques*
- *Controlling datum display*

Creating a datum coordinate system by rotating another coordinate system

You can position a rectangular, cylindrical, or spherical datum coordinate system by selecting a coordinate system, an axis of rotation, and specifying an angle of rotation.

The figure below shows an example of creating a rectangular datum coordinate system by rotating a default coordinate system about a given axis by a given angle.

1. From the main menu bar, select **Tools->Datum**.

   The **Create Datum** dialog box appears. The dialog box outlines the types of datum geometry you can create.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also create a datum coordinate system using the tool, located in the module toolbox. For a diagram of the datum tools in the toolbox, see *Using the Datum toolset*.

2. From the list of types at the top of the dialog box, choose **CSYS**.

   The **Method** list indicates the methods you can use to create a datum coordinate system.

3. From the **Method** list, select **Rotate from CSYS**.

   Abaqus/CAE displays the **Create Datum CSYS** dialog box.

4. From the dialog box, enter the name of the datum coordinate system.

   To help keep track of your datum coordinate systems, Abaqus/CAE displays its name in the Model Tree. In addition, you can use the Model Tree to rename the datum coordinate system.

5. From the dialog box, select one of the following datum coordinate systems:

   - **Rectangular**: The *X*-, *Y*-, and *Z*-axes are aligned with the 1-, 2-, and 3-global axes, respectively.
   - **Cylindrical**: The *R*-, θ-, and *Z*-axes are aligned with the 1-, 2-, and 3-global axes, respectively.
   - **Spherical**: The *R*-, θ-, and ϕ-axes are aligned with the 1-, 2-, and 3-global axes, respectively.

6. From the **Create Datum CSYS** dialog box, click **Continue**.
7. If desired, select **Make Independent** from the prompt area to create the datum as an independent feature.
8. If desired, select **Fix Origin**. This will ensure that the origin of the rotated datum coordinate system remains the same as the origin of the selected default coordinate system. If this option stays unchecked, the origin also rotates about the axis.
9. From the current viewport, select a datum coordinate system.
10. From the part or assembly in the current viewport, select a linear edge or datum axis for the axis of rotation.
11. In the text field in the prompt area, enter the value of the angle.

The datum coordinate system appears. You can modify the position of the datum coordinate system by selecting **Feature > Edit** from the main menu bar and modifying the value of the angle of rotation or whether to fix/unfix the origin.

Additional information

- *Datum creation techniques*
- *Controlling datum display*

The Discrete Field toolset

A discrete field is a spatially varying field where values are associated with a node or an element. The Discrete Field toolset allows you to create and manage discrete fields.

In this section:

- *Using the Discrete Field toolset*
- *Creating discrete fields*
- *Evaluating discrete fields*
- *Creating discrete fields for material volume fractions*

Using the Discrete Field toolset

The Discrete Field toolset allows you to define spatially varying parameters. The parameters in a discrete field can be associated with specified elements or nodes. For example, you can define a spatially varying thickness or orientation (Cartesian, cylindrical, or spherical). The Discrete Field toolset is available in the Property module, Interaction module, and Load module.

Select **Tools**->**Discrete Field**->**Create** from the main menu bar to create a new discrete field; select **Edit** from the same menu to change an existing discrete field. Either command opens the discrete field editor, which allows you to associate data with elements or nodes.

Creating discrete fields

The Discrete Field toolset is available in the Property module, Interaction module, and Load module. Select **Tools->Discrete Field->Create** from the main menu bar to create a discrete field.

1. From the main menu bar, select **Tools->Discrete Field->Create**.

   Tip: You can also click **Create** in the **Discrete Field Manager**.

2. In the **Name** text field, enter a name for the discrete field. For information on naming objects, see *Using basic dialog box components*.
3. In the **Description** text field, enter a description for the discrete field.
4. Choose **Elements** or **Nodes** to specify the type of location to which the field will be applied.
5. Choose the data type.
   - Choose **Scalar** to enter scalar field data.
   - The **Orientation** option is available for fields associated with elements. Choose **Orientation**, and do the following:
     1. Choose the coordinate system type—**Cartesian**, **Cylindrical**, or **Spherical**.
     2. Toggle on **Supplied orientation directions are defined in part space** to specify that the orientation directions are defined at the part or part instance level. When you define the orientations in the part space, Abaqus transforms the orientation values from the part's coordinate system into the assembly coordinate system using the part instance transformation. Toggle off this option to specify that the orientation directions are defined at the assembly level.
   - Choose **Prescribed condition** to include degree of freedom values in the field data.
6. Enter the default component value or values. For information on how Abaqus uses the default values, see *Evaluating discrete fields*. Scalar discrete fields require one default component value. Orientation discrete fields require six default component values. Prescribed condition discrete fields require six default component values and up to six degree of freedom values.
7. In the **Field Data** table, enter the following values:
   - Element or node number and its associated component value or values.

     When creating discrete fields that will be used with assembly-level or history objects, such as loads or interactions, you must specify the complete name of the node or element numbers, as described in *Naming Conventions*. For example, you would specify the part instance name and element id using the notation *Part_instance_name.EID*, such as `PART-2-1.20`.
   - For prescribed condition discrete fields, enter the degree of freedom values.

   Click mouse button 3 on the table to see a menu that allows you to do the following:
   - Cut, copy, and paste values
   - Insert and delete rows
   - Clear a table cell or the entire table
   - Read from or write to a comma-separated file

   For more information, see *Entering tabular data*.

8. Click **OK** to create the discrete field and to exit the editor.

Additional information

- *Defining sections*
- *Composite layups*

Evaluating discrete fields

If you specify a discrete field for a prescribed condition, Abaqus/CAE evaluates the discrete field when the input file is written.

- If an element or node is found in both the region selected for the prescribed condition and the discrete field, Abaqus/CAE multiplies the magnitude of the prescribed condition by the value at each element or node to determine the final values that are submitted to the analysis. A material assignment predefined field is the only exception; this prescribed condition has no magnitude.
- If an element or node is found in the region selected for the prescribed condition but not in the discrete field, the magnitude of the prescribed condition is multiplied by the default value and submitted to the analysis.

Table 1 summarizes how the value written to the input file is determined for scalar discrete fields.

Table 1: Evaluating scalar discrete fields.

Element or node in region selected for prescribed condition?	Element or node in discrete field?	Value written to input file
Yes	Yes	Magnitude of prescribed condition × magnitude specified in discrete field
Yes	No	Magnitude of prescribed condition × default value specified in discrete field
No	Yes	Not written to input file

For prescribed conditions that have multiple degrees of freedom, such as displacements, prescribed condition discrete fields are used; and evaluating the discrete field becomes more complex. For prescribed conditions where you can activate the individual degrees of freedom, only the active degrees of freedom in the prescribed condition are considered; any degree of freedom that is not active in the prescribed condition will be ignored. The magnitudes specified for each degree of freedom in the prescribed condition are multiplied by either the magnitude specified in the discrete field or the default value for that degree of freedom in the discrete field.

For example, if you define a displacement boundary condition, as shown in *Figure 1*, for `Node-set-1` (containing nodes `Part-2-1.10`, `Part-2-1.20`, and `Part-2-1.30`) and a prescribed condition discrete field, as shown in *Figure 2*, the values that are submitted to the input file are shown in *Table 2*.

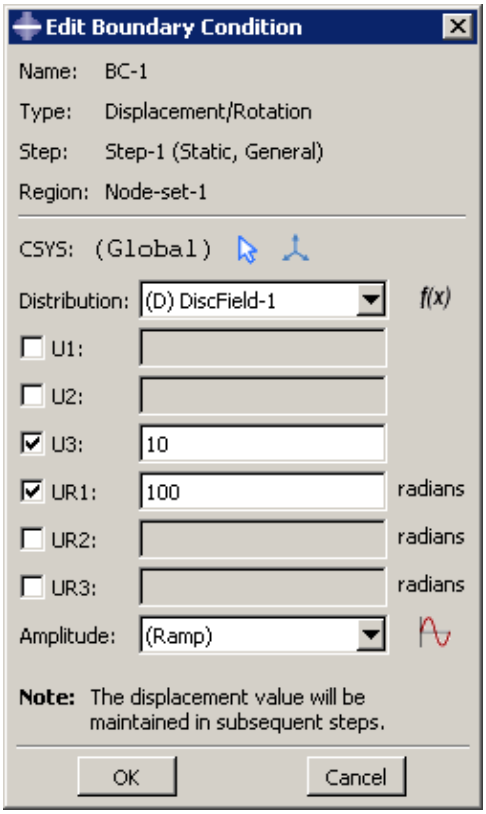

Figure 1: Displacement boundary condition with two degrees of freedom activated.

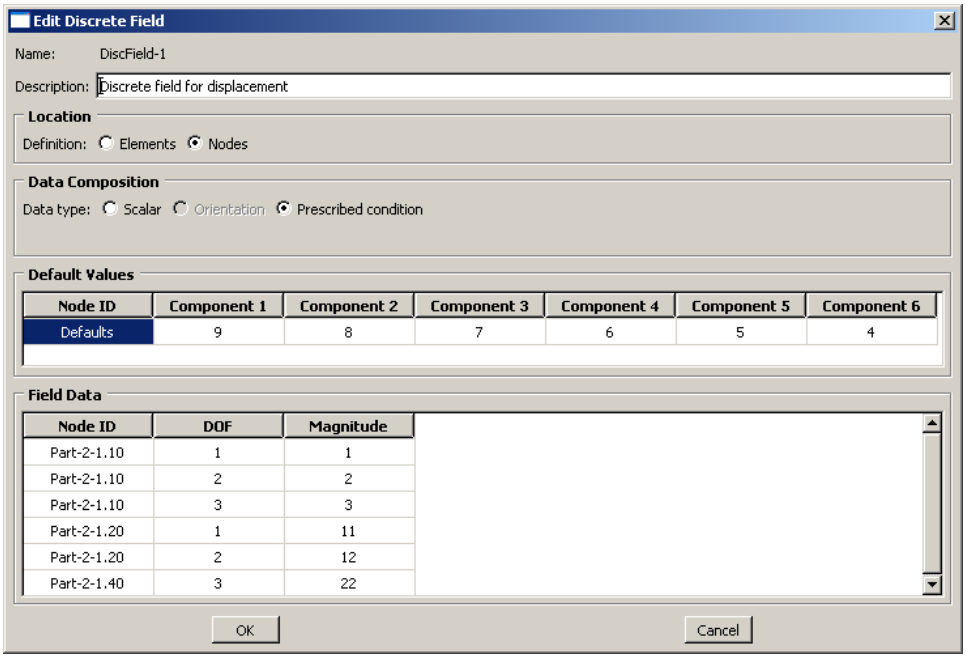

Figure 2: Prescribed condition discrete field used to define a spatially varying displacement boundary condition.

Table 2: Results for evaluating a prescribed condition discrete field.

Node ID	Degree of freedom	Value written to input file
`Part-2-1.10`	3 (**U3**)	30
`Part-2-1.10`	4 (**UR1**)	600
`Part-2-1.20`	3 (**U3**)	70
`Part-2-1.20`	4 (**UR1**)	600
`Part-2-1.30`	3 (**U3**)	70
`Part-2-1.30`	4 (**UR1**)	600
`Part-2-1.40`	3 (**U3**)	None

Degrees of freedom for boundary conditions and predefined fields that result in a zero magnitude are written to the input file as such; however, degrees of freedom for loads that result in zero magnitudes are not written to the input file.

When creating discrete fields that will be used with assembly-level and history objects, such as loads or interactions, you must specify the complete name of the node or element numbers, as described in *Naming Conventions*.

Creating discrete fields for material volume fractions

The volume fraction tool is used to create discrete fields representing the overlap between two part instances on an element-by-element basis. One of the part instances must be a meshed Eulerian part. The other part instance acts as reference geometry. The discrete field that is created associates each element in the Eulerian part with a volume fraction based on the amount of space that the reference part instance occupies within that element. This discrete field can be used to assign materials in an Eulerian model (see *Assigning materials to Eulerian part instances*). For an overview on using the volume fraction tool in Eulerian models, refer to *Using the volume fraction tool*.

The volume fraction tool is available in the Interaction module and the Load module. Select **Tools->Discrete Field->Volume Fraction Tool** from the main menu bar to create a discrete field using the volume fraction tool.

1. From the main menu bar, select **Tools->Discrete Field->Volume Fraction Tool**.
2. In the viewport, select a meshed Eulerian part instance. The discrete field that is created will be associated with the elements in this Eulerian part.

   Warning:

   You should not regenerate or edit the Eulerian part mesh after using the volume fraction tool. Any changes to the mesh—including regenerating it from replay or journal files—may invalidate the created discrete field.

3. In the viewport, select a reference part instance that intersects the previously selected Eulerian part instance. This part instance must be a three-dimensional solid or a three-dimensional shell. The reference part instance cannot contain free edges or interior dividing faces (free or non-manifold edges).

   Note:

   If the reference instance consists of meshed geometry, Abaqus/CAE always uses the meshed representation of the part instance to calculate volume fractions. If the reference instance is partially meshed, only the meshed portion of the part is considered in the volume fraction calculations.

   The **Volume Fraction Tool** dialog box appears.

4. In the **Name** text field, enter a name for the discrete field. For information on naming objects, see *Using basic dialog box components*.
5. In the **Description** text field, enter a description for the discrete field.
6. To change the Eulerian instance or reference instance, click **Edit**, and select a new part instance in the viewport.
7. Specify the **Accuracy** (**Low**, **Medium**, or **High**) for the volume fraction calculations. A lower accuracy results in faster performance for the tool.
8. Specify the **Material location**:
   - Selecting **Inside reference instance** implies that the material will be assigned to the region that is occupied or enclosed by the reference instance. A nonzero value is assigned to all Eulerian elements within this region.
   - Selecting **Outside reference instance** implies that the material will be assigned to the region that is not occupied or enclosed by the reference instance. A nonzero value is assigned to all elements that are not fully occupied or enclosed by the reference instance.
9. Specify a **Scale factor** between zero and one. All values in the discrete field are multiplied by this scale factor. By default, the scale factor is one.

10. To create a set of all nodes connected to elements with nonzero volume fractions in the discrete field, toggle on **Node set**, and enter a name for the set.
11. To create a set of all elements connected to elements with nonzero volume fractions in the discrete field, toggle on **Element set**, and enter a name for the set.
12. Click **OK** to create the discrete field and to close the **Volume Fraction Tool** dialog box.

- *Using the Discrete Field toolset*

The Edit Mesh toolset

You can use the Edit Mesh toolset in the Mesh module to improve the mesh quality. You can modify an orphan mesh, or you can modify an Abaqus native mesh.

In this section:

- *What can I do with the Edit Mesh toolset?*
- *What is the difference between editing an orphan mesh, a meshed part, and a meshed part instance in the assembly?*
- *Meshing strategies and mesh editing techniques*
- *Using the mesh editing tools*
- *Editing nodes*
- *Editing elements*
- *Editing the entire mesh*
- *Editing and refining an orphan mesh*
- *Undoing or redoing a change in the Edit Mesh toolset*

What can I do with the Edit Mesh toolset?

This section describes how you can use the Edit Mesh toolset to modify a mesh in the Mesh module. All of the tools are available when you are modifying a mesh that contains orphan elements and nodes; however, only a few of the tools are available for modifying mesh nodes or elements that are tied to geometry, including meshed part instances in the assembly.

In this section:

- *Manipulating nodes*
- *Manipulating elements*
- *Manipulating the mesh*
- *Refining the mesh*

Manipulating nodes

The Edit Mesh toolset provides the following tools that allow you to manipulate the nodes in your mesh:

- Create a node. You can specify the coordinates of the new node either in the global coordinate system or in a datum coordinate system that you specify.
- Edit nodes. You can specify the new coordinates of the nodes either in the global coordinate system or in a datum coordinate system that you specify. Alternatively, you can specify an offset from the current position. You can edit a single node, or you can edit multiple nodes simultaneously.
- Drag nodes. You can click and drag the nodes in a model. You can drag only one node at a time, and you can use the **Project to geometry** option to project an exterior node to the geometry with which it is associated. Element quality checks are automatically activated to show element errors and warnings while you drag a node. For more information on element quality checks, see *Verifying element quality*.
- Project nodes. You can specify a vertex, edge, or face and Abaqus/CAE projects the nodes from their current positions onto the selected entity. You can project a single node, or you can project multiple nodes simultaneously. You can also project nodes to other nodes, element edges, element faces, datum points, datum axes, or datum planes.
- Delete nodes. Any elements associated with the deleted nodes are also deleted. In addition, you have the option of deleting any remaining nodes that would be left unassociated with any elements once the nodes selected for deletion and their associated elements are deleted.
- Merge selected nodes. If you select only two nodes to merge, Abaqus/CAE creates a new node at the midpoint of the selected nodes. If you select more than two nodes, you can specify the **Node merging tolerance**, which is the maximum distance between nodes that will be merged. Abaqus/CAE deletes nodes that are closer than the specified distance and replaces them with a single new node. The location of the new node is the average position of the group of nodes that were merged into the new node.

  While Abaqus/CAE is removing duplicate nodes, you can choose to remove duplicate elements that have the same connectivity. You can also merge instances of parts in the Assembly module and you have the option to merge nodes within this process; for more information, see *Merging and cutting part instances*.
- Smooth selected nodes. You can select external nodes, and Abaqus/CAE smooths the node positions with respect to the surrounding nodes. You can smooth any external nodes of the native mesh on a part or on an assembly as long as they are not part of a region boundary; you can also smooth external orphan mesh nodes that lie within a planar mesh face.
- Adjust the position of the midside node of second-order elements to allow for the singularity at the crack tip in a fracture mechanics analysis. You can select nodes and enter a bias parameter between 0 and 1. Abaqus/CAE moves the midside nodes along connected element edges to a position based on the parameter that you entered. For example, if you enter a parameter of 0.25, Abaqus/CAE biases the position of the midside nodes one quarter of the length of the element edge away from the selected nodes.

  For more information, see *Controlling the singularity at the crack tip for a small-strain analysis*, and *Constructing a Fracture Mechanics Mesh for Small-Strain Analysis with the Conventional Finite Element Method*.
- Renumber selected nodes within an orphan mesh. You can renumber the selected nodes by specifying a starting label and an increment or by offsetting the existing label by a specified value.

Tip: The Mesh Edit Undo feature can roll back any change you make to the nodes in the mesh. For more information, see *Undoing or redoing a change in the Edit Mesh toolset*.

For detailed instructions about each of these node manipulation techniques, see *Editing nodes*.

Manipulating elements

The Edit Mesh toolset provides the following tools that allow you to manipulate the elements in your mesh:

- Create an element. You must specify the shape of the element that you want to create, and you must select the nodes in the order appropriate for that element shape.
- Delete elements. You have the option of deleting any nodes that would be left unassociated with any elements once the selected elements are deleted.
- Flip the surface normal direction of shell elements.
- Collapse a selected edge of quadrilateral or triangular elements. Collapsing an edge is useful for removing slivers from quadrilateral and triangular elements, as shown in *Figure 1*.

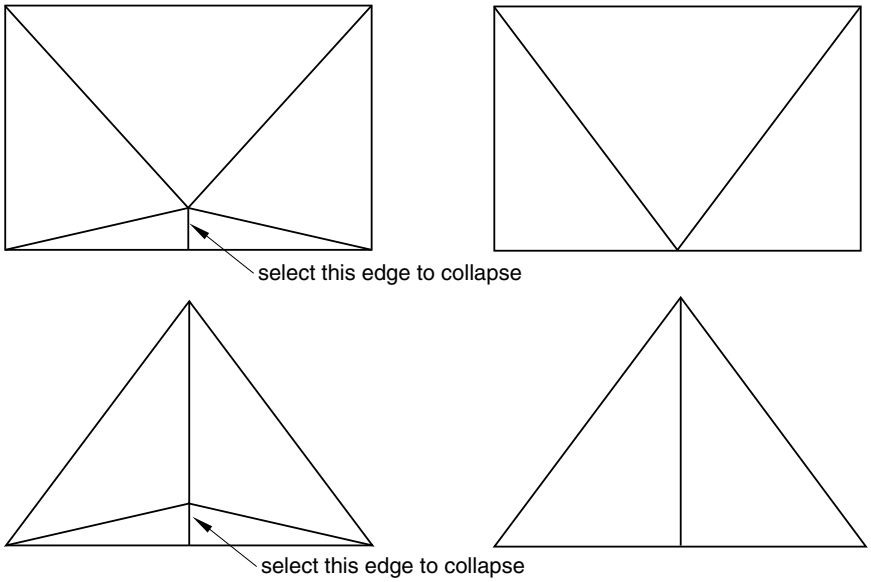

Figure 1: Collapsing an edge to remove slivers from quadrilateral and triangular elements.

When you preview a tetrahedral boundary mesh, you can collapse selected edges of the triangular elements to remove slivers. In some cases, when you create an all-quadrilateral mesh using the advancing front algorithm, Abaqus/CAE may generate quadrilateral elements with a short edge. You can collapse the short edge and create a well-formed triangular element, as shown in *Figure 2*.

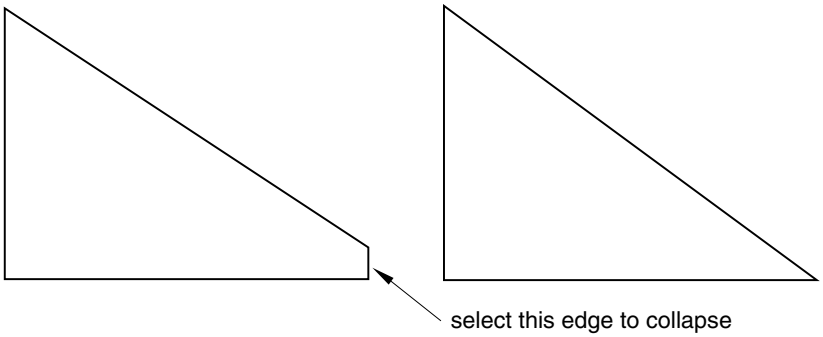

Figure 2: Collapsing an edge of a quadrilateral element.

- Split a selected edge of a quadrilateral or triangular element into two parts. You can split the edge at its midpoint, or you can click on the location of the split. You can use a combination of tools to clean up your mesh. For example,

Figure 3 illustrates how you can split an edge and then collapse the resulting edge to remove a long narrow triangular element.

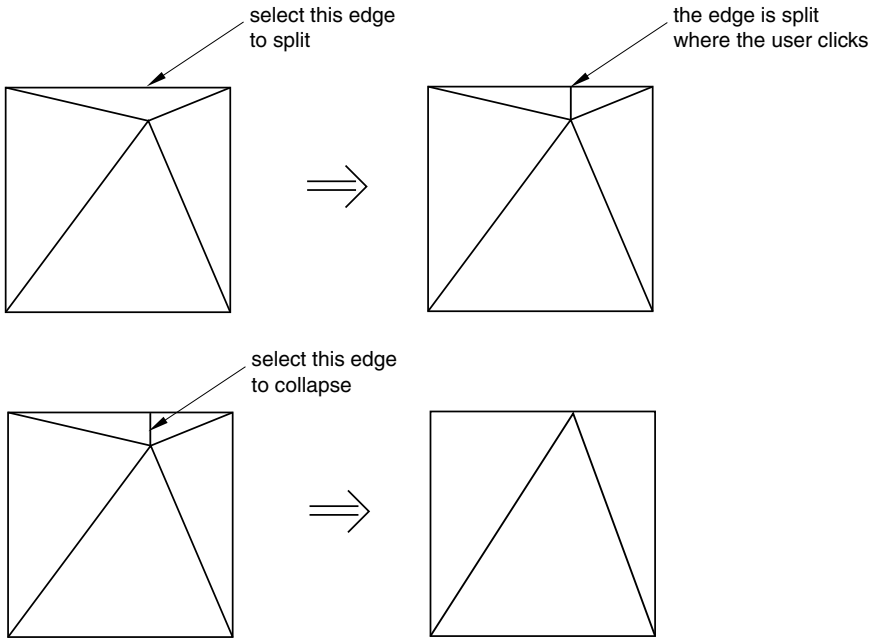

Figure 3: Splitting and collapsing edges of a triangular element.

If you are editing a native mesh in the Mesh module, Abaqus/CAE projects the new node on the geometry. As a result, you can use this tool for improving a coarse mesh around curved edges, as shown in *Figure 4*.

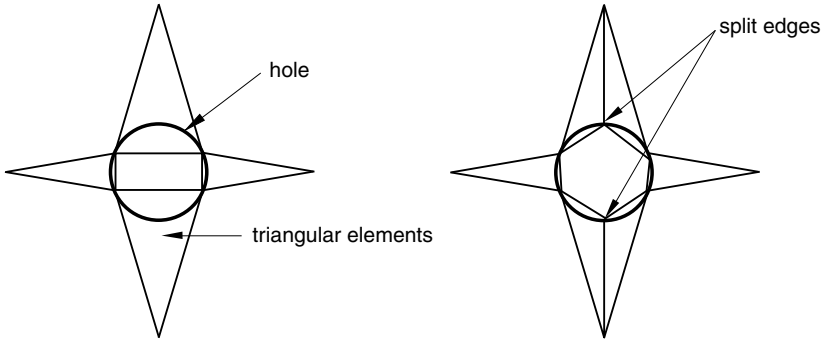

Figure 4: Improving the mesh around a hole by splitting edges.

- Swap the diagonal of a pair of adjacent triangular elements, as shown in *Figure 5*. You can swap the diagonal of either first- or second-order adjacent triangular elements if they are the same order. In addition, the adjacent triangular elements must have consistent normals. If necessary, you can flip the normals to make them consistent.

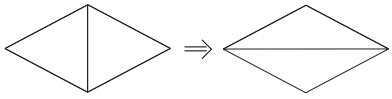

Figure 5: Swap the diagonal of a pair of adjacent triangular elements.

- Split a quadrilateral element into two triangular elements, as shown in *Figure 6*. You cannot split a 5-node quadrilateral element, and you cannot split a gasket element.

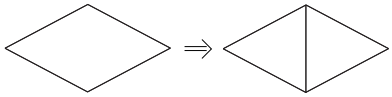

Figure 6: Split a quadrilateral element into two triangular elements.

- Combine two adjacent triangular elements into one quadrilateral element, as shown in *Figure 7*. You can combine either first- or second-order elements, but you cannot combine a combination of both. In addition, you can combine elements only if the adjacent triangular elements have consistent normals. If necessary, you can flip the normals to make them consistent.

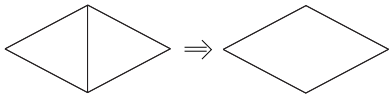

Figure 7: Combine two adjacent triangular elements into one quadrilateral element.

- Orient the stack direction of a continuum shell, cohesive, cylindrical, or gasket mesh. You can stack only hexahedral, wedge, and quadrilateral elements to form a continuum shell, cohesive, cylindrical, or gasket mesh. As a result, you can use this tool to orient the stack direction of only hexahedral, wedge, and quadrilateral elements. If you have assigned cylindrical elements or second-order gasket elements to the region, you must first change the assignment to conventional elements before you reorient the stack direction. You can then convert the region back to a cylindrical or gasket mesh by reassigning cylindrical elements or second-order gasket elements.
- Renumber selected elements within an orphan mesh. You can renumber the selected elements by specifying a starting label and an increment or by offsetting the existing label by a specified value.

Tip: The Mesh Edit Undo feature can roll back any change you make to the element in the mesh. For more information, see *Undoing or redoing a change in the Edit Mesh toolset*.

For detailed instructions about manipulating elements, see *Editing elements*.

Manipulating the mesh

The Edit Mesh toolset provides the following tools that allow you to manipulate the mesh:

- Create layers of solid elements that are offset normal to selected element faces of an existing mesh, as shown in *Figure 1*. This tool is useful for meshing shell-like parts with solid elements. You can specify the total thickness of all the layers and the number of layers to create. The first layer of elements can be merged with the existing elements, or it can be offset by a specified distance. The selected element faces can be from either shell or solid elements, but not from both. If you selected shell element faces, you can choose whether to delete the shell elements after Abaqus/CAE generates the layers of solid elements.

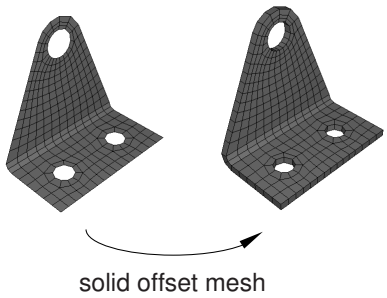

Figure 1: Creating layers of solid elements.

  You should use this tool to generate continuum shell and cohesive elements, because the solid elements that Abaqus/CAE generates are stacked normal to the surface from which they were offset.

- Create layers of shell elements that are offset normal to selected element faces from an existing mesh, as shown in *Figure 2*.

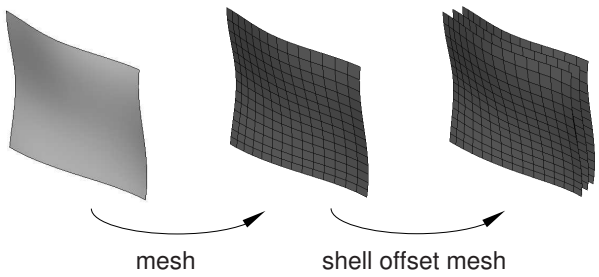

Figure 2: Creating layers of shell elements.

  This tool is similar to the previous tool; however, instead of specifying the total thickness of the layers, you specify the distance between the layers. You should use this tool to create an offset copy of an existing shell mesh and to create multi-layered composite models or reinforcements.

- Wrap a mesh. You can wrap a planar orphan mesh about the global *Z*-axis at a specified radius. The wrapping procedure will relocate a node at point (x, y) on the planar mesh to (r, θ, z), where r is the specified radius, $\theta = \frac{x}{r}$, and $z=y$.

- Collapse edges. You can specify the minimum element edge size desired in the mesh. Abaqus/CAE merges the end nodes of element edges that are shorter than the specified length. By default, Abaqus/CAE checks all element edges in a mesh part, but you can specify a different element domain.

  For structured meshes you can specify a thickness direction or reference edge to limit the edge directions considered for collapse. If you select a thickness direction, Abaqus/CAE uses the direction vector to measure the elements instead of measuring only the distance between nodes. If elements are oriented such that the direction is topologically

ambiguous, Abaqus/CAE highlights the elements so you can either select a domain that excludes them or add a reference edge to further define the desired edges. When you choose a reference edge, with or without a thickness direction, Abaqus/CAE considers edges for collapse only if they are topologically parallel to the reference edge. A reference edge can be applied only within a single section of structured mesh; multiple separate sections must be handled in separate collapse operations if reference edges are required.

You cannot collapse small edges in an element domain that contains quadratic elements.

- Grow edges. You can specify the minimum element edge size that you want to appear in the model, and Abaqus/CAE grows smaller edges to the specified minimum length by adjusting the nodes outward, effectively taking pieces from adjacent edges. Abaqus/CAE cannot increase the length of an edge if adjusting its nodes would cause the adjacent element edges to be too small. However, if you add a thickness direction, Abaqus/CAE will grow all the elements in that direction such that they will meet the minimum size.

  The options for this tool are the same as those for the collapse edges tool; you can specify an element domain other than the entire mesh part, and you can use a thickness direction or a reference edge within a structured mesh to grow only those edges that meet your direction criteria. You cannot grow edges in an element domain that contains quadratic elements.

  Note:

  Use care when specifying an element domain other than the entire mesh. Abaqus/CAE considers for growth only those element edges within the selected domain. If short element edges exist near the border of the domain, Abaqus/CAE does not check the length of adjacent edges outside the domain before growing the ones inside the domain. Growth of edges at the domain border could result in short edges or inverted elements outside the domain.

- Convert triangular elements to tetrahedral elements. You can convert a closed three-dimensional shell of triangular elements into a solid mesh of tetrahedral elements. The triangular shell elements must completely enclose a volume that can be filled with solid elements.
- Convert solid orphan mesh elements to shell orphan mesh elements. This tool creates triangular or quadrilateral shell elements on the free faces of the part. For mesh parts with unmerged nodes that create crack features or mesh parts that have joined faces with incompatible meshes, Abaqus/CAE creates shell elements on both sides of the interface.
- Merge layers. You can select a group of adjacent elements and join them along a specified direction. Each merged element will have the combined shape of the parent elements and the same element type. After selecting the elements to merge, you choose an edge within the elements to be merged to indicate the merge direction, as shown on the left in *Figure 3*. The top two layers of elements were selected using the **by topology** selection method (for more information, see *Using the topology method to select multiple elements*); for clarity the selection is not shown in the figure.

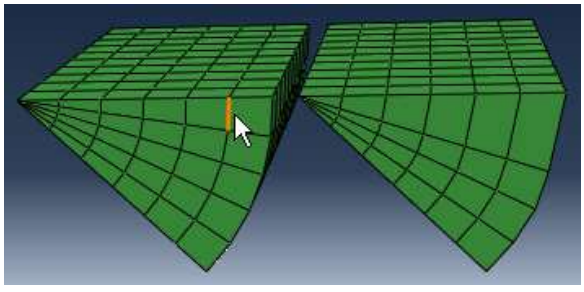

Figure 3: Merging element layers.

You need not select entire layers of elements to merge. However, if you do not select entire layers, Abaqus/CAE will warn you that the new elements will be incompatible with the surrounding mesh. You can then choose to continue or cancel the merge procedure. You cannot merge quadratic elements.

- Subdivide layers. You can select a group of elements and split them by equally dividing the element edges. Abaqus/CAE prompts you to select an edge, a face, or **All Directions** to indicate the direction along which the new layers will be created and enter the number of divisions to make from each element edge. You cannot subdivide quadratic elements.
- Copy a mesh pattern. You can apply a two-dimensional mesh pattern to a similar geometric target on the same part or assembly. After selecting the source mesh and target geometry, you select several nodes and map them to points on the geometry, then Abaqus/CAE finishes the mapping process to apply the mesh pattern to the target.
- Associate mesh with geometry. You can associate orphan or bottom-up mesh entities with a selected geometric entity. Abaqus/CAE prompts you to select a vertex, edge, or face, and then select the node, element edges, or element faces to associate with the geometry. Association can be used to apply loads to a mesh or to create a compatible mesh at the interface between orphan mesh elements and geometry.
- Delete mesh association. You can delete the mesh-geometry association for vertices, edges, faces, or entire geometric regions. You can also delete the association of a native mesh to create an orphan mesh for a portion of a model.
- Insert cohesive seams. You can open pairs of connected elements at crack regions and insert a layer of pore pressure cohesive elements that are created as orphan elements in the gap region. Abaqus/CAE creates several sets and surfaces to help you make selections in subsequent procedures, such as section assignment.

Tip: The Mesh Edit Undo feature can roll back any change you make to the mesh. For more information, see *Undoing or redoing a change in the Edit Mesh toolset*.

In addition, *Changing the labels of all nodes and elements*, describes how you can renumber all of the nodes and/or elements of a part or selected part instances in the assembly.

For detailed instructions about manipulating the mesh, see *Editing the entire mesh*.

Refining the mesh

The Edit Mesh toolset provides the following tools that allow you to refine a planar mesh of triangular elements:

- Set size. You can specify a global element size for the remesh procedure. Abaqus/CAE changes the density of the new mesh to reflect the new target element size. You can change the element size if the mesh contains either linear or quadratic elements.
- Remove size. You can maintain the global element size during the remesh procedure. Abaqus/CAE maintains the edges of the elements along the boundary of the part while improving the mesh quality in the interior. You can refine the mesh if the mesh contains either linear or quadratic elements.
- Remesh. You can remesh a planar mesh containing linear or quadratic triangular elements.

Tip: The Mesh Edit Undo feature can roll back any mesh refinement changes. For more information, see *Undoing or redoing a change in the Edit Mesh toolset*.

For detailed instructions about mesh refinement, see *Editing and refining an orphan mesh*.

What is the difference between editing an orphan mesh, a meshed part, and a meshed part instance in the assembly?

You can display either parts containing a combination of orphan and native mesh components or the assembly in the Mesh module. You can use all of the tools in the Edit Mesh toolset to edit an orphan mesh; however, you can use only the following tools to edit a meshed part instance in the assembly:

- Edit, drag, project, merge, and smooth nodes
- Delete elements
- Collapse element edges
- Split an edge of a quadrilateral or triangular element
- Swap the diagonal of a pair of adjacent triangular elements
- Split a quadrilateral element into two triangular elements
- Combine two triangular elements into one quadrilateral element

If you select a part instead of a part instance in the assembly, you can use the mesh editing tools listed above plus the following additional tools:

- Create nodes and elements
- Offset mesh layers to create solid or shell layers
- Associate the mesh with geometry
- Delete mesh associativity
- Copy mesh pattern

In general, you cannot use the Edit Mesh toolset to modify the mesh of a dependent part instance. However, you can edit, drag, and project the nodes of a dependent part instance; Abaqus/CAE modifies the original meshed part, and your modifications appear on all dependent instances of the part.

You can create an orphan mesh in the Mesh module, or you can import an orphan mesh from an output database or an Abaqus input file. You can add geometric features to an orphan mesh in the Part module. An instance of an orphan mesh is always a dependent instance and; therefore, you cannot use the Edit Mesh toolset to edit an instance of an orphan mesh in the assembly. However, you can display the original orphan mesh that was used to create the instance and edit the part. For more information, see *What is the difference between a dependent and an independent part instance?*.

The Mesh Edit Undo feature can roll back any change you make to the mesh. For more information, see *Undoing or redoing a change in the Edit Mesh toolset*.

Meshing strategies and mesh editing techniques

This section describes strategies for improving your mesh using the Edit Mesh toolset and techniques that you can use to create the desired mesh.

In this section:

- *A strategy for improving the mesh*
- *Using offset meshes in Abaqus/CAE*
- *Reducing element distortion and collapse during mesh offsetting*
- *Allowing for branching in offset solid meshes*
- *Creating a mid-plane shell mesh from a thin solid model*
- *Using a combination of tools to mesh an imported solid part with tetrahedral elements*

A strategy for improving the mesh

If you have a complex assembly, you should select **Mesh->Verify** to verify the quality of the mesh before you submit the job for analysis. The mesh verify tool can do the following:

- Highlight elements of a selected shape that do not meet specified criteria, such as aspect ratio.
- Print mesh statistics, such as the total number of elements of the chosen shape, the number of highlighted elements, and the average and worst values of the selection criterion.
- Highlight elements that do not pass the mesh quality tests that are included with the input file processor in Abaqus/Standard and Abaqus/Explicit.

If the mesh verify tool indicates that you should try to improve the quality of the mesh, you should first try the following before turning to the Edit Mesh toolset:

- Change the seed distribution
- Add or modify partitions
- Change the mesh technique

In addition, you might try modifying the parts in the Part module, or you might try using the Virtual Topology toolset and regenerating the mesh. You should treat the Edit Mesh toolset as the final step in the meshing process and use it only to make minor adjustments to nodes and elements. Abaqus/CAE tries to preserve attributes, such as loads and boundary conditions, if you make changes to the mesh. If you modify a part, Abaqus/CAE deletes the mesh when you return to the Mesh module; as a result, you will lose any edits that you made to the mesh.

Using offset meshes in Abaqus/CAE

The offset mesh tools in the Edit Mesh toolset have many uses in Abaqus/CAE, as follows:

Continuum shell meshes

You can use the solid offset mesh tool to mesh thin solids that are essentially thickened shells, such as sheet metal, composites, or molded plastic components. The solid offset mesh tool is useful for creating continuum shell elements because Abaqus/CAE orients the elements consistently in the thickness direction. For more information, see *Meshing parts with continuum shell elements*.

Cohesive elements

You can assign cohesive elements to quadrilateral elements of a two-dimensional model. For three-dimensional models you can use the solid offset mesh tool to generate a layer of cohesive elements on a mesh. The offset mesh tool generates elements that are oriented consistently with a stack direction that is normal to the thickness direction, and it is a convenient tool for quickly creating a layer of cohesive elements. For more information, see *Embedding cohesive elements in an existing three-dimensional mesh*.

Skin reinforcements

If your skin can be defined as a single layer, creating the skin in the Property module is the preferred approach. However, you can use the shell offset mesh tool to create a skin that uses multiple reinforcement layers. For more information, see *Using offset meshes to create skin reinforcements*.

You can also use the solid offset mesh tool in conjunction with the mesh generation tools in the Mesh module by doing the following:

1. Create a portion of the mesh in the Mesh module.
2. Use the solid offset mesh tool to complete the mesh.

You can create sets containing the elements from an offset mesh. You can create a single set that contains the offset elements, or you can create separate sets for each layer of offset elements. In addition, if you are creating a solid offset mesh, you can create surfaces from the top and the bottom of the offset mesh, provided the first layer of elements is not embedded in the original mesh. You can use these sets and surfaces in subsequent procedures to help you select elements from the offset mesh. For example, you can select a set when assigning a section to a layer of offset elements. Similarly, you can select a surface when you tie one side of a layer of cohesive elements to the surrounding bulk material.

Reducing element distortion and collapse during mesh offsetting

Abaqus/CAE creates an offset mesh by

- offsetting the nodes normal to the boundary of an existing mesh surface, and
- building elements that propagate out in the normal direction.

When you create a mesh that is offset from a concave mesh surface, the elements tend to converge, as shown in *Figure 1*.

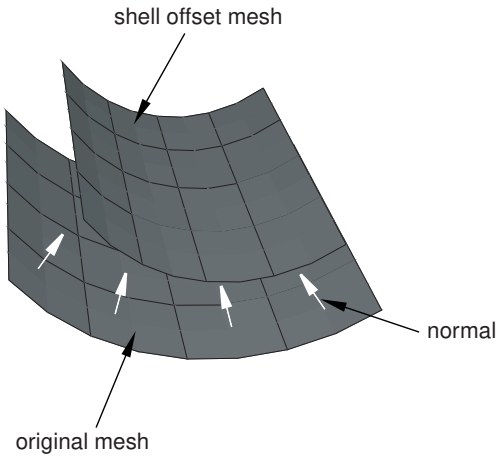

Figure 1: Elements converge when offset from a concave surface.

As a result, elements may collapse or become inverted, and the magnitude of the offset is limited by a combination of the degree of curvature and the element size, as shown in *Figure 2*.

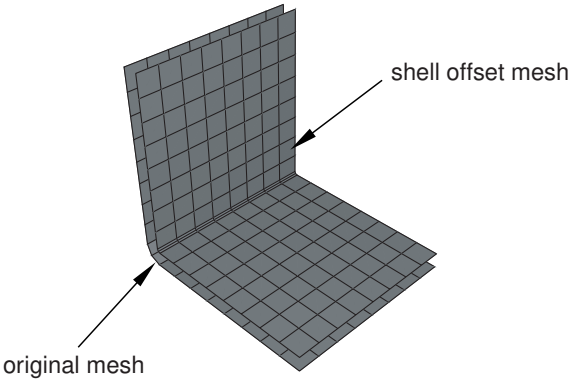

Figure 2: When you offset small elements in a concave region, the elements may collapse or become inverted.

You can try to avoid element collapse and element inversion by selecting **Constant thickness around corners** from the **Offset Mesh** dialog box. When this option is selected, Abaqus/CAE tapers the offset elements that propagate from sharp corners. The resulting elements have a constant nodal offset distance as opposed to a constant distance between the layers of the element faces. *Figure 3* illustrates the effect on the offset mesh pattern of requesting a constant thickness around corners.

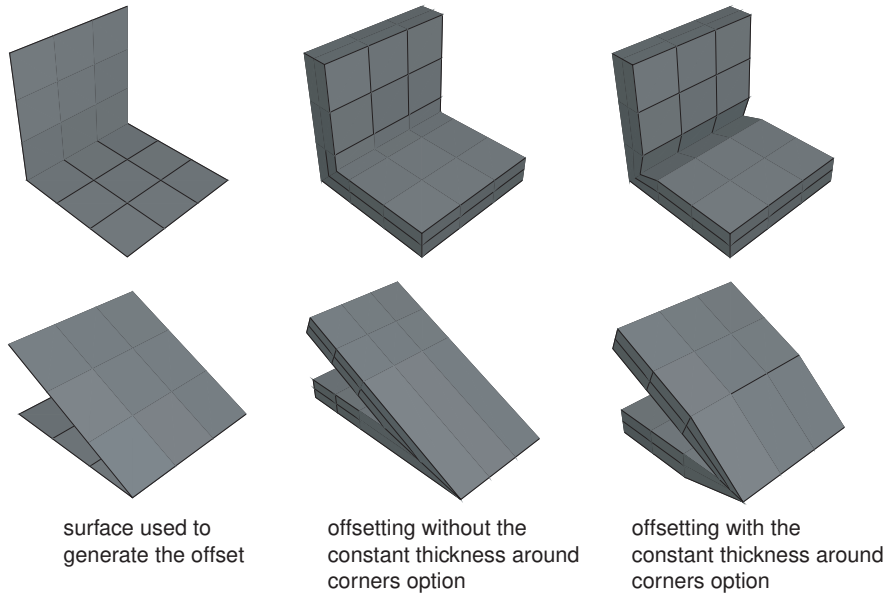

Figure 3: The effect on the offset mesh pattern of requesting a constant thickness around corners.

The effect on the offset mesh pattern is similar for both solid and shell offset meshes. You can also reduce element distortion by using a larger element size in the location of the concave region. However, you can control the element size only if you can regenerate the mesh from which you are offsetting.

In contrast, when you create a mesh that is offset from a convex mesh surface, the elements tend to fan out, as shown in *Figure 4*.

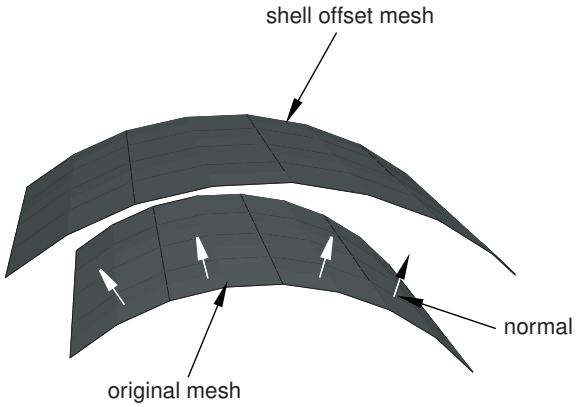

Figure 4: Elements diverge when offset from a convex surface.

Allowing for branching in offset solid meshes

If a part has “branches,” as shown in *Figure 1*, creating an offset solid mesh is not straightforward because the direction in which to offset is ambiguous in the region of the branch.

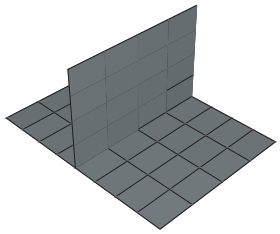

Figure 1: The direction in which to offset is ambiguous in the region of the branch.

To help you mesh this configuration, Abaqus/CAE provides the option to copy the elements in the region of the branch to a set.

You can then do the following:

1. Use display groups to remove the set containing elements in the region of the branch from the orphan mesh.
2. Create offset solid meshes from the non-branching regions that remain, as shown in *Figure 2*.

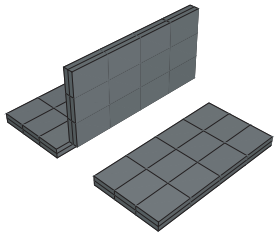

Figure 2: Create offset solid meshes from the non-branching regions.

3. Use display groups to show only the set containing the branch, as shown in *Figure 3*.

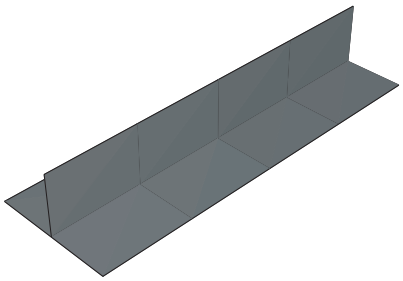

Figure 3: Use display groups to show only the set containing the branch.

4. Create an offset solid mesh from one side of the branching region. Take care that the offset direction is correct (Abaqus/CAE indicates the offset direction by coloring the element faces). In addition, do not delete the base shell elements until you have finished offsetting the branch.
5. Create an offset solid mesh from the other side of the branching region, as shown in *Figure 4*.

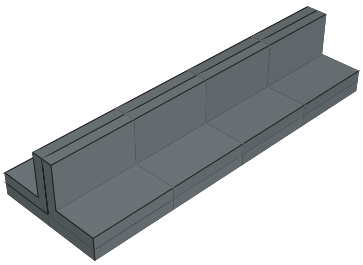

Figure 4: The offset mesh in the branching region.

6. Use display groups to show both regions.
7. Use the merge nodes tool in the Edit Mesh toolset to merge the offset meshes created in Steps 2, 4, and 5.

Creating a mid-plane shell mesh from a thin solid model

You can use the following procedure to create a mid-plane shell mesh from a thin solid model using the offset meshing tool:

1. Convert the solid part to a shell using the **From solid** shell tool in the Part module.
2. Isolate a collection of faces on the upper or lower surface of the part using the **Remove faces** tool in the Geometry Edit toolset.
3. Mesh the simplified model with shell elements, and create a mesh part.
4. Create an offset shell mesh, and specify an **Initial Offset** corresponding to half the model thickness.

Using a combination of tools to mesh an imported solid part with tetrahedral elements

In some cases you may not be able to mesh an imported solid part with tetrahedral elements because of very thin triangular elements in the surface mesh or because some sliver faces cannot be meshed with triangles. The following procedure explains how you can use a combination of tools in the Mesh module to mesh the part successfully:

1. Do one of the following:
   - Start with a tetrahedral boundary mesh. Go to the Mesh module, and create a tetrahedral boundary mesh on the solid.
   - Start with a mesh of linear triangles.
     1. Convert the solid part into a shell part by selecting **Shape->Shell->From Solid** from the main menu bar.
     2. Go to the Mesh module, and mesh the shell part with linear triangular elements.
2. Select **Mesh->Create Mesh Part** from the main menu bar to create a new part that is an orphan mesh. For more information, see *Creating a mesh part*.
3. Change the displayed object to the orphan mesh.
4. Select **Tools->Edit Mesh** from the main menu bar, and do the following to clean the mesh:
   1. From the **Category** field, choose **Mesh**.
   2. From the **Method** list, select **Collapse edges**.

   Cleaning the mesh will automatically merge nodes on short element edges and remove the collapsed elements. For more information, see *Collapsing short edges of a linear orphan mesh*.
5. Use the Edit Mesh toolset to repair any remaining bad elements or gaps manually. For more information, see *Editing elements*.
6. Select **Tools->Edit Mesh** from the main menu bar, and select **Conversion** to replace the shell mesh of linear triangles with a solid mesh of linear tetrahedrons. For more information, see *Converting a triangular shell mesh to a solid tetrahedral mesh*.
7. Go to the Assembly module, and select **Instance->Replace** to replace the original shell part instance with an instance of the orphan mesh.
8. If you want the orphan mesh to use second-order tetrahedral elements, you can assign a quadratic element type to the orphan mesh in the Mesh module.

Using the mesh editing tools

This section is an overview of the tools that are available in the Edit Mesh toolset.

You can access the tools from the main menu bar by selecting **Mesh->Edit**. Abaqus/CAE displays the **Edit Mesh** dialog box. You can also display the **Edit Mesh** dialog box using the  tool, located at the bottom of the Mesh module toolbox.

Node editing tools

The following tools are available for editing nodes:

- Create node. For more information, see *Creating a node*.
- Edit node. For more information, see *Editing the position of selected nodes*.
- Drag node. For more information, see *Dragging nodes*.
- Project nodes. For more information, see *Projecting nodes*.
- Delete node. For more information, see *Deleting nodes*.
- Merge nodes. For more information, see *Merging nodes*.
- Adjust midside nodes. For more information, see *Adjusting the position of midside nodes*.
- Smooth external nodes. For more information, see *Smoothing external nodes*.
- Renumber nodes. For more information, see *Renumbering nodes*.

Element editing tools

The following tools are available for editing elements:

- Create element. For more information, see *Creating an element*.
- Delete element. For more information, see *Deleting elements*.
- Flip normal. For more information, see *Reversing the surface normal direction of shell elements*.
- Orient stack direction. For more information, see *Orienting the stack direction*.
- Collapse edge. For more information, see *Collapsing an edge of a quadrilateral or triangular element*.
- Split edge. For more information, see *Splitting an edge of a quadrilateral or triangular element*.
- Swap diagonal. For more information, see *Swapping the diagonal of a pair of adjacent triangular elements*.
- Split. For more information, see *Splitting quadrilateral elements*.
- Combine. For more information, see *Combining triangular elements*.
- Renumber elements. For more information, see *Renumbering elements*.

Mesh editing tools

The following tools are available for editing the entire mesh:

- Offset solid. For more information, see *Generating layers of solid elements offset from an existing mesh*.
- Offset shell. For more information, see *Generating layers of shell elements offset from an existing mesh*.
- Wrap. For more information, see *Wrapping a mesh about the Z-axis*.
- Collapse. For more information, see *Collapsing short edges of a linear orphan mesh*.

- Grow. For more information, see *Growing short edges of a linear orphan mesh*.
- Convert. For more information, see *Converting a triangular shell mesh to a solid tetrahedral mesh*, and *Converting a solid orphan mesh to a shell orphan mesh*.
- Merge. For more information, see *Merging elements*.
- Subdivide. For more information, see *Subdividing elements*.
- Copy mesh pattern. For more information, see *Copying a mesh pattern*.
- View and edit mesh-geometry associativity. For more information, see *Viewing and editing mesh-geometry associativity*.
- Delete mesh-geometry associativity. For more information, see *Deleting mesh-geometry associativity*.
- Insert cohesive seams. For more information, see *Inserting cohesive seams*.

Mesh refinement tools

The following tools are available for refining the mesh:

- Set size.
- Remove size.
- Remesh.

For more information, see *Editing and refining an orphan mesh*.

Undo and redo for mesh edits

You can undo and redo multiple changes that you make using the tools in the Edit Mesh toolset, and control the number of available undo levels. For more information, see *Undoing or redoing a change in the Edit Mesh toolset*.

Editing nodes

This section describes how you can use the Edit Mesh toolset to edit the nodes that comprise orphan meshes and Abaqus/CAE native meshes.

In this section:

- *Creating a node*
- *Editing the position of selected nodes*
- *Dragging nodes*
- *Projecting nodes*
- *Deleting nodes*
- *Merging nodes*
- *Adjusting the position of midside nodes*
- *Smoothing external nodes*
- *Renumbering nodes*
- *Selecting the nodes to edit*

Creating a node

Select **Mesh->Edit** from the main menu bar to create a node by entering its coordinates in either the global coordinates system or a local coordinate system.

1. Enter the Mesh module.
2. From the **Object** field in the context bar, select **Part**, and select a part from the list.
3. From the main menu bar, select **Mesh->Edit**.

   Abaqus/CAE displays the **Edit Mesh** dialog box.

   Tip: You can also display the **Edit Mesh** dialog box using the tool, located at the bottom of the Mesh module toolbox.

4. In the dialog box, do the following:
   a. In the **Category** field, select **Node**.
   b. From the **Method** list, select **Create**.

   Abaqus/CAE displays the existing nodes. In hidden and shaded mode, only the visible nodes are displayed.
5. If desired, you can enter the coordinates for the new node in a datum coordinate system that you have created rather than in the global coordinate system:
   a. In the prompt area, click **Select**.
   b. In the viewport, select the datum coordinate system to be associated with the coordinates of the new node. (For more information, see *Creating datum coordinate systems*.)
6. In the **Coordinates** field in the prompt area, enter the coordinates of the new node.

   Abaqus/CAE creates the new node.

   Tip: If you make a mistake while creating a node, click **Undo** in the **Edit Mesh** dialog box to remove the most recently created node.

7. Repeat Steps 3 and 4 as often as necessary to create additional nodes.
8. When you have finished creating nodes, click the cancel button in the prompt area to exit the procedure.

Additional information

- *What can I do with the Edit Mesh toolset?*

Editing the position of selected nodes

You can edit the position of one or more selected nodes from a meshed part, a meshed part instance in the assembly, or an orphan mesh.
In addition, if you select multiple nodes to edit, you can assign a single value to a particular coordinate for each of the nodes. For example, you can select a group of nodes and assign an *X*-axis coordinate of `10.0` to each of the nodes. This is particularly useful when you want to position the nodes in the same plane; for example, when defining the mating surface of a cylinder head or engine block.

In general, you cannot use the Edit Mesh toolset to edit a dependent part instance; however, you can edit the nodes of a dependent part instance. Abaqus/CAE moves the nodes of the original mesh, and your modifications appear on all dependent instances of the part.

Note:

You can undo or redo the changes you make to nodal position directly from the **Undo** portion of the **Edit Nodes** dialog box. The **Undo** and **Redo** buttons in this dialog box provide rollback control for nodal position changes only; if you want to undo or redo other mesh editing operations, use the **Edit Mesh** dialog box. For more information about edit mesh undo, see *Undoing or redoing a change in the Edit Mesh toolset*.

1. Enter the Mesh module, and do one of the following:
   - From the **Object** field in the context bar, select **Assembly**.
   - From the **Object** field in the context bar, select **Part**, and select a part from the list.
2. From the main menu bar, select **Mesh->Edit**.

   Abaqus/CAE displays the **Edit Mesh** dialog box.

   Tip: You can also display the **Edit Mesh** dialog box using the  tool, located at the bottom of the Mesh module toolbox.
3. In the dialog box, do the following:
   a. In the **Category** field, select **Node**.
   b. From the **Method** list, select **Edit**.

      Abaqus/CAE displays the existing nodes. In hidden and shaded mode, only the visible nodes are displayed.
4. From the prompt area, choose the selection method and select the nodes to edit. For more information, see *Selecting the nodes to edit*.

   Tip: You can use the **Selection** toolbar to change the picking behavior. For more information, see *Selecting objects within the viewport*.

   Abaqus/CAE displays the **Edit Nodes** dialog box and the minimum and maximum values of the coordinates of the selected nodes along each axis.
5. If desired, you can enter the new coordinates for the nodes in a datum coordinate system that you have created rather than in the global coordinate system:
   a. At the top of the **Edit Nodes** dialog box, click **Select**.
   b. In the viewport, select the datum coordinate system to be associated with the new nodal coordinates. (For more information, see *Creating datum coordinate systems*.)

6. To specify the new position of the selected nodes by offset, choose **Offsets** from the **Specification method** options, then do one of the following:

Enter values

Type the 1-, 2-, and 3-components of the offset from the current location directly into the dialog box.

Measure offset vector

Click  and pick two points in the viewport. Abaqus/CAE populates the 1-, 2-, and 3-components of the offset based on the components of the vector from your first selected point to your second selected point.

7. To specify the new position of the selected nodes by coordinates, choose **Coordinates** from the **Specification method** options, then do one of the following:

Enter values

Type the 1-, 2-, and 3-components directly into the dialog box. A value of **As is** indicates that the coordinate along a particular axis is different for at least two of the selected nodes; click the arrow to the right of the component field, and select **Specify** to specify a value.

Measure coordinates

Click  and pick the new point from the viewport.

8. If you are editing nodes on the boundary of an Abaqus/CAE native mesh in the Mesh module, Abaqus/CAE first moves the nodes to the new position and then projects them back to the geometry on which they were originally located. As a result, nodes that were located on a surface will remain on that surface but in a different position. Toggle off **Project to geometry** to move the nodes to their new position independently from the underlying geometry.
9. Click **OK** or **Apply** to move the nodes to the new position. If you click **OK**, Abaqus/CAE moves the nodes and prompts you to select new nodes to edit. If you click **Apply**, Abaqus/CAE moves the nodes; however, the nodes remain selected, and you can continue specifying a new position.

Tip: If you make a mistake while editing nodes, click **Undo** in the **Edit Mesh** dialog box to undo the edit. Abaqus/CAE restores the node or nodes to their original position.

10. Repeat the previous steps as often as necessary to edit additional nodes.
11. When you have finished editing nodes, click **Cancel** to close the **Edit Nodes** dialog box.

Additional information

- *What can I do with the Edit Mesh toolset?*

Dragging nodes

You can drag nodes on a meshed part, a meshed part instance in the assembly, or an orphan mesh. Dragging provides a quick way to reposition nodes and to improve element quality. When you activate the node dragging function, Abaqus/CAE automatically activates the solver element quality checks, highlighting elements with warnings in yellow and highlighting elements with errors in magenta. You can also include tests for shape metrics or size metrics among the tests that Abaqus/CAE automatically performs on elements as you drag nodes. The highlighting is updated as you drag a node into a new position; therefore, you can immediately see whether you are improving the element quality. In general, you cannot use the Edit Mesh toolset to modify the mesh of a dependent part instance; however, you can drag the nodes of a dependent part instance. Abaqus/CAE modifies the nodes of the original mesh, and your modifications appear on all dependent instances of the part.

Dragging nodes does not change their association. Nodes that are associated with a geometric feature prior to dragging will remain associated with that feature; unassociated nodes will remain unassociated after you drag them onto geometry.

1. Enter the Mesh module, and do one of the following:
   - From the **Object** field in the context bar, select **Assembly**.
   - From the **Object** field in the context bar, select **Part**, and select a part from the list.
2. From the main menu bar, select **Mesh->Edit**.

   Abaqus/CAE displays the **Edit Mesh** dialog box.

   Tip: You can also display the **Edit Mesh** dialog box using the  tool, located at the bottom of the Mesh module toolbox.
3. In the dialog box, do the following:
   a. In the **Category** field, select **Node**.
   b. From the **Method** list, select **Drag**.

      Abaqus/CAE displays the existing nodes.
4. If desired, click **Element failure criteria** from the prompt area to include shape metrics or size metrics among the tests that Abaqus/CAE automatically performs as you drag nodes.
5. From the prompt area, toggle **Project to geometry** to control the drag behavior of exterior nodes.
   - If you toggle on **Project to geometry**, Abaqus/CAE constrains dragged exterior nodes to their associated geometry. You can drag a node on a mesh face as long as it remains within the underlying geometric face. Likewise, you can drag an edge node only along the polyline that created the edge, and you cannot drag a node associated with a vertex. In orphan mesh regions, you can drag any node; but you cannot drag a node beyond the outer edges of the mesh.
   - If you toggle off **Project to geometry**, Abaqus/CAE constrains dragged nodes to a plane parallel to the computer screen and passing through the original position of the node. Therefore, you can change the available drag locations by using the view manipulation tools before dragging a node. This is also the behavior if you drag interior nodes since they are not constrained to a geometric feature.
6. Position the cursor over the node you want to move, and click and hold mouse button 1 while dragging the node to a new location.

   When you release mouse button 1, Abaqus/CAE displays the node number and new coordinates in the message area.

7. Repeat the previous steps as often as necessary to drag additional nodes.

Additional information

- *What can I do with the Edit Mesh toolset?*
- *Verifying element quality*

Projecting nodes

You can project one or more selected nodes from a meshed part, a meshed part instance in the assembly, or an orphan mesh to a selected vertex, edge, face, node, element edge, element face, datum point, datum axis, or datum plane. This is particularly useful if you want to move nodes in a bottom-up mesh onto nearby geometry. In general, you cannot use the Edit Mesh toolset to modify the mesh of a dependent part instance; however, you can project the nodes of a dependent part instance. Abaqus/CAE projects the nodes of the original mesh, and your modifications appear on all dependent instances of the part.

Projecting nodes does not change their association. Nodes that are associated with a geometric feature prior to projection will remain associated with that feature; unassociated nodes will remain unassociated after you project them onto geometry.

1. Enter the Mesh module, and do one of the following:
   - From the **Object** field in the context bar, select **Assembly**.
   - From the **Object** field in the context bar, select **Part**, and select a part from the list.
2. From the main menu bar, select **Mesh->Edit**.

   Abaqus/CAE displays the **Edit Mesh** dialog box.

   Tip: You can also display the **Edit Mesh** dialog box using the  tool, located at the bottom of the Mesh module toolbox.
3. In the dialog box, do the following:
   a. In the **Category** field, select **Node**.
   b. From the **Method** list, select **Project**.

      Abaqus/CAE displays the existing nodes. In hidden and shaded mode, only the visible nodes are displayed.
4. From the prompt area, choose the selection method and select the nodes to project. For more information, see *Selecting the nodes to edit*.

   Tip: You can use the **Selection** toolbar to change the picking behavior. For more information, see *Selecting objects within the viewport*.
5. Select a vertex, edge, face, node, element edge, element face, datum point, datum axis, or datum plane to which Abaqus/CAE will move the selected nodes.

   Abaqus/CAE colors the selected entity magenta.
6. Select **Yes** in the prompt area to confirm your selections.

   Abaqus/CAE projects the selected nodes to their new positions using a shortest distance algorithm. If you selected an edge, face, element edge, or element face, Abaqus/CAE projects the nodes onto the axis or plane that would be created by extending the selected edge or face.

   Tip: If you make a mistake while editing nodes, click **Undo** in the **Edit Mesh** dialog box to undo the edit. Abaqus/CAE restores the nodes to their original positions.

   If you select **No**, your node and entity selections are cancelled and the procedure continues from Step 4.

7. Repeat the previous steps as often as necessary to project additional nodes.

Additional information

• *What can I do with the Edit Mesh toolset?*

Deleting nodes

Select **Mesh->Edit** from the main menu bar to delete orphan mesh nodes. Abaqus/CAE also deletes any elements associated with the deleted nodes. If the nodes and associated elements that you are deleting belong to existing node or element sets, those sets are updated accordingly.

1. Enter the Mesh module.
2. From the **Object** field in the context bar, select **Part**, and select a part from the list. This tool is available only for deleting orphan mesh nodes.
3. From the main menu bar, select **Mesh->Edit**.

   Abaqus/CAE displays the **Edit Mesh** dialog box.

   Tip: You can also display the **Edit Mesh** dialog box using the tool, located at the bottom of the Mesh module toolbox.

4. In the dialog box, do the following:
   a. In the **Category** field, select **Node**.
   b. From the **Method** list, select **Delete**.

      If the **Delete** method is not shown, there are no orphan nodes in the selected part.

      Abaqus/CAE displays the existing nodes. In hidden and shaded mode only the visible nodes are displayed.

5. In the viewport, select the nodes to delete. You can **[Shift] + Click** on individual nodes to add them to your selection, or **[Ctrl] + Click** on selected nodes to remove them from your selection.

   Tip: You can use the **Selection** toolbar to change the picking behavior. For more information, see *Selecting objects within the viewport*.

   If you would rather select from a list of existing node sets, do the following:
   a. Click **Sets** on the right side of the prompt area.

      Abaqus/CAE displays the **Region Selection** dialog box containing a list of node sets that you have created.
   b. Select the set of nodes that you want to delete, and click **Continue**.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

   Abaqus/CAE displays the selected nodes and the elements associated with the selected nodes. (Both the nodes that you have selected and any elements associated with those nodes will be deleted.)
6. When you have finished selecting nodes to delete, click mouse button 2.
7. The elements associated with the selected nodes may also be associated with unselected nodes. If those unselected nodes would be left unassociated with any element after the nodes and associated elements are deleted, click **Yes** in the prompt area if you want Abaqus/CAE to delete those unselected nodes as well.

   Tip: If you make a mistake while deleting nodes, click **Undo** in the **Edit Mesh** dialog box to undo the deletion. Abaqus/CAE restores the deleted node or nodes.

8. Repeat the previous steps as often as necessary to delete additional nodes.

9. When you have finished deleting nodes, click mouse button 2 or the cancel button  in the prompt area to exit the procedure.

Additional information

• *What can I do with the Edit Mesh toolset?*

Merging nodes

Select **Mesh->Edit** from the main menu bar to merge nodes. If you select only two nodes to merge, Abaqus/CAE creates a new node at the midpoint of the selected nodes. If you select more than two nodes, you can specify the maximum distance between nodes, and Abaqus/CAE will merge nodes that are closer than the specified distance. You can also choose to remove duplicate elements that have the same connectivity.

1. Enter the Mesh module.
2. From the **Object** field in the context bar, select **Part**, and select a part from the list. This tool is available only for working on parts that contain either orphan mesh nodes or nodes created using the bottom-up meshing procedure.
3. From the main menu bar, select **Mesh->Edit**.

   Abaqus/CAE displays the **Edit Mesh** dialog box.

   Tip: You can also display the **Edit Mesh** dialog box using the tool, located at the bottom of the Mesh module toolbox.

4. In the dialog box, do the following:
   a. In the **Category** field, select **Node**.
   b. From the **Method** list, select **Merge**.
5. From the prompt area, choose the selection method and select the nodes to merge. For more information, see *Selecting the nodes to edit*.

   Tip: You can use the **Selection** toolbar to change the picking behavior. For more information, see *Selecting objects within the viewport*.

6. If you selected only two nodes to merge, Abaqus/CAE creates a new node at the midpoint of the selected nodes.
7. If you selected more than two nodes to merge, do the following:
   a. In the prompt area, enter the **Node merging tolerance** to specify the maximum distance between nodes that you want to merge.
   b. If the value that you entered for the **Node merging tolerance** is too large, Abaqus/CAE may detect duplicate nodes from the same element. Abaqus/CAE will not merge nodes from the same element, but the large tolerance can result in a distorted mesh. If the **Node merging tolerance** is too large, Abaqus/CAE asks if you want to continue merging the selected nodes.
      - Click **Yes** to continue.
      - Click **No** to cancel the merging procedure.

   c. Abaqus/CAE highlights in magenta any nodes that will be merged and asks if you wish to proceed.
      - Click **Yes** to continue.
      - Click **No** to cancel the merging procedure.

      Abaqus/CAE merges the nodes that are closer than the specified distance and replaces them with a single new node. The location of the new node is the average position of the group of nodes that were merged into the new node.

      You can also merge part instances in the Assembly module. For more information, see *Performing Boolean operations on part instances*.

If you previously created node or element sets that include nodes or elements that are deleted by the merge operation, Abaqus/CAE updates your sets accordingly.

Tip: If you make a mistake while merging nodes, click **Undo** in the **Edit Mesh** dialog box to undo the merge. Abaqus/CAE restores the nodes as they were before the merge.

8. Repeat the above steps as often as necessary to merge additional nodes.
9. When you have finished merging nodes, click mouse button 2 or the cancel button  in the prompt area to exit the procedure.

Additional information

- *What can I do with the Edit Mesh toolset?*

Adjusting the position of midside nodes

Select **Mesh->Edit** from the main menu bar to adjust the position of midside nodes of second-order elements.

You can use this tool to allow for the singularity at the crack tip in a fracture mechanics analysis. However, this tool will allow you to edit any second-order elements; it does not check that you are editing the degenerate quadrilateral or wedge elements required by a fracture mechanics analysis. For more information, see *Controlling the singularity at the crack tip for a small-strain analysis* and *Constructing a Fracture Mechanics Mesh for Small-Strain Analysis with the Conventional Finite Element Method*.

You can select nodes and enter a bias parameter between 0 and 1. Abaqus/CAE moves the midside nodes along connected element edges to a position based on the parameter that you entered. For example, if you enter a parameter of 0.25, Abaqus/CAE biases the position of the midside nodes one quarter of the length of the element edge away from the selected nodes.

1. Enter the Mesh module.
2. From the **Object** field in the context bar, select **Part**, and select a part from the list. This tool is available only for working on an parts that contain orphan mesh nodes.
3. From the main menu bar, select **Mesh->Edit**.

   Abaqus/CAE displays the **Edit Mesh** dialog box.

   Tip: You can also display the **Edit Mesh** dialog box using the tool, located at the bottom of the Mesh module toolbox.

4. In the dialog box, do the following:
   a. In the **Category** field, select **Node**.
   b. From the **Method** list, select **Adjust midside**.

   Abaqus/CAE displays the existing nodes. In hidden and shaded mode only the visible nodes are displayed.
5. Select the nodes toward which the position of midside nodes along connected element edges will be adjusted. You can select nodes, or you can select element edges. If you select element edges, Abaqus/CAE selects the nodes along the element edges.

   You can **[Shift] + Click** on individual nodes to add them to your selection, or **[Ctrl] + Click** on selected nodes to remove them from your selection.

   Tip: You can use the **Selection** toolbar to change the picking behavior. For more information, see *Selecting objects within the viewport*.

   If you would rather select from a list of existing node sets, do the following:
   a. Click **Sets** on the right side of the prompt area.

      Abaqus/CAE displays the **Region Selection** dialog box containing a list of node sets that you have created.
   b. Select the set of nodes, and click **Continue**.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.
6. In the prompt area, enter the value of the bias parameter. You must enter a value between 0 and 1.

Abaqus/CAE moves the midside nodes along connected element edges to the specified position.

Tip: If you make a mistake while adjusting nodes, click **Undo** in the **Edit Mesh** dialog box to undo the adjustment. Abaqus/CAE restores the nodes to their previous positions.

7. Repeat Steps 4 and 5 as often as necessary to adjust additional midside nodes.

8. When you have finished adjusting nodes, click the cancel button  in the prompt area to exit the procedure.

Additional information

- *What can I do with the Edit Mesh toolset?*
- *Controlling the singularity at the crack tip for a small-strain analysis*
- *Constructing a Fracture Mechanics Mesh for Small-Strain Analysis with the Conventional Finite Element Method*

Smoothing external nodes

Select **Mesh->Edit** from the main menu bar to smooth the positions of nodes on the surfaces of parts or assemblies. The node smoothing operation can improve transitions in mesh density or otherwise improve local mesh quality without remeshing the region or manually repositioning nodes. You can use node smoothing to improve the mesh on a surface before using it as the source of a bottom-up mesh or a swept mesh.

Abaqus/CAE applies a Laplacian smoothing algorithm at each node that you select. The selected nodes are repositioned to equalize their distance from adjoining nodes, creating a smoother surface mesh.

You can select only external nodes of parts or assemblies for smoothing. Boundary nodes are not repositioned by the smoothing operation.

1. Enter the Mesh module, and do one of the following:
   - From the **Object** field in the context bar, select **Assembly**.
   - From the **Object** field in the context bar, select **Part**, and select a part from the list.
2. From the main menu bar, select **Mesh->Edit**.

   Abaqus/CAE displays the **Edit Mesh** dialog box.

   Tip: You can also display the **Edit Mesh** dialog box using the  tool, located at the bottom of the Mesh module toolbox.
3. In the dialog box, do the following:
   a. In the **Category** field, select **Node**.
   b. From the **Method** list, select **Smooth**.

   Abaqus/CAE displays the existing nodes. In hidden and shaded mode only the visible nodes are displayed.
4. Select the nodes to be smoothed.

   You can **[Shift] + Click** on individual nodes to add them to your selection, or **[Ctrl] + Click** on selected nodes to remove them from your selection.

   Tip: You can use the **Selection** toolbar to change the picking behavior. For more information, see *Selecting objects within the viewport*.

   If you would rather select from a list of existing node sets, do the following:
   a. Click **Sets** on the right side of the prompt area.

      Abaqus/CAE displays the **Region Selection** dialog box containing a list of node sets that you have created.
   b. Select the set of nodes, and click **Continue**.

   Note: The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.
5. In the prompt area, click **Done**.

   Abaqus/CAE smooths the position of the selected nodes.

Tip: If you want to restore the nodes to their previous positions, click **Undo** in the **Edit Mesh** dialog box to undo the smoothing.

6. Repeat Steps 4 and 5 as often as necessary to smooth additional nodes.

   You can apply smoothing to the same node multiple times. After a few iterations, a node will no longer be moved by the smoothing algorithm unless other surrounding nodes are moved.

7. When you have finished adjusting nodes, click the cancel button  in the prompt area to exit the procedure.

Additional information

- *What can I do with the Edit Mesh toolset?*

Renumbering nodes

The Edit Mesh toolset allows you to renumber nodes.

Select **Mesh->Edit** from the main menu to renumber selected nodes of an orphan mesh. You can renumber the selected nodes by specifying a starting node label and an increment or by offsetting the existing node label by a specified value. (For information on renumbering the nodes of an Abaqus/CAE native mesh, see *Changing the labels of all nodes and elements*.)

1. Enter the Mesh module.

   This tool is available only for working on parts that do not contain any geometry. You can work in the part or assembly context. However, any renumbering applied to a part instance is applied at the part level and, therefore, affects all instances of that part.

2. From the main menu, select **Mesh->Edit**.

   Abaqus/CAE displays the **Edit Mesh** dialog box.

   Tip: You can also display the **Edit Mesh** dialog box using the  tool, located at the bottom of the Mesh module toolbox.

3. In the dialog box, do the following:

   a. In the **Category** field, select **Node**.

   b. From the **Method** list, select **Renumber**.

   Abaqus/CAE displays the **Node Renumbering** dialog box. If a single mesh part is displayed in the viewport, the **Part Label Range** displays the range of node labels for the entire part.

4. Do either of the following to specify the renumbering method:

   - Choose **By Start Label**, and enter the value of the first node label and the increment that will be used to number subsequent nodes.
   - Choose **By Offset**, and enter the value by which the existing node labels will be offset.

5. Use one of the following methods to select the nodes that you want to renumber:

Selecting all nodes of a part

- Select **All** (in the part context) or **Part** (in the assembly context) to renumber all the orphan mesh nodes of a part. If there is more than one mesh part instance in the viewport, click the  button to select a part instance.

Selecting nodes using the unordered method

1. Select **Specify** and **Unordered** to select the nodes in any sequence.
2. Click **Select** to select the nodes to renumber.
3. From the prompt area, choose the selection method and select the nodes to renumber. For more information, see *Selecting the nodes to edit*.

Selecting nodes using the directed path method

1. Select **Specify** and **Directed Path** to renumber the nodes along a feature edge from a selected start node to a selected end node.
2. Click **Select** to select the nodes to renumber.
3. Select the start node. Abaqus/CAE displays all the nodes along the feature edge. If desired, modify the angle to redefine how Abaqus/CAE defines a feature edge.
4. Select **Done** from the prompt area. The start node is displayed in purple.
5. Select the end node. The start and end nodes must lie on the same feature edge.

Selecting nodes using the sequence method

1. Select **Specify** and **Sequence** to renumber the nodes based on the sequence in which you select the nodes.
2. Click **Select** to select the nodes to renumber.
3. Select the start node and each additional node in sequence.
4. When you have finished selecting nodes, click mouse button 2.

The **Part Label Range** displays the range of node labels for the renumbered nodes.

6. Click **OK** or **Apply** to renumber the nodes. If you click **Apply**, Abaqus/CAE renumbers the nodes; however, the nodes remain selected, and you can continue renumbering them.
7. Repeat the previous steps as often as required to renumber additional nodes.
8. When you have finished renumbering nodes, click **Cancel** to close the **Node Renumbering** dialog box.

Additional information

- *Changing the labels of all nodes and elements*
- *What can I do with the Edit Mesh toolset?*

Selecting the nodes to edit

When you are selecting the nodes to edit, Abaqus/CAE displays a menu in the prompt area that allows you to choose the technique that you will use to select the nodes. The techniques allow you to select individual nodes or groups of adjacent nodes.

1. Use one of the following methods to select the nodes that you want to edit:

To select individual nodes:

1. From the menu in the prompt area, select **Individually**.
2. Select a node that you want to renumber, or drag-select a group of nodes.
3. **[Shift] + Click** on additional nodes to add them to your selection.
4. If necessary, **[Ctrl] + Click** on selected nodes to remove them from your selection.

To select nodes using the angle method:

1. From the menu in the prompt area, select **by angle**.
2. Enter an angle (from 0° to 90°), and select a node.

   Abaqus/CAE selects every node on element faces adjacent to the selected node until the angle between the element faces is equal to or exceeds the angle that you entered. (See *Using the angle and feature edge method to select multiple objects*, for more information.)
3. After you use the **by angle** method, you can **[Shift] + Click** on additional nodes to add them to your selection or **[Ctrl] + Click** on selected nodes to remove them from your selection. (See *Combining selection techniques*, for more information.)

To select nodes using the feature edge method:

1. From the menu in the prompt area, select **by feature edge**.
2. Enter an angle (from 0° to 90°).

   Abaqus/CAE identifies all the feature edges in your model by finding all the element edges where the angle between two adjacent element faces is greater than the angle specified.
3. Select an element edge or node.

   Abaqus/CAE follows the feature edge that passes through the selected element edge or node. The feature edge is truncated if another feature edge intersects it at an angle greater than the angle specified in the previous step.
4. Abaqus/CAE selects all the nodes along the feature edge. (See *Using the angle and feature edge method to select multiple objects*, for more information.) Alternatively, you can select the node at the intersection of multiple feature edges, and Abaqus/CAE selects the nodes along all these feature edges.
5. After you use the **by feature edge** method, you can **[Shift] + Click** on additional nodes to add them to your selection or **[Ctrl] + Click** on selected nodes to remove them from your selection. (See *Combining selection techniques*, for more information.)

To select nodes by specifying an existing node set:

1. Click **Sets** on the right side of the prompt area. Abaqus/CAE displays the **Region Selection** dialog box containing a list of node sets that you have created.
2. Select the set of nodes that you want to renumber, and click **Continue**.

Note:

The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

2. When you have finished selecting nodes, select **Done** from the prompt area.

Additional information

- *Selecting objects within the current viewport*
- *What can I do with the Edit Mesh toolset?*

Editing elements

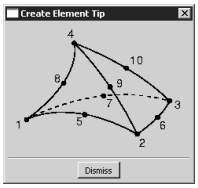
This section describes how you can use the Edit Mesh toolset to edit the elements that comprise orphan meshes and Abaqus/CAE native meshes.

In this section:

- *Creating an element*
- *Deleting elements*
- *Reversing the surface normal direction of shell elements*
- *Orienting the stack direction*
- *Collapsing an edge of a quadrilateral or triangular element*
- *Splitting an edge of a quadrilateral or triangular element*
- *Swapping the diagonal of a pair of adjacent triangular elements*
- *Splitting quadrilateral elements*
- *Combining triangular elements*
- *Renumbering elements*
- *Selecting the elements to edit*

Creating an element

Select **Mesh->Edit** from the main menu bar to create elements from selected nodes.



1. Enter the Mesh module.
2. From the **Object** field in the context bar, select **Part** and select a part from the list.
3. From the main menu bar, select **Mesh->Edit**.

   Abaqus/CAE displays the **Edit Mesh** dialog box.

   Tip: You can also display the **Edit Mesh** dialog box using the tool, located at the bottom of the Part module and Mesh module toolbox.

4. In the dialog box, do the following:
   a. In the **Category** field, select **Element**.
   b. From the **Method** list, select **Create**.

   Abaqus/CAE displays the existing nodes. In hidden and shaded mode only the visible nodes are displayed.
5. In the prompt area, click the arrow next to the **Element shape** field, and select the element shape of your choice from the list that appears.
6. In the viewport, select the nodes that will define the element. You must select the required number of nodes for the element shape specified in the previous step. In addition, you must select the nodes in a specific order. From the right of the prompt area, click **Tip** to see a figure of the element shape and connectivity. For example, Abaqus/CAE displays the following figure when you are creating a 10-node tetrahedral element:

   Once you have selected the required number of nodes, Abaqus/CAE creates the new element.

   Tip: If you make a mistake while creating an element, click **Undo** in the **Edit Mesh** dialog box to remove the most recently created element.

7. Repeat the previous steps as often as necessary to create additional elements. If you change the element shape, click the **Tip** button again to update the element shape and connectivity figure.
8. When you have finished creating elements, click mouse button 2 or the cancel button in the prompt area to exit the procedure.

Additional information

- *What can I do with the Edit Mesh toolset?*

Deleting elements

Select **Mesh->Edit** from the main menu bar to delete elements. You have the option of instructing Abaqus/CAE to delete any nodes that are left unassociated with any elements once the elements are deleted. If the elements and associated nodes that you are deleting belong to existing element or node sets, those sets are updated accordingly.

1. Enter the Mesh module.
2. From the **Object** field in the context bar, select **Part** and select a part from the list. This tool is available only for working on orphan mesh elements or for working on elements created using the bottom-up meshing procedure
3. From the main menu bar, select **Mesh->Edit**.

   Abaqus/CAE displays the **Edit Mesh** dialog box.

   Tip: You can also display the **Edit Mesh** dialog box using the tool, located at the bottom of the Mesh module toolbox.

4. In the dialog box, do the following:
   a. In the **Category** field, select **Element**.
   b. From the **Method** list, select **Delete**.
5. If you want to delete all nodes that are left unassociated with any elements once the selected elements are deleted, toggle on **Delete associated unreferenced nodes** in the prompt area.
6. Select the elements to delete. You can **[Shift] + Click** on elements to add them to your selection or **[Ctrl] + Click** on selected elements to remove them from your selection.

   Tip: You can use the **Selection** toolbar to change the picking behavior. For more information, see *Selecting objects within the viewport*.

   If you would rather select from a list of existing element sets, do the following:
   a. Click **Sets** on the right side of the prompt area.

      Abaqus/CAE displays the **Region Selection** dialog box containing a list of element sets that you have created.
   b. Select the set of elements that you want to delete, and click **Continue**.

   Note: The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

   Abaqus/CAE displays the selected elements.
7. When you have finished selecting elements to delete, click mouse button 2.

   Abaqus/CAE deletes the selected elements. In addition, if you toggled on **Delete associated unreferenced nodes**, Abaqus/CAE also deletes nodes that would be left unassociated with any elements once the selected elements are deleted. The elements and nodes are also removed from any existing sets.

   Tip: If you make a mistake while deleting elements, click **Undo** in the **Edit Mesh** dialog box to undo the deletion. Abaqus/CAE restores the deleted element or elements.
8. Repeat the above steps as often as necessary to delete additional elements.

9. When you have finished deleting elements, click mouse button 2 or the cancel button  in the prompt area to exit the procedure.

Additional information

- *What can I do with the Edit Mesh toolset?*

Reversing the surface normal direction of shell elements

Select **Mesh->Edit** from the main menu bar to reverse the surface normals of selected shell elements. The elements can be either quadrilaterals or triangles. During the procedure to reverse the surface normals, Abaqus/CAE displays the part using the shaded render style, and the front and back faces of each shell element appear in different colors. If you change the direction of the surface normal in a region, Abaqus/CAE does not change the orientation of prescribed conditions or named surfaces applied to that region.

1. Enter the Mesh module.
2. From the **Object** field in the context bar, select **Part** and select a part from the list.
3. From the main menu bar, select **Mesh->Edit**.

   Abaqus/CAE displays the **Edit Mesh** dialog box.

   Tip: You can also display the **Edit Mesh** dialog box using the tool, located at the bottom of the Mesh module toolbox.

4. In the dialog box, do the following:
   a. In the **Category** field, select **Element**.
   b. From the **Method** list, select **Flip Normal**.

      Abaqus/CAE displays the part using the shaded render style. The front of each element is colored brown, and the back of each element is colored purple.

5. From the prompt area, choose the type of region, **Geometry** or **Mesh**, and toggle **Highlight conflicting edges** to display or hide a yellow border between connecting elements that have conflicting normals.
6. From the prompt area, choose the selection method and select the shell region or orphan shell elements whose normals you want to reverse. For more information, see *Selecting the elements to edit*.
7. When you have finished selecting regions or elements, select **Done** from the prompt area.

   If you selected geometric regions, Abaqus/CAE changes the normals of the elements and returns to Step 5.
8. If you selected orphan elements, choose a method for reversing the surface normal:
   - Click **Flip all** to reverse the normal of all selected elements.
   - Click **Select normal** to change the normals of the selected elements so that they point in the same direction as the normal of a reference element that you specify.
9. If you chose **Select normal** in the previous step, do the following:
   a. In the viewport, select the reference element.
   b. In the prompt area, click **OK**.

      Abaqus/CAE changes the normals of the selected elements so that they point in the same direction as the reference element normal and returns to Step 5 so you can make more selections.
10. Click mouse button 2 to exit the procedure.

    Abaqus/CAE reverts to the render style that was selected prior to starting the procedure to reverse the surface normals.

Tip: If you make a mistake while reversing the surface normals of orphan elements, click **Undo** in the **Edit Mesh** dialog box to undo the change. Abaqus/CAE restores the original surface normals for the selected elements.

If you make a mistake while reversing the surface normals of native elements in a geometric region, select the region and reverse the normals again.

Additional information

- *What can I do with the Edit Mesh toolset?*

Orienting the stack direction

Select **Mesh->Edit** from the main menu bar to orient the stack direction of elements in a continuum shell, cohesive, cylindrical, or gasket mesh. You can orient only hexahedral, wedge, and quadrilateral elements because these are the only elements that can be stacked to form a continuum shell, cohesive, cylindrical, or gasket mesh. If you have assigned cylindrical elements or second-order gasket elements to the region, you must first change the assignment to conventional elements before you reorient the stack direction. You can then convert the region back to a cylindrical or gasket mesh by reassigning cylindrical elements or second-order gasket elements. If you change the orientation of the stack direction of elements in a region, Abaqus/CAE does not change the orientation of prescribed conditions or named surfaces applied to that region.

1. Enter the Mesh module.
2. From the **Object** field in the context bar, select **Part** and select a part from the list. This tool is available only for working on orphan mesh elements. To change the stack direction of native elements, see *Applying a mesh stack orientation*.
3. From the main menu bar, select **Mesh->Edit**.

   Abaqus/CAE displays the **Edit Mesh** dialog box.

   Tip: You can also display the **Edit Mesh** dialog box using the  tool, located at the bottom of the Mesh module toolbox.

4. In the dialog box, do the following:
   a. In the **Category** field, select **Element**.
   b. From the **Method** list, select **Orient stack direction**.

      For hexahedral and wedge elements, Abaqus/CAE colors the bottom face of the mesh stack purple and the top face brown. Similarly, an arrow indicates the orientation of quadrilateral elements. In addition, Abaqus/CAE highlights in red any element faces and edges that have inconsistent orientation. For more information, see *Continuum shells*, *Creating a model with cohesive elements using geometry and mesh tools*, *Gaskets*, and *Swept meshing of cylindrical solids*.

5. In the viewport, select the elements to orient. You can **[Shift] + Click** on individual elements to add them to your selection or **[Ctrl] + Click** on selected elements to remove them from your selection.

   Tip: You can use the **Selection** toolbar to change the picking behavior. For more information, see *Selecting objects within the viewport*.

6. When you have finished selecting elements to orient, click mouse button 2.
7. If your part is meshed with hexahedral or wedge elements, pick a face from one of the selected elements. Abaqus/CAE uses the picked face to represent the top face of the reference orientation. If your part is meshed with quadrilateral elements, pick an edge from one of the selected elements. Abaqus/CAE orients the elements toward the picked edge.

   Tip: If you make a mistake while orienting elements, click **Undo** in the **Edit Mesh** dialog box to undo the change. Abaqus/CAE restores the original orientation for those elements.

8. Repeat the previous steps as often as necessary to orient additional elements.

9. When you have finished orienting elements, click mouse button 2 or the cancel button  in the prompt area to exit the procedure.

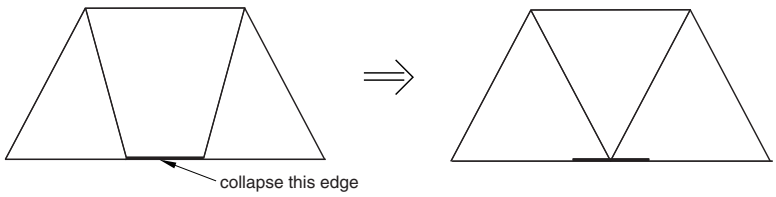
Collapsing an edge of a quadrilateral or triangular element

The Edit Mesh toolset allows you to replace the two nodes at either end of particular element edges with a single node.

Select **Mesh->Edit** from the main menu bar to collapse a selected edge of a triangular or quadrilateral element. In effect, you are replacing the two nodes at either end of the element edge with a single node. You can choose between two methods for positioning the single node:



direction

Choose **direction** to collapse the element edge in the specified direction. From the buttons in the prompt area, select **Flip** to change the direction in which Abaqus/CAE will collapse the element. The following figure shows how the **direction** method collapses an element edge along with the effect of changing the direction:

average

Choose **average** to collapse the element edge and readjust the remaining element edges to meet at the midpoint of the collapsed edge. The following figure shows how the **average** method collapses an element edge:

1. Enter the Mesh module.
2. From the **Object** field in the context bar, select **Part** and select a part from the list.
3. From the main menu bar, select **Mesh->Edit**.

   Abaqus/CAE displays the **Edit Mesh** dialog box.

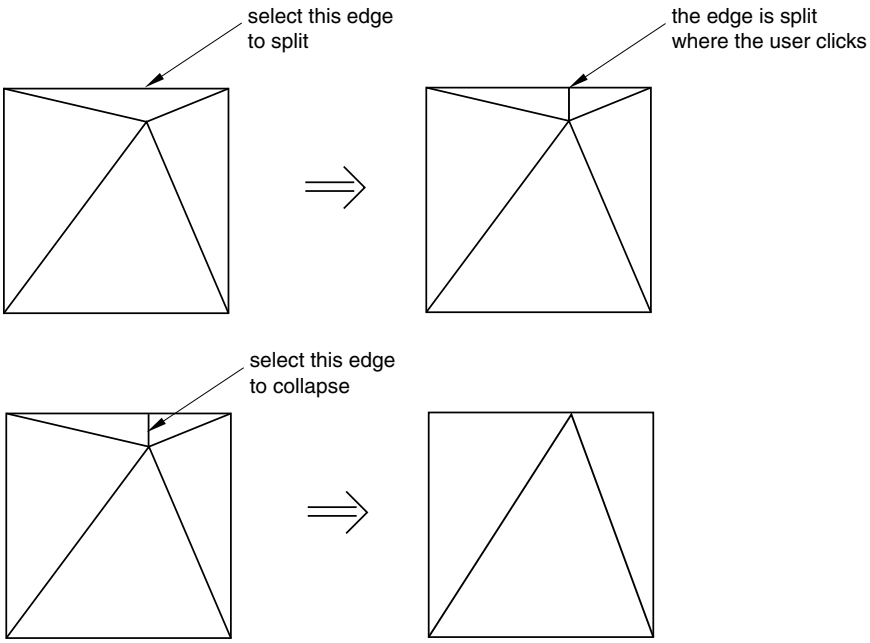
Tip: You can also display the **Edit Mesh** dialog box using the tool, located at the bottom of the Mesh module toolbox.

4. In the dialog box, do the following:
   a. In the **Category** field, select **Element**.
   b. From the **Method** list, select **Collapse edge (tri/quad)**.
5. From the menu in the prompt area, choose the method that Abaqus/CAE will use to collapse the edge.
   - Choose **direction** to collapse the element edge in the specified direction.
   - Choose **average** to collapse the element edge and readjust the remaining elements to meet at the midpoint of the collapsed edge.
6. Select the element edge to collapse. You can select only a single edge.

   Abaqus/CAE highlights the selected edge and prompts you to confirm that you want to collapse the selected edge.
7. From the buttons in the prompt area, click **Yes** to collapse the selected edge.

   Abaqus/CAE prompts you to select the next edge to collapse.
8. Repeat the previous steps as often as necessary to collapse additional edges.
9. When you have finished collapsing edges, click mouse button 2 or the cancel button in the prompt area to exit the procedure.

Tip: If you make a mistake while collapsing edges, click **Undo** in the **Edit Mesh** dialog box to undo the change. Abaqus/CAE restores the mesh to its state just before the operation.



Additional information

- *What can I do with the Edit Mesh toolset?*

Splitting an edge of a quadrilateral or triangular element

The Edit Mesh toolset allows you to split an edge of a quadrilateral or triangular element into two parts.

Select **Mesh->Edit** from the main menu bar to split an edge of a quadrilateral or triangular element into two parts. The following figure shows how you can split an edge and then collapse the resulting edge to remove a long narrow triangular element:

When you split a quadrilateral element, Abaqus/CAE creates the edges that will result in the best-shaped elements based on angle measurements. You cannot select which edges Abaqus/CAE will create. However, after Abaqus/CAE splits the edge, you can use the **Swap diagonal (tri)** tool to change the diagonal; for more information, see *Swapping the diagonal of a pair of adjacent triangular elements*.

1. Enter the Mesh module and do one of the following:
   - From the **Object** field in the context bar, select **Assembly**.
   - From the **Object** field in the context bar, select **Part** and select a part from the list.
2. From the main menu bar, select **Mesh->Edit**.

   Abaqus/CAE displays the **Edit Mesh** dialog box.

   Tip: You can also display the **Edit Mesh** dialog box using the tool, located at the bottom of the Mesh module toolbox.
3. In the dialog box, do the following:
   a. In the **Category** field, select **Element**.
   b. From the **Method** list, select **Split edge (tri/quad)**.
4. From the menu in the prompt area, select the method that you will use to determine the location of the split along the edge. You can choose either **midpoint** or **picked location**.

5. If you chose **midpoint** to determine the location, select the edge to split. You can select only a single edge.

   Abaqus/CAE highlights the edges it will insert to split the selected edge at the midpoint.

6. If you chose **picked location** to determine the location, click on the edge at the location of the desired split.

   Abaqus/CAE highlights the edges it will insert to split the selected edge at the picked location.

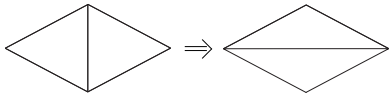
7. From the prompt area, click **Split Edge**.

   Abaqus/CAE splits the edge and prompts you to select the next edge to split.

   Tip: If you make a mistake while splitting element edges, click **Undo** in the **Edit Mesh** dialog box to undo the split.

8. Repeat the above steps as often as necessary to split additional edges.

9. When you have finished splitting edges, click mouse button 2 or the cancel button  in the prompt area to exit the procedure.



Additional information

- *What can I do with the Edit Mesh toolset?*

Swapping the diagonal of a pair of adjacent triangular elements

The Edit Mesh toolset allows you to swap the diagonal of a pair of adjacent triangular elements.

Select **Mesh->Edit** from the main menu bar to swap the diagonal of a pair of adjacent triangular elements, as shown in the following figure:

The adjacent triangular elements must have consistent normals. If necessary, you can use the Edit Mesh toolset to flip the normals; for more information, see *Reversing the surface normal direction of shell elements*.

1. Enter the Mesh module and do one of the following:
   - From the **Object** field in the context bar, select **Assembly**.
   - From the **Object** field in the context bar, select **Part** and select a part from the list.
2. From the main menu bar, select **Mesh->Edit**.

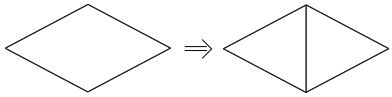
   Abaqus/CAE displays the **Edit Mesh** dialog box.

   Tip: You can also display the **Edit Mesh** dialog box using the tool, located at the bottom of the Mesh module toolbox.
3. In the dialog box, do the following:
   a. In the **Category** field, select **Element**.
   b. From the **Method** list, select **Swap diagonal (tri)**.
4. Select the edge of the adjacent triangular elements to swap. You can select only a single edge.

   Abaqus/CAE highlights the selected edge and prompts you to confirm that you want to swap the selected edge.
5. Click **Yes** to swap the element edge.

   Abaqus/CAE prompts you to select the next element edge to swap.

   Tip: If you make a mistake while swapping a diagonal, click **Undo** in the **Edit Mesh** dialog box to undo the change. Abaqus/CAE restores the original diagonal in the two adjacent elements.
6. When you have finished swapping diagonals, click mouse button 2 or the cancel button in the prompt area to exit the procedure.



Additional information

- *What can I do with the Edit Mesh toolset?*

Splitting quadrilateral elements

The Edit Mesh toolset allows you to split quadrilateral elements into two triangular elements.

Select **Mesh->Edit** from the main menu bar to split quadrilateral elements into two triangular elements, as shown in the following figure:

You cannot split a 5-node quadrilateral element, and you cannot split a quadrilateral-shaped gasket element. You can select multiple quadrilateral elements to split as long as they are from the same part.

1. Enter the Mesh module and do one of the following:
   - From the **Object** field in the context bar, select **Assembly**.
   - From the **Object** field in the context bar, select **Part** and select a part from the list.
2. From the main menu, select **Mesh->Edit**.

   Abaqus/CAE displays the **Edit Mesh** dialog box.

   Tip: You can also display the **Edit Mesh** dialog box using the tool, located at the bottom of the Mesh module toolbox.
3. In the dialog box, do the following:
   a. In the **Category** field, select **Element**.
   b. From the **Method** list, select **Split (quad to tri)**.
4. Select the quadrilateral elements to split. You can use any of the selection techniques described in *Selecting objects within the current viewport*.

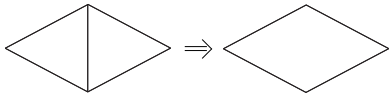
   If your selection includes elements that are not quadrilaterals, Abaqus/CAE automatically removes them from the selection.

   Abaqus/CAE highlights the diagonal it will use to split each quadrilateral element into two triangular elements and prompts you to continue. Abaqus/CAE selects the diagonals that will create the best-shaped elements based on angle measurements. You cannot select which diagonal of the quadrilateral Abaqus/CAE uses to split the element. However, after Abaqus/CAE splits the elements, you can use the **Swap diagonal (tri)** tool to change the diagonals; for more information, see *Swapping the diagonal of a pair of adjacent triangular elements*.
5. Click **Yes** to split the selected elements.

   Abaqus/CAE prompts you to select more elements to split.

   Tip: If you make a mistake while splitting quadrilateral elements, click **Undo** in the **Edit Mesh** dialog box to undo the change.

6. When you have finished splitting elements, click mouse button 2 or the cancel button  in the prompt area to exit the procedure.



Additional information

- *What can I do with the Edit Mesh toolset?*

Combining triangular elements

The Edit Mesh toolset allows you to combine two adjacent triangular elements into a single quadrilateral element.

Select **Mesh->Edit** from the main menu bar to combine two adjacent triangular elements into a single quadrilateral element, as shown in the following figure:

You can combine either first- or second-order elements, but you cannot combine a combination of both. In addition, you can combine elements only if the adjacent triangular elements have consistent normals. If necessary, you can use the Edit Mesh toolset to flip the normals; for more information, see *Reversing the surface normal direction of shell elements*.

1. Enter the Mesh module and do one of the following:
   - From the **Object** field in the context bar, select **Assembly**.
   - From the **Object** field in the context bar, select **Part** and select a part from the list.
2. From the main menu bar, select **Mesh->Edit**.

   Abaqus/CAE displays the **Edit Mesh** dialog box.

   Tip: You can also display the **Edit Mesh** dialog box using the tool, located at the bottom of the Mesh module toolbox.
3. In the dialog box, do the following:
   a. In the **Category** field, select **Element**.
   b. From the **Method** list, select **Combine (tri to quad)**.
4. Select the first triangular element to combine.
5. Select the second triangular element to combine. The second element must be adjacent to the first, and the second element must be the same order as the first.

   Abaqus/CAE indicates how it will combine two adjacent triangular elements into a single quadrilateral element and prompts you to continue.
6. Click **Yes** to combine the elements.

   Abaqus/CAE prompts you to select the next elements to combine.

   Tip: If you make a mistake while combining triangular elements, click **Undo** in the **Edit Mesh** dialog box to undo the change. Abaqus/CAE restores the two triangular elements.
7. When you have finished combining elements, click mouse button 2 or the cancel button in the prompt area to exit the procedure.

Additional information

- *What can I do with the Edit Mesh toolset?*

Renumbering elements

The Edit Mesh toolset allows you to renumber elements.

Select **Mesh->Edit** from the main menu to renumber selected elements. You can renumber the selected elements by specifying a starting label and an increment or by offsetting the existing label by a specified value. (For information on renumbering the elements of an Abaqus/CAE native mesh, see *Changing the labels of all nodes and elements*.)

1. Enter the Mesh module.

   This tool is available only for working on parts that do not contain any geometry. You can work in the part or assembly context. However, any renumbering applied to a part instance is applied at the part level and, therefore, affects all instances of that part.

2. From the main menu, select **Mesh->Edit**.

   Abaqus/CAE displays the **Edit Mesh** dialog box.

   Tip: You can also display the **Edit Mesh** dialog box using the  tool, located at the bottom of the Mesh module toolbox.

3. In the dialog box, do the following:

   a. In the **Category** field, select **Element**.

   b. From the **Method** list, select **Renumber**.

   Abaqus/CAE displays the **Element Renumbering** dialog box. If a single mesh part is displayed in the viewport, the **Part Label Range** displays the range of element labels for the entire part.

4. Do either of the following to specify the renumbering method:

   - Choose **By Start Label**, and enter the value of the first element label and the increment that will be used to number subsequent elements.
   - Choose **By Offset**, and enter the value by which the existing element labels will be offset.

5. Use one of the following methods to select the elements that you want to renumber:

Selecting all elements of a part

- Select **All** (in the part context) or **Part** (in the assembly context) to renumber all the orphan mesh elements of a part. If there is more than one mesh part instance in the viewport, click the  button to select a part instance.

Selecting elements using the unordered method

1. Select **Specify** and **Unordered** to select the elements in any sequence.
2. Click **Select** to select the elements to renumber.
3. From the prompt area, choose the selection method and select the elements to renumber. For more information, see *Selecting the elements to edit*.

Selecting elements using the directed path method

1. Select **Specify** and **Directed Path** to renumber the elements along an edge from a selected start element to a selected end element.
2. Click **Select** to select the elements to renumber.
3. Select the start element. Abaqus/CAE displays all the elements along the feature edge. If desired, modify the angle to redefine how Abaqus/CAE defines a feature edge.
4. Select **Done** from the prompt area.
5. Select the end element. The start and end elements must lie on the same feature edge.

Selecting elements using the sequence method

1. Select **Specify** and **Sequence** to renumber the elements based on the sequence in which you select the elements.
2. Click **Select** to select the elements to renumber.
3. Select the start element. Abaqus/CAE displays all the elements along the feature edge. If desired, modify the angle to redefine how Abaqus/CAE defines a feature edge.
4. Select **Done** from the prompt area. The start element is displayed in purple.
5. Select the end element. The start and end elements must lie on the same feature edge.

The **Part Label Range** displays the range of element labels for the renumbered elements.

6. Click **OK** or **Apply** to renumber the elements. If you click **Apply**, Abaqus/CAE renumbers the elements; however, the elements remain selected, and you can continue renumbering them.
7. Repeat the previous steps as often as required to renumber additional elements.
8. When you have finished renumbering elements, click **Cancel** to close the **Element Renumbering** dialog box.

Additional information

- *Changing the labels of all nodes and elements*
- *What can I do with the Edit Mesh toolset?*

Selecting the elements to edit

When you are selecting the elements to edit, Abaqus/CAE displays a menu in the prompt area that allows you to choose the technique that you will use to select the elements. The techniques allow you to select individual nodes or groups of adjacent elements.

1. Use one of the following methods to select the elements that you want to edit:

Selecting individual elements

1. From the menu in the prompt area, select **Individually**.
2. Select an element that you want to renumber, or drag-select a group of elements.
3. **[Shift] + Click** on additional elements to add them to your selection.
4. If necessary, **[Ctrl] + Click** on selected elements to remove them from your selection.

Selecting elements using the angle method

1. From the menu in the prompt area, select **by angle**.
2. Enter an angle (from 0° to 90°), and select an element. Abaqus/CAE selects every element on element faces adjacent to the selected element until the angle between the element faces is equal to or exceeds the angle that you entered. (See *Using the angle and feature edge method to select multiple objects*, for more information.)
3. After you use the **by angle** method, you can **[Shift] + Click** on additional elements to add them to your selection or **[Ctrl] + Click** on selected elements to remove them from your selection. (See *Combining selection techniques*, for more information.)

Selecting elements using the feature edge method

1. From the menu in the prompt area, select **by feature edge**.
2. Enter an angle (from 0° to 90°). Abaqus/CAE identifies all the feature edges in your model by finding all the element edges where the angle between two adjacent element faces is greater than the angle specified.
3. Select an element edge. Abaqus/CAE follows the feature edge that passes through the selected element edge or node. The feature edge is truncated if another feature edge intersects it at an angle greater than the angle specified in the previous step.
4. Abaqus/CAE selects all the elements along the feature edge. (See *Using the angle and feature edge method to select multiple objects*, for more information.) Alternatively, you can select the node at the intersection of multiple feature edges, and Abaqus/CAE selects the elements along all these feature edges.
5. After you use the **by feature edge** method, you can **[Shift] + Click** on additional elements to add them to your selection or **[Ctrl] + Click** on selected elements to remove them from your selection. (See *Combining selection techniques*, for more information.)

Specifying an existing element set

1. Click **Sets** on the right side of the prompt area. Abaqus/CAE displays the **Region Selection** dialog box containing a list of element sets that you have created.

2. Select the set of elements that you want to renumber, and click **Continue**.

Note:

The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

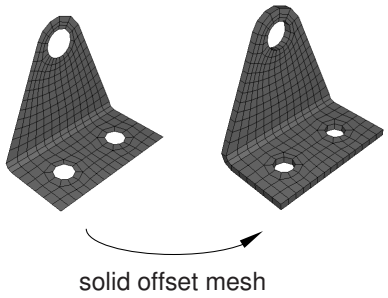
2. When you have finished selecting elements, select **Done** from the prompt area.

Additional information

- *Selecting objects within the current viewport*
- *What can I do with the Edit Mesh toolset?*

Editing the entire mesh

This section describes how you can use the Edit Mesh toolset to perform a global edit of a mesh containing orphan mesh components or Abaqus/CAE native mesh components or a combination of both mesh types.



In this section:

- *Generating layers of solid elements offset from an existing mesh*
- *Generating layers of shell elements offset from an existing mesh*
- *Wrapping a mesh about the Z-axis*
- *Collapsing short edges of a linear orphan mesh*
- *Growing short edges of a linear orphan mesh*
- *Converting a triangular shell mesh to a solid tetrahedral mesh*
- *Converting a solid orphan mesh to a shell orphan mesh*
- *Merging elements*
- *Subdividing elements*
- *Copying a mesh pattern*
- *Viewing and editing mesh-geometry associativity*
- *Deleting mesh-geometry associativity*
- *Inserting cohesive seams*

Generating layers of solid elements offset from an existing mesh

The Edit Mesh toolset allows you to generate layers of solid elements that are offset normal to element faces selected from an existing mesh.

Select **Mesh->Edit** from the main menu bar to generate layers of solid elements that are offset normal to element faces selected from an existing mesh, as shown in the following figure:

1. Enter the Mesh module.
2. From the **Object** field in the context bar, select **Part** and select a part from the list.
3. From the main menu bar, select **Mesh->Edit**.

   Abaqus/CAE displays the **Edit Mesh** dialog box.

   Tip: You can also display the **Edit Mesh** dialog box using the tool, located at the bottom of the Mesh module toolbox.

4. In the dialog box, do the following:
   a. In the **Category** field, select **Mesh**.
   b. From the **Method** list, select **Offset (create solid layers)**.
5. Use one of the following methods to select the element faces from which Abaqus/CAE will generate the layers of solid elements. You can select shell element faces or solid element faces, but you cannot select both. If you select shell element faces, the direction of the surface normals of adjacent shell elements must be consistent. You can reverse the surface normal direction of shell elements using the **Flip normal** tool. For more information, see *Reversing the surface normal direction of shell elements*.

Selecting individual elements

1. From the menu in the prompt area, select **Individually**.
2. Select the element faces.
3. **[Shift] + Click** additional element faces to add them to your selection.
4. If necessary, **[Ctrl] + Click** selected element faces to unselect them.
5. When you have finished selecting element faces, click mouse button 2.

Specifying an existing surface

1. Click **Surfaces** on the right side of the prompt area.

Abaqus/CAE displays the **Region Selection** dialog box containing a list of surfaces that you have created.

2. Select the surfaces, and click **Continue**. The surface must contain only quadrilateral or triangular faces.

Note:

The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Surfaces** on the right side of the prompt area.

Selecting elements using the angle method

1. From the menu in the prompt area, select **by angle**.
2. Enter an angle (from 0° to 90°), and select an element face. Abaqus/CAE selects every adjacent element face from the selected face until the angle between the element faces is equal to or exceeds the angle that you entered. (See *Using the angle and feature edge method to select multiple objects*, for more information.)
3. After you use the **by angle** method, you can **[Shift] + Click** additional element faces to add them to your selection or **[Ctrl] + Click** selected element faces to remove them from your selection. (See *Combining selection techniques*, for more information.)
4. When you have finished selecting element faces, click mouse button 2.

6. From the **Offset Mesh - Solid Layers** dialog box that appears, do the following:
   a. If you selected shell element faces from which to offset, you can choose the color that indicates the desired offset direction. The two colors from which you can choose correspond to the two sides of the selected element faces. You can also choose **Both** to indicate that Abaqus/CAE should create layers of solid elements on both sides of the selected shell elements.
   b. Enter the **Total thickness** of all the layers combined. The value that you enter must be positive. However, you can enter a value of 0 if you are creating zero-thickness elements that will be used in a cohesive analysis.
   c. Enter the **Number of layers**.
   d. If desired, toggle on **Specify initial offset**, and enter a value for the initial offset. A negative initial offset indicates overclosure between elements.
   e. If the surface from which you are offsetting contains sharp corners, toggle on **Constant thickness around corners**. You should also toggle this option on if you anticipate that the generated offset elements may collapse or become inverted. For more information, see *Reducing element distortion and collapse during mesh offsetting*.
   f. To share the nodes of the first layer of solid elements with the nodes of the selected element faces, toggle on **Share nodes with base shell/surface**. This option is available only if the first layer of solid elements is not offset from the selected element faces.
   g. To delete the selected shell elements after creating the layers of solid elements, toggle on **Delete base shell elements**. This option is available only if you selected orphan shell element faces from which to offset.
   h. If you want to create a single set containing all of the elements from the solid offset mesh, toggle on **Create a set for new elements**.
   i. If you want to create separate sets containing the elements from each layer of the solid offset mesh, toggle on **Separate set for each layer**. Abaqus/CAE appends **Layer-*layer number*** to the set name prefix when it creates separate sets for each layer.

j. If all or part of the solid offset mesh will not be embedded in the existing mesh, you can create surfaces from the top and bottom surfaces of the offset mesh. by toggling on **Create top and bottom surfaces**. Abaqus/CAE appends **BottomSurf** and **TopSurf** to the name prefix when it creates the two surfaces.

k. If desired, enter a new name for the single set or a new prefix for the separate sets and/or surfaces.

7. Abaqus/CAE creates the layers of solid elements offset normal to the selected element faces. When you have finished generating layers of solid elements, click mouse button 2 or the cancel button  in the prompt area to exit the procedure.

Tip: If you make a mistake while generating layers of elements, click **Undo** in the **Edit Mesh** dialog box to undo the change. Abaqus/CAE restores the mesh to its state just before the operation.

After editing an orphan mesh, you should always verify node-, element-, and surface-based features such as section assignments, loads, and interactions to ensure that they are correctly applied to the modified mesh.

Generating layers of shell elements offset from an existing mesh

The Edit Mesh toolset allows you to generate layers of shell elements that are offset normal to element faces selected from an existing mesh.

Select **Mesh->Edit** from the main menu bar to generate layers of shell elements that are offset normal to element faces selected from an existing mesh, as shown in the following figure:

1. Enter the Mesh module.
2. From the **Object** field in the context bar, select **Part** and select a part from the list.
3. From the main menu bar, select **Mesh->Edit**.

   Abaqus/CAE displays the **Edit Mesh** dialog box.

   Tip: You can also display the **Edit Mesh** dialog box using the tool, located at the bottom of the Mesh module toolbox.

4. In the dialog box, do the following:
   a. In the **Category** field, select **Mesh**.
   b. From the **Method** list, select **Offset (create shell layers)**.
5. Use one of the following methods to select the element faces from which Abaqus/CAE will generate the layers of shell elements. You can select shell element faces or solid element faces, but you cannot select both. If you select shell element faces, the direction of the surface normals of adjacent shell elements must be consistent. You can reverse the surface normal direction of shell elements using the **Flip normal** tool. For more information, see *Reversing the surface normal direction of shell elements*.

Selecting individual elements

1. From the menu in the prompt area, select **Individually**.
2. Select the element faces.
3. **[Shift] + Click** additional element faces to add them to your selection.
4. If necessary, **[Ctrl] + Click** selected element faces to unselect them.
5. When you have finished selecting element faces, click mouse button 2.

Specifying an existing surface

1. Click **Surfaces** on the right side of the prompt area.

Abaqus/CAE displays the **Region Selection** dialog box containing a list of surfaces that you have created.

2. Select the surfaces, and click **Continue**. The surface must contain only quadrilateral or triangular faces.

Note:

The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Surfaces** on the right side of the prompt area.

Selecting elements using the angle method

1. From the menu in the prompt area, select **by angle**.
2. Enter an angle (from 0° to 90°), and select an element face. Abaqus/CAE selects every adjacent element face from the selected face until the angle between the element faces is equal to or exceeds the angle that you entered. (See *Using the angle and feature edge method to select multiple objects*, for more information.)
3. After you use the **by angle** method, you can **[Shift] + Click** additional element faces to add them to your selection or **[Ctrl] + Click** selected element faces to remove them from your selection. (See *Combining selection techniques*, for more information.)
4. When you have finished selecting element faces, click mouse button 2.

6. From the **Offset Mesh - Shell Layers** dialog box that appears, do the following:
   a. If you selected shell element faces from which to offset, you can choose the color that indicates the desired offset direction. The two colors from which you can choose correspond to the two sides of the selected element faces. You can also choose **Both** to indicate that Abaqus/CAE should create layers of shell elements on both sides of the selected shell elements.
   b. Enter the **Distance between layers**. You can enter a value of 0; for example, if you want to create multiple layers of skin reinforcements that share nodes.
   c. Enter the **Number of layers**.
   d. If desired, toggle on **Specify initial offset**, and enter a value for the initial offset. A negative initial offset indicates overclosure between elements.
   e. If the surface from which you are offsetting contains sharp corners, toggle on **Constant thickness around corners**. You should also toggle this option on if you anticipate that the generated offset elements may collapse or become inverted. For more information, see *Reducing element distortion and collapse during mesh offsetting*.
   f. To share the nodes of the first layer of shell elements with the nodes of the selected element faces, toggle on **Share nodes with base shell/surface**. This option is available only if the first layer of shell elements is not offset from the selected element faces.
   g. To delete the selected shell elements after creating the layers of shell elements, toggle on **Delete base shell elements**. This option is available only if you selected orphan shell element faces from which to offset.
   h. If you want to create a single set containing all of the elements from the shell offset mesh, toggle on **Create a set for new elements**.
   i. If you want to create separate sets containing the elements from each layer of the shell offset mesh, toggle on **Separate set for each layer**. Abaqus/CAE appends **Layer-*layer number*** to the set name prefix when it creates separate sets for each layer.
   j. If desired, enter a new name for the single set or a new prefix for the separate sets.

7. Abaqus/CAE creates the layers of shell elements offset normal to the selected element faces. When you have finished generating layers of shell elements, click mouse button 2 or the cancel button  in the prompt area to exit the procedure.

    **Tip:** If you make a mistake while generating layers of elements, click **Undo** in the **Edit Mesh** dialog box to undo the change. Abaqus/CAE restores the mesh to its state just before the operation.

After editing an orphan mesh, you should always verify node-, element-, and surface-based features such as section assignments, loads, and interactions to ensure that they are correctly applied to the modified mesh.

Wrapping a mesh about the Z-axis

Use the Abaqus Scripting Interface method `wrapMesh` to wrap a planar orphan mesh around a cylindrical surface defined by the global *Z*-axis and a specified radius.
The planar mesh must lie in the *X*–*Y* plane, and the modeling space of the part should be three-dimensional. If necessary, you can change the modeling space of a part by clicking mouse button 3 on the part in the Model Tree and selecting **Edit** from the menu that appears.

The wrapping procedure will relocate a node at point (x, y) on the planar mesh to (r, θ, z), where r is the specified radius, $\theta = \frac{x}{r}$, and $z=y$, as shown in *Figure 1*. A point on the planar orphan mesh located at (0, 0) is mapped to location $(r, 0, 0)$ on the cylindrical surface.

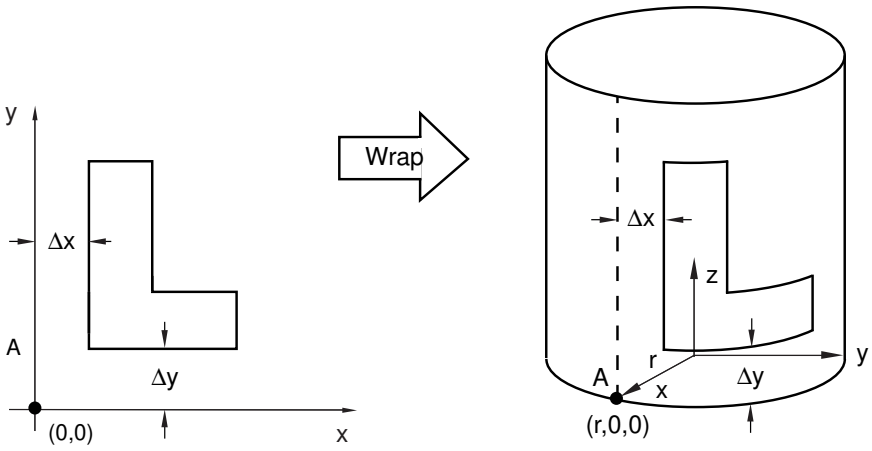

Figure 1: Wrapping a planar orphan mesh.

Because only part instances can be positioned and only parts can be wrapped, if you want to create an instance of an orphan mesh that is wrapped and oriented properly in the assembly, some planning is required. The following steps will help you achieve the desired goal:

1. Use the tools in the Assembly module to translate and/or rotate an instance of the planar orphan mesh in the assembly.
2. Use the **Create Mesh Part** tool in the Mesh module to create a planar mesh part from the reoriented instance.
3. Wrap the reoriented mesh part.
4. Create an instance of the wrapped part, and use the tools in the Assembly module to translate and/or rotate the instance in the assembly.

If you are trying to create a full 360° wrap, discretization approximations may result in a small gap between nodes along the seam edge. You must use the merge nodes tool to stitch the seam by merging pairs of nodes into a single node; for more information, see *Merging nodes*.

The following shows an example of using the Abaqus Scripting Interface to wrap a mesh:

```
model = mdb.models['Model-1']
part = model.parts['Part-1']
part.wrapMesh(radius=5.0)
```

You can use the command line interface to enter Abaqus Scripting Interface commands, as described in *Using the Python interpreter*.

Additional information

- *What can I do with the Edit Mesh toolset?*

• *Edit mesh commands*

Collapsing short edges of a linear orphan mesh

Select **Mesh->Edit** from the main menu bar to collapse selected edges of a linear orphan mesh. You can specify the minimum length of the edges of elements that should be collapsed, and Abaqus/CAE will merge the end nodes of element edges that are shorter than the specified length. You can specify an element domain other than the entire mesh, and you can specify a direction and/or reference edge to collapse only those edges that match these criteria. You can collapse the mesh only if the element domain contains only linear elements.

1. Enter the Mesh module. Select **Part** from the **Object** field in the context bar, and select a part from the list.
2. From the main menu bar, select **Mesh->Edit**.

   Abaqus/CAE displays the **Edit Mesh** dialog box.

   Tip: You can also display the **Edit Mesh** dialog box using the  tool, located at the bottom of the Mesh module toolbox.

3. From the **Category** field, choose **Mesh**.
4. From the **Method** list, select **Collapse short edges**.

   Abaqus/CAE displays the **Collapse short edges** dialog box.
5. Enter the **Edge tolerance** to specify the minimum length of the edges of elements indicating that you want to collapse element edges that are shorter than the tolerance. The default value is approximately 10% of the average element size in the part.
6. If desired, toggle on **Specify** and click **Select** to choose an element domain other than the entire mesh.
7. If desired, toggle on **Thickness direction** and enter a direction vector or click the arrow icon to create a vector by picking points in the viewport.

   Abaqus/CAE uses the direction vector to measure the elements instead of measuring only the distance between nodes. When you use a direction vector, the collapse operation must be limited to specific edges of the selected elements to avoid collapsing edges that are perpendicular to the intended direction. If elements are oriented such that the direction is topologically ambiguous, Abaqus/CAE highlights the elements so you can either select a domain that excludes them or add a reference edge to further define the desired edges.
8. If desired, toggle on **Reference edge** and click **Select** to choose a reference edge.

   When you use a reference edge, Abaqus/CAE checks for short edges in only those element edges that are topologically parallel to the selected edge.

   Note:

   If your element domain includes unconnected element sections, you can select a reference edge only within a single contiguous part of the domain. You may need to use the **Collapse short edges** tool multiple times on smaller element domains to achieve the desired results.
9. Click **OK**.

   Abaqus/CAE highlights the elements that will have edges collapsed. Click **Yes** in the prompt area to collapse the edges or **No** to return to the **Collapse short edges** dialog box.

   If none of the element edges are shorter than the minimum length specified, Abaqus/CAE displays an error message that indicates the shortest element length.

Tip: If you make a mistake while collapsing short edges in a mesh, click **Undo** in the **Edit Mesh** dialog box to undo the change. Abaqus/CAE restores the original mesh.

After editing an orphan mesh, you should always verify node-, element-, and surface-based features such as section assignments, loads, and interactions to ensure that they are correctly applied to the modified mesh.

Additional information

- *What can I do with the Edit Mesh toolset?*

Growing short edges of a linear orphan mesh

Select **Mesh->Edit** from the main menu bar to grow selected edges of a linear orphan mesh. You can specify the minimum length of the edges of elements that should be grown, and Abaqus/CAE will move the end nodes of element edges that are shorter than the specified length. You can specify an element domain other than the entire mesh, and you can specify a direction and/or reference edge to grow only those edges that match these criteria. You can grow edges in the mesh only if the element domain contains only linear elements.

1. Enter the Mesh module. Select **Part** from the **Object** field in the context bar, and select a part from the list.
2. From the main menu bar, select **Mesh->Edit**.

   Abaqus/CAE displays the **Edit Mesh** dialog box.

   Tip: You can also display the **Edit Mesh** dialog box using the  tool, located at the bottom of the Mesh module toolbox.

3. From the **Category** field, choose **Mesh**.
4. From the **Method** list, select **Grow short edges**.

   Abaqus/CAE displays the **Grow short edges** dialog box.
5. Enter the **Edge tolerance** to specify the minimum length of the edges of elements indicating that you want to grow element edges that are shorter than the tolerance. The default value is approximately 10% of the average element size in the part.
6. If desired, toggle on **Specify** and click **Select** to choose an element domain other than the entire mesh.

   Note:

   Abaqus/CAE does not check edges outside of the specified domain at all. If there are short element edges adjacent to the selected domain and an edge within the domain grows, the repositioned nodes could make an element outside the domain too small or possibly invert an element.

7. If desired, toggle on **Thickness direction** and enter a direction vector or click the arrow icon to create a vector by picking points in the viewport.

   Abaqus/CAE uses the direction vector to measure the elements instead of measuring only the distance between nodes. When you use a direction vector, the grow operation must be limited to specific edges of the selected elements to avoid growing edges that are perpendicular to the intended direction. If elements are oriented such that the direction is topologically ambiguous, Abaqus/CAE highlights the elements so you can either select a domain that excludes them or add a reference edge to further define the desired edges.
8. If desired, toggle on **Reference edge** and click **Select** to choose a reference edge.

   When you use a reference edge, Abaqus/CAE checks for short edges in only those element edges that are topologically parallel to the selected edge.

   Note:

   If your element domain includes unconnected element sections, you can select a reference edge only within a single contiguous part of the domain. You may need to use the **Grow short edges** tool multiple times on smaller element domains to achieve the desired results.

9. Click **OK**.

   Abaqus/CAE highlights the elements that will have edges grown. Click **Yes** in the prompt area to grow the edges or **No** to return to the **Grow short edges** dialog box.

   If none of the element edges are shorter than the minimum length specified, Abaqus/CAE displays an error message that indicates the shortest element length.

   Tip: If you make a mistake while collapsing short edges in a mesh, click **Undo** in the **Edit Mesh** dialog box to undo the change. Abaqus/CAE restores the original mesh.

After editing an orphan mesh, you should always verify node-, element-, and surface-based features such as section assignments, loads, and interactions to ensure that they are correctly applied to the modified mesh.

Additional information

- *What can I do with the Edit Mesh toolset?*

Converting a triangular shell mesh to a solid tetrahedral mesh

Select **Mesh->Edit** from the main menu bar to convert a closed three-dimensional shell of triangular elements into a solid mesh of tetrahedral elements. The original shell part must be meshed with triangular elements that fully enclose a volume with no gaps.

1. Enter the Mesh module.
2. From the **Object** field in the context bar, select **Part** and select a part from the list. This tool is available only for working on orphan mesh elements.
3. From the main menu bar, select **Mesh->Edit**.

   Abaqus/CAE displays the **Edit Mesh** dialog box.

   Tip: You can also display the **Edit Mesh** dialog box using the  tool, located at the bottom of the Mesh module toolbox.

4. From the **Category** field, choose **Mesh**.
5. From the **Method** list, select **Convert tri to tet**.
6. From the buttons that appear in the prompt area, click **Yes**.

   Abaqus/CAE converts the triangular mesh to a tetrahedral mesh.

   Tip: You can recover the triangular mesh in its state just before the conversion by clicking **Undo** in the **Edit Mesh** dialog box.

After editing an orphan mesh, you should always verify node-, element-, and surface-based features such as section assignments, loads, and interactions to ensure that they are correctly applied to the modified mesh.

Additional information

- *What can I do with the Edit Mesh toolset?*

Converting a solid orphan mesh to a shell orphan mesh

Select **Mesh->Edit** from the main menu bar to convert a solid orphan mesh to a shell orphan mesh. The **Convert solid to shell** tool creates triangular or quadrilateral shell elements on the free element faces of the part; that is, the element faces that do not share all of their nodes with another face. If your part contains joined faces with elements of different element shapes or with elements of a different geometric order, Abaqus/CAE creates shell elements on both sides of the interface. Likewise, if your solid mesh part contains neighboring element faces that reference different coincident nodes (like the nodes that represent cracks), Abaqus/CAE creates shell elements on both sides of the interface.

1. Enter the Mesh module.
2. From the **Object** field in the context bar, select **Part** and select a part from the list. This tool is available only for working on orphan mesh elements.
3. From the main menu bar, select **Mesh->Edit**.

   Abaqus/CAE displays the **Edit Mesh** dialog box.

   Tip: You can also display the **Edit Mesh** dialog box using the tool, located at the bottom of the Mesh module toolbox.

4. From the **Category** field, choose **Mesh**.
5. From the **Method** list, select **Convert solid to shell**.
6. From the buttons that appear in the prompt area, click **Yes**.

   Abaqus/CAE converts the solid mesh to a shell mesh.

   Tip: You can recover the solid mesh in its state just before the conversion by clicking **Undo** in the **Edit Mesh** dialog box.

After editing an orphan mesh, you should always verify node-, element-, and surface-based features such as section assignments, loads, and interactions to ensure that they are correctly applied to the modified mesh.

Additional information

- *What can I do with the Edit Mesh toolset?*

Merging elements

Select **Mesh->Edit** from the main menu bar to merge adjacent orphan mesh elements. The merged elements have the same element type and basic shape as the originals. You can merge elements in the mesh only if the element domain contains only linear elements.

1. Enter the Mesh module. Select **Part** from the **Object** field in the context bar, and select a part that contains orphan mesh elements from the list.
2. From the main menu bar, select **Mesh->Edit**.

   Abaqus/CAE displays the **Edit Mesh** dialog box.

   Tip: You can also display the **Edit Mesh** dialog box using the tool, located at the bottom of the Mesh module toolbox.

3. From the **Category** field, choose **Mesh**.
4. From the **Method** list, select **Merge layers**.
5. Select the elements that you want to merge. You can use any of the following methods:

   - Select elements from the viewport. You can select elements individually, by angle, by feature edge, or by topology (for more information, see *Selecting objects within the current viewport*). Click mouse button 2 when you have finished making selections.
   - Select one or more existing element sets. Click **Sets** on the right side of the prompt area to display the **Region Selection** dialog box containing a list of available sets. Select one or more sets from the list, and click **Continue**.

   Elements being merged must be adjacent to each other.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

6. Select an element edge to indicate the merge direction.

   Abaqus/CAE attempts to merge the elements. If merging the elements will create incompatibilities in the mesh, Abaqus/CAE highlights the nodes at which the incompatibilities will occur and asks if you want to continue. Click **Yes** to merge the elements or **No** to clear your selections and return to Step 4.

   Tip: If you make a mistake while merging elements in a mesh, click **Undo** in the **Edit Mesh** dialog box to undo the change. Abaqus/CAE restores the original mesh.

After editing an orphan mesh, you should always verify node-, element-, and surface-based features such as section assignments, loads, and interactions to ensure that they are correctly applied to the modified mesh.

Additional information

- *What can I do with the Edit Mesh toolset?*

Subdividing elements

Select **Mesh->Edit** from the main menu bar to subdivide one or more selected orphan mesh elements. The elements to be subdivided must be connected. You can select an edge, a face (solid elements), or **All Directions** to divide elements in one, two, or all directions—two for shell elements, three for solid elements. You must also specify the number of divisions to make. Abaqus/CAE divides the elements evenly into the specified number of divisions in each direction. The new elements have the same element type as the originals. You can subdivide elements in the mesh only if the element domain contains only linear elements.

1. Enter the Mesh module. Select **Part** from the **Object** field in the context bar, and select a part that contains orphan mesh elements from the list.
2. From the main menu bar, select **Mesh->Edit**.

   Abaqus/CAE displays the **Edit Mesh** dialog box.

   Tip: You can also display the **Edit Mesh** dialog box using the tool, located at the bottom of the Mesh module toolbox.

3. From the **Category** field, choose **Mesh**.
4. From the **Method** list, select **Subdivide layers**.
5. Select the elements that you want to subdivide. You can use any of the following methods:

   - Select elements from the viewport. You can select elements individually, by angle, by feature edge, or by topology (for more information, see *Selecting objects within the current viewport*). Click mouse button 2 when you have finished making selections.
   - Select one or more existing element sets. Click **Sets** on the right side of the prompt area to display the **Region Selection** dialog box containing a list of available sets. Select one or more sets from the list, and click **Continue**.

   The selected elements must form a single connected set.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

6. Select an element edge to indicate a single direction of subdivision; select the face of a solid element to indicate two directions; select **All Directions** in the prompt area to indicate all directions—two for shell elements or three for solid elements.

   Abaqus/CAE attempts to subdivide the elements. If dividing the elements will create incompatibilities in the mesh, Abaqus/CAE displays a dialog box indicating that the resulting mesh will be nonconforming. Click **Yes** to divide the elements or **No** to clear your selections and return to Step 4.

   Tip: If you make a mistake while dividing elements in a mesh, click **Undo** in the **Edit Mesh** dialog box to undo the change. Abaqus/CAE restores the original mesh.

After editing an orphan mesh, you should always verify node-, element-, and surface-based features such as section assignments, loads, and interactions to ensure that they are correctly applied to the modified mesh.

Additional information

- *What can I do with the Edit Mesh toolset?*

Copying a mesh pattern

Select **Mesh->Edit** from the main menu bar to copy a two-dimensional mesh pattern onto a target face. The elements of the pattern must form a connected set that can cover a geometric face. The target face must be a portion of the same assembly or part as the pattern, and the target face must contain at least as many loops as the pattern.

1. Enter the Mesh module, and do one of the following:
   - From the **Object** field in the context bar, select **Assembly**.
   - From the **Object** field in the context bar, select **Part**, and select a part from the list.
2. From the main menu bar, select **Mesh->Edit**.

   Abaqus/CAE displays the **Edit Mesh** dialog box.

   Tip: You can also display the **Edit Mesh** dialog box using the  tool, located at the bottom of the Mesh module toolbox.
3. From the **Category** field, choose **Mesh**.
4. From the **Method** list, select **Copy mesh pattern**.
5. Select the source mesh. You can use any of the following methods:
   - Select elements from the viewport. You can select elements individually, by face angle, or by face curvature (for more information, see *Selecting objects within the current viewport*). Click mouse button 2 when you have finished making selections.
   - Select an existing surface. Click **Surfaces** on the right side of the prompt area to display the **Region Selection** dialog box containing a list of available surfaces. Select a surface from the list, and click **Continue**.

   The selected elements must form a single connected two-dimensional face.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Surfaces** on the right side of the prompt area.
6. Select the target face.

   The target face must be part of the same assembly or part as the source, and the face must contain at least as many loops as the source.
7. In the **Copy mesh pattern** dialog box, associate node positions on the source mesh with points on the target face.

   You should associate at least three nodes from the outer edge (primary loop) of the source mesh with points on the target geometry.

   a. Click  in the **Copy mesh pattern** dialog box to add nodes and points to the table.
   b. Select the desired nodes from the source mesh, and click **Done** in the prompt area.
   c. Select the corresponding points on the target face.

      Abaqus/CAE highlights the current node in pink as you make selections. When you have selected a point for each node, the **Copy mesh pattern** dialog box appears with the selections displayed in the table.

d. Highlight a position in the table, and click  to edit the position.

Tip: You cannot edit nodes. To change a node selection use  to delete the highlighted row, then add a new node and position to replace it.

e. Click **OK** in the dialog box

Abaqus/CAE maps the remaining nodes onto the target face and displays the copied mesh pattern. If there are problems mapping the remaining nodes to the target, Abaqus/CAE displays error messages to help you resolve them.

Tip: If the copied mesh pattern does not meet your expectations, click **Undo** in the **Edit Mesh** dialog box to remove it.

Additional information

• *What can I do with the Edit Mesh toolset?*

Viewing and editing mesh-geometry associativity

You can view or edit the association between orphan or bottom-up mesh elements and the underlying geometry by selecting **Mesh->Associate Mesh with Geometry** from the main menu bar and choosing a vertex, edge, or face that bounds a bottom-up region or a group of orphan elements. Elements generated by a top-down technique are associated automatically with the region geometry; you cannot view or edit the associativity between these native mesh elements and the corresponding region geometry.

1. Enter the Mesh module. Select **Part** from the **Object** field in the context bar, and select a part that contains orphan mesh or bottom-up elements from the list.
2. From the main menu bar, select **Mesh->Associate Mesh with Geometry**.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also click the  tool in the Mesh module toolbox, or you can click the  tool to display the **Edit Mesh** dialog box—the mesh association method is located in the **Mesh** category within the dialog box. (For more information on the Mesh module toolbox, see *Using the Mesh module toolbox*.)

3. Select a geometric entity—a vertex, edge, or face—whose associativity you want to view or edit.

   Abaqus/CAE highlights in yellow any nodes, element edges, or element faces that are associated with the selected geometry. If nothing is highlighted in yellow, no part of the mesh is associated with the selected entity.
4. Use the following selection techniques to change the mesh-geometry associativity (for more information, see *Selecting objects within the viewport*"):
   a. Click a node, element edge, or element face to cancel any existing selections and begin selecting new items.
   b. **[Shift] + Click** to add nodes, element edges, or element faces to the current selection, or **[Ctrl] + Click** to unselect items.
   c. Use the **by angle** selection method available in the prompt area to select element faces based on the angle between them.
   d. You can use the tools in the **Selection** toolbar to limit the types of objects that you can select in the viewport.

   Note:

   In some cases you may need to pick interior mesh faces or edges to create the correct mesh-geometry association. To allow you to select interior objects, Abaqus/CAE does not limit your associativity selections to the "Objects closest to the screen" even when this selection option is active (see *Filtering your selection based on the position of the object*, for more information). As a result, you need to ensure that you do not inadvertently associate unwanted elements, especially if you use drag-select to select multiple objects.
5. When you have finished selecting mesh objects to associate, click **Done**.

   Abaqus/CAE saves the new associativity.

6. Repeat Steps 3 through 5 to verify or change the association of other areas, or click the cancel button  in the prompt area to end the associativity procedure.

Additional information

- *Selecting objects within the viewport*
- *Bottom-up meshing*
- *Mesh-geometry association*
- *Using the Mesh module toolbox*
- *What can I do with the Edit Mesh toolset?*

Deleting mesh-geometry associativity

You can delete the association between nodes, element edges, or elements and the underlying geometry by selecting **Mesh->Delete Mesh Associativity** from the main menu bar and choosing a vertex, edge, or face. If you delete the associativity between Abaqus/CAE geometry and the mesh, the affected mesh components become orphan mesh nodes and elements. This may be useful if you are working with a complex part and want to keep some portions of the mesh unchanged while changing the geometry in other areas.

1. Enter the Mesh module. Select **Part** from the **Object** field in the context bar, and select a part from the list.
2. From the main menu bar, select **Mesh->Delete Mesh Associativity**.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also click the tool in the Mesh module toolbox, or you can click the tool to display the **Edit Mesh** dialog box—the delete associativity method is located in the **Mesh** category within the dialog box. (For more information on the Mesh module toolbox, see *Using the Mesh module toolbox*.)

3. Select one or more geometric entities—vertices, edges, faces, or entire regions—whose associativity you want to delete.

   You can use a combination of drag select, **[Shift] + Click**, and **[Ctrl] + Click** to select geometric entities. For more information, see *Selecting objects within the current viewport*.

   Note:

   To delete the association of a native mesh region and create an orphan mesh, you must select the entire region.

4. If desired, you can toggle off **Delete association from bounding entities** in the prompt area.

   By default, when you delete the associativity of a region, Abaqus/CAE also deletes the association between nodes, element edges, and faces and the corresponding vertices, edges, and faces.

5. When you have finished selecting geometric entities, click **Done**.

   Abaqus/CAE highlights the geometric entities in red and the associated mesh entities in yellow so you can confirm your selections.

6. Click **Yes** to delete the mesh association or **No** to cancel your selections.

7. Repeat Steps 3 through 6 to delete the associativity of other areas, or click the cancel button in the prompt area to end the procedure.

Additional information

- *Selecting objects within the viewport*
- *Bottom-up meshing*
- *Mesh-geometry association*
- *Using the Mesh module toolbox*
- *What can I do with the Edit Mesh toolset?*

Inserting cohesive seams

Select **Mesh->Edit** from the main menu bar to insert pore pressure cohesive elements in crack regions, which allows you to model fluid flow into the adjacent material. You can select faces (solid cells), element faces (three-dimensional orphan meshes), edges (shells), or element edges (two-dimensional orphan meshes) to identify the crack regions. The region around the crack must be meshed prior to inserting cohesive seams. By default, Abaqus/CAE creates several sets and surfaces to help you make selections in subsequent procedures, such as section assignment.

1. Enter the Mesh module. Select **Part** from the **Object** field in the context bar, and select a part that contains the crack region from the list.
2. From the main menu bar, select **Mesh->Edit**.

   Abaqus/CAE displays the **Edit Mesh** dialog box.

   Tip: You can also display the **Edit Mesh** dialog box using the  tool, located at the bottom of the Mesh module toolbox.

3. From the **Category** field, choose **Mesh**.
4. From the **Method** list, select **Insert cohesive seams**.
5. Select the faces (for three-dimensional objects) or edges (for two-dimensional objects) that represent crack regions. You can use any of the following methods:

   - Select faces or edges from the viewport. You can select faces individually, by angle, or, for native meshes, by face curvature. You can select edges individually or by edge angle (for more information, see *Selecting objects within the current viewport*). Click mouse button 2 when you have finished making selections.
   - Click **Sets/Surfaces** (for native meshes) or **Surfaces** (for orphan meshes) on the right side of the prompt area to display the **Region Selection** dialog box containing a list of available sets or surfaces. Select one or more sets or surfaces from the list, and click **Continue**.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets/Surfaces** (or **Surfaces**) on the right side of the prompt area.

6. By default, Abaqus/CAE creates several sets and surfaces. Click **Options** on the right side of the prompt area to select the sets or surfaces to be created and, if desired, to change the set or surface names from the default values.
7. From the buttons along the bottom of the **Options** dialog box, do the following:

   - Click **OK** to save your settings and to close the dialog box.
   - Click **Defaults** to reset the set and surface selections and names to the default values.
   - Click **Clear** to clear all of the set and surface selections and names.
   - Click **Cancel** to close the dialog box.

8. Click **Done** in the prompt area.

Abaqus/CAE inserts cohesive pore pressure elements and creates the specified sets and surfaces.

Additional information

• *What can I do with the Edit Mesh toolset?*

Editing and refining an orphan mesh

You can use the Edit Mesh toolset to refine an orphan mesh.
You can refine a planar, triangular mesh with or without a specified global element size.

Select **Mesh->Edit** from the main menu bar to refine a planar, triangular mesh. You can remesh the part using the following methods:

With a specified global element size

Before you remesh the part, you have the option of assigning a target element size to the entire part. You can then remesh the part, and the density of the new mesh reflects the new target element size. For example, when the part in *Figure 3* is remeshed with a global element size of 15.0, *Figure 1* shows the resulting mesh.

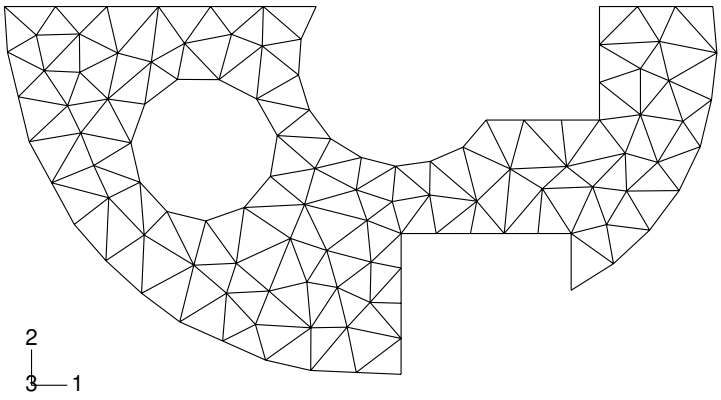

Figure 1: A global element size of 15.0.

Figure 2 shows the part remeshed with a global element size of 8.0.

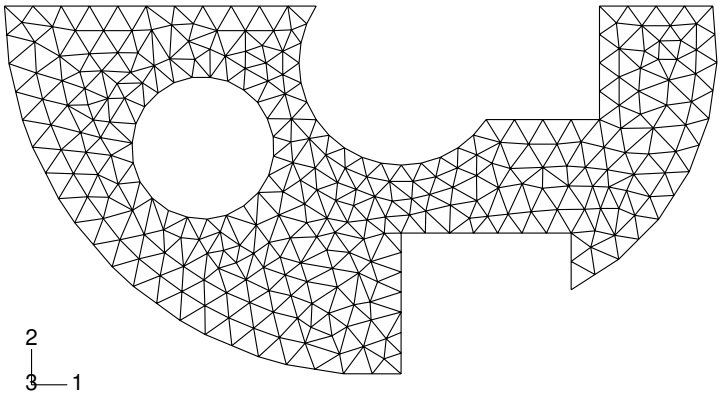

Figure 2: A global element size of 8.0.

Without a specified global element size

If no global element size is specified, Abaqus/CAE maintains the edges of the elements along the boundary of the part while improving the mesh quality in the interior of the part. The resulting mesh topology is different from the original mesh topology. For example, *Figure 3* shows a distorted mesh.

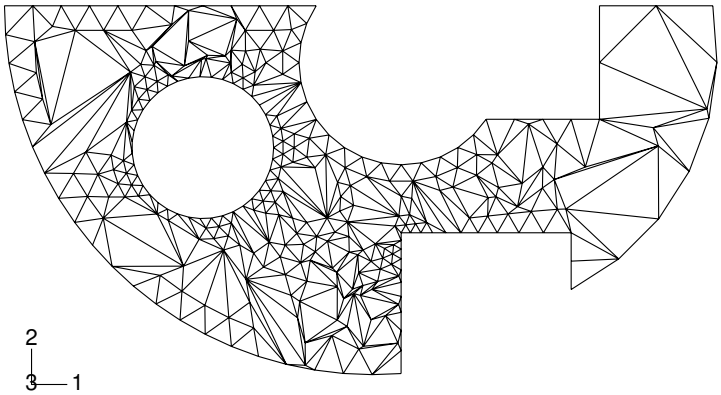

Figure 3: A distorted mesh.

When the part is remeshed, the quality of the mesh improves dramatically, as shown in *Figure 4*.

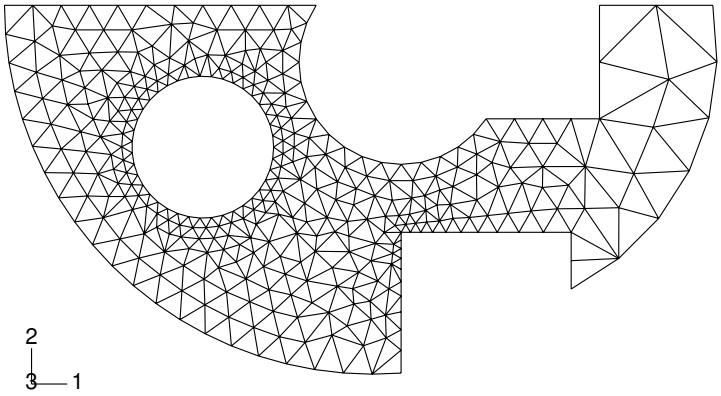

Figure 4: The part is remeshed without specifying a global element size.

Additional information

- *What can I do with the Edit Mesh toolset?*

Refine a planar, triangular mesh with a specified global element size

1. Enter the Mesh module.
2. From the **Object** field in the context bar, select **Part** and select a part that contains only orphan mesh elements from the list.

   Tip: To refine the orphan elements within a hybrid part, suppress the geometric features and resume them after completing the refinement operation.

3. From the main menu bar, select **Mesh->Edit**.

   Abaqus/CAE displays the **Edit Mesh** dialog box.

   Tip: You can also display the **Edit Mesh** dialog box using the tool, located at the bottom of the Mesh module toolbox.

4. In the dialog box, choose **Refinement** from the **Category** field.
5. From the **Method** list, select **Set size**.
6. In the prompt area, type the global element size of your choice, and press **[Enter]**.

   Abaqus/CAE displays a circle that indicates what the size of the elements will be after you remesh the part.
7. From the **Method** list, select **Remesh**.
8. From the buttons that appear in the prompt area, click **Yes**.

   Abaqus/CAE attempts to refine the mesh. If you make a mistake while refining the mesh, click **Undo** in the **Edit Mesh** dialog box to undo the refinement.

Refine a planar, triangular mesh without a specified global element size

1. Enter the Mesh module.
2. From the **Object** field in the context bar, select **Part** and select a part that contains orphan mesh elements from the list.

   Tip: To refine the orphan elements within a hybrid part, suppress the geometric features and resume them after completing the refinement operation.

3. From the main menu bar, select **Mesh->Edit**.

   Abaqus/CAE displays the **Edit Mesh** dialog box.

   Tip: You can also display the **Edit Mesh** dialog box using the tool, located at the bottom of the Mesh module toolbox.

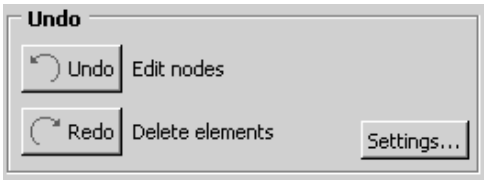
4. In the dialog box, choose **Refinement** from the **Category** field.
5. From the **Method** list, select **Remove size**.
6. From the **Method** list, select **Remesh**.
7. From the buttons that appear in the prompt area, click **Yes**.

Abaqus/CAE attempts to refine the mesh. If you make a mistake while refining the mesh, click **Undo** in the **Edit Mesh** dialog box to undo the refinement.

Undoing or redoing a change in the Edit Mesh toolset

This section describes how you can undo or redo mesh changes that you make with the tools in the Edit Mesh toolset. This section also explains how you can configure the cache that stores the rollback information for your Edit Mesh operations.

These topics also apply to undoing and redoing bottom-up meshing operations (for more information on bottom-up meshing, see *Bottom-up meshing*).



In this section:

- *Support for undo and redo in the Edit Mesh toolset*
- *Undoing or redoing mesh editing actions*
- *Enabling undo and managing the cache*

Support for undo and redo in the Edit Mesh toolset

Abaqus/CAE supports multiple levels of undo and redo for any of the tools in the Edit Mesh toolset and for meshes that you generate using the bottom-up meshing technique.

This capability means that a single undo removes your most recent change to the mesh, a second undo removes the next most recent change, and so on. Similarly, a single redo restores the most recently undone mesh change. The graphic below shows that the **Undo** section of the **Edit Mesh** dialog box includes short descriptions next to the **Undo** and **Redo** buttons, highlighting the mesh change that will be undone or redone if you click the button.

When undo is disabled, a note appears in the description space instead, indicating that undo is disabled under **Settings**. To re-enable undo, see *Enabling undo and managing the cache*.

Abaqus/CAE supports undo operations by recording a history of your mesh editing and bottom-up meshing operations in a memory cache. The allowable size of this cache, the size of your mesh, and the types of mesh editing you performed all determine how many levels of undo are permitted. For example, if your mesh has 100,000 elements and you define a maximum cache size of 0.5 million elements, Abaqus/CAE can provide at least five levels of undo. Operations such as creating or moving nodes do not require a large cache to undo.

Tip: You can determine the number of elements in your mesh by running a **Part mesh** or **Instance mesh** query. For more information, see *Querying the model*.

Large caches can consume a lot of memory, so consider the number of levels of undo you will need for your part or part instance. If you want to ensure at least one level of undo for any mesh editing operation, specify a cache size at least as large as the number of elements in your part or part instance.

Undoing or redoing mesh editing actions

The undo and redo options that appear in the **Undo** section of the **Edit Mesh** and **Create Bottom-Up Mesh** dialog boxes are specific to the selected part, part instance, or assembly. When you switch to a different item and edit its mesh, the undo options change to reflect the history of the selected item. Abaqus/CAE updates the state of the buttons and their descriptions to reflect the history of the newly selected part, part instance, or assembly.

1. Enter the Mesh module.
2. From the main menu bar, select **Mesh->Edit**.

   Abaqus/CAE displays the **Edit Mesh** dialog box.

   Tip: You can also display the **Edit Mesh** dialog box using the tool, located at the bottom of the Mesh module toolbox.

   The **Undo** section of this dialog box includes the **Undo** and **Redo** buttons and next to each button descriptions of the mesh editing action that will be undone or redone when you click it.
3. Click **Undo** to undo the indicated mesh editing operation or click **Redo** to redo the indicated mesh editing operation.

   Abaqus/CAE performs the indicated change.
4. Continue editing the mesh or undoing or redoing changes; close the **Edit Mesh** dialog box when you are done.

Note:

When you perform a new mesh editing operation, or any other operation that alters the mesh , any redo information about the affected part or part instance will be lost. Undo and redo information is also deleted if you delete a region mesh, apply top-down meshing, or add partitions if the added partitions require part of the mesh to be deleted.

Additional information

- *Bottom-up meshing*
- *What can I do with the Edit Mesh toolset?*
- *Enabling undo and managing the cache*

Enabling undo and managing the cache

Enabling undo is global and persistent; when this setting is enabled, you will be able to undo mesh editing changes for any part or assembly meshes during your session. The setting remains enabled during your next Abaqus/CAE session as well. Disabling undo frees any memory associated with this setting and causes any existing undo or redo cache on any parts or assemblies to be lost.

1. Enter the Mesh module.
2. From the main menu bar, select **Mesh->Edit**.

   Abaqus/CAE displays the **Edit Mesh** dialog box.

   Tip: You can also display the **Edit Mesh** dialog box using the  tool, located at the bottom of the Mesh module toolbox.

3. Click **Settings**.

   The **Mesh Edit Undo Settings** dialog box appears.
4. Toggle on **Enable Undo** to enable undo for mesh editing operations.
5. Enter a value in the **Max total cache size** field in units of millions of elements, and click **OK**.

The Feature Manipulation toolset

You build a model in Abaqus/CAE by creating a series of features.
For detailed discussions of features and feature-based modeling, see *The relationship between parts and features* and *Manipulating features in the Assembly module*. This chapter explains how to use the Feature Manipulation toolset to modify and manage the existing features in your model and how to tune the performance of feature regeneration.

In this section:

- *Using the Feature Manipulation toolset*
- *Using the Model Tree to manage features*
- *Tuning feature regeneration*
- *Modifying and manipulating features*

Using the Feature Manipulation toolset

You can access the Feature Manipulation toolset by selecting **Feature** from the main menu bar or by clicking mouse button 3 on a feature in the Model Tree. You can also access the feature tools from the module toolboxes. *Figure 1* shows the icons for all the feature tools in the module toolboxes.

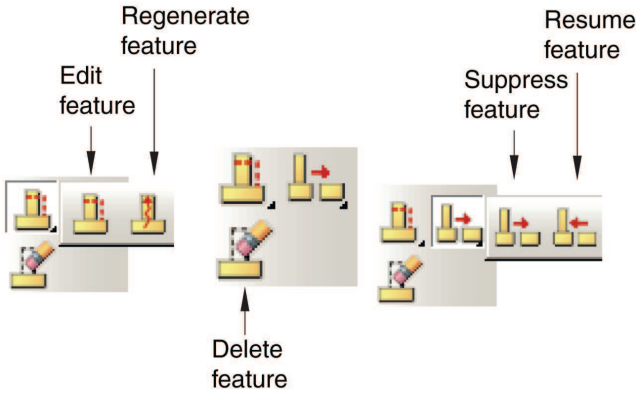

Figure 1: The feature tools.

The following list describes how you can use the **Edit**, **Regenerate**, **Suppress**, **Resume**, and **Delete** tools to modify features or to control the appearance of features in a part or assembly.

Edit a feature

You can edit the features of a part only in the Part module. Any changes that you make to a part are applied automatically to each instance of that part in the assembly. Likewise, you can edit features of the assembly only in the Assembly and Mesh modules. For information on restrictions that apply to editing partitions and datum geometry, see *Understanding a datum as a feature*, and *Understanding partitions*.

Regenerate a feature

Regeneration is the process of recalculating model geometry after a feature of the model has been modified. By default, Abaqus/CAE automatically regenerates a part or assembly after you have edited one of its features. However, you can control whether or not features are regenerated automatically by toggling the **Regenerate on OK** option off or on in the **Feature Editor**. For more information, see *Editing a feature*.

Suppress a feature

When you are manipulating many features in a complex model (for example, when you are exploring design alternatives), Abaqus/CAE allows you to temporarily disable certain features to simplify the display or to speed regeneration. A suppressed feature is not visible and cannot be partitioned or meshed. In addition, Abaqus/CAE ignores all suppressed features when regenerating a part or assembly. You can edit a suppressed feature, although your changes will have no effect on the part or assembly until you resume the feature. Suppressing a feature also suppresses any children of that feature. (For information on parent and child features, see *The relationship between parts and features*.)

Abaqus/CAE does not include a suppressed feature in the input file that it generates when you submit a job for analysis. However, Abaqus/CAE does include in the input file prescribed conditions that refer to the suppressed feature or regions of the suppressed feature. To ensure that the analysis completes successfully, you should do one of the following:

- Resume the suppressed feature.
- Edit the prescribed condition, and apply the prescribed condition to a different region.
- Delete the prescribed condition.

If you want to temporarily make a part instance invisible in the assembly, you can hide the part instance by selecting options in the **Assembly Display Options** dialog box. For more information, see *Controlling instance visibility*.

Resume a feature

When you resume a suppressed feature, it reappears in the display of the part or assembly and becomes reestablished in the model. If you edited the feature when it was suppressed, resuming the feature causes Abaqus/CAE to regenerate the model automatically to take into account your changes. When you resume a feature, you have the option of resuming all of its children as well. (You cannot resume a child feature without also resuming its parent.)

Tuning regeneration performance

Tuning feature regeneration performance is a balance between the convenience of saved states and the effect on performance of memory consumption. In most cases the default settings will result in acceptable regeneration performance; however, you can tune the speed of regeneration by selecting **Feature->Options** from the main menu bar. For more information, see *Tuning feature regeneration*.

Delete a feature

Deleting a feature removes the feature from the model permanently. If you delete a parent feature, all of its children will also be deleted and cannot be recovered.

In addition, you can reduce all the feature and parameter information to a simple definition of the part when you copy a part to a new part. If you reduce the feature list while copying a part, Abaqus/CAE will regenerate the new part faster if you subsequently modify it; however, you will no longer be able to modify any parameters of the new part. To copy a part, select **Part->Copy** from the main menu bar in the Part module.

Additional information

• *Modifying and manipulating features*
• *Copying a part*

Using the Model Tree to manage features

The Model Tree, shown in *Figure 1*, includes a list of all available features in the model. You can click mouse button 3 on a feature in the Model Tree and use the menu that appears to manage the features.

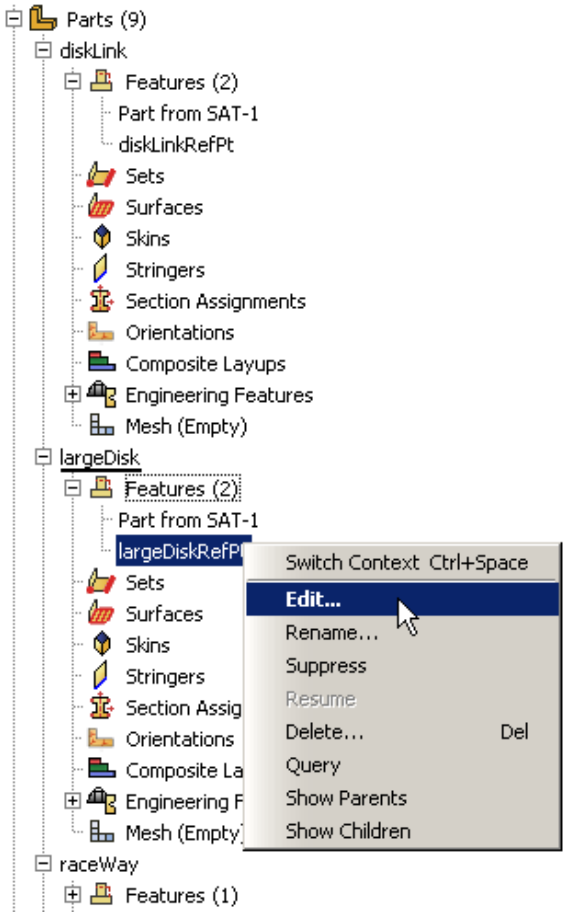

Figure 1: The Model Tree.

You must use the Model Tree to manipulate assembly constraints, suppressed features, or failed features since they are not visible in the viewport. You can also select multiple features to delete, suppress, or resume at the same time. As you select features in the Model Tree, they are highlighted in the viewport (if they are visible). In addition, parents or children of any feature can be highlighted in the viewport.

The Model Tree displays the status of each feature in the model. The icon before each feature name indicates the status:

- A yellow check mark indicates that the feature is modified but has not been regenerated. If a part is locked by a database upgrade, all active features show this status until they are regenerated when the part is unlocked. Abaqus/CAE also displays a yellow check mark next to a feature that you edited but did not subsequently regenerate.
- A padlock indicates that a part or the assembly has been locked by the user or by a database upgrade.
- A red “X” indicates that the feature is suppressed.
- A red “!” indicates that the feature has failed to regenerate. A red “!” next to the part name indicates that the part is invalid.

To get more information about a feature, click mouse button 3 on the feature in the Model Tree and select **Query** from the menu that appears. The information is displayed in the message area.

Additional information

- *Using the Feature Manipulation toolset*
- *Manipulating features in the Assembly module*
- *Modifying and manipulating features*

Tuning feature regeneration

This section describes how you can tune feature regeneration using settings in the **Feature Options** dialog box. You open the **Feature Options** dialog box by selecting **Feature->Options** from the main menu bar. In most cases the default settings will result in acceptable regeneration performance. You should modify the feature options only if Abaqus/CAE takes a long time to regenerate a part or the assembly or if memory consumption is excessive.

The settings in the **Feature Options** dialog box apply only to the current model and are saved in the model database. If you change to a different model, Abaqus/CAE reverts to the default settings or to any modified settings associated with the new model.

In this section:

- *What is regeneration?*
- *What is a geometric state?*
- *What is a cache?*
- *What are self-intersection checks?*
- *How are position constraints regenerated?*

What is regeneration?

Whenever you modify a feature of a part, Abaqus/CAE has to regenerate the part. Similarly, to incorporate the modified feature into any instances of the part, Abaqus/CAE also regenerates features in the assembly when you enter an assembly-related module. However, to save time, Abaqus/CAE determines the minimum number of features that need to be regenerated and regenerates only the features that were affected by the modification. If your parts and your assembly are relatively simple, you will not notice Abaqus/CAE performing this regeneration. However, in a more complex model the regeneration can result in a decrease in performance. Modifications to features that trigger regeneration include using the Feature Manipulation toolset to edit, suppress, resume, and delete a feature.

The Model Tree indicates that a feature needs to be regenerated using a yellow check mark, as described in *Using the Model Tree to manage features*. You can always force Abaqus/CAE to regenerate a part of the assembly by selecting **Feature->Regenerate** from the main menu bar or by clicking mouse button 3 on the **Features** container in the Model Tree.

What is a geometric state?

A geometric state refers to the internal geometric representation of a part or of the assembly; for example, the equations of the curves and surfaces that define the topology and the connectivity of those curves and surfaces. A geometric state is a snapshot of this internal representation. Abaqus/CAE stores this snapshot and creates a geometric state in memory at regular intervals while you work on your model and then regenerate features.

If Abaqus/CAE did not save geometric states, regeneration would start from the first feature that you created and continue through all the features that need to be regenerated, making regeneration very costly. By saving states, Abaqus/CAE can determine which state is closest to the feature that was modified. Regeneration starts from that point and continues through all the features that need to be regenerated. As a result, the speed of regeneration can be increased significantly.

Ideally, to gain the maximum regeneration performance, you would save the geometric state after every feature modification. However, storing every state would consume large amounts of memory and hinder overall performance. Deciding how many states to save is a tradeoff between regeneration speed and memory consumption.

By default, Abaqus/CAE automatically saves up to five geometric states for each part and for the assembly. If Abaqus/CAE has already stored the specified number of states, it deletes one of the older states before saving the most recent state. You can use the **Geometry Caching for Fast Regeneration** options in the **Options** dialog box to change the number of states automatically saved by Abaqus/CAE. Abaqus/CAE uses an internal logic to decide when to create a geometric state; you cannot control when a state is created.

What is a cache?

A cache is a portion of memory. Abaqus/CAE uses the following feature-related caches to store geometric states:

- The **Current part cache** contains snapshots of the geometric state of the current part. Abaqus creates one part cache for each part in the model.
- The **All part caches** contains snapshots of the geometric state of all the parts in the current model.
- The **Assembly cache** contains snapshots of the geometric state of the assembly. Abaqus creates one assembly cache for the model.

If you find that Abaqus/CAE is consuming an excessive amount of memory on your workstation and affecting the performance of your system, you can use the **Clear** buttons in the **Options** dialog box to erase the memory associated with the part and assembly caches. Clearing this memory will increase performance; however, the snapshots of the geometric state will be erased and regeneration will be slower. If you toggle off the option to cache geometric states, Abaqus/CAE does not clear the states that have already been stored. In addition, Abaqus/CAE stores a separate cache for each model. As a result, you can make more memory available by deleting the caches of any models that you are not currently working on.

If you spent a lot of time making a series of changes to a part and are satisfied that your design is correct, you can manually save the current state in memory by clicking **Cache current state** in the **Options** dialog box. As a result, Abaqus/CAE can return to this state and regenerate any subsequent additions or modifications. However, if you continue to automatically cache geometric states, Abaqus/CAE may erase the state that you saved manually after it has saved the maximum number of geometric states. Alternatively, you can toggle off the option to automatically cache geometric states and continue to manually save states at significant intervals.

The **Geometry Caching for Fast Regeneration** options in the **Options** dialog box indicate how many geometric states are stored in the three feature-related caches. A cache can contain a combination of geometric states that you saved manually and states that Abaqus/CAE saved automatically. You can query the **Current part cache** and the **Assembly cache** to determine the positioning of geometric states relative to the sequence of features.

What are self-intersection checks?

Self-intersection checks are tests used to help ensure that complex geometry you create in Abaqus/CAE is valid for analysis.
If faces of a feature intersect other faces of the same feature, Abaqus/CAE displays a warning that there are invalid intersections and does not create the feature. A feature that intersects itself may not be meshable and may cause problems with the analysis. Abaqus/CAE allows you to check for self-intersection during feature creation; however, the checking process will slow down creation of the feature. In addition, checking for self-intersection will slow down regeneration of the feature. The time required to complete the tests varies with the complexity of the feature you are attempting to create or regenerate.

The **Feature Options** dialog box allows you to toggle self-intersection checks on and off. **Perform self-intersection checks** is toggled off by default. In general, self-intersection is possible only when you are creating features with complex geometry, such as loft features (for more information, see *What is lofting?* and *Self-intersection checks*). If you know that your features do not self-intersect or if you plan to remove the self-intersection during a subsequent operation, you can leave **Perform self-intersection checks** toggled off to speed up feature regeneration.

How are position constraints regenerated?

By default, when Abaqus/CAE regenerates the assembly, it regenerates all of the position constraints before regenerating other features that might depend on the position, such as partitions and datums.

However, if the position constraint uses an entity that was created by selecting from a part instance in the Assembly module, such as a face created by a partition or a datum axis running through two vertices, Abaqus/CAE changes its behavior and regenerates features in the order that you created them. As a result, partitions and datums that you created before the position constraint may not move along with the movable instance.

If you are working in the assembly-related modules, the **Feature Options** dialog box includes a **Constraints** field that allows you to control this regeneration behavior. For more information, see *Tuning regeneration performance*.

Modifying and manipulating features

This section describes how to use the Feature Manipulation toolset.

In this section:

- *Editing a feature*
- *Renaming a feature*
- *Suppressing features*
- *Resuming suppressed features*
- *Deleting features*
- *Regenerating a part or assembly*
- *Tuning regeneration performance*
- *Using the Model Tree to obtain feature information*

Editing a feature

Select **Feature->Edit** from the main menu bar to modify geometric information for a selected feature. You can also edit a feature by clicking mouse button 3 on the feature in the Model Tree and selecting **Edit** from the menu that appears.

The changes that you can make to a feature depend on how it was created. You can change any numerical parameters that define the feature, and, where applicable, you can change a section sketch. However, you cannot modify a feature that was created by picking geometric entities, such as points and edges, on the screen. For example, you can modify the following parameters:

- Depth of an extrusion
- Radius of a fillet
- Coordinates of a datum point
- Shape of an extruded solid

If you cannot make the required changes with the Feature Manipulation toolset, you must delete the feature and create a new one that incorporates the changes.

1. From the main menu bar, select **Feature->Edit**.

    **Tip:** You can also edit a feature by clicking the  tool located in the module toolbox.

2. Select a feature to modify. You can select the feature either directly from the current viewport or from the Model Tree. For more information, see *Selecting objects within the viewport* and *Working with the Model Tree and the Results Tree*.

   The feature editor appears.

3. Edit the feature by doing one of the following:

   - In the **Parameters** field, type a new value for the desired parameter.
   - Select **Edit Section Sketch** to start the Sketcher and make the changes to your sketch. For information on using the Sketcher, see *The Sketch module*.

4. + Click **OK** to implement the changes in your model.

   If you are editing a part feature, the part is regenerated immediately to incorporate your changes, and the assembly is regenerated the next time you enter a module that displays the assembly. If you are editing an assembly feature, the assembly is regenerated immediately.

    **Note:** By default, Abaqus/CAE regenerates the part or assembly every time you edit a feature. If you prefer to postpone regeneration of the part or assembly, toggle **Regenerate on OK** off before you click **OK** in the feature editor. When you are ready to regenerate the part or assembly, select **Feature->Regenerate** from the main menu bar.

Additional information

• *Using the Feature Manipulation toolset*

Renaming a feature

You can rename a feature by clicking mouse button 3 on the feature in the Model Tree and selecting **Rename** from the menu that appears.

1. Click mouse button 3 on the feature in the Model Tree, and select **Rename** from the menu that appears.
   The **Rename Features** dialog box appears.
2. Enter a new name for the feature.
3. + Click **OK** to complete renaming the feature.
   The Model Tree displays the new name.

Additional information

• *Using the Feature Manipulation toolset*

Suppressing features

Select **Feature->Suppress** from the main menu bar to suppress selected features. Suppressing features is equivalent to temporarily removing them from the part or assembly. Suppressed features remain suppressed when you regenerate a part or assembly. You can also suppress a feature by clicking mouse button 3 on the feature in the Model Tree and selecting **Suppress** from the menu that appears.

You cannot suppress the base feature. In addition, if you suppress parent features, all of their child features are also suppressed automatically. Suppressed features can be restored by selecting **Feature->Resume** from the main menu bar or by clicking mouse button 3 on the feature in the Model Tree. When you resume a suppressed feature, its children are not resumed unless you select them. To help you select a feature's children, you can click mouse button 3 on the feature in the Model Tree and select **Show children** from the menu that appears.

1. From the main menu bar, select **Feature->Suppress**.

    **Tip:** You can also suppress features using the  tool located in the module toolbox.

2. Select one or more features to suppress. You can select features from the current viewport or from the Model Tree. For more information, see *Selecting objects within the viewport*," and *Working with the Model Tree and the Results Tree*.

   Abaqus/CAE highlights the selected feature. If you selected features that have child features, Abaqus/CAE also highlights the children.

   If you selected features from the viewport, click **Done** in the prompt area when you are finished making selections.

3. If you selected features from the viewport, click **Yes** in the prompt area. If you selected features from the Model Tree, click mouse button 3 on one of the feature names and select **Suppress** from the menu that appears.

   The selected features and any child features disappear from the viewport.

4. To exit the suppress procedure, either

   - click the cancel button  in the prompt area, or
   - click mouse button 2 anywhere in the Abaqus/CAE window, or
   - select another operation from the **Feature** menu.

Additional information

- *Using the Feature Manipulation toolset*
- *Resuming suppressed features*

Resuming suppressed features

Select **Feature->Resume** from the main menu bar to resume suppressed features. You can also resume a group of features by selecting the features in the Model Tree, clicking mouse button 3, and selecting **Resume** from the menu that appears.

Resuming a feature fully restores it to the part or assembly. You can resume the last feature you suppressed, all suppressed features, or just selected features. When you resume a child feature, Abaqus/CAE also resumes the parent features automatically. However, when you resume a parent feature, its children are not resumed unless you select them. To help you select a feature's children, you can click mouse button 3 on the feature in the Model Tree and select **Show children** from the menu that appears.

1. From the main menu bar, select **Feature->Resume**.

    **Tip:** You can also resume a feature using the  tool located in the module toolbox.

2. Do one of the following:

   - Click **Last Set** to resume the most recently suppressed feature and all its parents.
   - Click **All** to resume all suppressed features.
   - Select the feature to resume from the Model Tree. You can select multiple features to resume.

   The resumed features reappear in the viewport.

Additional information

- *Using the Feature Manipulation toolset*
- *Suppressing features*

Deleting features

Select **Feature->Delete** from the main menu bar to delete selected features. You can also delete a feature by clicking mouse button 3 on the feature in the Model Tree and selecting **Delete** from the menu that appears.

When you delete parent features, you also delete all of their child features. You cannot resume deleted features.

1. From the main menu bar, select **Feature->Delete**.

   Tip: You can also delete features using the tool located in the module toolbox.

2. Select one or more features to delete. You can select features from the current viewport or from the Model Tree. For more information, see *Selecting objects within the viewport*," and *Working with the Model Tree and the Results Tree*.

   Abaqus/CAE highlights the selected features. If you selected features that have child features, Abaqus/CAE also highlights the children.

   If you selected features from the viewport, click **Done** in the prompt area when you are finished making selections.

3. If you selected features from the viewport, click **Yes** in the prompt area. If you selected features from the Model Tree, click mouse button 3 on the feature and select **Delete** from the menu that appears.

   The selected features and any child features are deleted.

4. To exit the delete procedure, either

   - click the cancel button in the prompt area, or
   - click mouse button 2 anywhere in the Abaqus/CAE window, or
   - select another operation from the **Feature** menu.

Additional information

- *Using the Feature Manipulation toolset*

Regenerating a part or assembly

When you modify features in a complex part or assembly, it may be convenient to postpone regeneration until you make all your changes, since regeneration can be time consuming. (For more information, see *Editing a feature*.) When you are ready to regenerate the part or assembly, you can select **Feature->Regenerate** from the main menu bar. You can also regenerate a feature by clicking mouse button 3 on the feature in the Model Tree and selecting **Regenerate** from the menu that appears.

1. From the main menu bar, select **Feature->Regenerate**.

   Tip: You can also regenerate a feature using the  tool located in the module toolbox.

   Abaqus/CAE regenerates the part or assembly.

2. If regeneration fails, a dialog box appears. In this case you can choose one of the following options:

   - + Click**Undo Changes** to return to the original part or assembly and discard all your changes.
   - + Click**Keep Changes** to continue the regeneration, suppressing those features that failed to regenerate.

     Note:

     Features that are suppressed as a result of the failure are resumed automatically if you correct the cause of the failure.

Additional information

- *Using the Feature Manipulation toolset*
- *Suppressing features*

Tuning regeneration performance

The **Feature Options** dialog box provides settings that enable you to control whether Abaqus/CAE performs self-intersection checks and, in the Assembly module, to control the order in which Abaqus/CAE regenerates position constraints relative to other features. Tuning these options can help you speed up feature regeneration for your part or assembly. Select **Feature->Options** from the main menu bar to display the **Feature Options** dialog box. You can also tune regeneration by clicking mouse button 3 on the feature in the Model Tree and selecting **Options** from the menu that appears.

In most cases the default settings will result in acceptable regeneration performance. You should modify the feature options only if Abaqus/CAE takes a long time to regenerate a part or the assembly. For more information, see *Tuning feature regeneration*.

Note:

Abaqus/CAE provides access to additional performance tuning options on the **Memory** tabbed page of the **Options** dialog box. The options on this page enable you to specify a limit for kernel memory, set a threshold for when Abaqus/CAE runs in reduced memory mode, and control geometric states in a memory cache. For more information, see *Customizing memory limits and regeneration options*.

1. From the main menu bar, select **Feature->Options**.

   Abaqus/CAE displays the **Feature Options** dialog box.
2. If you know that your features do not self-intersect or if you plan to remove the self-intersection during a subsequent operation, you can toggle off **Perform self-intersection checks** to speed up feature regeneration. For more information, see *What are self-intersection checks?*.
3. If desired, modify the behavior that determines how Abaqus/CAE regenerates position constraints. For more information, see *How are position constraints regenerated?*.
4. + Click **OK** to change the feature options for the current model.

   The feature options apply only to the current model and are saved in the model database.

   If desired, you can also change the cache settings in the **Memory** tabbed page of the **Options** dialog box to change the number of geometric states that Abaqus/CAE automatically caches in memory; clear the memory associated with the part and assembly caches; or cache the current state of the part. For more information, see *Customizing memory limits and regeneration options*.

Using the Model Tree to obtain feature information

The Model Tree displays the feature names along with icons that indicate their status—active, suppressed, modified, or failed. In addition, you can display information on a particular feature by clicking mouse button 3 on the feature in the Model Tree and selecting from the menu that appears.

1. Click mouse button 3 on the feature in the Model Tree.
2. From the menu that appears, choose one of the following options:

   - Select **Show Parents** or **Show Children** to display the parents or children of that feature in the current viewport. Abaqus/CAE also selects the parents or children.
   - Select **Query** to display detailed information. Abaqus/CAE displays the following information about the selected feature:

     - Name and description; for example, solid extrude
     - Status—active or suppressed
     - The name of its parent, if any
     - The names of its children, if any
     - The value of any parameters that define the feature

   The query information appears in the message area and is also written to the replay file (`abaqus.rpy`) in the form of comments.

Additional information

• *Using the Feature Manipulation toolset*

The Filter toolset

Filters allow you to remove extraneous field output data or history output data—noise—during the analysis of a model without a loss of resolution in the desired data range. You can also use filters to filter field output or history output before the data are saved to the output database (`.odb`) file; as a result, filters can also reduce the size of the output database.
The Filter toolset allows you to create and manage filters in the Step module.

In this section:

- *Filtering field and history data*
- *Applying bounding values to field and history data*
- *Creating a filter*

Filtering field and history data

You can create filters in Abaqus/CAE and apply them to field output requests or history output requests for Abaqus/Explicit analyses. Abaqus filters data while the analysis is running; filtering during the analysis (“real time” filtering) can reduce the size of the output database by excluding high-frequency data before it is saved. Real time filtering also avoids potential aliasing problems in the resulting data. Aliasing is a loss of valid results data; aliasing will occur if the sampling frequency (the frequency at which the data are saved) is less than twice the highest frequency expected in the results. For example, if a sine wave was sampled at only two points, the aliased result would appear to be a straight line, whereas sampling at least four points would reproduce the shape of the curve.

The Filter toolset allows you to create the following filters for use with Abaqus/Explicit field output requests and history output requests:

- **Butterworth**
- **Type I Chebyshev**
- **Type II Chebyshev**

For more specific information about these filters, see *Filtering Output and Operating on Output in Abaqus/Explicit*. The different filter types are distinguished by their capabilities to transition from the acceptance of low-frequency data to the rejection of data above the filter's **Cutoff frequency**. An ideal filter would stop all data above the cutoff frequency and have a flat response (no affect on accepted data); “real” filters include a transition band around the cutoff where some data are accepted and they usually have some effect on the accepted data. The Butterworth filter provides a maximally flat response magnitude with a wider transition band (slower transition) than the Chebyshev filters. The Chebyshev filters introduce an oscillation—a ripple—in the response magnitude, but they have a narrower transition band than the Butterworth filter. The two types of Chebyshev filters differ in where in their response ripples occur; the **Ripple factor** indicates how much oscillation you will allow in exchange for an improved filter response. You can also specify the **Order** of the filter, which determines the size of the filter's transition band: the higher the order, the narrower the transition band, although the computational cost increases as the order increases. The filter order must be a positive, even integer no greater than 20.

In addition to the filters that you can define using the Filter toolset, Abaqus also includes a default **Antialiasing** filter. Abaqus automatically sets the cutoff frequency of the **Antialiasing** filter based on the time interval at which the field output or history output is saved during the analysis. When you define a filter, you must specify the cutoff frequency based on your knowledge of the frequencies expected in the solution. Whether you set the cutoff or Abaqus calculates it, no checks are performed to ensure that the cutoff frequency is appropriate. If the cutoff is set too low, valid data will be filtered from the results; if it is set too high (above half the sampling frequency), no filtering will be performed.

Select **Tools->Filter->Create** from the main menu to create a new filter definition; select **Edit** from the same menu to make changes to an existing definition. Either command opens the filter editor, which allows you to select the options and provide the data needed to define your filter.

To apply a filter to an analysis, include it in a field output request or history output request for an Abaqus/Explicit analysis procedure (for more information, see *Defining output requests*).

Additional information

• *Filtering Output and Operating on Output in Abaqus/Explicit*

Applying bounding values to field and history data

Bounding values in a filter definition enable you to investigate the maximum or minimum values for a particular output request and to establish an upper or lower bound on the variable values that are returned for an output request. You can establish bounding values for both filtered and unfiltered data; to specify these values in a filter definition without performing Butterworth filtering or either type of Chebyshev filtering on your data, define an **Operator** filter, which enables you to implement bounding values on an output request without changing the output data in any other way.

Abaqus/CAE provides three types of bounding values:

- **Maximum** bounding values return the highest value within each output interval for the variables in an output request.
- **Minimum** bounding values return the lowest value within each output interval for the variables in an output request.
- **Absolute maximum** bounding values return the highest absolute value for the variables in an output request within each output interval.

In addition, you can set a limit on the bounding value, which determines the highest or lowest value that Abaqus/CAE records for variables that use this filter. If desired, you can stop the analysis when any variables in an output request reach this limiting value.

By default, each component of a tensor or vector quantity is filtered individually and the maximum, minimum, or absolute maximum value and the limiting values are reported separately for each component. You can, however, apply a filter directly to an invariant.

Creating a filter

Select **Tools->Filter->Create** from the main menu bar to create a filter.
For more information on filters including a default filter type created automatically by Abaqus, see *Filtering field and history data*.

1. From the main menu bar, select **Tools->Filter->Create**.

   Tip: You can also create a filter by clicking **Create** in the **Filter Manager**.

   The **Create Filter** dialog box appears.

2. In the **Name** field, enter a name for the filter. For information on naming objects, see *Using basic dialog box components*.
3. From the **Type** list, select one of the following, then click **Continue**:

   - **Butterworth**
   - **Type I Chebyshev**
   - **Type II Chebyshev**
   - **Operator**

   The **Edit Filter** dialog box appears.

4. If you selected the **Butterworth** filter type or one of the **Chebyshev** filter types, perform the following steps:

   a. Enter the **Cutoff frequency**.

   Note:

   Abaqus does not perform any checks to ensure that the cutoff frequency is appropriate. If the cutoff is set too low, valid data will be filtered from the results; if it is set too high, no filtering will be performed.

   b. Enter the **Order** for the filter, which must be a positive, even integer value no greater than 20.

5. If you selected one of the **Chebyshev** filter types, accept the default ripple factor or enter a value.

   The ripple factor determines the magnitude of data oscillation that you will allow in exchange for a faster transition between accepted and rejected data. For more information, see *Filtering Output and Operating on Output in Abaqus/Explicit*.

6. If desired, specify the type of bounding value for which you want to filter data.

   - Select **Maximum** to output the maximum value within each output interval for each variable in the output request.
   - Select **Minimum** to output the minimum value within each output interval for each variable in the output request.
   - Select **Absolute maximum** to output the maximum absolute value within each output variable for each variable in the output request.

   You can also select **None** to toggle off all bounding value–related output requests for this filter.

7. If desired, specify a limit for bounding value requests by entering a value in the **Bounding value limit** field. This value limits the highest or lowest value that Abaqus/CAE records for variables that use this filter.

You can also stop the analysis if the bounding value limit is reached. Toggle on **Stop analysis upon reaching limit** to halt a job when the maximum or minimum value equals the limit value for variables that use this filter.

8. If you selected **Minimum**, **Maximum**, or **Absolute Maximum** for the type of bounding value, you can apply the filter directly to an invariant. To filter the invariant, select **First** or **Second** as the **Invariant**.
9. Click **OK** to create the filter.

To apply the filter in an analysis, select **Apply filter** when you create an output request for an Abaqus/Explicit analysis procedure. For more information, see *Modifying field output requests* or *Modifying history output requests*.

The Free Body toolset

Free body cuts display the resultant forces and moments transmitted across a selected surface of your model. Free body cuts simply integrate the internal forces in an element over a section; therefore, they cannot be used accurately across sections containing surface tractions due to cohesive contact or other sources. The Free Body toolset is available only in the Visualization module, and you can create a free body cut only when the current step and frame of the output database includes element force nodal output (NFORC).

This chapter explains how to use the Free Body toolset to create and delete free body cuts, display or hide them in the viewport, and customize several aspects of their appearance.

Abaqus/CAE also enables you to generate reports or create *X–Y* data objects that describe the forces and moments in all active free body cuts in your session. See *Producing a tabular report*, and *Reading X–Y data from all active free body cuts*, respectively.

Abaqus/CAE provides two other methods for displaying free body data:

- You can display resultant forces and moments along an arbitrary plane through your model by toggling on free body display for a planar view cut. For more information, see *Understanding view cuts*.
- You can display the free body nodal forces in a symbol plot to determine which nodes have an imbalance of forces or moments due to applied loads or to visualize the nodal force distribution on internal sections. For more information, see *Producing a symbol plot of free body nodal forces*.

In this section:

- *Resultant forces and moments on free body cuts in Abaqus/CAE*
- *Creating or editing a free body cut*
- *Selection methods for free body cross-sections*
- *Displaying, hiding, and highlighting free body cuts*
- *Customizing free body cut display*

Resultant forces and moments on free body cuts in Abaqus/CAE

A free body cross-section in Abaqus/CAE is an area of your model across which you want to display resultant forces and moments. Once you define a cross-section, Abaqus/CAE displays vectors that show the magnitude and direction of the resultant forces and moments across the area you select. Force vectors are displayed with a single arrowhead and moment vectors with a double arrowhead, as shown in the example in *Figure 1*; by default, the force vectors are red and the moment vectors are blue.

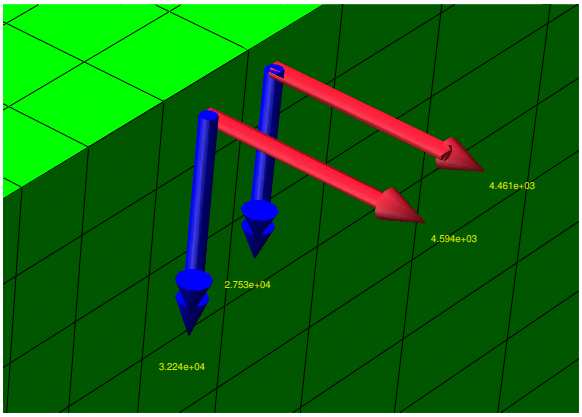

Figure 1: Resultant force and moment display.

You can define the nodes and elements that comprise the cross-section using processes that closely resemble the definition of display groups. Abaqus/CAE enables you to specify the components of the cross-section by including surfaces, display groups, and elements or nodes by number; and you can pick items from the viewport, either by feature angle or individually. See *Creating or editing a free body cut* for detailed instructions. After you define the physical components of your free body cross-section, you can set the location of the summation point (about which resultant moments are taken), and you can indicate the coordinate system transformation that applies when vectors are displayed in component form.

Cross-sections can be created along mesh boundaries only; you cannot specify a cross-section along an arbitrary plane. You can create and display free body cuts only in the Visualization module.

Creating or editing a free body cut

To create a free body cut, select the nodes and elements that comprise your free body cross-section; that is, select the surface of your model across which you want to investigate the resultant force and moment.

Abaqus/CAE provides several methods for selecting the nodes and elements for a cross-section:

- For three-dimensional objects, you can select individual element faces to include in the cross-section. The contribution from all elements connected to the nodes of the selected faces will be considered.
- For two- or three-dimensional objects, you can select individual element edges to include in the cross-section. Each edge provides Abaqus/CAE with an element definition and two or three nodes to include in the cross-section. The contribution from all elements connected to the nodes of the selected edges will be considered.
- For any type of model, you can select the nodes and elements you want to include individually. This method is recommended for selecting nodes and elements from geometrical areas, such as the ends of beams, in which it might be awkward or difficult to select nodes and elements using their edges or faces. The contribution from only the selected elements will be considered.

You can also display a free body cut on a view cut. For more information, see *Understanding view cuts*.

When you define a cross-section using element faces or element edges, Abaqus/CAE provides three additional selection methods that enable you to select the nodes and elements for this definition:

- You can select the faces or edges by picking components in the viewport, either individually or by angle.
- You can select a surface set, which is defined in the output database.
- You can select one or more display groups to use as part of your surface definition.

When you define a cross-section by selecting nodes and elements individually, you can specify the nodes or elements you want to include in the definition by typing their labels directly into the **Free Body Cross-Section** dialog box.

Abaqus/CAE also enables you to customize the summation point for a free body cut, which is the three-dimensional location about which resultant moments are taken. By default, the summation point is placed at the area centroid of the element faces contributing to the free body computation, but you can move the summation point to the centroid location of the nodes for the cross-section or to any three-dimensional location in your model.

You can also adjust the orientation of component vector display for a free body cut. In many cases the most desirable coordinate system for a free body cut is one in which one axis is normal to the surface of the model and another axis is tangential to the surface. This “normal and tangential” coordinate system is created internally and used by default for the display of component vectors. However, you can change the orientation to use any custom coordinate system available in your session, or you can create a new datum coordinate system.

When you edit a free body cut, Abaqus/CAE enables you to change the components included in the free body cross-section, the summation point settings, and the component resolution settings. However, you cannot change the selection method that was used to define a free body cut; for example, if you defined the free body cut using three-dimensional element faces, your subsequent edits to the free body cut will also use this method.

By default, free body cuts persist only for the duration of your session. If you want to retain a free body cut that you have defined to make it available in subsequent sessions, you can save it to an XML file, to the model database, or to an output database. For more information, see *Managing session objects and session options*.

1. Locate the options for creating or editing a free body cut:
   - To create a free body cut, select **Tools->Free Body Cut->Create** from the main menu in the Visualization module.

     Tip: You can also create a free body cut using the  tool in the Visualization module toolbox.

- To edit a free body cut, select **Tools->Free Body Cut->Edit** from the main menu in the Visualization module, and select the free body cut you want to edit.

  Tip: You can also use the free body cut manager to edit a free body cut. From the main menu bar, select **Tools->Free Body Cut->Manager**, and click **Edit** from the dialog box that appears.

  The **Free Body Cross-Section** dialog box opens, from which you can customize the edges, faces, or elements and nodes that constitute the cross-section.

2. If you are creating a free body cut, choose one of the following from the **Selection Method** options, and click **OK**:

   - Select **Based on view cut** to calculate and display a free body cut based on the current view cut. If you choose this selection method, Abaqus/CAE opens the **View Cut Manager**, from which you can display and position a view cut for your model and customize the display of an associated free body cut. For more information, see *Customizing display and calculation of resultant force and moment on the active view cuts*.
   - Select **2D element edges** to specify the nodes and elements implicitly (or indirectly) by selecting element edges. This method is recommended for two-dimensional models.
   - Select **3D element faces** to specify the nodes and elements implicitly (or indirectly) by selecting element faces. This method is recommended for three-dimensional models.
   - Select **Elements and nodes** to select the elements or nodes individually for your free body cross-section.

   The **Free Body Cross-Section** dialog box opens, from which you can select the edges, faces, or elements and nodes that constitute the cross-section.

3. From the **Item** list at the top left of the dialog box, select **Surfaces**, **Display groups**, **Elements**, or **Nodes** as the type of model component to use for the free body cross-section.

   Abaqus/CAE refreshes the **Method** list.

4. Choose a selection method from the **Method** list; and/or select the specific items for the free body cross-section by picking from the viewport, selecting items from the list that appears on the right side of the dialog box, or entering data in the right side of the dialog box.

   For more information about selection options, see *Selection methods for free body cross-sections*.

   Certain items can be highlighted in the viewport to verify your selection. Toggle **Highlight items in viewport** if available.

5. When you have completed your selections, click **OK** to close the **Free Body Cross-Section** dialog box.

   The **Edit Free Body Cut** dialog box opens.

6. If desired, customize the summation point or the coordinate system transformation options for the selected free body cut.

   a. From the **Summation point** options, select the three-dimensional location from which the vectors in the free body cut originate.

      - Select **Centroid of cut** to place the summation point automatically at the area centroid of the element faces contributing to the free body computation.

Note:

When the view cut cuts through a shell, the centroid is based on the length times the shell thickness.

When the view cut cuts through a beam, the centroid is at the nodal connectivity line.

- Select **Nodal average** to place the summation point automatically at the averaged deformed coordinates of all nodes included in the free body cut.
- Select **User-defined**, and specify a custom three-dimensional location in space or click  to select the summation point from the viewport. The summation point is highlighted in the viewport.

b. From the **Component resolution** options, you can specify the coordinate system transformation that takes place when vectors are displayed in component form. (See *Customizing general display options for free body cuts*, for more information about displaying force and moment vectors in component form.)

- Select **Normal and tangential** to orient the component vectors with the normal and the tangent of the surface you select.
- Select **CSYS** and a coordinate system to transform the component vectors to a custom coordinate system. Alternatively, you can click **Create** to create a new datum coordinate system.

The **Component resolution** options affect display of free body cuts only when component vector display is selected in the **Free Body Plot Options** dialog box.

7. Click **OK**.

Abaqus/CAE creates the free body cut and displays it in the viewport.

Additional information

- *Displaying, hiding, and highlighting free body cuts*
- *Customizing free body cut display*

Selection methods for free body cross-sections

You can use the following selection methods to specify the items that will be contained in a free body cross-section:

- To specify edges or faces by picking them directly from the viewport, select **Surfaces** from the **Item** list, then select **Pick from viewport** from the **Method** list. Abaqus/CAE automatically enters the pick mode and prompts you to select items for the display group. See *Selecting objects within the viewport* for more information on picking items in the viewport.

  Click **Done** in the prompt area when you have finished picking items in the viewport.

  Click **Edit selection**, **Add selection**, or **Delete selection** in the dialog box to further modify your viewport selections.
- To specify elements or nodes by number, select **Element labels** or **Node labels** from the **Method** list. Select the name of the part instance to which the nodes or elements belong from the list in the **Part instance** field on the right side of the **Free Body Cross-Section** dialog box. In the **Labels** field, type a list of element or node numbers separated by commas or a range of numbers optionally followed by an increment; for example, 1:10 or 1:10:2.

  You can specify elements or nodes by number when you create a free body cross-section using the **Elements and nodes** selection method.
- To specify element, node, or surface sets, select **Element sets**, **Node sets**, or **Surface sets** from the **Method** list. A list of the available set names in your model appears on the right side of the **Free Body Cross-Section** dialog box. Select one or more set names from this list (see *Selecting multiple items from lists and tables* for more information).
- If you selected **Display groups** from the **Item** list, a list of the available display groups in your model appears on the right side of the **Free Body Cross-Section** dialog box. Select one or more display group names from this list (see *Selecting multiple items from lists and tables* for more information).

Displaying, hiding, and highlighting free body cuts

You can display or hide free body cuts individually in the current viewport by toggling their **Show** check boxes in the **Free Body Cut Manager**, and you can display or hide all of the free body cuts in your session by clicking **Set All On** or **Set All Off**. Active free body cuts are displayed in the viewport and are included in free body cut reports; for more information about reporting free body cut data, see *Generating tabular data reports*. The manager displays all free body cuts defined in your session and indicates whether each one is currently displayed.

You can highlight one or more free body cuts in the viewport by selecting their shortcuts under the **Free Body Cuts** container in the Results Tree.

By default, Abaqus/CAE retains no record of which free body cuts were active when you save free body cut definitions to a file for future use. If you want to retain a record of the activation status of free body cuts, toggle on **List of active view cuts + free bodies** when you save session objects to a file. For more information, see *Managing session objects and session options*.

Customizing free body cut display

This section describes how you can customize the content and appearance of free body cuts using settings in the **Free Body Plot Options** dialog box.
You can open the **Free Body Plot Options** dialog box by selecting **Options->Free Body** from the main menu bar of the Visualization module of Abaqus/CAE.

The changes you make in the **Free Body Plot Options** dialog box apply to all active free body cuts, including those displayed on view cuts, in the current viewport only. Each viewport has separate free body plot options, which provides greater flexibility in displaying free body cuts. For example, you can display only the resultant force vectors for a model's free body cuts in one viewport and display only the resultant moment vectors for the same model and free body cuts in a different viewport.

You can also control the default settings that appear in the **Free Body Plot Options** dialog box by editing the Abaqus environment file (`abaqus_v6.env`). For more information, see *Environment File Settings*.

In this section:

- *Customizing general display options for free body cuts*
- *Customizing colors for vector components*
- *Displaying or hiding individual component vectors*
- *Scaling vector length for free body cuts*
- *Customizing the display of labels in a free body cut*

Customizing general display options for free body cuts

The options on the **General** tabbed page of the **Free Body Plot Options** dialog box enable you to toggle the display of force vectors and moment vectors for free body cuts. You can also customize vector display by showing only the resultant vector or showing component vectors in the *x*-, *y*-, or *z*-directions for both force and moment values.

1. Locate the **General** options.

   Select **Options**->**Free Body** from the main menu bar in the Visualization module.
2. Toggle on **Show forces** to display force vectors for all free body cuts in the current viewport.
3. Toggle on **Show moments** to display moment vectors for all free body cuts in the current viewport.
4. Toggle on **Use constant-length arrows** to display all force and moment values with arrows of the same length. When this option is not selected, the force and moment vectors are displayed with lengths according to their magnitude.
5. From the **Vector display** options, select one of the following options:

   - Select **Resultant** to display only the resultant force and moment vectors.
   - Select **Component** to display the component force and moment vectors in the *x*-, *y*-, or *z*-directions.
6. Click **OK** to implement your changes in the current viewport and to close the **Free Body Plot Options** dialog box.

   By default, your changes are saved for the duration of the session and will affect all subsequent free body cuts plots in that viewport. If you want to retain your changes for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

Customizing colors for vector components

You can adjust the color that Abaqus/CAE uses to display the resultant vector and each component vector in the 1-, 2-, or 3-directions. These settings are available independently for force vectors and moment vectors; the **Free Body Plot Options** dialog box provides identical (but independent) options for **Force** and **Moment** vector colors. By default, the resultant force and component vectors are red and the resultant moment and component vectors are blue.

1. Locate the **Colors** options.

   Select **Options->Free Body** from the main menu bar in the Visualization module, and click the **Color & Style** tab in the dialog box that appears. The **Colors** options appear at the top of the page.

2. Click the **Force** tab or the **Moment** tab to set vector colors for force vectors or moment vectors, respectively.

3. Change the vector color for one of the vectors:

   a. Click the color sample () for the resultant vector or for one of the component vectors.

      Abaqus/CAE displays the **Select Color** dialog box.

   b. Use one of the methods in the **Select Color** dialog box to select a new color. For more information, see *Customizing colors*.

   c. Click **OK** to close the **Select Color** dialog box.

      The color sample and the selected vector change to the selected color.

   Repeat these steps to change the vector color for one or more of the other vectors.

4. Click **OK** to implement your changes and to close the **Free Body Plot Options** dialog box.

   By default, your changes are saved for the duration of the session and will affect all subsequent free body cuts plots in that viewport. If you want to retain your changes for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

Displaying or hiding individual component vectors

When free body cuts are configured to display individual component vectors in the 1-, 2-, or 3-directions instead of the resultant vector, you can display or hide each of these individual component vectors. These settings are available independently for force vectors and moment vectors; for example, you can hide component vectors for forces in the 3-direction but display component vectors for moments in the same direction.

Toggling the display of individual component vectors does not change the resultant vector display. Resultant vectors are still displayed using all three components.

1. Locate the **Color & Style** options.

   Select **Options**->**Free Body** from the main menu bar in the Visualization module, and click the **Color & Style** tab in the dialog box that appears.

2. Click the **Force** tab or the **Moment** tab to display or hide individual component vectors for force vectors or moment vectors, respectively. The **Components** options appear in the middle of the page.
3. Toggle on the **1**, **2**, or **3** options to include the selected component in vector display.
4. Click **OK** to implement your changes and to close the **Free Body Plot Options** dialog box.

   By default, your changes are saved for the duration of the session and will affect all subsequent free body cuts plots in that viewport. If you want to retain your changes for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

Scaling vector length for free body cuts

The **Scaling** options enable you to adjust the length of the vectors displayed in your free body cuts. Abaqus/CAE calculates vector length as a percentage of the size of your model or the size of your viewport. If multiple free body cuts are displayed, Abaqus/CAE uses the largest force vector or moment vector as the basis for length calculations. You can change the percentage value to increase or decrease the size of vectors, and you can choose either the model or the viewport as the basis for the vector length calculation. You can also set different vector scaling values for display of force vectors and moment vectors; the **Free Body Plot Options** dialog box provides identical (but independent) options for **Force** and **Moment** vector scaling.

1. Locate the **Color & Style** options.

   Select **Options->Free Body** from the main menu bar in the Visualization module, and click the **Color & Style** tab in the dialog box that appears.
2. Click the **Force** tab or the **Moment** tab to change vector scaling settings for force vectors or moment vectors, respectively. The **Scaling** options are in the lower third of the page.
3. From the **Basis** options, select **Screen size** or **Model size**.
4. Drag the **Percent** slider to establish the vector length as a percentage of the size of the screen or model.
5. Click **OK** to implement your changes and to close the **Free Body Plot Options** dialog box.

   By default, your changes are saved for the duration of the session and will affect all subsequent free body cuts plots in that viewport. If you want to retain your changes for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

Customizing the display of labels in a free body cut

Click the **Labels** tab to customize the display of the numeric labels that appear with the vectors in a free body cut. You can customize the appearance of the force and moment vector labels separately; the **Free Body Plot Options** dialog box includes identical (but independent) options for **Force** and **Moment** vector labels.

You can toggle the display of numeric labels on and off, and you can customize the following settings for these labels:

- The text color of the labels.
- The font of the labels.
- The format of the labels (scientific, fixed, or engineering).
- The number of decimal places displayed for the label values.

In addition, you can establish threshold values for label display. If a vector's value is smaller than the threshold value, Abaqus/CAE hides its label.

1. Locate the **Labels** options.

   Select **Options->Free Body** from the main menu bar in the Visualization module, and click the **Labels** tab in the dialog box that appears.
2. Click the **Force** tab or the **Moment** tab to customize label display for force vectors or moment vectors, respectively.
3. Toggle on **Display value next to vector symbol** to show vector labels for the selected type of vector.
4. Select the color of the vector labels for the selected type of vector.

   a. Click the **Text color** color sample .

      Abaqus/CAE displays the **Select Color** dialog box.

   b. Use one of the methods in the **Select Color** dialog box to select a new color. For more information, see *Customizing colors*.

   c. Click **OK** to close the **Select Color** dialog box.
5. Select the font of the vector labels for the selected type of vector.

   a. Click **Set Font**.

      Abaqus/CAE displays the **Select Font** dialog box.

   b. Use one of the methods in the **Select Font** dialog box to select a new font, size, and style. For more information, see *Customizing fonts*.

   c. Click **OK** to close the **Select Font** dialog box.
6. To change the format of the vector labels for the selected vector type, click the **Number Format** arrow and select one of the following formats:

   - Select **Scientific** to display legend values in scientific notation, which expresses legend values as a decimal value between 1 and 10 multiplied by a power of 10. When you select this format, the number 501,000 is displayed in the legend as `5.01e5`.
   - Select **Fixed** to display legend values without using exponent values. When you select this format, the number 501,000 is displayed in the legend as `501000.00`.
   - Select **Engineering** to select engineering notation, which expresses values in a similar format to scientific notation but allows exponent values that are multiples of three only. When you select this format, the number 501,000 is displayed in the legend as `501E3`.
7. Click the **Decimal places** arrows to specify the desired number of decimal places for each label.

8. Specify a **Threshold** value for the selected type of vector label. Vectors with a value smaller than this threshold will have their labels hidden in the viewport. The default threshold for vector label display is `1E-006`.
9. Click **OK** to implement your changes and to close the **Free Body Plot Options** dialog box.

   By default, your changes are saved for the duration of the session and will affect all subsequent free body cuts plots in that viewport. If you want to retain your changes for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

The Options toolset

The Options toolset allows you to control memory and regeneration options, configure view manipulation shortcuts, and specify a scale factor for icons.

In this section:

- *Customizing memory limits and regeneration options*
- *Using view manipulation shortcuts*
- *Scaling the size of icons*

Customizing memory limits and regeneration options

A geometric state is a snapshot of the internal representation of a part or an independent part instance. Saving geometric states in a memory cache speeds up regeneration performance; however, the saved states can consume large amounts of memory and decrease overall performance.

The options on the **Memory** tabbed page of the **Options** dialog box allow you to control the amount of memory allocated to the Abaqus kernel, specify the percentage of memory use that will prompt Abaqus/CAE to run in reduced memory mode, and tune the balance between the convenience of saving states and the performance degradation from increasing memory consumption. Select **Tools->Options** from the main menu bar to display the **Options** dialog box, then click the **Memory** tab.

In most cases the default settings will result in acceptable regeneration performance. You should modify the feature options only if Abaqus/CAE takes a long time to regenerate a part or the assembly. For more information, see *Tuning feature regeneration*.

1. From the main menu bar in any module, select **Tools->Options**.

   The **Options** dialog box appears.
2. Display the **Memory** tabbed page.
3. If desired, specify a new **Kernel memory limit** in megabytes. If this setting is zero, no limit is imposed on kernel memory.
4. Toggle on **Run in reduced memory mode when memory reaches**, and specify a percentage of the kernel memory limit above which Abaqus/CAE runs in reduced memory mode. Abaqus/CAE reduces memory by either paging geometric data to disk or by deleting data in inactive parts that can be automatically regenerated when needed.
5. If desired, change the number of geometric states that Abaqus/CAE automatically caches in memory. Ideally, to gain the maximum regeneration performance, you would save the geometric state after every feature modification. However, storing a large number of geometric states consumes large amounts of memory and hinders overall performance. Deciding how many states to save is a tradeoff between regeneration speed and memory consumption. For more information, see *What is a geometric state?*.
6. If you find that Abaqus/CAE is consuming a lot of memory on your workstation and affecting the performance of your system, you can use the **Clear** buttons in the **Options** dialog box to erase the memory associated with the part and assembly caches. Clearing this memory will increase performance; however, the snapshots of the geometric state will be erased and regeneration will be slower. For more information, see *What is a cache?*.
7. If you want to save a current state in memory, click **Cache current state** in the **Options** dialog box. Abaqus/CAE can return to this state and regenerate any subsequent additions or modifications.

   The **Options** dialog box indicates how many geometric states are stored in the caches. Click **Query** to determine the positioning of geometric states relative to the sequence of features in the current part cache or the assembly cache. When Abaqus/CAE is running in reduced memory mode, the geometric states may be deleted if the memory consumption is higher than the specified threshold.
8. + Click **OK** to change the memory limits and regeneration performance options for the current model.

   The options apply only to the current session and are not saved in the model database.

Using view manipulation shortcuts

You can access the pan, rotate, and magnify view manipulation tools using combinations of keyboard and mouse actions. These shortcuts can make it easier and less interruptive to manipulate the view of a model while performing other tasks (for example, selecting elements to define a set). Abaqus/CAE activates the specified view manipulation tool as long as the associated combination of keyboard and mouse buttons is depressed; to exit the view manipulation tool, release the associated keyboard and mouse buttons.

In addition to the default Abaqus/CAE shortcuts, you can configure the view manipulation shortcuts to mimic five other common CAD applications, as outlined in *Table 1*. Change the shortcuts configuration by selecting **Tools->Options** from the main menu bar and changing the **View Manipulation** options. Your configuration is saved for future Abaqus/CAE sessions.

Table 1: View manipulation shortcuts for available configurations ("MB" stands for "mouse button").

Application	Pan	Rotate	Zoom
Abaqus/CAE (default)	**[Ctrl][Alt][MB2]**	**[Ctrl][Alt][MB1]**	**[Ctrl][Alt][MB3]**
CATIA V5	**[MB2]**	**[MB2][MB3]**; or **[MB2][MB1]**	**[MB2][MB3]**, then release **[MB3]**; or **[MB2][MB1]**, then release **[MB1]**
SOLIDWORKS	**[Ctrl][MB2]**	**[MB2]**	**[Shift][MB2]**
HyperView	**[Ctrl][MB3]**	**[Ctrl][MB1]**	**[Ctrl][MB2]**
Creo	**[Shift][MB2]**	**[MB2]**	**[Ctrl][MB2]**
NX	**[MB2][MB3]**	**[MB2]**	**[MB2][MB1]**

Note:

The HyperView key combination for rotation (**[Ctrl][MB1]**) conflicts with the Abaqus/CAE use of this combination to unselect objects in the viewport. To make complex viewport selections where unselecting individual objects might be useful, it is recommended that you choose one of the other shortcut configurations.

Nondefault configurations of the view manipulation shortcuts change the behavior of the magnify tool. In the default Abaqus/CAE configuration, the magnify tool operates by dragging the cursor horizontally; in all other configurations, the magnify tool operates by dragging the cursor vertically.

In the default Abaqus/CAE shortcuts configuration, you can access the alternate modes of the pan, rotate, and magnify tools by holding the **[Shift]** key in addition to the other shortcut keys (see *The view manipulation tools*, for details). This convention conflicts with some of the shortcut combinations in nondefault configurations; therefore, you cannot access alternate modes of the view manipulation tools while using nondefault shortcuts. The alternate modes are always available, regardless of your shortcuts configuration, if you access a view manipulation tool using the standard methods (selecting a tool from the **View** menu in the main menu bar or clicking a tool in the View Manipulation toolbar).

1. From the main menu bar in any module, select **Tools->Options**.

   The **Options** dialog box appears.
2. Display the **View Manipulation** tabbed page.
3. Select the **Application** whose view manipulation shortcuts you want to mimic. Refer to *Table 1* for a summary of shortcuts in different applications.
4. Click **OK** to apply your specified configuration and to close the **Options** dialog box.

Scaling the size of icons

The default size for icons in toolbars and toolboxes is 24 × 24 pixels. The default size for icons in the Model Tree and the Results Tree is 16 × 16 pixels. You can specify a scale factor to increase or decrease the size of these icons so that they appear at a size that is appropriate for your display resolution. For example, increasing the icon size scale factor to 1.5 prompts Abaqus/CAE to display toolbar and toolbox icons at 36 × 36 pixels and Model Tree and Results Tree icons at 24 × 24 pixels.

Changes to icon size are implemented when you restart Abaqus/CAE. Your selected scale factor is saved for future Abaqus/CAE sessions.

1. From the main menu bar in any module, select **Tools->Options**.

   The **Options** dialog box appears.
2. Display the **Icons** tabbed page.
3. Click the arrows to the right of the **Scale factor** field to increase or decrease the size of icons in Abaqus/CAE. The maximum scale factor is 3; the minimum scale factor is 0.5.
4. Click **OK** to apply your specified configuration and to close the **Options** dialog box. You must restart your Abaqus/CAE session to view your changes.

The Geometry Edit toolset

The Geometry Edit toolset provides a set of tools in the Part module that allow you to create or edit the geometry of a part.
You can use the tools to edit the regions of a part that make it invalid or imprecise.

In this section:

- *Editing techniques*
- *Editing techniques*
- *What is stitching?*
- *A strategy for repairing geometry*
- *Creating a part from orphan elements*
- *Editing and repairing edges*
- *Editing and repairing faces*
- *Editing parts*

Editing techniques

You can use the Geometry Edit toolset in the Part module to edit or repair the geometry of a part. The Geometry Edit toolset enables you to edit an imported part to improve its precision and validity; however, Abaqus/CAE does not require parts to be completely precise. In addition, you can use the Geometry Edit toolset to remove small features from a part. You can use the Geometry Edit toolset to edit edges, faces, or the entire part. *Editing techniques*, provides an overview of the methods available for each type of partition. Abaqus/CAE stores most of the edit operations as features. As a result, you can undo an edit by deleting or suppressing the corresponding feature using the Feature Manipulation toolset.

You can access the edit tools by selecting **Tools->Geometry Edit** from the main menu and choosing the desired tool from the **Geometry Edit** dialog box that appears. You can also access the Geometry Edit tools through the Part module toolbox. *Figure 1* shows the hidden icons for all the Geometry Edit tools in the Part module toolbox.

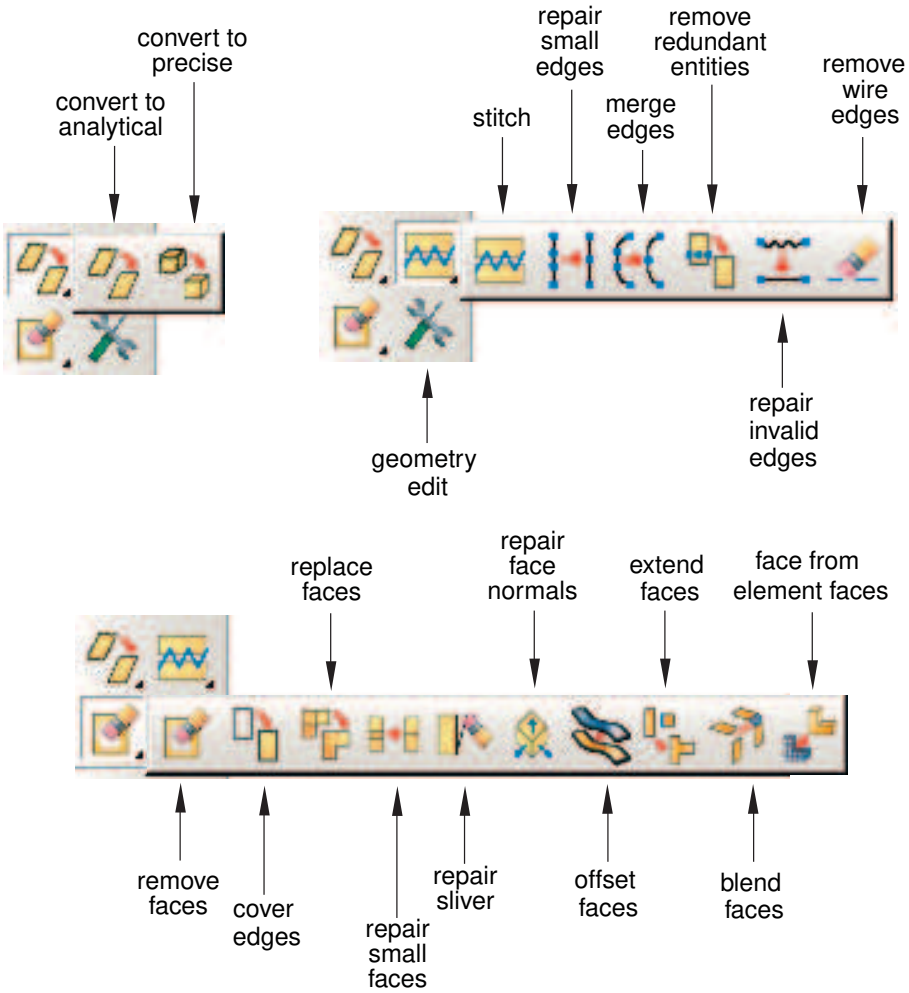

Figure 1: The Geometry Edit toolset toolbox.

To see a tooltip containing a short description of each Geometry Edit tool, hold the mouse over the tool for a moment. For more information, see *Using toolboxes and toolbars that contain hidden icons*.

Editing techniques

This section provides an overview of the different editing techniques.

In this section:

- *Methods for editing edges*
- *Methods for editing faces*
- *Methods for editing entire parts*

Methods for editing edges

Select **Tools->Geometry Edit** from the main menu to display the **Geometry Edit** dialog box.
When you choose **Edge** from the dialog box, the **Tool** list displays the following methods for editing edges:

Stitch

If a part is imported as a group of disconnected faces, you can stitch the resulting small edge gaps. Similarly, you can stitch the resulting gaps after you remove small faces or small slivers from a part. You can perform stitching as a global operation during which Abaqus/CAE stitches all gaps in the part, or you can pick the edges that you want to stitch, stitch edges with gaps smaller than a user-specified tolerance, or use both of these options. You should perform a global stitching operation for your entire part for small gaps only, and this process can be lengthy. For more information, see *What is stitching?*. You can use the Query toolset to highlight any free edges. For more information, see *Using the geometry diagnostic tools*.

Repair small

You can repair selected small edges. Abaqus/CAE removes the small edges and edits the adjoining edges to create a closed geometry.

Merge

You can select a series of connected edges, and Abaqus/CAE merges them into a single edge and deletes redundant vertices along the edges. *Figure 1* illustrates the effect of merging edges.

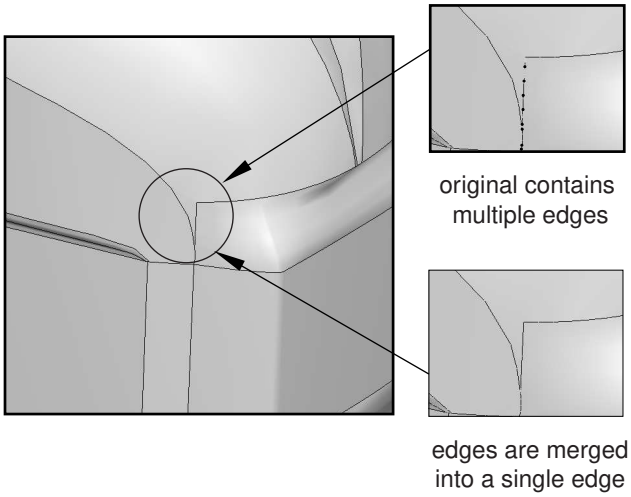

Figure 1: Merging edges.

Remove redundant entities

An imported part can contain redundant vertices that are positioned along a continuous edge. Similarly, an imported part can include redundant edges that are internal edges. Redundant vertices and edges do not change the shape or the area of a part and are not required for a complete definition, as shown in *Figure 2*.

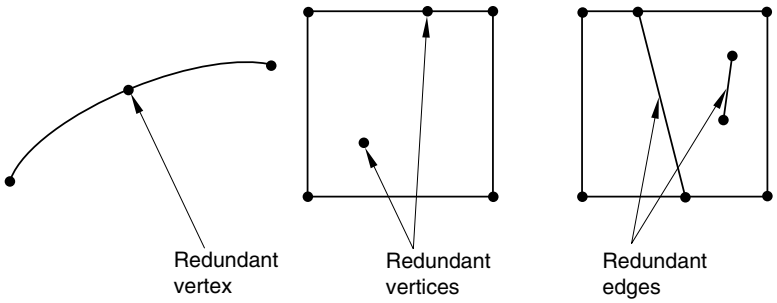

Figure 2: Redundant edges and vertices.

Repair invalid 

In rare cases after you import a part, Abaqus will report that some of its edges are invalid. The **Repair invalid** tool will try to repair the invalid edges by recomputing the data that define them. You should also use this tool if the Query toolset indicates that the part contains only invalid edges.

Remove wire 

You can remove selected wire edges. Abaqus/CAE removes the wire edges.

Methods for editing faces

When you choose **Face** from the **Geometry Edit** dialog box, the **Tool** list displays the following methods for repairing faces:

Remove 

You can remove selected faces (including chamfers, fillets, and holes) from a three-dimensional solid or shell or from a two-dimensional planar part. After you have selected the faces to remove, Abaqus/CAE looks for adjacent faces that define a feature. You can remove the entire feature, or you can remove only the selected faces. When you remove one or more faces from a three-dimensional solid part, Abaqus/CAE converts the part to a shell.

Cover edges 

You can create a face on a three-dimensional part by selecting one or more edges of the new face. Abaqus/CAE loops through the adjacent edges and calculates the location of the new face. If you selected multiple edges that are not connected by a common loop, Abaqus/CAE creates multiple faces, one for each loop of edges. Abaqus/CAE creates the new faces as shells. If the new shells form a closed part, you can use the solid-from-shell tool to convert the part to a solid.

Replace 

In some cases Abaqus/CAE may not be able to accurately recreate some of the faces when you import a part. For example, a planar face may appear wavy or distorted, or Abaqus/CAE might create small faces that have a large impact on the mesh density. You can select connected faces, and Abaqus/CAE replaces them with a single face. The new face has minimal faceting and will be smoother than the original faces. *Figure 1* illustrates the effect of replacing selected faces.

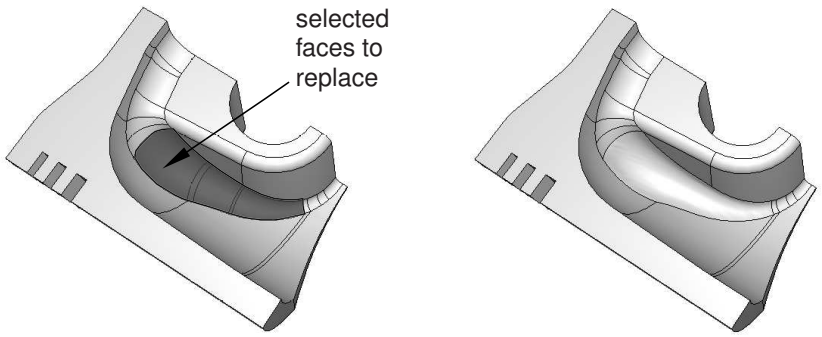

Figure 1: The effect of replacing selected faces.

Alternatively, you can replace the selected faces with a single face that is formed by extending neighboring faces. You can use this tool to remove bosses and small details from imported parts, as shown in *Figure 2*.

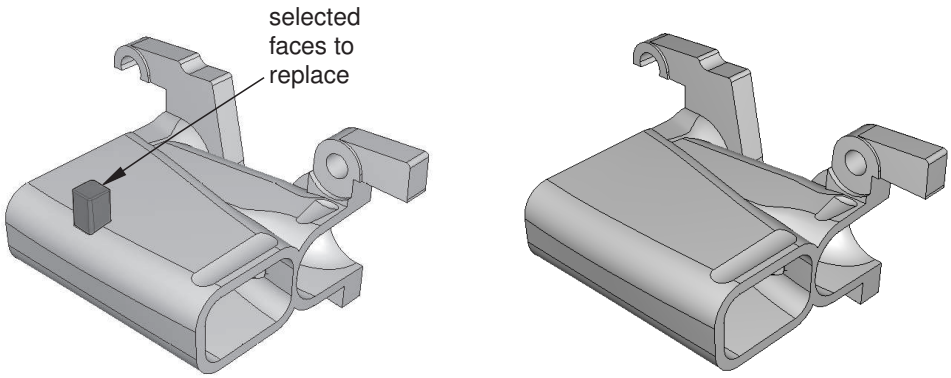

Figure 2: The effect of replacing selected faces and extending neighboring faces.

Repair small

You can repair selected small faces. Abaqus/CAE removes the small faces and edits the adjoining faces to create a closed geometry. *Figure 3* illustrates the effect of repairing small faces.

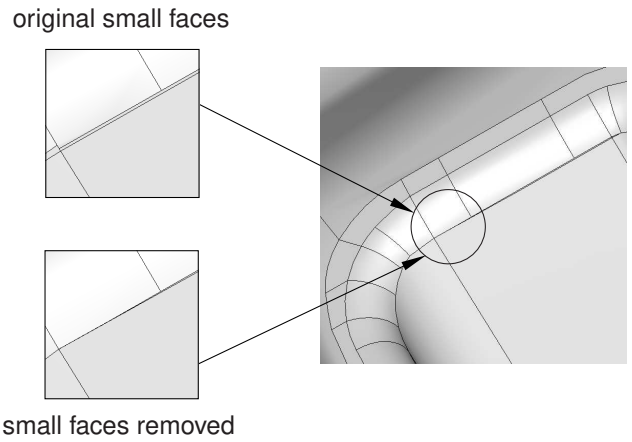

Figure 3: Repairing small faces.

Repair sliver

A sliver can be thought of as a small, sharp piece of extra material. You can remove an unwanted sliver from a face of a three-dimensional solid or shell or from a two-dimensional planar part. You must select the face containing the sliver to remove and two points from the face. Abaqus/CAE draws a line between the two points that divides the selected face into two regions. The first region is the face that will remain; the second region is the sliver that will be removed. *Figure 4* illustrates the effect of removing a sliver.

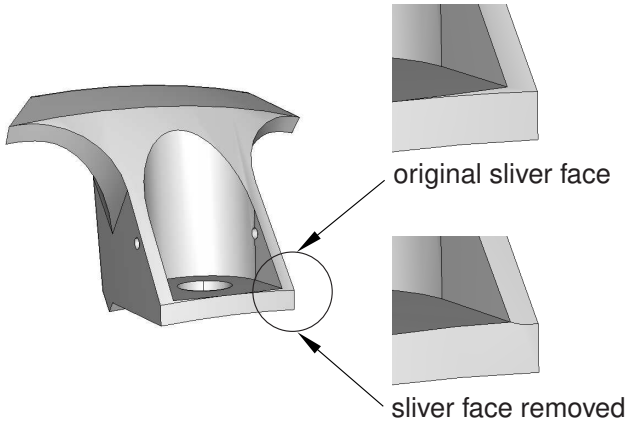

Figure 4: Removing a sliver.

Repair normals

You can repair the face normals of shell and solid imported parts, and you can perform these repairs on either manifold parts (parts in which every edge is shared by only one or two faces) and non-manifold parts. The tool has different uses for solid and shell parts.

Solid

In rare cases the Query toolset reports that the volume of an imported solid part is negative because the face normals indicate it was inside out in the CAD system from which it originated. The **Repair face normals** tool will flip the normals and turn the solid right side out.

Shell

An imported shell part can contain faces that have normals pointing in opposite directions. The **Repair face normals** tool will align all the normals on a shell part. If the face normals are already aligned, this tool will flip all the normals so that they remain aligned but point in the opposite direction.

Note:

The element normal orientation, which is specified using the **Element Normal** assignment in the Property module, specifies the relative element normal with respect to the geometry normal. These element normals will be updated using the new geometry normals after the **Repair face normals** operation.

When you perform repairs of non-manifold shell parts, you cannot align the normals for all of the faces in the part in a single operation; you must select faces individually to flip the direction of their normals. You can perform a query using the **Shell element normals** option from the **Query** dialog box to assess the orientation of the face normals before you repair your shell part.

Offset

You can create faces on a three-dimensional part by selecting the faces to be offset then specifying an offset distance or selecting target faces and a distance calculation method. The offset direction is opposite to the face

normal direction for the source face, and offset can be positive or negative. Abaqus/CAE creates the new face using the same process as that used for offsets in the Sketcher (for more information, see *Offsetting objects*).

Note:

regardless of the offset distance calculation method, Abaqus/CAE applies a constant offset to create the new face. You cannot use this method to create a face equidistant from two converging or diverging faces.

Extend 

You can extend existing faces by specifying an extension distance or selecting target faces to control the extension distance. Abaqus/CAE replaces the existing faces with the extended face feature.

Blend 

You can create new faces that blend the contours of existing edges in the model to form faces between those edges. You can choose to create the new faces by using tangency to existing faces at each edge, by calculating the shortest path between the edges, or by specifying a wire shape as the path.

Face from element faces 

You can create a new geometric face from orphan element faces. Abaqus/CAE creates a new geometric face based on the node positions of the selected element faces. Vertices are created at edge nodes where there is a significant change in the element edge direction.

Methods for editing entire parts

When you choose **Part** from the **Geometry Edit** dialog box, the **Tool** list displays the following methods for repairing entire parts:

Convert to analytical 

Abaqus/CAE tries to change the internal definition of edges, faces, and cells into a simpler form that can be represented analytically. For example, a face that is nearly planar will be converted to an equation that represents the plane. Converting to an analytical representation usually provides the following advantages:

- Processing of the part is faster.
- The converted entity is available during feature operations. For example, the extrude operation requires a planar face and a linear edge.
- The geometry is improved.
- If you subsequently need to stitch the part, the stitching operation is more likely to be successful.

Convert to precise 

Abaqus/CAE offers two methods to convert entities to precise geometry:

- If you choose **Tighten Gaps**, Abaqus/CAE attempts to improve the precision of the faces, edges, and vertices in your model. This method is faster but does not perform a full computation of the geometry.
- If you choose **Recompute Geometry**, Abaqus/CAE tries to change neighboring entities so that their geometry matches exactly. Recomputing geometry usually results in precise geometry; however, this operation can be lengthy and increases the complexity of the imported part, which means that processing of the part is slower. Moreover, if the part contains many complex surfaces, converting to a precise representation is likely to fail. If possible, you should return to the CAD application that generated the original file and increase the precision.

What is stitching?

When you select this option, Abaqus/CAE tries to join adjoining faces along their free edges. The intent of stitching is usually to create a solid part. Stitching edges usually results in valid geometry. Abaqus/CAE stitches gaps between trimmed surfaces by adjusting the underlying surfaces until the edges intersect. *Figure 1* illustrates the stitching process.

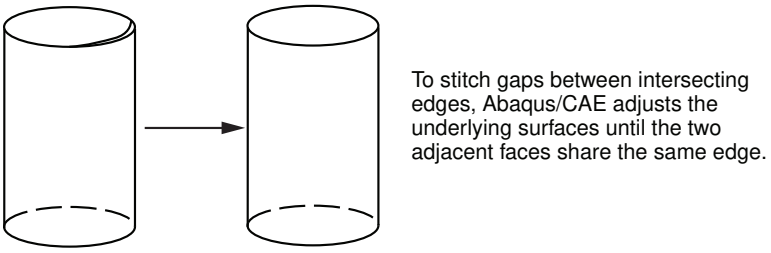

Figure 1: Stitching edges until they intersect.

Abaqus/CAE tries to recognize the edges of a solid from a set of trimmed surfaces. If the edges of each trimmed surface are close to an edge of an adjacent surface (within a user-specified tolerance), Abaqus/CAE stitches the trimmed surfaces. The end result of stitching is a B-rep solid in which the edge definition is shared between the two intersecting surfaces. For more information on B-rep solids, see *How do solid modelers represent a solid?*. Stitching fails in the presence of wires or internal faces.

When you import an IGES- or VDA-FS-format part, Abaqus/CAE stitches the part by default. However, because of the internal tolerances of IGES- and VDA-FS-format parts, the resulting representation of small features may not match the geometry that was intended in the original file.

In some cases stitching an IGES- or VDA-FS-format part results in Abaqus/CAE importing a single part that should have been imported as separate parts. If you copy the imported part to a new part, you can choose to separate disconnected regions into separate parts. For more information, see *Copying a part*.

A strategy for repairing geometry

The tools in the Geometry Edit toolset are often used to repair geometry that was imported into Abaqus/CAE. The goals of the repair operations are to create a part with no invalid entities and to create a part that has the smallest number of edges and faces to avoid impacting the mesh generation. If you are unable to create a valid part, you can ignore the invalidity. For more information, see *Working with invalid parts*. Ideally, the part will have no small edges or faces. You do not have to create a precise part, and you should continue to work with an imprecise part if possible. Parts with imprecise geometry can be meshed. However, in rare cases other operations may fail on parts with imprecise geometry; for example, other meshing functions, adding geometry features, and partitioning. If you cannot work with the imprecise part and you cannot make the part precise, you should return to the CAD application that generated the original file and increase the precision. For more information, see *What is a valid and precise part?*.

Abaqus/CAE provides many different editing tools, and it is often difficult to decide which of the tools to use and in which order to use them. In general, repairing the geometry of an imported part is an art that requires experimentation and experience. The best approach depends on the complexity of the part and how much detail you want to remain in the part when you mesh the part and analyze it.

The following guidelines will help you develop an efficient approach to repairing your parts:

Use the geometry diagnostic tools

Use the geometry diagnostic tools to query the part for invalid and imprecise entities, free edges, short edges, small faces, and sharp corner angles.

Use selection groups

You can use mouse button 3 to create temporary selection groups to make the combination of geometry diagnostic tools and repair tools easier to use. You can use the geometry diagnostic tools to highlight a region of invalid and imprecise geometry, and you can copy the region into a selection group. You can then paste the selection group into the Geometry Edit toolset when specifying the region to repair.

Use display groups

Use display groups to selectively remove faces and cells to help you see inside complex parts and to determine which entities are highlighted by the geometry diagnostic tools.

Take an incremental approach

Use the repair tools on small groups of selected faces and edges and check that the outcome of the repair process is correct before proceeding.

Keep solids intact

Try not to convert a solid into a shell by removing faces from the solid. To avoid removing faces, use the **Replace** tool for faces, and the **Repair small** tools for edges and faces.

Avoid creating wires

If your part is a solid or a shell, try not to perform operations that result in wires. It is difficult for Abaqus/CAE to reconstruct faces from wires.

Remove fillets and chamfers

Use the **Replace** tool and the **Extend neighboring faces** option to remove fillets and chamfers from your part and extend the neighboring faces to close the resulting gap.

Remove faces that meet tangentially

Use the **Replace** tool or the **Repair small** tool to repair faces that are approximately tangential. You should use the **Repair small** tool to remove faces that are relatively small. The **Repair small** tool simply extends the remaining faces until they meet. The small face is deleted in the process, although the result may be imprecise. Use the **Replace** tool for relatively large faces that meet tangentially. The **Replace** tool uses underlying points to replace the original faces with an approximate surface.

Check the validity of the part

If your part is invalid, you can check if the repair operations have made the part valid by clicking mouse button 3 on the part in the Model Tree and selecting **Update validity** from the menu that appears. Checking the validity can be a lengthy operation, and you should wait until you have finished editing the part before you check its validity. If a part is already valid, none of the repair operations will make it invalid.

Create partitions after you repair

If your part contains partitions, the Geometry Edit toolset may delete them during a repair operation. To avoid this problem, you should wait to partition the part until after you have finished editing it.

Creating a part from orphan elements

You can use tools from the Geometry Edit toolset to create geometry from the faces of orphan mesh elements. This technique is useful when you have a meshed part that requires modifications, but you do not have some or all of its geometry available. The decision to add geometric features to an orphan mesh, recreate the part geometry from scratch, or reverse engineer geometry from the orphan elements depends on a number of factors, including:

- complexity of the existing part
- complexity of the features to be added
- degree of difficulty required to modify the existing orphan mesh
- desire to create a new mesh for the entire part

Other factors such as the time constraints for the project and the ability to export model geometry may also be involved in your decision.

The goal of creating a part from an orphan mesh is to create geometry that matches the original design intent while providing a platform for current and future modifications. The geometry must also be suitable for creation of a native mesh by either full association with the current mesh or creation of a new mesh.

The following guidelines will help you create geometry for an orphan mesh:

Create new geometric faces

Use the **Face from element faces** tool  to create the outer surface geometry for the model. Each use of the tool creates a single shell face from selected exterior orphan element faces. The tool includes several unique methods for selection of multiple orphan element boundary faces, and it automatically stitches the newly created face to any adjacent geometry. For more information, see *Create face from element faces*. When you are finished creating faces, all exterior orphan element faces should be covered by geometric faces.

Remove extra edges and faces

Use other tools from the Geometry Edit toolset to remove extra edges, small faces, and any other features that would restrict generation of a good quality mesh. If necessary, convert the part to precise geometry. For more information, see *A strategy for repairing geometry*.

Convert to solid

If you are working with a solid part, use the **Create solid from shell** tool  to fill the space inside the created shell faces.

Partition and mesh the part

Suppress or delete the orphan mesh, and create a new mesh for the part.

Create partitions after you repair

If your part contains partitions, the Geometry Edit toolset may delete them during a repair operation. To avoid this problem, you should wait to partition the part until after you have finished editing it.

Editing and repairing edges

This section describes the tools that you can use to repair edges.

In this section:

- *Stitching edges to create faces*
- *Repairing small edges*
- *Merging edges*
- *Removing redundant entities*
- *Repairing invalid edges*
- *Removing wire edges*

Stitching edges to create faces

You can create new faces by automatically stitching any gaps between free edges. Stitching gaps allows you to replace small faces, fillets, or chamfers that you previously deleted. The operation to stitch gaps is stored as a feature of the part; therefore, you can use the Model Tree to delete the stitch and revert to the original part. For more information, see *What is stitching?*.

You can stitch gaps in either manifold parts (parts in which every edge is shared by only one or two faces) or non-manifold parts.

1. From the main menu bar, select **Tools->Geometry Edit**.

   Abaqus/CAE displays the **Geometry Edit** dialog box.

   Tip: You can also stitch edges using the  tool, located with the edit tools in the Part module toolbox. For a diagram of the edit tools in the toolbox, see *Editing techniques*.

2. From the dialog box, select the **Edge** category and the **Stitch** method.
3. From the warning dialog box that appears, click **OK**.
4. If desired, specify a stitch tolerance from the prompt area for the stitching operation. Abaqus/CAE will stitch only gaps smaller than the tolerance value that you specify.
5. Do one of the following:

   - If you want to select the edges for the stitching operation individually, toggle on **Pick edges**, click mouse button 2, then specify the edges you want to select. All the edges you select must be free edges because when Abaqus/CAE attempts only manifold stitching when **Pick edges** is selected. The stitching operation fails if you select any edges that are shared by more than one face.

     Tip: You can select edges individually, specify an existing set that includes edges, or select edges using the angle method. For more information about selecting geometry in the viewport, see *Selecting objects within the current viewport*.

   - If you want to stitch edges throughout the entire model, toggle off **Pick edges** and click mouse button 2. When **Pick edges** is toggled off, Abaqus/CAE can attempts both manifold and non-manifold stitching on the whole model. If any of the edges of the model are shared by more than one face, the resultant model will be non-manifold.

   Abaqus/CAE attempts to stitch the part according to your specifications. If the repair is successful, Abaqus/CAE prompts you to update the validity of the part.

6. If you have editing the part, you should check its validity by clicking mouse button 3 on the part in the Model Tree and selecting **Update validity** from the menu that appears.

Additional information

- *Valid parts, precise parts, and tolerance*
- *Methods for editing faces*

Repairing small edges

You can repair selected small edges from a part. Abaqus/CAE removes the small edges and repairs the adjoining edges and faces to create a closed geometry. The operation to repair small edges is stored as a feature of the part; therefore, you can use the Model Tree to delete or suppress the operation.

1. From the main menu bar, select **Tools->Geometry Edit**.

   Abaqus/CAE displays the **Geometry Edit** dialog box.

   Tip: You can also repair small faces using the  tool, located with the edit tools in the Part module toolbox. For a diagram of the edit tools in the toolbox, see *Editing techniques*.

2. From the dialog box, select the **Edge** category and the **Repair small** method.
3. Select the edges that you want to repair. You can select the edges from the viewport or select an existing set containing the edges.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

   You can use a combination of drag select, **[Shift] + Click**, **[Ctrl] + Click**, and the angle method to select more than one small edge to repair. For more information, see *Selecting objects within the current viewport*.

   Tip: If you are unable to select the desired edges, you can use the **Selection** toolbar to change the selection behavior. For more information, see *Using the selection options*.

4. Click mouse button 2 to indicate that you have finished selecting small edges.

   Abaqus/CAE removes the selected small edges from the part and prompts you to update the validity of the part.

5. Do one of the following:

   - Click **Yes** to update the validity of the part. (You should update the validity of the part whenever you repair small edges.)
   - Click **No** to skip the update and continue your repairs.
   - Click **Cancel** to cancel the changes in the current repair operation.

   You can also update the validity of a part at any time by clicking mouse button 3 on the part in the Model Tree and selecting **Update validity** from the menu that appears.

Additional information

- *Valid parts, precise parts, and tolerance*
- *Methods for editing edges*

Merging edges

You can merge selected edges from a part into a single edge. Merging edges also removes redundant vertices and edges. When you select an edge to merge, Abaqus/CAE searches for all connected edges until it encounters a branch and appends the connected edges to your selection. The operation to merge edges is stored as a feature of the part; therefore, you can use the Model Tree to delete or suppress the operation.

1. From the main menu bar, select **Tools->Geometry Edit**.

   Abaqus/CAE displays the **Geometry Edit** dialog box.

   Tip: You can also merge edges using the  tool, located with the edit tools in the Part module toolbox. For a diagram of the edit tools in the toolbox, see *Editing techniques*.

2. From the dialog box, select the **Edge** category and the **Merge** method.
3. Select the edges that you want to merge. Abaqus/CAE searches for all connected edges until it encounters a branch and selects all of the connected edges.

   You can select the edges from the viewport or select an existing set containing the edges.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

   You can use a combination of drag select, **[Shift] + Click**, **[Ctrl] + Click**, and the angle method to select more than one edge to merge. For more information, see *Selecting objects within the current viewport*.

   Tip: If you are unable to select the desired edges, you can use the **Selection** toolbar to change the selection behavior. For more information, see *Using the selection options*.

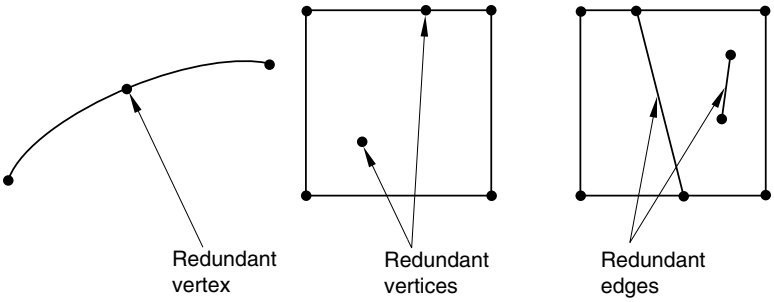
4. Click mouse button 2 to indicate that you have finished selecting edges.

   Where possible, Abaqus/CAE merges selected edges into single edges. Abaqus/CAE displays an error message if no edges can be merged; otherwise, Abaqus/CAE prompts you to update the validity of the part.

5. Do one of the following:

   - Click **Yes** to update the validity of the part. (You should update the validity of the part whenever you merge edges.)
   - Click **No** to skip the update and continue your repairs.
   - Click **Cancel** to cancel the changes in the current repair operation.

   You can also update the validity of a part at any time by clicking mouse button 3 on the part in the Model Tree and selecting **Update validity** from the menu that appears.



Additional information

- *Valid parts, precise parts, and tolerance*
- *Methods for editing edges*

Removing redundant entities

You can use the **Remove redundant entities** tool to remove redundant vertices and edges from a selected region.

An imported part can contain redundant vertices that are not attached to an edge or are positioned along a straight edge. Similarly, an imported part can include redundant edges that are not connected to a face or are internal edges. Redundant vertices and edges do not change the shape or the area of a part and are not required for a complete definition, as shown in the following figure:

The Query toolset provides a set of geometry diagnostic tools that allow you to locate areas of invalid and imprecise geometry. For more information, see *Using the Query toolset in the Part module*. The operation to remove redundant entities is stored as a feature of the part; therefore, you can use the Model Tree to restore vertices and edges that you deleted.

1. From the main menu bar, select **Tools->Geometry Edit**.

   Abaqus/CAE displays the **Geometry Edit** dialog box.

   Tip: If you are using the Part module, you can also remove redundant entities using the tool, located with the edit tools in the module toolbox. For a diagram of the edit tools in the Part module toolbox, see *Editing techniques*.

2. From the dialog box, select the **Edge** category and the **Remove redundant entities** method.
3. Select the region from which Abaqus/CAE should remove redundant edges and vertices. You can select the region from the viewport or select an existing set containing the region.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

4. From the prompt area, toggle off **Remove redundant edge vertices** if you do not want to remove vertices.
5. From the prompt area, click **Done**.

   Abaqus/CAE removes the redundant entities from the selected region and prompts you to update the validity of the part.

6. Do one of the following:

   - Click **Yes** to update the validity of the part. (You should update the validity of the part whenever you remove redundant entities.)
   - Click **No** to skip the update and continue your edits.

- Click **Cancel** to cancel the changes in the current editing operation.

You can also update the validity of a part at any time by clicking mouse button 3 on the part in the Model Tree and selecting **Update validity** from the menu that appears.

Additional information

- *Valid parts, precise parts, and tolerance*
- *Methods for editing edges*

Repairing invalid edges

In rare cases after you import a part, Abaqus will report that all of its edges are invalid. The **Repair invalid** tool attempts to repair the invalid edges by recomputing the data that define them, which can help repair some types of invalidity. You should also use this tool if only invalid edges remain after automatically repairing a part.

The Query toolset provides a set of geometry diagnostic tools that determine if a part contains invalid edges. For more information, see *Using the Query toolset in the Part module*. The operation to repair invalid edges is stored as a feature of the part; therefore, you can use the Model Tree to delete or suppress the operation.

1. From the main menu bar, select **Tools->Geometry Edit**.

   Abaqus/CAE displays the **Geometry Edit** dialog box.

   Tip: You can also repair invalid edges using the  tool, located with the edit tools in the Part module toolbox. For a diagram of the edit tools in the toolbox, see *Editing techniques*.

2. From the dialog box, select the **Edge** category and the **Repair invalid** method.

   Abaqus/CAE repairs invalid edges and prompts you to update the validity of the part.

3. Do one of the following:

   - Click **Yes** to update the validity of the part. (You should update the validity of the part whenever you repair invalid edges.)
   - Click **No** to skip the update and continue your repairs.
   - Click **Cancel** to cancel the changes in the current repair operation.

   You can also update the validity of a part at any time by clicking mouse button 3 on the part in the Model Tree and selecting **Update validity** from the menu that appears.

Additional information

- *Valid parts, precise parts, and tolerance*
- *Methods for editing edges*

Removing wire edges

You can remove selected wire edges from a part. Wire edges are wires, as opposed to edges of a solid or shell feature. The operation to remove wire edges is stored as a feature of the part; therefore, you can use the Model Tree to delete or suppress the operation.

1. From the main menu bar, select **Tools->Geometry Edit**.

   Abaqus/CAE displays the **Geometry Edit** dialog box.

   Tip: You can also remove wire edges using the  tool, located with the edit tools in the Part module toolbox. For a diagram of the edit tools in the toolbox, see *Editing techniques*.

2. From the dialog box, select the **Edge** category and the **Remove wire** method.
3. Select the wire edges that you want to remove. You can select the edges from the viewport or select an existing set containing the edges.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

   You can use a combination of drag select, **[Shift] + Click**, **[Ctrl] + Click**, and the angle method to select more than one wire edge to remove. For more information, see *Selecting objects within the current viewport*.

   Tip: If you are unable to select the desired edges, you can use the **Selection** toolbar to change the selection behavior. For more information, see *Using the selection options*.

4. Click mouse button 2 to indicate that you have finished selecting wire edges.

   Abaqus/CAE removes the wire edges and prompts you to update the validity of the part.

5. Do one of the following:

   - Click **Yes** to update the validity of the part. (You should update the validity of the part whenever you remove wire edges.)
   - Click **No** to skip the update and continue your repairs.
   - Click **Cancel** to cancel the changes in the current repair operation.

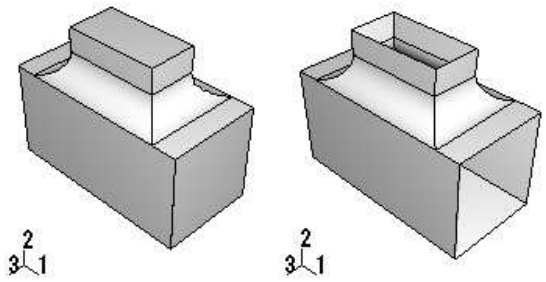
   You can also update the validity of a part at any time by clicking mouse button 3 on the part in the Model Tree and selecting **Update validity** from the menu that appears.

Additional information

- *Valid parts, precise parts, and tolerance*
- *Methods for editing edges*

Editing and repairing faces

This section describes the tools that you can use to repair faces.



In this section:

- *Removing faces*
- *Covering edges with a new face*
- *Replace faces*
- *Repairing small faces*
- *Repairing a sliver*
- *Repairing face normals*
- *Offset faces*
- *Extend faces*
- *Blend faces*
- *Create face from element faces*

Removing faces

To make a part valid or precise, you can use the remove faces tool to remove selected faces from a three-dimensional solid or shell or from a two-dimensional planar part.

After you have selected the faces to remove, Abaqus/CAE looks for adjacent faces that define a feature. You can remove the entire feature, or you can remove only the selected faces. When you remove one or more faces from a solid part, Abaqus/CAE converts all of the cells in the part to a shell, as shown in the following figure:

The Query toolset provides a set of geometry diagnostic tools that allow you to locate areas of invalid and imprecise geometry. For more information, see *Using the Query toolset in the Part module*. The operation to remove faces is stored as a feature of the part; therefore, you can use the Model Tree to restore faces that you deleted.

1. From the main menu bar, select **Tools->Geometry Edit**.

   Abaqus/CAE displays the **Geometry Edit** dialog box.

   Tip: You can also remove faces using the tool, located with the edit tools in the Part module toolbox. For a diagram of the edit tools in the toolbox, see *Editing techniques*.

2. From the dialog box, select the **Face** category and the **Remove** method.
3. Select the faces that you want to remove. You can select the faces from the viewport or select an existing set containing the faces.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

   You can use a combination of drag select, **[Shift] + Click**, **[Ctrl] + Click**, and the angle method to select more than one face to remove. For more information, see *Selecting objects within the current viewport*.

   Tip: If you are unable to select the desired faces, you can use the **Selection** toolbar to change the selection behavior. For more information, see *Using the selection options*.

4. Click mouse button 2 to indicate that you have finished selecting faces.

   Note:

   If you are removing one or more faces from a solid part, Abaqus/CAE indicates that removing the faces will result in the solid being converted to a shell and prompts you to continue.

Abaqus/CAE removes the selected faces.

Additional information

- *Valid parts, precise parts, and tolerance*
- *Methods for editing faces*

Covering edges with a new face

You can create a face by selecting the edges that the new face will cover. The selected edges must form a closed loop. Abaqus/CAE creates the new face as a shell. If the new shell forms a closed part, you can use the solid-from-shell tool to convert the part to a solid. For more information, see *Creating a solid feature from a shell*. The cover edges operation is stored as a feature of the part; therefore, you can use the Model Tree to delete faces that you created. Abaqus/CAE creates the new face by projecting a face on the plane formed by the selected edges. Therefore, you should not use the **Cover edges** tool if the resulting face would be very convex.

1. From the main menu bar, select **Tools->Geometry Edit**.

   Abaqus/CAE displays the **Geometry Edit** dialog box.

   Tip: You can also create a face using the tool, located with the edit tools in the Part module toolbox. For a diagram of the edit tools in the toolbox, see *Editing techniques*.

2. From the dialog box, select the **Face** category and the **Cover edges** method.
3. Select the edges that form a loop and define the edges of the new face. You can select the edges from the viewport or select an existing set containing the edges. You can select more than one loop, and Abaqus/CAE will create more than one face. However, the loops should not be concentric.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

4. From the prompt area, click **Done**.

   Abaqus/CAE creates the new face.

5. If you have finished editing the part, you should check its validity by clicking mouse button 3 on the part in the Model Tree and selecting **Update validity** from the menu that appears.

Additional information

- *Valid parts, precise parts, and tolerance*
- *Methods for editing faces*

Replace faces

If faces from an imported part do not appear to have been formed correctly, you can replace the faces with a new face generated by Abaqus/CAE based on the underlying geometry. Because Abaqus/CAE relies on the underlying geometry, you should not use the **Replace** tool if the resulting face would be very convex. If you select more than one face to replace, the faces must be connected.

Alternatively, you can replace a face by extending neighboring faces. This tool is useful for removing bosses or small bumps from your parts.

1. From the main menu bar, select **Tools->Geometry Edit**.

   Abaqus/CAE displays the **Geometry Edit** dialog box.

   Tip: You can also replace faces using the  tool, located with the edit tools in the Part module toolbox. For a diagram of the edit tools in the toolbox, see *Editing techniques*.

2. From the dialog box, select the **Face** category and the **Replace** method.
3. Select the faces that you want to replace. The faces must be connected. You can select the faces from the viewport or click mouse button 3 to paste faces into your selection from a temporary selection group (for details, see *What is a selection group?*).

   You can use a combination of drag select, **[Shift] + Click**, **[Ctrl] + Click**, and the angle method to select more than one face to replace. For more information, see *Selecting objects within the current viewport*.

   Tip: If you are unable to select the desired faces, you can use the **Selection** toolbar to change the selection behavior. For more information, see *Using the selection options*.

4. From the prompt area, toggle on **Extend neighboring faces** to replace the selected faces with a single face that is formed by extending neighboring faces.
5. Click mouse button 2 to indicate that you have finished selecting faces.

   Abaqus/CAE replaces the selected faces.

6. If you have finished editing the part, you should check its validity by clicking mouse button 3 on the part in the Model Tree and selecting **Update validity** from the menu that appears.

Additional information

- *Valid parts, precise parts, and tolerance*
- *Methods for editing faces*

Repairing small faces

You can repair selected small faces of a part. Abaqus/CAE removes the small faces and repairs the adjoining edges and faces to create a closed geometry. The operation to repair small faces is stored as a feature of the part; therefore, you can use the Model Tree to delete or suppress the operation.

1. From the main menu bar, select **Tools->Geometry Edit**.

   Abaqus/CAE displays the **Geometry Edit** dialog box.

   Tip: You can also repair small faces using the  tool, located with the edit tools in the Part module toolbox. For a diagram of the edit tools in the toolbox, see *Editing techniques*.

2. From the dialog box, select the **Face** category and the **Repair small** method.
3. Select the faces that you want to repair. You can select the faces from the viewport or select an existing set containing the faces.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

   You can use a combination of drag select, **[Shift] + Click**, **[Ctrl] + Click**, and the angle method to select more than one small face to repair. For more information, see *Selecting objects within the current viewport*.

   Tip: If you are unable to select the desired faces, you can use the **Selection** toolbar to change the selection behavior. For more information, see *Using the selection options*.

4. Click mouse button 2 to indicate that you have finished selecting small faces.

   Abaqus/CAE repairs the small faces and prompts you to update the validity of the part.

5. Do one of the following:

   - Click **Yes** to update the validity of the part. (You should update the validity of the part whenever you repair small faces.)
   - Click **No** to skip the update and continue your repairs.
   - Click **Cancel** to cancel the changes in the current repair operation.

   You can also update the validity of a part at any time by clicking mouse button 3 on the part in the Model Tree and selecting **Update validity** from the menu that appears.

Additional information

- *Valid parts, precise parts, and tolerance*
- *Methods for editing faces*

Repairing a sliver

You can think of a sliver as a piece of extra material in a face. You can repair an unwanted sliver and remove it from a face of a three-dimensional solid or shell or from a two-dimensional planar part. You must select the face containing the sliver to repair and two points from the face. Abaqus/CAE uses the two points to divide the selected face into two regions. It then deletes the smaller region (the sliver) and retains the larger region. If the smaller region is relatively large compared with its neighbors, the operation fails. The operation to repair a sliver is stored as a feature of the part; therefore, you can use the Model Tree to delete or suppress the operation.

1. From the main menu bar, select **Tools->Geometry Edit**.

   Abaqus/CAE displays the **Geometry Edit** dialog box.

   Tip: You can also remove a sliver using the  tool, located with the edit tools in the Part module toolbox. For a diagram of the edit tools in the toolbox, see *Editing techniques*.

2. From the dialog box, select the **Face** category and the **Repair sliver** method.
3. Select the face that you want to repair. You can select the face from the viewport or select an existing set containing the face.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

   Tip: If you are unable to select the desired face, you can use the **Selection** toolbar to change the selection behavior. For more information, see *Using the selection options*.

4. Select a point that defines a corner of the sliver.
5. Select a second point that defines the opposite corner of the sliver.
6. Abaqus/CAE draws a line between the two selected points and removes the resulting small face.

Additional information

- *Valid parts, precise parts, and tolerance*
- *Methods for editing faces*

Repairing face normals

You can repair the face normals of shell and solid imported parts, and you can perform these repairs on either manifold parts (parts in which every edge is shared by only one or two faces) or non-manifold parts.

If Abaqus reports that the volume of an imported part is negative, it means that the solid has been turned inside out. The **Repair normals** tool will flip the normals and turn the solid right side out.

An imported shell part can contain faces that have normals pointing in opposite directions. The **Repair normals** tool will align all the selected normals on a shell part. If the face normals are already aligned, this tool will flip all the selected normals so that they remain aligned but point in the opposite direction.

Note:

Abaqus/CAE does not flip normals that have been assigned to shell faces manually using the **Element Normal** assignment option in the Property module.

When you perform repairs of non-manifold shell parts, you cannot flip the normals for all of the faces in the part in a single operation; you must select each face individually to flip the direction of its normal. Performing a query using the **Shell element normals** option from the **Query** dialog box can help you assess the orientation of the face normals before you repair your shell part.

The Query toolset provides a set of geometry diagnostic tools that calculate the volume of a solid part and display the normals of shells and membranes. For more information, see *Using the Query toolset in the Part module*. The operation to repair face normals is stored as a feature of the part; therefore, you can use the Model Tree to delete or suppress the operation.

1. From the main menu bar, select **Tools->Geometry Edit**.

   Abaqus/CAE displays the **Geometry Edit** dialog box.

   Tip: You can also repair face normals using the  tool, located with the edit tools in the Part module toolbox. For a diagram of the edit tools in the toolbox, see *Editing techniques*.

2. From the dialog box, select the **Face** category and the **Repair normals** method.
3. Select one of the following options from the prompt area:
   - Click **Entire Part** to repair face normals for every incorrectly oriented face in your part.
   - Click **Select Faces** to select individual faces in your part.
4. If you are selecting individual faces in your part, choose the face normals that you want to repair from the viewport, then click **Done** from the prompt area.

   You can use a combination of drag-select, **[Shift] + Click**, and **[Ctrl] + Click** to select faces in your part, and you can also use the angle method or the face curvature method to select faces. For more information, see *Selecting objects within the current viewport*.

   Abaqus/CAE repairs the face normals.

Additional information

- *Valid parts, precise parts, and tolerance*
- *Methods for editing faces*

Offset faces

You can create faces by offsetting them from existing faces. Abaqus/CAE creates the new faces as a shell. The offset operation is stored as a feature of the part; therefore, you can use the Model Tree to delete faces that you created. You can use offset faces when creating a midsurface model; for information, see *Midsurface modeling*."

You can use target faces to compute an offset distance as shown in *Figure 1*, or you can specify an offset distance.

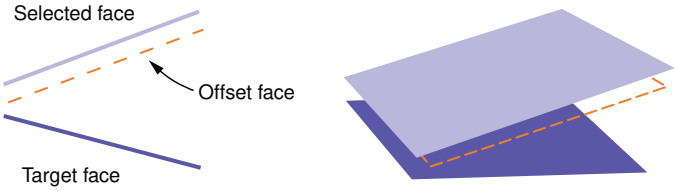


Figure 1: A constant offset distance between diverging faces.

Regardless of the offset distance method that you choose, Abaqus/CAE creates all new faces at a constant offset distance from the selected faces, as shown in the figure. However, if you use target faces to compute the offset distance, Abaqus/CAE uses the selected faces and the target faces to calculate the thickness and offset distance at each node in the offset faces such that the behavior of the offset faces approximates the behavior of the original sections. You can view the result of these calculations after the part is meshed by showing the native mesh and toggling on **Render shell thickness** with a **Scale factor** of 1 in the **Part Display Options** dialog box.

You can review and edit the shell thickness values with the **Assign thickness and Offset** tool (for more information, see *Assigning thicknesses and offsets*), or you can specify a thickness for the new faces when you assign a section to them.

1. From the main menu bar, select **Tools->Geometry Edit**.

   Abaqus/CAE displays the **Geometry Edit** dialog box.

   Tip: You can also offset faces using the tool, located with the edit tools in the Part module toolbox. For a diagram of the edit tools in the toolbox, see *Editing techniques*.

2. From the dialog box, select the **Face** category and the **Offset** method.
3. Select the faces to offset. You can select faces individually, by face angle, or by face curvature; and you can select an existing set containing the faces. For more information on selecting objects in the viewport, see *Selecting objects within the current viewport*.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

4. From the prompt area, click **Done**.

   Abaqus/CAE displays the **Offset Faces** dialog box.

5. Choose one of the available options to determine the offset distance:

   Note:

   Regardless of the calculation method, Abaqus/CAE applies a constant offset to the faces as shown in *Figure 1*. You must use another method to create new faces centered between converging or diverging faces.

Use target faces to compute distance

Select a target face or faces. Abaqus/CAE computes the distance between the faces to be offset and the target faces by sampling the faces at several points. Use one of the following distance options:

- Select **Half the average distance** to offset the new faces by this amount.
- Select **Fraction distance to closest point on face**, and enter a value.

  Abaqus/CAE offsets the new faces by the distance to the closest point on the target faces times the entered value.
- Select **Fraction distance to farthest point on face**, and enter a value.

  Abaqus/CAE offsets the new faces by the distance to the farthest point on the target faces times the entered value.

You can select the target faces using the same methods you used in Step 3. If your original faces are part of the reference representation for a midsurface model, you can click **Auto Select** to have Abaqus/CAE select appropriate faces from the opposite side of the reference representation. Varying distances between potential target faces may result in selections that only partially match the original faces. If necessary, click **Edit** to modify the selections in the viewport.

Distance

Enter an offset distance, or select  to measure and enter a distance between objects in the viewport.

Negative values for the fraction or actual distance create an offset in the face normal direction; positive values create an offset in the opposite direction. If you are uncertain of the normal directions, use the **Shell element normals** general query to view the normal directions for shells in the model. For more information, see *Obtaining general information about the model*. The normals for solids point toward the outside, so a positive offset will create a face inside the part unless the offset distance is greater than the part thickness.

6. If the model contains a reference representation, toggle **Auto trim to reference representation** to control whether Abaqus/CAE matches the offset faces to the reference representation.

   If this option is toggled on, Abaqus/CAE extends the offset faces along their free edges and trims them where they intersect with the reference representation.

   Note:

   Face extension may fail for complex faces. If face extension fails, Abaqus/CAE indicates the error and trims any unextended faces that intersect with the reference representation.

7. Click **OK**.

   Abaqus/CAE creates new faces at the prescribed distance from the originals, and the procedure restarts at Step 3.

8. To exit the offset procedure, either

   - click the cancel button  in the prompt area, or
   - click mouse button 2 anywhere in the Abaqus/CAE window, or

- select another operation from the Geometry Edit toolset or from the tools in the Part module.

Additional information

- *Valid parts, precise parts, and tolerance*
- *Using the offset face tool for midsurface modeling*
- *Methods for editing faces*

Extend faces

You can edit faces by extending existing faces. The extend operation is stored as a feature of the part; therefore, you can use the Model Tree to edit the distance parameter if the distance method is used or to delete the extended faces.

Figure 1 shows the use of target faces to extend a face. The top images show the complete part, which includes a central planar face separated from the surrounding faces by a small gap. The surrounding faces enclose about two and a half sides of the planar face. The planar face is selected for extension, and the surrounding faces are used as target faces. The selected face is extended along the three sides that would intersect with the target faces. The two lower images detail how you can control the extension where the selected face extends beyond the end of the target face on the left side. In the lower left image the **Trim to extended underlying target surfaces** option was used such that the entire left edge of the selected face is extended uniformly—as if the target face extended to the full height of the selected face. In the lower right image the face is extended only up to where the target face ends.

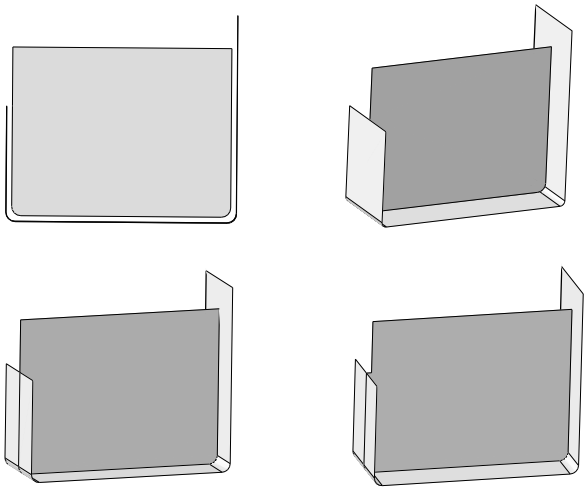

Figure 1: The effect of toggling the Trim to extended underlying target surfaces option when extending a face: initial model with gap (top left and right), on (lower left), and off (lower right).

1. From the main menu bar, select **Tools->Geometry Edit**.

   Abaqus/CAE displays the **Geometry Edit** dialog box.

   Tip: You can also extend faces using the tool, located with the edit tools in the Part module toolbox. For a diagram of the edit tools in the toolbox, see *Editing techniques*.

2. From the dialog box, select the **Face** category and the **Extend** method.

   Abaqus/CAE displays the **Extend Faces** dialog box.

3. Choose one of the following methods to extend faces:

   - Toggle on **Specify edges of faces to extend**, and pick one or more edges to extend the faces that are bounded by those edges along only the selected edges.
   - Toggle on **Specify faces to extend**, and pick faces to extend them along all their free edges.

   Click **Select** to specify the edges or faces to be extended.

You can select edges individually or by edge angle; and you can select faces individually, by face angle, or by face curvature. For more information on selecting objects in the viewport, see *Selecting objects within the current viewport*. You can also select an existing set of edges or faces.

Note:

The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

4. From the prompt area, click **Done**.
5. Choose one of the available methods to determine the extension distance:

Distance

Enter an extension distance, or select  to measure and enter a distance between objects in the viewport.

Up to target faces

Select a target face or faces to limit the extension.

Abaqus/CAE highlights the target faces in yellow.

If desired, toggle on **Trim to extended underlying target surfaces** to have Abaqus/CAE temporarily extend the target faces to create intersections with the faces that you want to extend.

Up to reference representation

Abaqus/CAE uses the faces of the reference representation to limit the extension. This option is not available if the model does not contain a reference representation.

6. Click **OK**.

   If you selected target faces in Step 5 that do not completely surround the faces being extended, Abaqus/CAE indicates the edges that will intersect with the target faces—a subset of your selection from Step 3—and gives you the option to extend only these edges instead of your original selection.

   Abaqus/CAE creates the extended face feature. If you used target faces or a reference representation to limit the extension, Abaqus/CAE trims the extended faces where they intersect with the limiting faces. The extended face feature replaces the original faces in the viewport, and the procedure restarts at Step 3 using the most recently used selection method.

7. To exit the extend procedure, either

   - click the cancel button  in the prompt area, or
   - click mouse button 2 anywhere in the Abaqus/CAE window, or
   - select another operation from the Geometry Edit toolset or from the tools in the Part module.

Additional information

- *Valid parts, precise parts, and tolerance*
- *Using the extend faces tool for midsurface modeling*
- *Methods for editing faces*

Blend faces

You can create blended faces to join existing faces in the model.

Abaqus/CAE closes the space between two sets of connected edges with new faces. You can choose whether to make the new faces tangent to the selected edges, connect the edges using the shortest path between them, or specify a path that the new faces must follow between the selected edges. *Figure 1* shows two faces with the selected edges highlighted. In this example, the tangent method creates a face with a smooth radius tangent to both original faces, the shortest path method creates a planar face, and the selected path method creates a face with the profile of the selected wire edge.

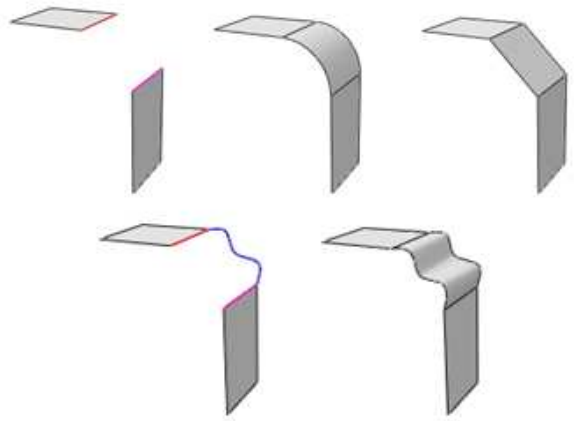

Figure 1: Creating blended faces using the tangent, shortest path, and specify path methods.

You can also create a blended face to join edges and faces. Abaqus/CAE creates blended faces between the selected edges and faces using the shortest path method. When you create a blended face feature between edges and an existing face, the new faces are always perpendicular to the existing face. The free edges are extended or shortened as needed to intersect with the edges of the face. *Figure 2* shows the selected edges and the feature created by blending between them and a planar face. The ends of the center edge are a perpendicular projection from the planar face, and the outer ends of the left and right edges are extended to meet the edges of the planar face.

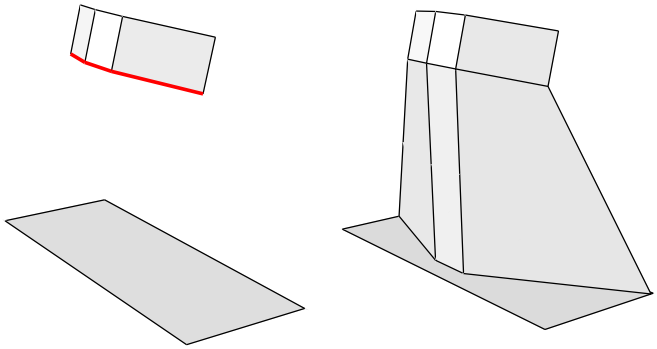

Figure 2: Creating a blended face between edges and a face.

The blend operation is stored as a feature of the part; therefore, you can use the Model Tree to delete faces that you created.

1. From the main menu bar, select **Tools->Geometry Edit**.

   Abaqus/CAE displays the **Geometry Edit** dialog box.

Tip: You can also blend faces using the  tool, located with the edit tools in the Part module toolbox. For a diagram of the edit tools in the toolbox, see *Editing techniques*.

2. From the dialog box, select the **Face** category and the **Blend** method.
3. Select edges for the first side of the blended face.

   You can select edges individually or by edge angle. For more information on selecting objects in the viewport, see *Selecting objects within the current viewport*. You can also select an existing set of edges.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

   From the prompt area, click **Done**.
4. Select edges or faces for the second side of the blended face.

   If you select faces for the second side, the edges selected in Step 3 must have a perpendicular projection onto the faces or Abaqus/CAE will not be able to create a blended face for the selections.

   From the prompt area, click **Done** to complete your selection and to open the **Blend Faces** dialog box.
5. Choose one of the available blend methods:

Tangent

Abaqus/CAE will create blended faces tangent to the faces containing the first and second side edges. To use this method, the edges selected in Step 3 and Step 4 must be free edges—edges that belong to only one feature face—so that Abaqus/CAE can calculate tangency.

Shortest path

Abaqus/CAE will create blended faces that connect the first and second side edges using the shortest path between them. If you selected a face or faces for the second side of the blend, this is the only blend method available.

Specify path

Specify a path between the edges. Click **Select** to choose an existing edge or wire feature that joins the end of one of the first side edges to the end of one of the second side edges. Abaqus/CAE will create blended faces using the profile of the selected path.

6. Click **Preview** to preview the blended face that would result from the current selections.
7. Click **OK**.

   Abaqus/CAE creates the blended face feature. The blend procedure restarts at Step 3 using the most recently used selection method.
8. To exit the blend procedure, either

   - click the cancel button  in the prompt area, or
   - click mouse button 2 anywhere in the Abaqus/CAE window, or

- select another operation from the Geometry Edit toolset or from the tools in the Part module.

Additional information

- *Valid parts, precise parts, and tolerance*
- *Methods for editing faces*

Create face from element faces

You can create a geometric face from orphan element faces in a part. Abaqus/CAE creates a new geometric face based on the nodal positions of the selected element faces. Vertices are created at edge nodes where there is a significant change in the element edge direction. The new face appears like other geometric faces in the model, and Abaqus/CAE stitches the new face to adjacent faces in the part. By default, the new face is associated with the mesh; you have the option to change this behavior. In the Model Tree, the new face appears as a **Face from mesh** feature. You cannot change the group of element faces that comprise the geometric face once it has been created; however, you can delete the face and create a new one, and you can stitch faces that were not stitched together in the original creation of the geometric face.

The new geometric face shares space with the existing orphan element faces in the model. This may result in some areas appearing with the gray unmeshed geometry coloring and others appearing with the dark green and visible element edges of the orphan mesh. This is similar to the appearance of a bottom-up meshed region, where the tan region coloring and the cyan mesh coloring appear together. You can suppress the orphan mesh in the Model Tree to view only the new geometry.

When creating geometry from orphan mesh faces, keep in mind your intended use for the resulting geometry. You want to create faces that will be a good basis for modification and meshing. For example, when you select orphan element faces, your selection should end at any sharp corners or other features so that the geometric face will also end there, creating a logical feature edge. If you do select element faces that span sharp corners, Abaqus/CAE will create a single geometric face that includes the corner—this geometry may be difficult or impossible to mesh using the available top-down meshing techniques.

Note:

When you are working with solid orphan elements, selections that include element faces on both sides of a corner (multiple selections from the same orphan element) are not acceptable for creation of a single geometric face.

When Abaqus/CAE creates a geometric face, it stitches together small gaps between edges and small gaps between analytical surfaces by default. You can customize the tolerance values that determine whether small gaps will be stitched in either case, and you can turn off stitching completely for small gaps between edges. Deferring most or all of the stitching until late in the modeling process can be a more efficient modeling option because each stitching operation is processor intensive. Fitting of analytical surfaces cannot be deferred; you must perform this step before the new geometric face is created.

1. From the main menu bar, select **Tools->Geometry Edit**.

   Abaqus/CAE displays the **Geometry Edit** dialog box.

   Tip: You can also create geometric faces from element faces using the  tool, located with the edit tools in the Part module toolbox. For a diagram of the edit tools in the toolbox, see *Editing techniques*.

2. From the dialog box, select the **Face** category and the **From element faces** method.
3. Select element faces for the new geometric face.

   You can select element faces individually, by angle, by limiting angle, by layer, or by analytic shape. For more information on selecting objects in the viewport, see *Selecting objects within the current viewport*. You can also select an existing surface. You cannot select element faces from two-dimensional or axisymmetric parts.

Note:

The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Surfaces** on the right side of the prompt area.

4. If you want to control stitching, analytical surface fitting, and the mesh association options, click **Options** in the prompt area, and do any of the following from the dialog box that appears:

   - Toggle on **Stitch with tolerance** to apply stitching of nodes in the geometric face you create, and specify the stitching tolerance value.
   - In the **Fit analytic surfaces with tolerance** field, specify the stitching tolerance value you want to use for fitting together analytical surfaces in your selection.
   - By default, Abaqus/CAE associates the geometric face with the mesh. To change this behavior, toggle off **Associate face with mesh**.

   Click **OK** to close the dialog box.

5. From the prompt area, click **Done**.

   Abaqus/CAE creates the geometric face feature. The procedure restarts at Step 3 using the most recently used selection method.

6. To exit the procedure, either

   - click the cancel button  in the prompt area, or
   - click mouse button 2 anywhere in the Abaqus/CAE window, or
   - select another operation from the Geometry Edit toolset or from the tools in the Part module.

Additional information

- *Valid parts, precise parts, and tolerance*
- *Creating a part from orphan elements*
- *Methods for editing faces*

Editing parts

This section describes the tools that you can use to repair entire parts.

In this section:

- *Converting to analytical*
- *Converting to precise*

Converting to analytical

When you convert a part to its analytical representation, Abaqus/CAE tries to change the internal definition of edges, faces, and cells into a simpler form that can be represented analytically. For example, a plane that is nearly planar will be converted to an equation that represents the plane. Converting to an analytical representation usually provides the following advantages:

- Processing of the part is faster.
- The converted entity is available during feature operations.
- The geometry is improved.
- If you subsequently need to stitch edges, the stitching operation is more likely to be successful.

After the operation is complete, you can use the geometry diagnostic tools in the Query toolset to locate any areas of invalid and imprecise geometry. For more information, see *Using the Query toolset in the Part module*.

1. From the main menu bar, select **Tools->Geometry Edit**.

   Abaqus/CAE displays the **Geometry Edit** dialog box.

   Tip: You can also convert to analytical using the  tool, located with the edit tools in the Part module toolbox. For a diagram of the edit tools in the toolbox, see *Editing techniques*.

2. From the dialog box, select the **Part** category and the **Convert to analytical** method.
3. From the warning dialog box that appears, click **OK**.

   Abaqus/CAE tries to convert the part to its analytical representation.
4. If you have finished editing the part, you should check its validity by clicking mouse button 3 on the part in the Model Tree and selecting **Update validity** from the menu that appears.

Additional information

- *Valid parts, precise parts, and tolerance*
- *Methods for editing entire parts*

Converting to precise

When you convert a part to precise, Abaqus/CAE tries to change neighboring entities so that their geometry matches exactly. Converting to a precise representation usually reduces the number of imprecise entities in a part, though for some parts the conversion can increase the number of imprecise entities. Even when the number of imprecise entities increases, the maximum tolerance of the healed part will still usually decrease; however, you should consider suppressing or deleting the convert to precise operation when the number of imprecise entities increases.

The convert to precise operation can be a lengthy one, and it can increase the complexity of the imported part; so subsequent processing of the part may be slower. Invalid entities may also result from this operation.

1. From the main menu bar, select **Tools->Geometry Edit**.

   Abaqus/CAE displays the **Geometry Edit** dialog box.

   Tip: You can also convert to precise using the  tool, located with the edit tools in the Part module toolbox. For a diagram of the edit tools in the toolbox, see *Editing techniques*.

2. From the dialog box, select the **Part** category and the **Convert to precise** method.
3. From the warning dialog box that appears, click **OK**.
4. Select one of the following methods for the conversion:

   ### Tighten Gaps

   Abaqus/CAE attempts to reduce the gaps between the nodes and edges in your part but does not perform a full computation of the geometry. This option provides a faster but less complete conversion.

   ### Recompute Geometry

   Abaqus/CAE tries to change neighboring entities so that their geometry matches exactly. Recomputing geometry usually results in precise geometry; however, this operation can be lengthy and increases the complexity of the imported part, which means that processing of the part is slower. Moreover, if the part contains many complex surfaces, converting to a precise representation is likely to fail. If possible, you should return to the CAD application that generated the original file and increase the precision.

   After you select a method, Abaqus/CAE tries to convert the part to its precise representation. If the conversion is successful, Abaqus/CAE prompts you to update the validity of the part.

5. If you have finished editing the part, you should check its validity by clicking mouse button 3 on the part in the Model Tree and selecting **Update validity** from the menu that appears.

Additional information

- *Valid parts, precise parts, and tolerance*
- *Methods for editing entire parts*

The Partition toolset

You use the Partition toolset to divide a part or assembly into regions.
Regions are used throughout the modeling process; for example, to indicate the location of a load, a change in material properties, or a mesh boundary.

This chapter explains how you use the Partition toolset to create and position partitions on an edge, a face, or a cell.

In this section:

- *Understanding the role of partitions*
- *Using the Partition toolset*
- *Understanding partitions*
- *Partitioning techniques*
- *Partitioning edges*
- *Partitioning faces*
- *Partitioning cells*

Understanding the role of partitions

As you proceed through the modeling process, you may find that you need to select a particular region that does not exist in your model. Such regions might be used to define material boundaries, indicate the location of loads and constraints, and help refine your mesh. You use the Partition toolset to partition your model into regions.

Partitions can be created on edges, faces, and cells. A partition along an edge creates a new vertex, while partitions through faces and cells create new edges and faces, respectively. In all cases, partitioning serves to subdivide the geometry being partitioned. *Figure 1* illustrates partitioning an edge, a face, and a cell.

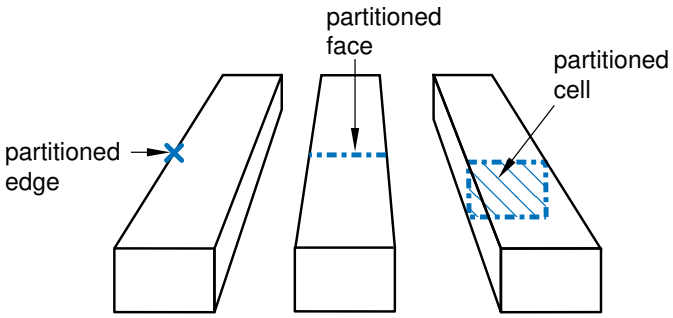

Figure 1: Partitioning an edge, a face, and a cell.

You partition edges, faces, and cells by defining partitions that refer to existing geometry. You can partition a part in either the Part module or the Property module, or you can partition an assembly in the modules that operate on the assembly. For example, you can partition a face of the assembly in the Mesh module, and you can seed the resulting internal edge to refine your mesh. A partition is a feature; and, like all features, it can be edited, deleted, suppressed, resumed, and queried. Similarly, a partition is regenerated when the assembly or a part is regenerated.

Using the Partition toolset

You can access the Partition toolset by selecting **Tools->Partition** from the menu bar. The **Create Partition** dialog box appears, and you choose the type of geometry to partition—edge, face, or cell—from the buttons in the **Type** region at the top of the dialog box. The **Method** list changes to reflect the partitions you can create. Select the desired partition tool from the **Method** list, and follow the prompts in the prompt area to create the partition. Most of the tools allow you to partition multiple edges, faces, or cells in one operation. You can use a combination of drag select, **[Shift] + Click**, **[Ctrl] + Click**, and the angle method to select the edges, faces, or cells to partition. For more information, see *Selecting objects within the current viewport*.

Partitioning techniques, provides an overview of the methods available for each type of partition. More information on creating partitions on parts and assemblies is provided in *Using the Partition toolset in the Part module* and *Partitioning the assembly*.

You can also access the Partition toolset from the module toolbox; *Figure 1* shows the hidden icons for all the partition tools in the module toolboxes.

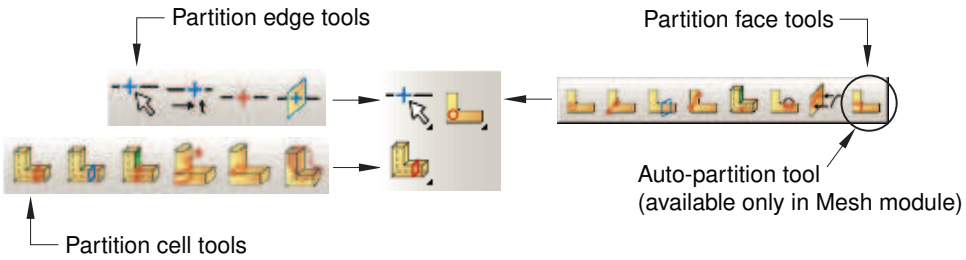

Figure 1: The partition tools.

To see a tooltip containing a short description of each partition tool, hold the mouse over the tool for a moment. For more information, see *Using toolboxes and toolbars that contain hidden icons*.

Understanding partitions

This section describes basic concepts you should understand before using the Partition toolset.

In this section:

- *Why partition?*
- *Partitions as features*

Why partition?

Deciding when to use the Partition toolset depends on how you will use the resulting regions, as described in the following list:

Partitioning parts

Use the Partition toolset in the Part or Property module to divide a part into regions. You might use the resulting regions in the Property module to apply section definitions, which include cross-sectional geometry information as well as material property information. Partitions created in the Part module and Property module are associated with the part and are available in every instance of the part in the assembly; however, you cannot modify or delete the partitions in a part instance.

Partitioning the assembly

Use the Partition toolset in the assembly-related modules to divide the part instances in the assembly into regions. You might use the resulting regions to do the following:

- Apply loads, boundary conditions, and predefined fields to regions.
- Associate an output request with regions.
- Gain finer control over the meshing process by adding internal edges that can be seeded.
- Subdivide complex three-dimensional regions into simpler regions that the automatic mesh generator can mesh.

Partitions created in an assembly are associated only with the assembly, not with the original parts, and are available in all the modules that operate on the assembly. They will not appear in other instances of the same part, and they are not available in the Part or Property module.

Additional information

- *Understanding partitions*
- *Partitioning techniques*

Partitions as features

The geometry of each part is constructed from a set of features; a partition is simply an additional geometric feature that you add to the part. Because partitions are features, they can be edited, deleted, suppressed, and resumed with the Feature Manipulation toolset.

If you create a partition and then modify the geometry of the underlying part or assembly, Abaqus/CAE regenerates the partition along with all the other features. Furthermore, the geometry of the regenerated partition is dependent on the method you used to create the partition. The following example illustrates that changes in underlying geometry can cause partitions to move or to change shape when the assembly is regenerated.

1. The user partitions a face using a line between two selected points (the centers of the two circles), as shown in *Figure 1*.

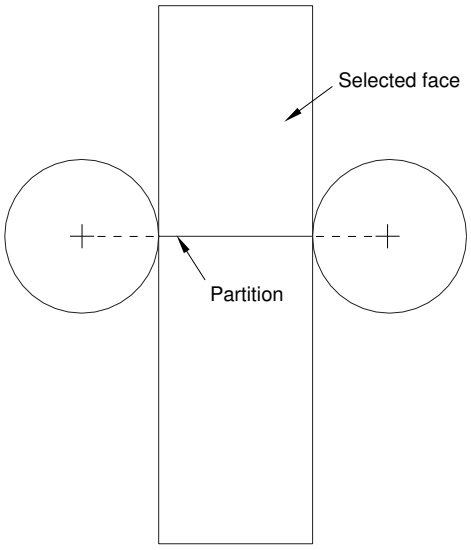

Figure 1: A partition between two selected points.

2. The user modifies the assembly, and the position of the selected points that defined the partition changes. When Abaqus/CAE regenerates the assembly, the partition is still defined as the line between the center of the two circles, as shown in *Figure 2*.

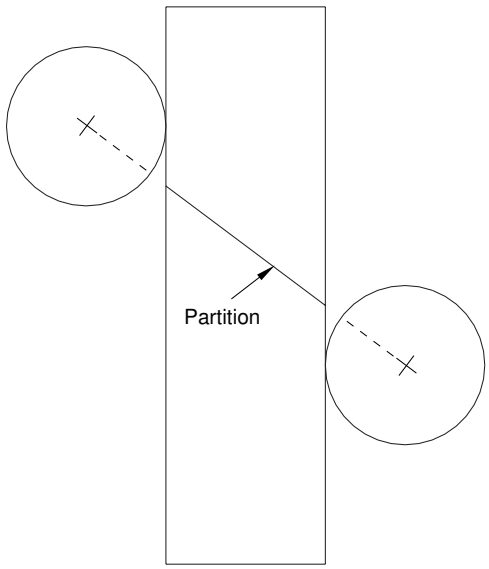

Figure 2: The partition after regeneration.

You can use the Feature Manipulation toolset to make limited modifications to some partitions:

- You can enter a parameter to partition an edge directly and to position a Bézier curve that partitions a face. The parameter must be between zero and one and represents a fraction of the length of an edge; the Feature Manipulation toolset allows you to edit the value you provided.
- You can sketch a partition on a face; the Feature Manipulation toolset allows you to edit the sketch.

If you need to change a partition that you cannot modify with the Feature Manipulation toolset, you must delete the partition and recreate it.

Additional information

• *Modifying and manipulating features*
• *Understanding partitions*
• *Partitioning techniques*

Partitioning techniques

This section provides an overview of the different partitioning techniques.

In this section:

- *Methods for partitioning edges*
- *Methods for partitioning faces*
- *Methods for partitioning cells*

Methods for partitioning edges

Select **Tools->Partition** from the main menu bar to display the **Create Partition** dialog box.
When you choose **Edge** from the **Create Partition** dialog box, the **Method** list displays the following methods for partitioning edges:

Specify parameter by location

Pick a point anywhere along the edge. For detailed instructions, see *Using the specify parameter by location method to partition edges*.

Enter parameter

Enter a parameter in the prompt area, as shown in *Figure 1*. An arrow along the edge indicates the direction of increasing parameter value from the start vertex (corresponding to an edge parameter value of zero) to the end vertex (corresponding to a value of one). For detailed instructions, see *Using the enter parameter method to partition edges*.

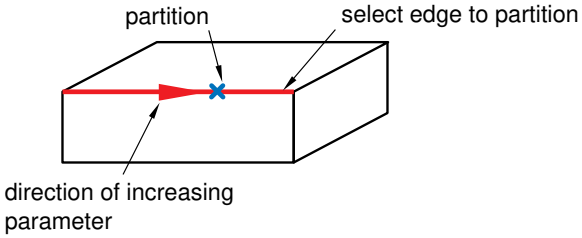

Figure 1: Entering a parameter to partition an edge.

Select midpoint/datum point

Select the midpoint of the edge or a datum point along the edge, as shown in *Figure 2*. For detailed instructions, see *Using the pick midpoint/datum point method to partition an edge*.

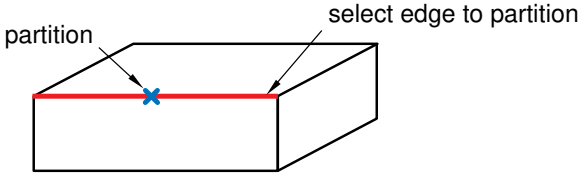

Figure 2: Selecting the midpoint or a datum to partition an edge.

Use datum plane

Select a datum plane. Abaqus/CAE creates the partition where the datum plane intersects the edges, as shown in *Figure 3*. Partitioning a group of selected edges with a datum plane is a useful technique for aligning a group of partitions. For detailed instructions, see *Using the datum plane method to partition edges*.

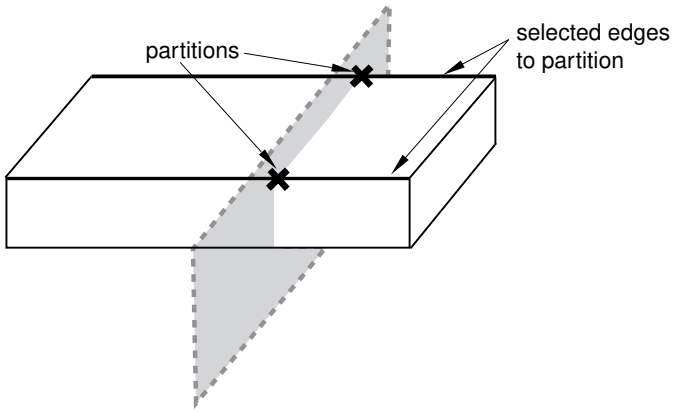

Figure 3: Selecting a datum plane to partition edges.

Additional information

- *Partitioning techniques*
- *Partitioning edges*
- *Understanding partitions*

Methods for partitioning faces

When you choose **Face** from the **Create Partition** dialog box, the **Method** list displays the following methods for partitioning faces:

Sketch planar partition

Partition a selected face by sketching a partition with the Sketcher, as shown in *Figure 1*. For detailed instructions, see *Using the sketch method to partition faces*.

You can sketch directly on the face to be partitioned, or you can sketch on a second face or datum plane and then project the sketch onto the face that you want to partition. For an example of projecting a sketch from a datum plane, see *Using the Datum toolset in the Part module*.

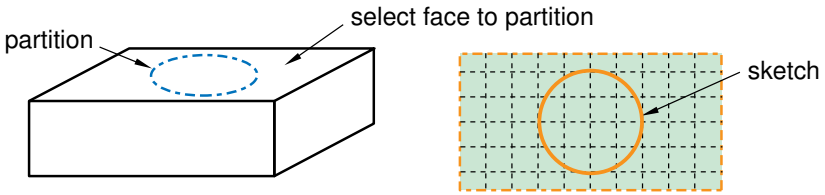

Figure 1: Partitioning a face using the Sketcher.

Shortest path between 2 points

Partition the face along the shortest path connecting two selected points; the resulting partition will be curved if the face being partitioned is curved, as shown in *Figure 2*. You can select points that are not associated with the face being partitioned; for example, the points can be located on a different face or even a different part instance. For detailed instructions, see *Using the shortest path method to partition faces*.

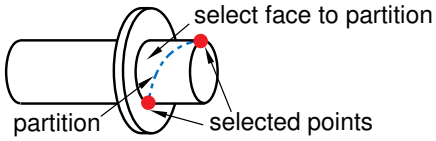

Figure 2: Partitioning a face using the shortest path between two points.

Use datum plane

Partition a face using the intersection with the extension of a datum plane, as shown in *Figure 3*. For detailed instructions, see *Using the datum plane method to partition faces*.

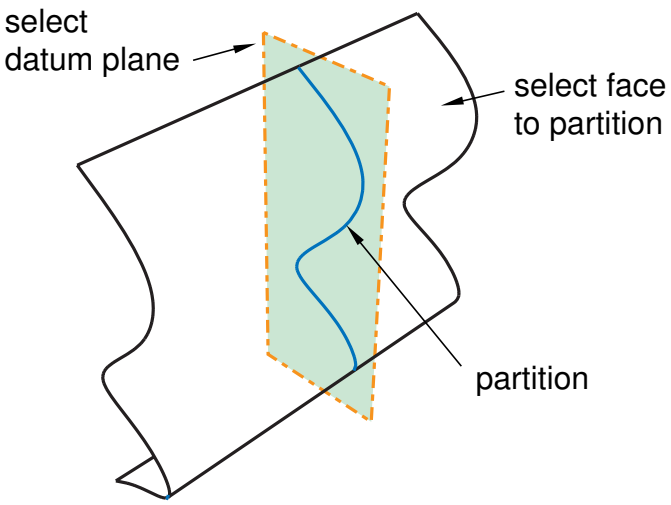

Figure 3: Partitioning a face using a datum plane.

Curved path normal to 2 edges

Partition the face along a Bézier curve that is normal to two of the face's edges, as shown in *Figure 4*. Position the curve by selecting two points anywhere along the two edges. The arc subtended by the two edges must be less than 180°. For detailed instructions, see *Using the curved path method to partition a face*.

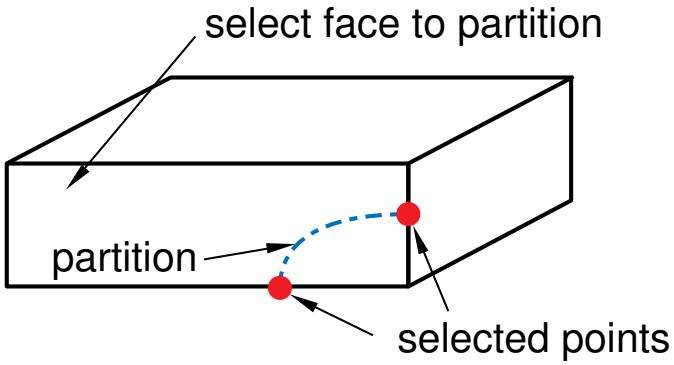

Figure 4: Partitioning a face using a Bézier curve.

Extend another face

Partition the face using the intersection with the extension of another face, as shown in *Figure 5*. The face being extended can be either planar, cylindrical, conical, or spherical; and it need not belong to the part containing the face to be partitioned. For detailed instructions, see *Using the extended face method to partition faces*.

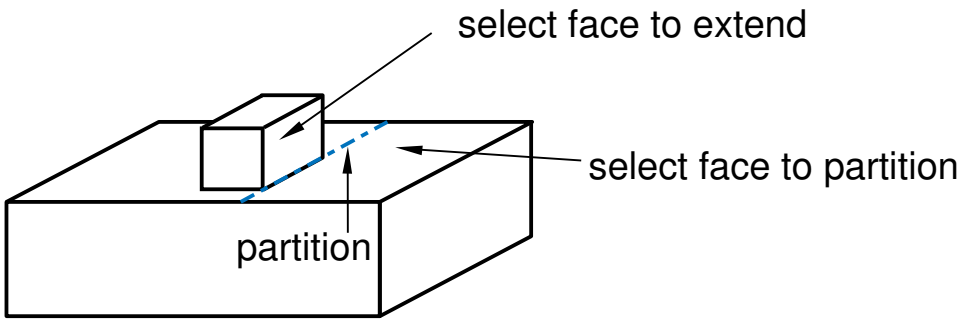

Figure 5: Partitioning a face using the extension of another face.

Intersect by other faces

Partition the face using the intersection of the target face with one or more other faces, as shown in *Figure 6*. The faces can be intersecting or tangential. For detailed instructions, see *Using the intersection method to partition faces*.

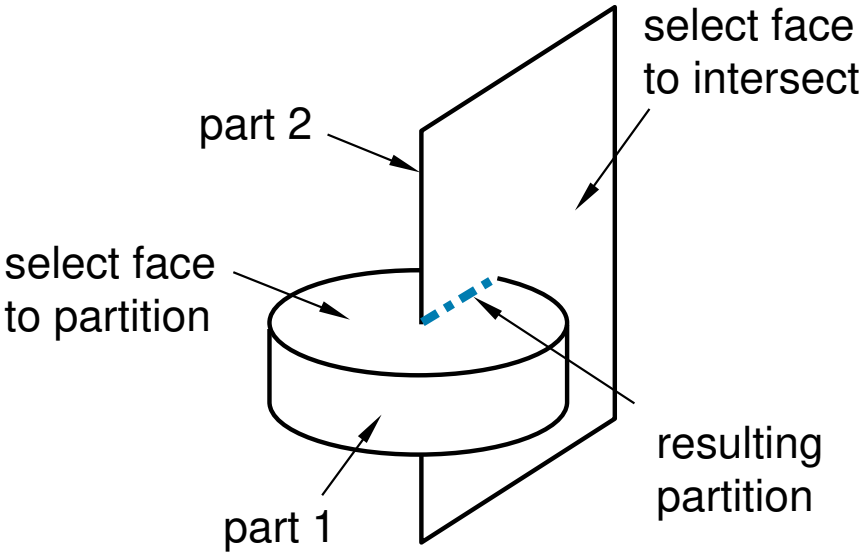

Figure 6: Partitioning a face using an intersection of faces.

Project edges

Partition the face by projecting edges in the model, as shown in *Figure 7*. The partition is created using a perpendicular projection from the face being partitioned to the partitioning edge. You can choose to use only the projection or, if necessary, to extend the ends of the projected edge to complete the face partition. For detailed instructions, see *Using the project edges method to partition faces*.

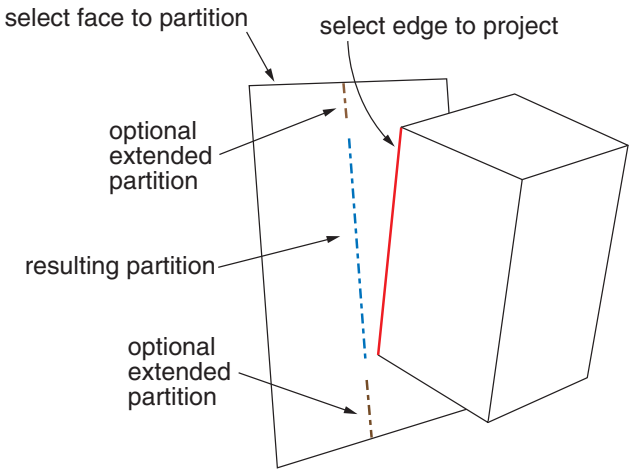

Figure 7: Partitioning a face by projecting an edge.

Auto-partition

When you mesh a face with quadrilateral elements using the free meshing technique, the Mesh module internally partitions the face into regions with three to five logical sides before meshing the face. For more information, see *Free meshing with quadrilateral and quadrilateral-dominated elements*. However, if you want to view and perhaps modify the automatically generated regions before generating the mesh, you can use the auto-partitioning tool to partition the face without meshing it. This tool is available only in the Mesh module. For detailed instructions, see *Using the automatic generation method to partition faces*.

Additional information

- *Partitioning techniques*
- *Understanding partitions*
- *Partitioning faces*

Methods for partitioning cells

When you choose **Cell** from the **Create Partition** dialog box, the **Method** list displays the following methods for partitioning cells:

Define cutting plane

Partition a cell by cutting it with a plane; the plane will pass completely through the cell. Use one of the following three methods to define the cutting plane:

- Select a point on the cutting plane; then pick an edge or datum axis that defines the normal to this plane, as shown in *Figure 1*.

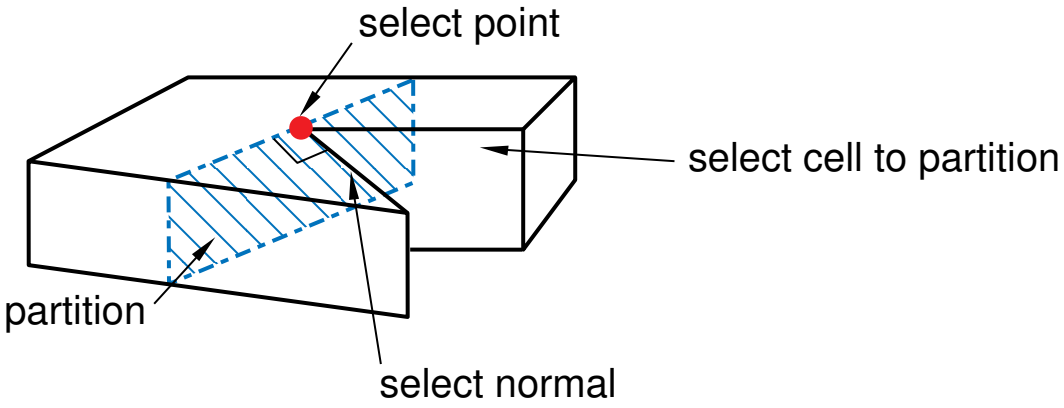

Figure 1: Defining the cutting plane with a point and a normal.

- Select three distinct and noncolinear points, as shown in *Figure 2*.

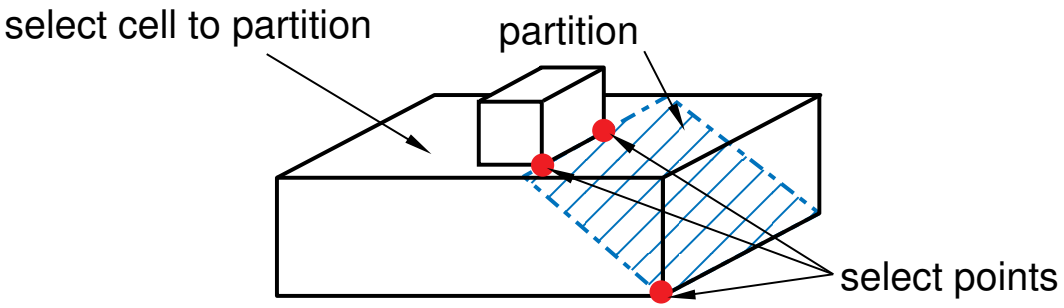

Figure 2: Defining the cutting plane with three points.

- Select an edge and a point along the edge; the cutting plane will be normal to the edge at the selected point, as shown in *Figure 3*.

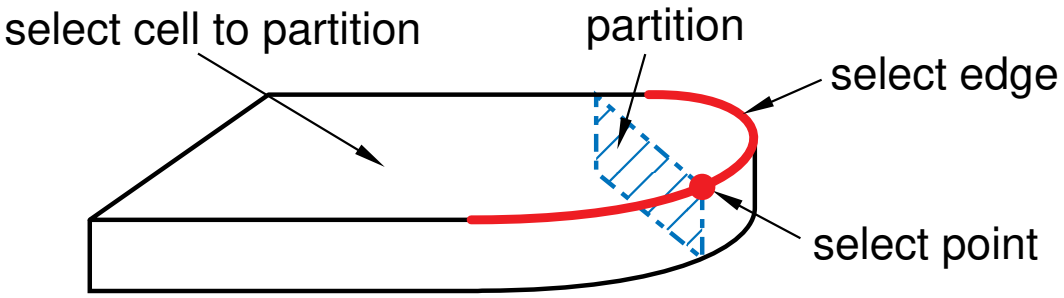

Figure 3: Defining the cutting plane with an edge and a point.

For detailed instructions, see *Using the cutting plane method to partition cells*.

Use datum plane

Partition a cell using the intersection with the extension of a datum plane, as shown in *Figure 4*. For detailed instructions, see *Using the datum plane method to partition cells*.

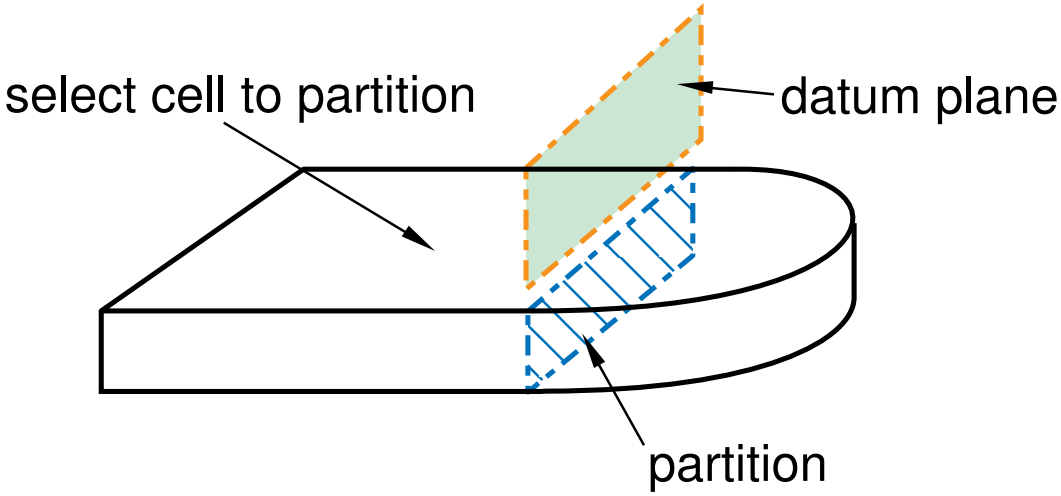

Figure 4: Partitioning a cell using a datum plane.

Extend face

Partition a cell by cutting it with a shell, where the shell is the extended geometry of a face, as shown in *Figure 5*. The face being extended can be planar, cylindrical, conical, or spherical. For detailed instructions, see *Using the extended face method to partition cells*.

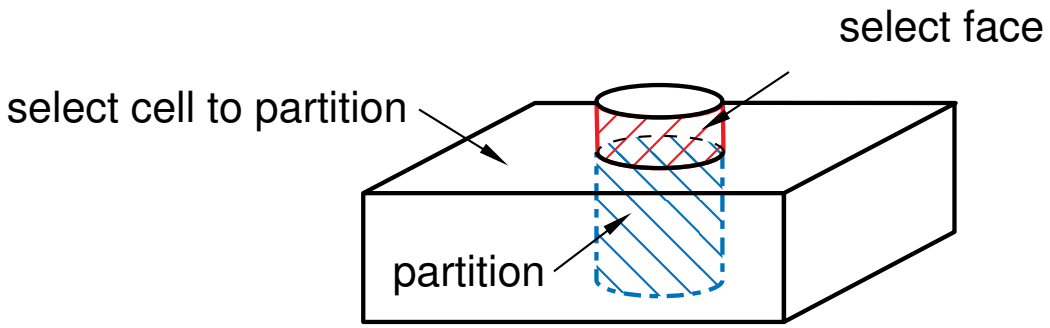

Figure 5: Partitioning a cell using an extension of a face.

Extrude/Sweep edges

Partition a cell by sweeping selected edges (that form the sweep profile) along a selected path (known as the sweep path). You can select any number of edges to be swept, although all the edges must lie on the same plane and must belong to the same part instance.

Use either of the following two methods to define the sweep path:

- Create a straight partition through the cell by extending the sweep profile infinitely in a direction parallel to a selected straight edge or datum axis that acts as a sweep path; the partition is created where the swept edge(s) pass through the selected cell, as shown in *Figure 6*. The sweep path must be straight and perpendicular to the set of edges being swept.

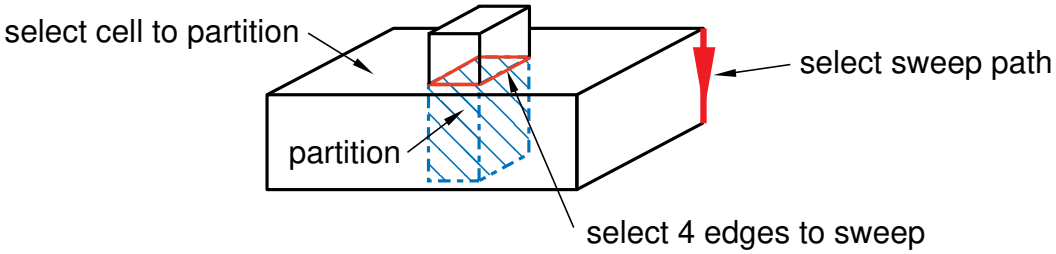

Figure 6: Sweeping a profile along a direction.

- Create a straight or curved partition through the cell by extending the sweep profile along or parallel to a selected edge. The partition extends only as far as the selected edge; and the partition is created where the swept edge(s) pass through the selected cell, as shown in *Figure 7*. The sweep path must begin in the plane containing the edges to be swept, and its tangent must be perpendicular to the same plane.

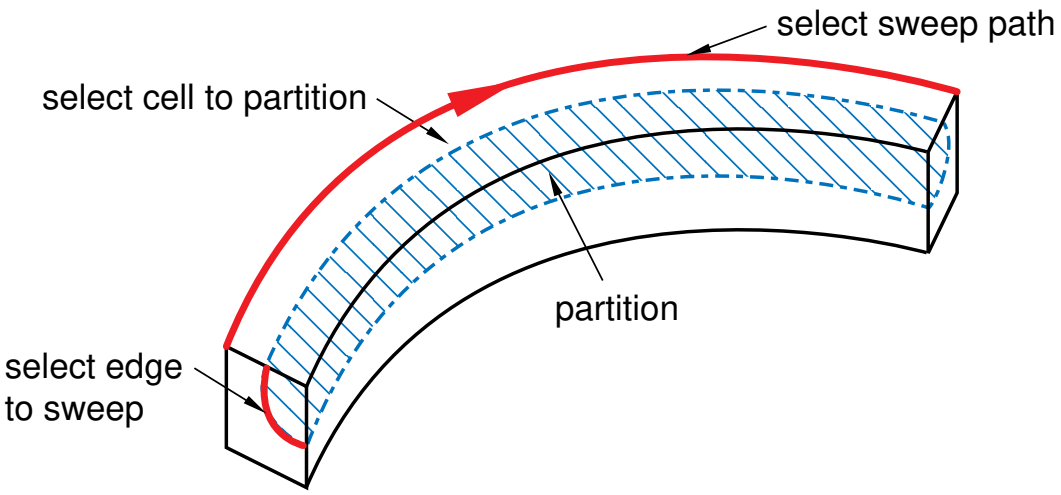

Figure 7: Sweeping a profile along an edge.

For detailed instructions, see *Using the extrude/sweep method to partition cells*.

Use n-sided patch

Partition a cell by dividing it with a surface patch formed from a loop of connected edges. The edges can be curved or straight, must be connected, and must belong to the same part as the cell to be partitioned. In addition, the patch must pass completely through the cell. Choose from the following methods to define the patch:

Select Edges

You can choose from the following methods to select the edges that form the N-sided patch:

Loop

Select a single edge, and allow Abaqus/CAE to search for a continuous loop of connected edges that will partition the cell, as shown in *Figure 8*. The resulting patch can have any number of edges.

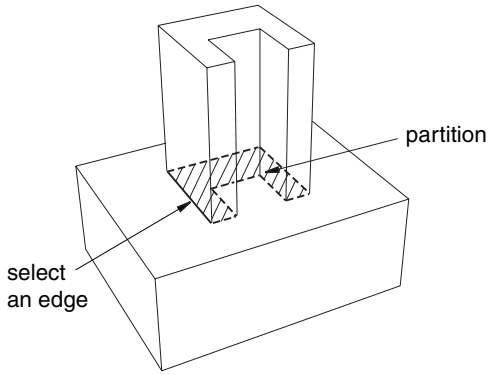

Figure 8: Allowing Abaqus/CAE to define a patch after selecting an edge.

Edges

Manually select the edges that will partition the cell. You can select any number of edges, and the selected edges must form a closed loop.

Select Corner Points

Select three, four, or five points that define the corners of the patch. If two of the points are connected by an existing edge, the resulting partition will follow the curve of the edge, as shown in *Figure 9*. The points must be on the boundary edges of the cell being partitioned.

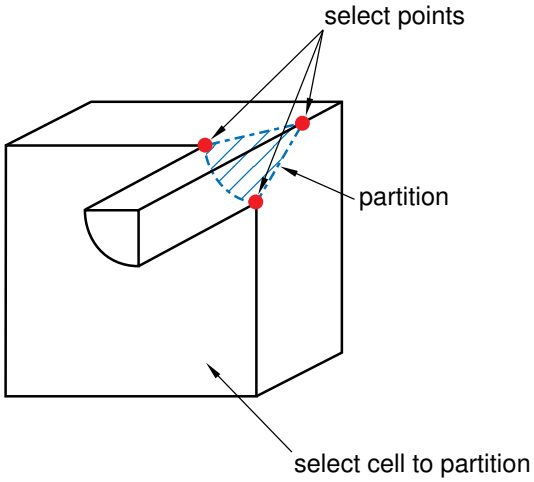

Figure 9: Defining a patch with corner points.

For detailed instructions, see *Using the N-sided patch method to partition a cell*.

Sketch planar partition

Partition a selected cell by sketching a partition with the Sketcher, as shown in *Figure 10*. In most cases you will sketch on a datum plane that intersects the selected cell. You can also select an existing face on which to sketch and draw the sketch outside the boundaries of the face. Abaqus/CAE creates the partition wherever the sketch intersects the cell.

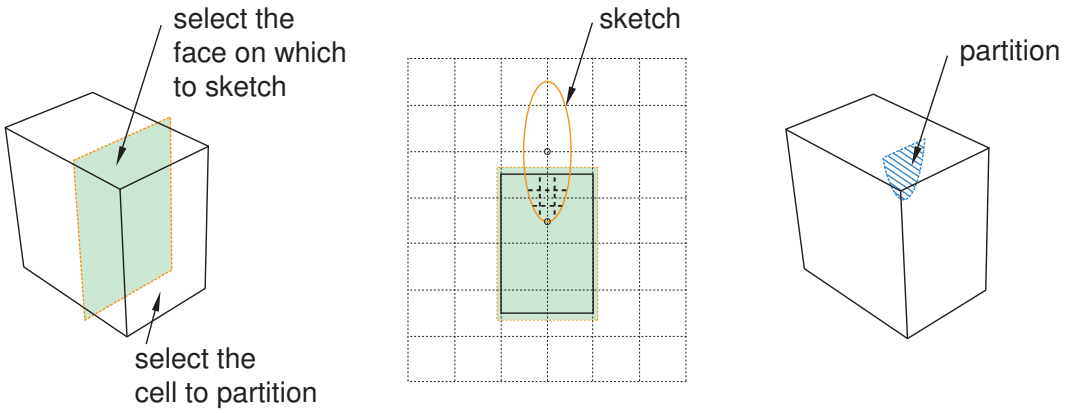

Figure 10: Partitioning a cell using the Sketcher.

For detailed instructions, see *Using the sketch planar partition method to partition a cell*.

Additional information

- *Partitioning techniques*
- *Understanding partitions*
- *Partitioning cells*

Partitioning edges

This section describes the tools that you can use to partition a selected edge.

In this section:

- *Using the specify parameter by location method to partition edges*
- *Using the enter parameter method to partition edges*
- *Using the pick midpoint/datum point method to partition an edge*
- *Using the datum plane method to partition edges*

Using the specify parameter by location method to partition edges

You can partition a selected edge anywhere along its length by clicking on the edge at the location of the partition. Abaqus/CAE converts the location to a parameter. As a result, you can use the Feature Manipulation toolset to modify the location of the partition.

1. From the main menu bar, select **Tools->Partition**.

   The **Create Partition** dialog box appears. Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also use the specify parameter method to partition edges using the  tool, located with the partition edge tools in the module toolbox. For a diagram of the partition tools in the toolbox, see *Using the Partition toolset*.

2. From the **Type** radio buttons at the top of the dialog box, choose **Edge**.

   The **Method** list displays the methods that you can use to partition an edge.

3. From the list of methods, select **Specify parameter by location**.
4. Click anywhere along the edge.

   Abaqus/CAE highlights the edge and the location along the edge that you picked.

5. If the location of the partition is not correct, click along the edge again.
6. If the location of the partition is correct, click **Create Partition** in the prompt area.

   Abaqus/CAE creates the partition.

Additional information

- *Partitioning techniques*
- *Methods for partitioning edges*

Using the enter parameter method to partition edges

An arrow along the selected edges points from the start vertex, corresponding to an edge parameter value of zero, to the end vertex, corresponding to a value of one. Partitions are created along the selected edges at the location determined by the parameter, as shown in the following figure:

To modify a partition that was created by entering a parameter, use the Feature Manipulation toolset to change the parameter.

1. From the main menu bar, select **Tools->Partition**.

   The **Create Partition** dialog box appears. Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also use the enter parameter method to partition edges using the tool, located with the partition edge tools in the module toolbox. For a diagram of the partition tools in the toolbox, see *Using the Partition toolset*.

2. From the **Type** radio buttons at the top of the dialog box, choose **Edge**.

   The **Method** list displays the methods that you can use to partition an edge.

3. From the list of methods, select **Enter Parameter**.
4. If the part or assembly contains more than one edge, select the edges to partition. You can use a combination of drag select, **[Shift] + Click**, **[Ctrl] + Click**, and the angle method to select more than one edge to partition. For more information, see *Selecting objects within the current viewport*.

   Tip: If you are unable to select the desired edges, you can use the **Selection** toolbar to change the selection behavior. For more information, see *Using the selection options*.

   Abaqus/CAE highlights the selected edges, and arrows indicate the direction of increasing parameter value.

5. In the prompt area, click **Done** to indicate you have finished selecting edges.
6. In the prompt area, enter the desired edge parameter as a value between zero and one.
7. In the prompt area, click **Create Partition**.

   Abaqus/CAE creates the partition.

- *Methods for partitioning edges*

Using the pick midpoint/datum point method to partition an edge

You can partition a selected edge by selecting the midpoint of the edge or a datum point along the edge.

The figure below shows an example of partitioning a selected edge by selecting the midpoint of the edge or a datum point along the edge.

You cannot directly modify a partition that was created by selecting an existing point. However, if you subsequently move the point, the partition will move along with the point.

1. From the main menu bar, select **Tools->Partition**.

   The **Create Partition** dialog box appears. Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also use the pick midpoint/datum point method to partition an edge using the −+− tool, located with the partition edge tools in the module toolbox. For a diagram of the partition tools in the toolbox, see *Using the Partition toolset*.

2. From the **Type** radio buttons at the top of the dialog box, choose **Edge**.

   The **Method** list displays the methods that you can use to partition an edge.

3. From the list of methods, select **Select midpoint/datum point**.
4. Select the edge to partition.

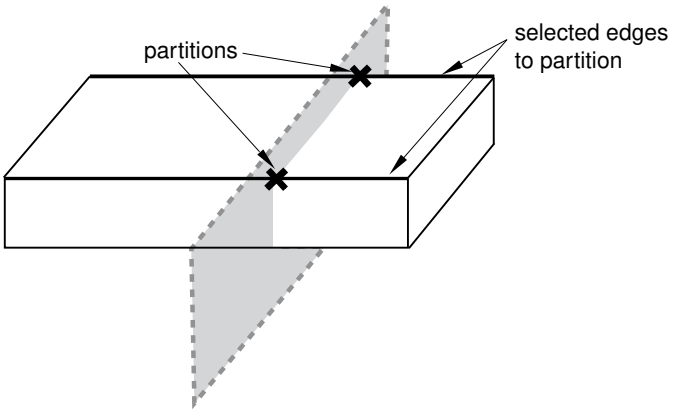
   Abaqus/CAE highlights the selected edge.

5. Select the midpoint of the edge or a datum point along the edge.

   Abaqus/CAE highlights the location of the partition.

6. In the prompt area, click **Create Partition**.

   Abaqus/CAE creates the partition.



Additional information

- *Partitioning techniques*
- *Methods for partitioning edges*

Using the datum plane method to partition edges

You can partition selected edges by cutting them with a datum plane

The figure below shows an example of partitioning selected edges by cutting them with a datum plane.

1. From the main menu bar, select **Tools->Partition**.

   The **Create Partition** dialog box appears. Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also use the datum plane method to partition edges using the tool, located with the partition edge tools in the module toolbox. For a diagram of the partition tools in the toolbox, see *Using the Partition toolset*.

2. From the **Type** radio buttons at the top of the dialog box, choose **Edge**.

   The **Method** list displays the methods that you can use to partition an edge.

3. From the list of methods, select **Use datum plane**.
4. If the part or assembly contains more than one edge, select the edges to partition. You can use a combination of drag select, **[Shift] + Click**, **[Ctrl] + Click**, and the angle method to select more than one edge to partition. For more information, see *Selecting objects within the current viewport*.

   Tip: If you are unable to select the desired edges, you can use the **Selection** toolbar to change the selection behavior. For more information, see *Using the selection options*.

   Abaqus/CAE highlights the selected edges.

5. Select an existing datum plane. If a datum plane does not exist in the desired location, create one using the Datum toolset.

   Abaqus/CAE highlights the selected datum plane.

6. In the prompt area, click **Create Partition**.

   Abaqus/CAE creates the partition.

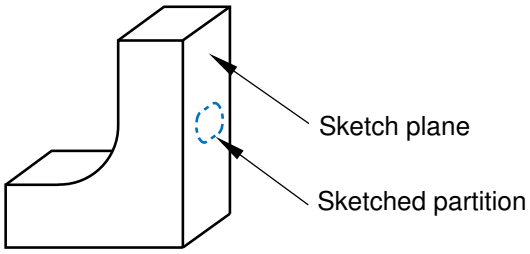
Partitioning faces

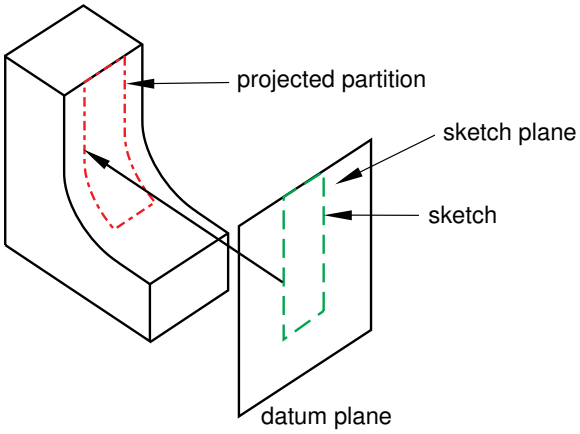
This section describes the tools that you use to partition a selected face.

In this section:



- *Using the sketch method to partition faces*
- *Using the shortest path method to partition faces*
- *Using the datum plane method to partition faces*
- *Using the curved path method to partition a face*
- *Using the extended face method to partition faces*
- *Using the intersection method to partition faces*
- *Using the project edges method to partition faces*
- *Using the automatic generation method to partition faces*

Using the sketch method to partition faces



You can partition selected faces by sketching the geometry of the partition using the Sketcher. You use the Sketcher when you want to create a partition whose shape cannot be achieved with any of the other partition tools. Sketching a partition offers other advantages:

- You can use the Feature Manipulation toolset to modify the sketch if you want to change the shape or the position of the partition.
- You can dimension the sketch precisely, and you can use the Feature Manipulation toolset to modify the dimensions.

If the faces to be partitioned are planar and lie in the same plane, you can sketch directly on that plane. Your sketch can extend beyond the boundaries of the selected faces, but the partition will not extend beyond the edge of the faces. The following figure illustrates a sketched partition on a planar face:

If any of the faces to be partitioned are nonplanar or do not lie in the same plane, you must select a planar face or datum plane on which to sketch. Abaqus/CAE creates the partition by projecting the sketch onto the faces to be partitioned. You can specify the direction of the projection and the distance of the projection, normal to the sketch plane. The following figure illustrates a sketched partition on a nonplanar face using the projection of a sketch drawn on a datum plane:

1. From the main menu bar, select **Tools->Partition**.

   The **Create Partition** dialog box appears. Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also use the sketch method to partition faces using the tool, located with the partition face tools in the module toolbox. For a diagram of the partition tools in the toolbox, see *Using the Partition toolset*.

2. From the **Type** radio buttons at the top of the dialog box, choose **Face**.

   The **Method** list displays the methods that you can use to partition a face.

3. From the list of methods, select **Sketch**.

   If the part or assembly contains only one face, Abaqus/CAE enters the Sketcher.

4. If the part or assembly contains more than one face, select the faces to partition and click mouse button 2. You can use a combination of drag select, **[Shift] + Click**, **[Ctrl] + Click**, and the angle method to select more than one face to partition. For more information, see *Selecting objects within the current viewport*.

   Tip: If you are unable to select the desired faces, you can use the **Selection** toolbar to change the selection behavior. For more information, see *Using the selection options*.

   - If the part or assembly is two-dimensional or axisymmetric, Abaqus/CAE enters the Sketcher and highlights the selected faces.
   - If the part or assembly is three-dimensional and the selected faces are planar, select an edge and the orientation of the edge on the Sketcher grid. The edge must not be perpendicular to the sketch plane. By default, the selected edge will appear vertical and on the right side of the Sketcher grid. To choose a different orientation for the edge, click the arrow on the right side of the dialog box and choose an orientation from the list that appears.

     Tip: If the part or assembly does not have an edge that will provide the desired orientation, you can create a datum axis. You can then select the datum axis to control the orientation of the part on the Sketcher grid.

     Abaqus/CAE highlights the selected edge, enters the Sketcher, and rotates the part until the selected planar face or datum plane aligns with the plane of the Sketcher grid and the selected edge aligns with the grid in the desired orientation. Abaqus/CAE highlights the selected faces.
   - If the part or assembly is three-dimensional and the selected faces are nonplanar or do not lie in the same plane, do the following:

     1. Select a planar face or a datum plane on which to sketch. Abaqus/CAE highlights the selected face.
     2. From the buttons in the prompt area, select a method to determine how far Abaqus/CAE projects the sketch normal to the sketch plane. The partition is created wherever the projected sketch extends through the selected faces. The three methods are illustrated in the following figure:

        - If you selected the **Through All** method, Abaqus/CAE asks you to choose which direction the sketch will be projected.
        - If you selected the **Enter Value** method, Abaqus/CAE asks you to choose the distance and direction that will be used to project the sketch. The default distance that Abaqus/CAE provides generates a partition that extends completely through the selected faces (resulting

in the same partition as selecting **Through All**). The Feature Manipulation toolset allows you to modify the projection distance after you create the partition.

- If you selected the **Select Point** method, Abaqus/CAE asks you to choose the point to which the sketch will be projected; the point defines both the direction and the projection distance.

3. Select an edge and the orientation of the edge on the Sketcher grid. The edge must not be perpendicular to the sketch plane. By default, the selected edge will appear vertical and on the right side of the Sketcher grid. To choose a different orientation for the edge, click the arrow on the right side of the dialog box and choose an orientation from the list that appears.

   Tip: If the part or assembly does not have an edge that will provide the desired orientation, you can create a datum axis. You can then select the datum axis to control the orientation of the part on the Sketcher grid.

   Abaqus/CAE highlights the selected edge, enters the Sketcher, and rotates the part until the selected planar face or datum plane aligns with the plane of the Sketcher grid with the projection direction into the screen and the selected edge aligns with the grid in the desired orientation. Abaqus/CAE highlights the selected faces.

5. Use the Sketcher to sketch the partition. From the main menu bar, click **Done** to indicate you have finished sketching the partition.
6. In the prompt area, click **Create Partition**.

   Abaqus/CAE creates the partition.

- *Methods for partitioning faces*

Using the shortest path method to partition faces

You can partition selected faces with a line or curve that forms the shortest possible path between two selected points.

The points can be vertices, midpoints, arc-centers, or datum points. The path will be curved if a face being partitioned is not planar, as shown in the following figure:

1. From the main menu bar, select **Tools->Partition**.

   The **Create Partition** dialog box appears. Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also use the shortest path method to partition faces using the tool, located with the partition face tools in the module toolbox. For a diagram of the partition tools in the toolbox, see *Using the Partition toolset*.

2. From the **Type** radio buttons at the top of the dialog box, choose **Face**.

   The **Method** list displays the methods that you can use to partition a face.

3. From the list of methods, select **Shortest path between 2 points**.
4. If the part or assembly contains more than one face, select the faces to partition. You can use a combination of drag select, **[Shift] + Click**, **[Ctrl] + Click**, and the angle method to select more than one face to partition. For more information, see *Selecting objects within the current viewport*.

   Tip: If you are unable to select the desired faces, you can use the **Selection** toolbar to change the selection behavior. For more information, see *Using the selection options*.

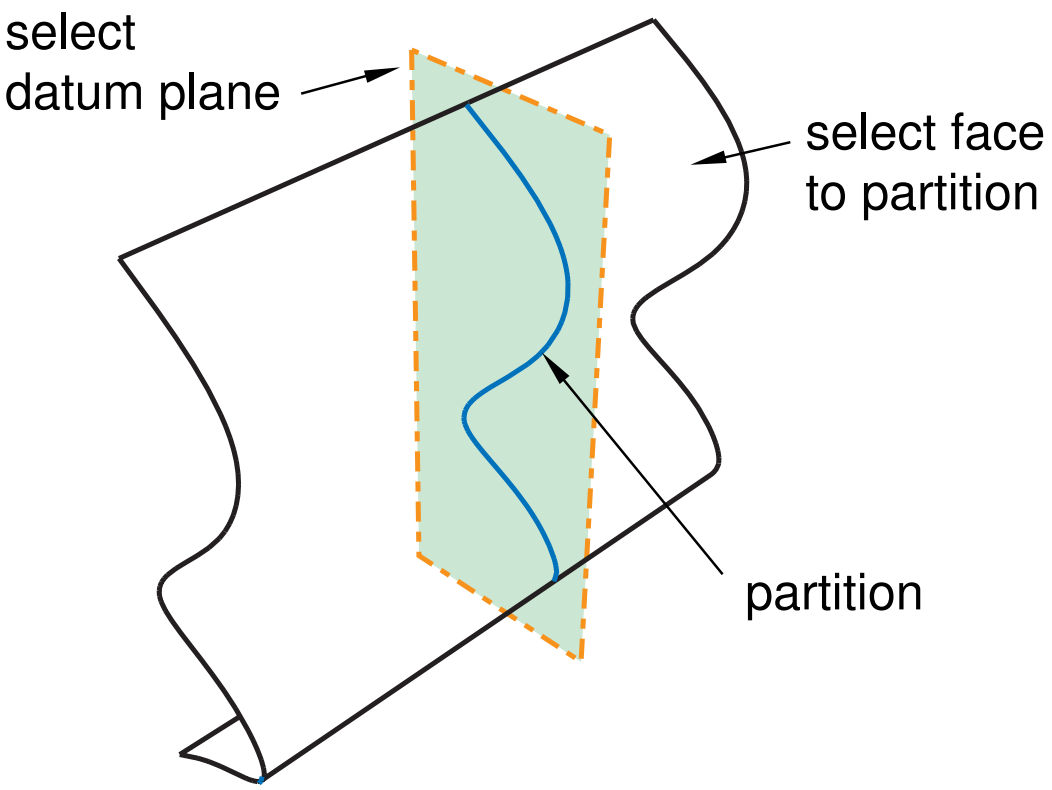
   Abaqus/CAE highlights the selected faces.

5. Select the vertices, midpoints, arc-centers, or datum points defining the start and end of the path.

   Abaqus/CAE highlights the points.

6. In the prompt area, click **Create Partition**.

   Abaqus/CAE creates the partition.



Additional information

- *Partitioning techniques*
- *Methods for partitioning faces*

Using the datum plane method to partition faces

You can partition selected faces by cutting them with a datum plane.

The figure below shows an example of partitioning selected faces by cutting them with a datum plane.

1. From the main menu bar, select **Tools->Partition**.

   The **Create Partition** dialog box appears. Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also use the datum plane method to partition faces using the tool, located with the partition face tools in the module toolbox. For a diagram of the partition tools in the toolbox, see *Using the Partition toolset*.

2. From the **Type** radio buttons at the top of the dialog box, choose **Face**.

   The **Method** list displays the methods that you can use to partition a face.

3. From the list of methods, select **Use datum plane**.

4. If the part or assembly contains more than one face, select the faces to partition. You can use a combination of drag select, **[Shift] + Click**, **[Ctrl] + Click**, and the angle method to select more than one face to partition. For more information, see *Selecting objects within the current viewport*.

   Tip: If you are unable to select the desired faces, you can use the **Selection** toolbar to change the selection behavior. For more information, see *Using the selection options*.

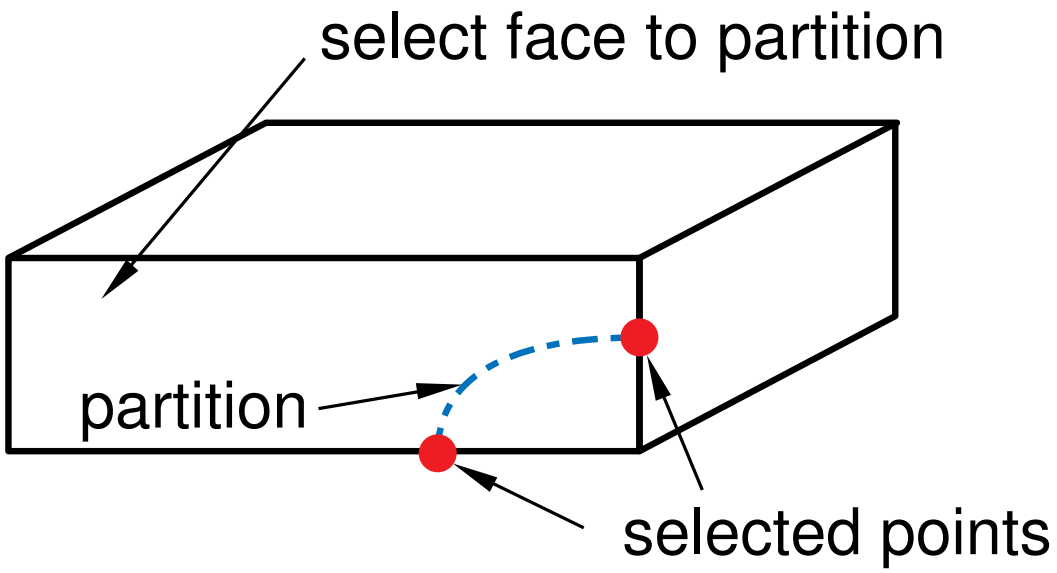
   Abaqus/CAE highlights the selected faces.

5. Select an existing datum plane. If a datum plane does not exist in the desired location, create the datum using the Datum toolset.

   Abaqus/CAE highlights the selected datum plane.

6. In the prompt area, click **Create Partition**.

   Abaqus/CAE creates the partition.



Additional information

- *Partitioning techniques*
- *Methods for partitioning faces*

Using the curved path method to partition a face

You can partition a face with a curve normal to two edges that bound the face.

The edges need not be contiguous, but they must bound the face and subtend an angle less than 180 degrees, as shown in the following figure:

You first select the face to partition and then select one of two methods to define the position of the partition along the two edges; Abaqus/CAE draws a Bézier curve connecting the two points. You can locate the partition along the selected edges by either:

- Entering a parameter value between zero and one, where zero represents the start vertex of the edge and one the end vertex. This method allows you to precisely position the partition anywhere along the edges. In addition, you can subsequently modify the partition using the Feature Manipulation toolset to edit the two parameters that you entered to locate the partition.
- Clicking the midpoint or a datum point along the edge. If you use this method to position a curved partition, you will not be able to modify the partition later.

1. From the main menu bar, select **Tools->Partition**.

   The **Create Partition** dialog box appears. Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also use the curved path method to partition a face using the tool, located with the partition face tools in the module toolbox. For a diagram of the partition tools in the toolbox, see *Using the Partition toolset*.

2. From the **Type** radio buttons at the top of the dialog box, choose **Face**.

   The **Method** list displays the methods that you can use to partition a face.

3. From the list of methods, select **Curved path normal to 2 edges**.
4. Select the face to partition.

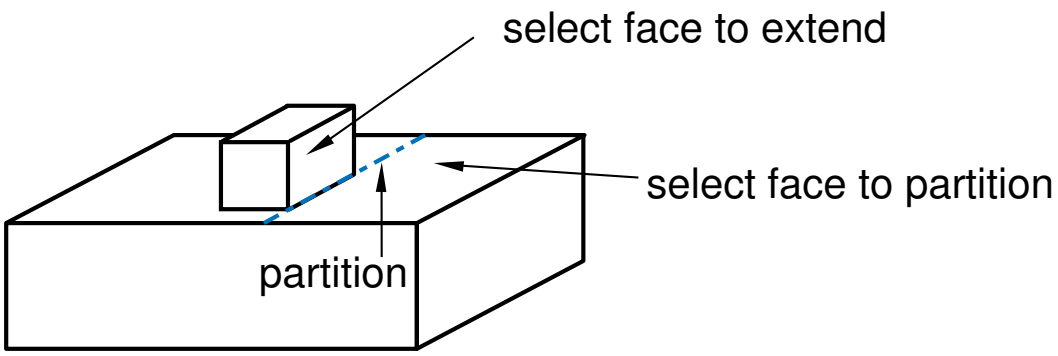
   Abaqus/CAE highlights the selected face.

5. From the buttons in the prompt area, select one of the following methods to locate the curve:
   - **Enter Parameter**
   - **Pick**
6. Select any of the edges bounding the selected face.

   Tip: If you are unable to select the desired edges, you can use the **Selection** toolbar to change the selection behavior. For more information, see *Using the selection options*.

   Abaqus/CAE highlights the selected edge.
7. Do one of the following:
   - If you selected the **Enter Parameter** method, enter a value between zero and one. An arrow on the selected edge indicates the direction of increasing parameter value.
   - If you selected the **Pick** method, click the midpoint or a datum point along the selected edge.
8. Select a second edge that bounds the face and repeat the previous step. The angle subtended by the two selected edges must be less than 180 degrees.
9. In the prompt area, click **Create Partition**.

   Abaqus/CAE creates the partition.



Additional information

- *Partitioning techniques*
- *Methods for partitioning faces*

Using the extended face method to partition faces

You can partition selected faces by extending another face so that it cuts through the selected faces.

Extending a face is analogous to creating an infinite plane that is coincident with that face. Abaqus/CAE creates a partition wherever this infinite plane slices the selected faces you are trying to partition, as shown in the following figure:

If the infinite plane cannot intersect any of the selected faces, Abaqus/CAE displays an error message. The extended face need not belong to the same part as the faces to be partitioned; for example, in the Assembly module you can partition the face of one part instance by extending the face of a second. Abaqus/CAE displays an error message if the part or assembly contains only one face.

1. From the main menu bar, select **Tools->Partition**.

   The **Create Partition** dialog box appears. Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also use the extended face method to partition faces using the tool, located with the partition face tools in the module toolbox. For a diagram of the partition tools in the toolbox, see *Using the Partition toolset*.

2. From the **Type** radio buttons at the top of the dialog box, choose **Face**.

   The **Method** list displays the methods that you can use to partition a face.

3. From the list of methods, select **Extend another face**.
4. Select the faces to partition. You can use a combination of drag select, **[Shift] + Click**, **[Ctrl] + Click**, and the angle method to select more than one face to partition. For more information, see *Selecting objects within the current viewport*.

   Tip: If you are unable to select the desired faces, you can use the **Selection** toolbar to change the selection behavior. For more information, see *Using the selection options*.

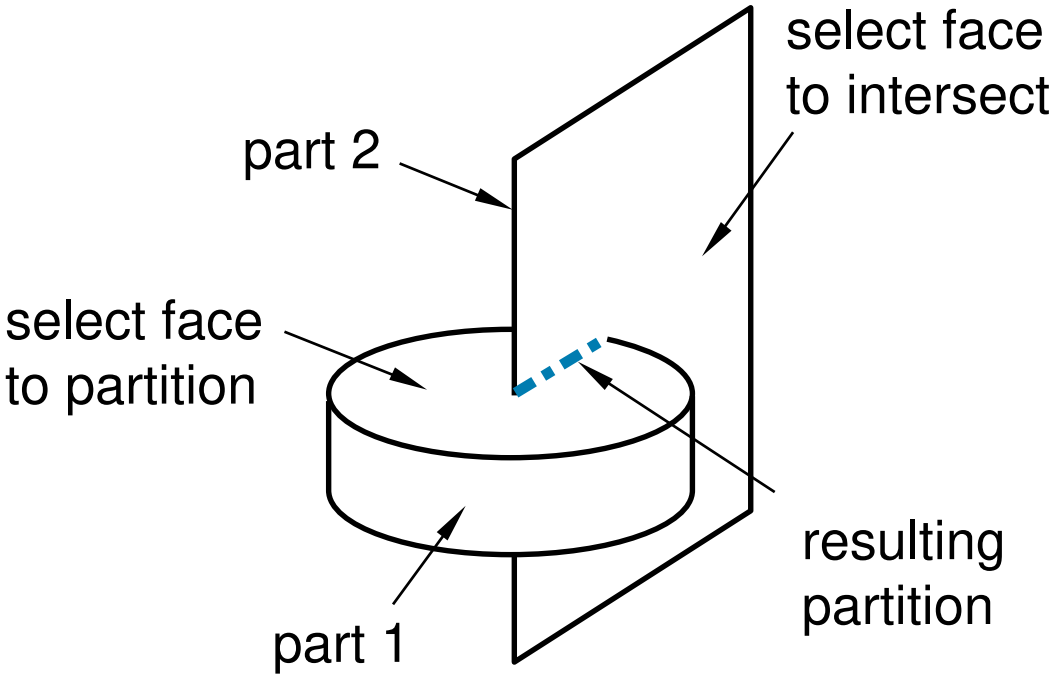
   Abaqus/CAE highlights the selected faces.

5. Select the face whose extension creates the desired partition.

   Abaqus/CAE highlights the selected face.

6. In the prompt area, click **Create Partition**.

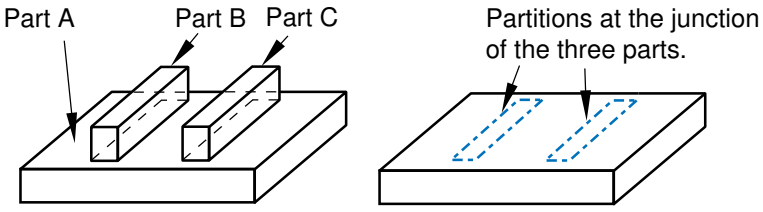
Abaqus/CAE creates the partition.



Additional information

- *Partitioning techniques*
- *Methods for partitioning faces*

Using the intersection method to partition faces



You can partition selected faces using their intersection or junction with one or more other faces.

The figure below shows an example of partitioning selected faces using their intersection or junction with one or more other faces.

The faces need not belong to the same part; for example, in the Assembly module you can partition the face belonging to one part instance using its intersection with a face belonging to a second part instance. The resulting regions are especially useful for defining contact or constraint interactions between part instances. Abaqus/CAE displays an error message if the part or assembly contains only one face.

The following figure shows two partitions that you might create at the intersection of three part instances:

1. From the main menu bar, select **Tools->Partition**.

   The **Create Partition** dialog box appears. Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

Tip: You can also use the intersection method to partition faces using the  tool, located with the partition face tools in the module toolbox. For a diagram of the partition tools in the toolbox, see *Using the Partition toolset*.

2. From the **Type** radio buttons at the top of the dialog box, choose **Face**.

   The **Method** list displays the methods that you can use to partition a face.

3. From the list of methods, select **Intersect by other faces**.
4. Select the faces to partition. You can use a combination of drag select, **[Shift] + Click**, **[Ctrl] + Click**, and the angle method to select more than one face to partition. For more information, see *Selecting objects within the current viewport*.

   Tip: If you are unable to select the desired faces, you can use the **Selection** toolbar to change the selection behavior. For more information, see *Using the selection options*.

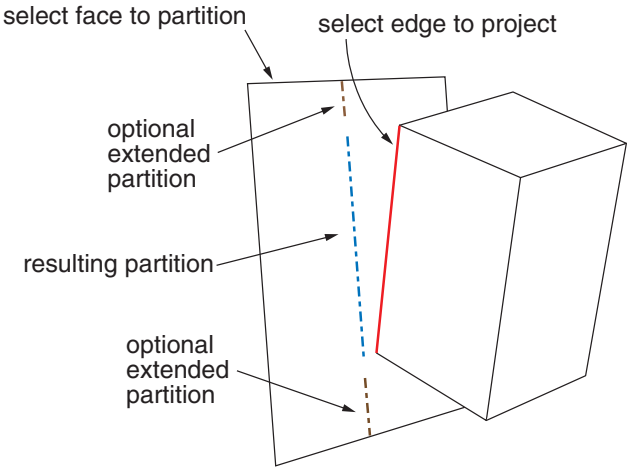
   Abaqus/CAE highlights the selected faces.

5. Select the faces that join or intersect the faces to be partitioned.

   Abaqus/CAE highlights the selected faces.

6. In the prompt area, click **Create Partition**.

   Abaqus/CAE creates the partition.



Additional information

- *Partitioning techniques*
- *Methods for partitioning faces*

Using the project edges method to partition faces

You can partition selected faces using their intersection or junction with the projection of one or more edges.

The figure below shows an example of partitioning selected faces using their intersection or junction with the projection of one or more edges.

Abaqus/CAE creates the partition by taking a perpendicular projection from the faces being partitioned to the selected edges; nonplanar faces or faces joined at a sharp edge such that there is a discontinuity in the perpendicular projection may significantly change the shape of the projected edges. As shown in the figure, you can create a partition that ends at the endpoints of the projected edges, or you can extend the projected edges to reach the face boundaries. If you extend the partition, Abaqus/CAE extends the free ends of the projected edges along their tangents to reach the boundary edges of the faces being partitioned.

The faces and edges need not belong to the same part; for example, in the Assembly module you can partition faces belonging to one part instance using edges projected from a second part instance. The faces to be partitioned must be part of the active model representation. The edges can be part of the active representation or part of the reference representation for a midsurface model.

1. From the main menu bar, select **Tools->Partition**.

   The **Create Partition** dialog box appears. Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also use the project edges method to partition faces using the tool, located with the partition face tools in the module toolbox. For a diagram of the partition tools in the toolbox, see *Using the Partition toolset*.

2. From the **Type** radio buttons at the top of the dialog box, choose **Face**.

   The **Method** list displays the methods that you can use to partition a face.

3. From the list of methods, select **Project edges**.
4. Select the faces to partition. You can use a combination of drag select, **[Shift] + Click**, **[Ctrl] + Click**, and the angle method to select more than one face to partition. For more information, see *Selecting objects within the current viewport*.

   Tip: If you are unable to select the desired faces, you can use the **Selection** toolbar to change the selection behavior. For more information, see *Using the selection options*.

Abaqus/CAE highlights the selected faces.

5. Select the edges to be projected onto the faces. If desired, toggle on **Extend edges** to have Abaqus/CAE extend the projected edges, preventing gaps in the new face partitions.

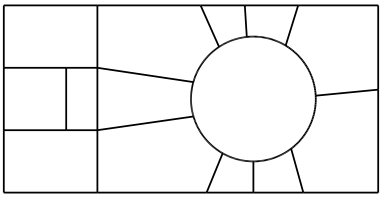
   Note:

   You can also toggle the **Extend edges** parameter on or off by editing the completed partition feature in the Model Tree.

   Abaqus/CAE highlights the selected edges.

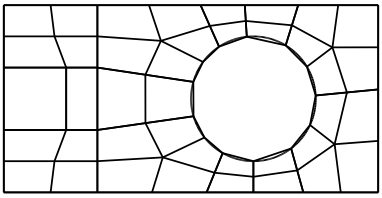
6. In the prompt area, click **Create Partition**.

   Abaqus/CAE projects the selected edges to create the partition.



Additional information

- *Partitioning techniques*
- *Methods for partitioning faces*



Using the automatic generation method to partition faces

The Mesh module is capable of meshing any two-dimensional face automatically.

Automatic meshing with quadrilateral elements begins by internally partitioning the face into regions having between three and five sides, as shown in the following figure:

Then, a mesh is generated on each of these regions, as shown in the following figure:

Normally, when you mesh a face, these two steps take place in what appears to be a single step. However, to gain more control over the meshing process, you can perform the partitioning step separately using the automatic partitioning tool in the Partition toolset.

Since the automatic partitioning tool is associated with meshing, it is available only within the Mesh module. After you automatically partition the face, you can gain additional control over the mesh by seeding or by adding or deleting partitions manually.

1. From the main menu bar, select **Tools**->**Partition**.

   The **Create Partition** dialog box appears. Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also use the automatic generation method to partition faces using the tool, located with the partition face tools in the module toolbox. For a diagram of the partition tools in the toolbox, see *Using the Partition toolset*.

2. From the **Type** radio buttons at the top of the dialog box, choose **Face**.

   The **Method** list displays the methods that you can use to partition a face.

3. From the list of methods, select **Auto-partition**.
4. If the part or assembly contains more than one face, select the faces to partition. You can use a combination of drag select, **[Shift] + Click**, **[Ctrl] + Click**, and the angle method to select more than one face to partition. For more information, see *Selecting objects within the current viewport*.

Tip: If you are unable to select the desired faces, you can use the **Selection** toolbar to change the selection behavior. For more information, see *Using the selection options*.

Abaqus/CAE highlights the selected faces.

5. In the prompt area, click **Create Partition**.

   Abaqus/CAE creates the partition.

Additional information

- *Partitioning techniques*
- *Methods for partitioning faces*

Partitioning cells

This section describes the partition tools that you use to partition a cell.

In this section:

- *Using the cutting plane method to partition cells*
- *Using the datum plane method to partition cells*
- *Using the extended face method to partition cells*
- *Using the extrude/sweep method to partition cells*
- *Using the N-sided patch method to partition a cell*
- *Using the sketch planar partition method to partition a cell*

Using the cutting plane method to partition cells

You can partition selected cells by cutting them with a plane. You first select the cells to partition and then select one of three methods to define the plane that partitions the cells. The three methods are:

- Select a point and any straight edge. The cutting plane will pass through the point, normal to the edge.
- Select three points. The cutting plane will pass through all three points.
- Select a straight or curved edge and a point on the edge. The cutting plane will pass through the point, normal to the edge at the selected point.

The following procedure illustrates the three methods.

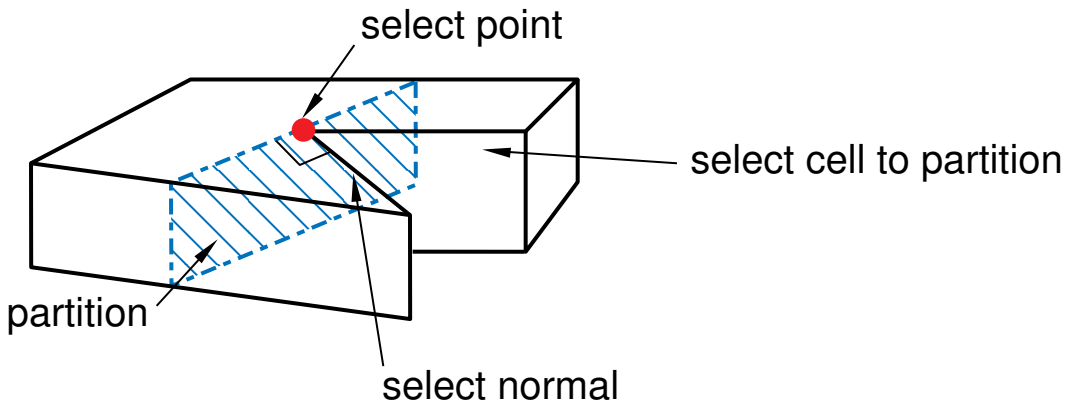
1. From the main menu bar, select **Tools->Partition**.

   The **Create Partition** dialog box appears. Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also use the plane method to partition cells using the tool, located with the partition cell tools in the module toolbox. For a diagram of the partition tools in the toolbox, see *Using the Partition toolset*.

2. From the **Type** radio buttons at the top of the dialog box, choose **Cell**.

   The **Method** list displays the methods that you can use to partition a cell.



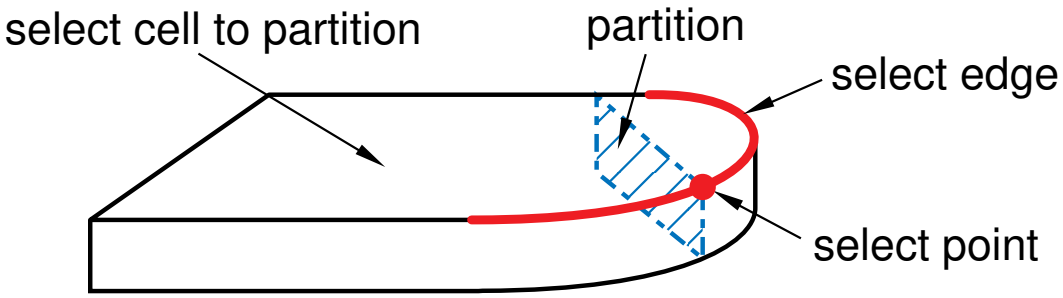
3. From the list of methods, select **Define cutting plane**.
4. If the part or assembly contains more than one cell, select the cells to partition. You can use a combination of drag select, **[Shift] + Click**, and **[Ctrl] + Click** to select more than one cell to partition.

   Tip: If you are unable to select the desired cells, you can use the **Selection** toolbar to change the selection behavior. For more information, see *Using the selection options*.

   Abaqus/CAE highlights the selected cell.

5. From the prompt area, click one of the following methods to define the cutting plane:

   - Use the **Point & normal** method to partition the selected cells along a plane that passes through a selected point and is normal to a selected straight edge or datum axis, as shown in the following figure:



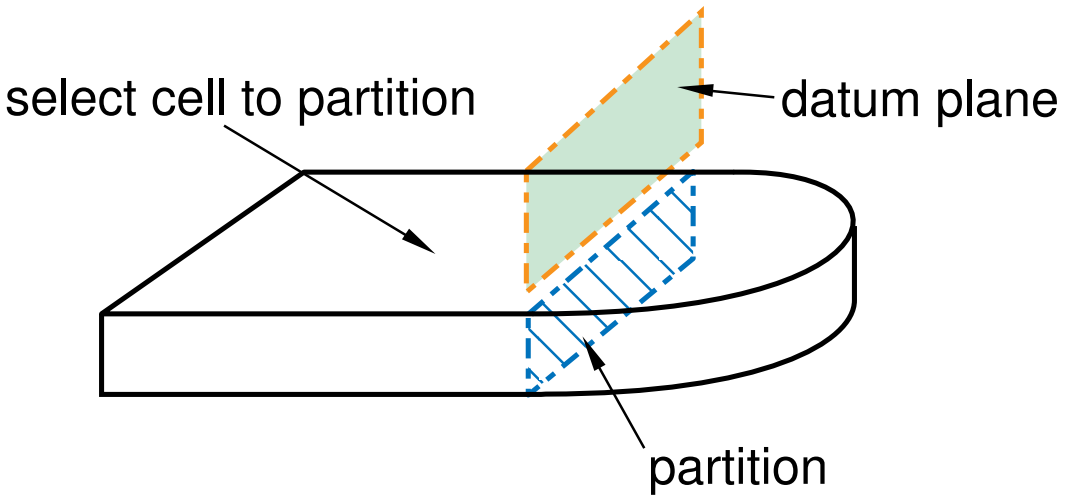
- Use the **3 Points** method to partition the selectes cells along a plane passing through three selected points, as shown in the following figure:

The three points can be anywhere on the part or assembly, but they must be distinct and they must not be colinear.

- Use the **Normal to edge** method to partition the selected cells along a plane that is normal to a selected edge and passes through a selected point on the edge. The edge can be straight or curved, and need not be part of the cells being partitioned, although you cannot select a datum axis. This method is useful when you want to partition a cell normal to a curved edge, as shown in the following figure:

6. Select points and edges as directed by the prompts in the prompt area. Points can be vertices, midpoints, arc centers, or datum points.
7. In the prompt area, click **Create Partition**.

   Abaqus/CAE creates the partition.



Additional information

- *Partitioning techniques*
- *Methods for partitioning cells*

Using the datum plane method to partition cells

You can partition selected cells by cutting them with a datum plane.

The figure below shows an example of partitioning selected cells by cutting them with a datum plane.

1. From the main menu bar, select **Tools->Partition**.

   The **Create Partition** dialog box appears. Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also use the datum plane method to partition cells using the tool, located with the partition cell tools in the module toolbox. For a diagram of the partition tools in the toolbox, see *Using the Partition toolset*.

2. From the **Type** radio buttons at the top of the dialog box, choose **Cell**.

   The **Method** list displays the methods that you can use to partition a cell.

3. From the list of methods, select **Use datum plane**.
4. If the part or assembly contains more than one cell, select the cells to partition. You can use a combination of drag select, **[Shift] + Click**, and **[Ctrl] + Click** to select more than one cell to partition.

   Tip: If you are unable to select the desired cells, you can use the **Selection** toolbar to change the selection behavior. For more information, see *Using the selection options*.

   Abaqus/CAE highlights the selected cell.

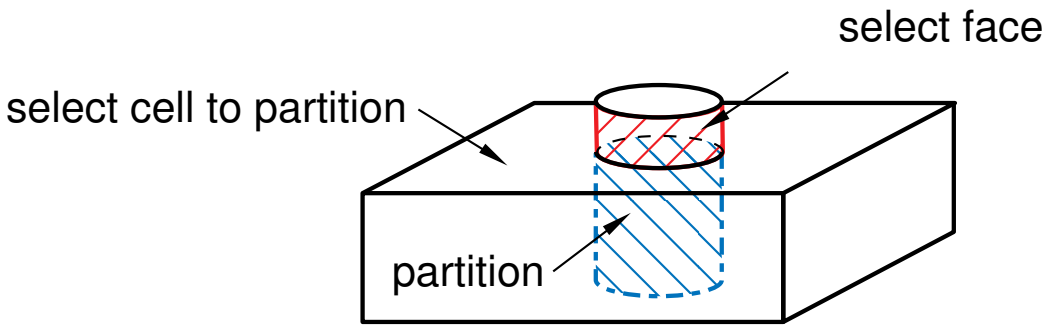
5. Select an existing datum plane. If a datum plane does not exist in the desired location, create the datum using the Datum toolset.

   Abaqus/CAE highlights the selected datum plane.

6. In the prompt area, click **Create Partition**.

   Abaqus/CAE creates the partition.

Additional information



- *Partitioning techniques*

• *Methods for partitioning cells*

Using the extended face method to partition cells

You can partition selected cells by extending another face until it cuts through the selected cells.

Extending a face is analogous to creating an infinite plane that is coincident with the face. Abaqus/CAE creates a partition wherever this infinite plane slices the cells that you are partitioning, as shown in the following figure:

If the infinite plane cannot intersect the cells, Abaqus/CAE displays an error message. The extended face need not belong to the same part as the cells to be partitioned; for example, in the Assembly module you can partition the cell of one part instance by extending the face of a second.

1. From the main menu bar, select **Tools->Partition**.

   The **Create Partition** dialog box appears. Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also use the datum plane method to partition cells using the tool, located with the partition cell tools in the module toolbox. For a diagram of the partition tools in the toolbox, see *Using the Partition toolset*.

2. From the **Type** radio buttons at the top of the dialog box, choose **Cell**.

   The **Method** list displays the methods that you can use to partition a cell.

3. From the list of methods, select **Extend face**.

4. If the part or assembly contains more than one cell, select the cells to partition. You can use a combination of drag select, **[Shift] + Click**, and **[Ctrl] + Click** to select more than one cell to partition.

   Tip: If you are unable to select the desired cells, you can use the **Selection** toolbar to change the selection behavior. For more information, see *Using the selection options*.

   Abaqus/CAE highlights the selected cell.

5. Select the face that will be extended to create the desired partition.

   Abaqus/CAE highlights the selected faces.

   Tip: If you are unable to select the desired faces, you can use the **Selection** toolbar to change the selection behavior. For more information, see *Using the selection options*.

6. In the prompt area, click **Create Partition**.

Abaqus/CAE creates the partition.

Additional information

- *Partitioning techniques*
- *Methods for partitioning cells*

Using the extrude/sweep method to partition cells

You can create complex three-dimensional partitions using the sweep tool to sweep two-dimensional profiles (known as sweep profiles) through three-dimensional parts or part instances. Using the sweep tool is a two-stage operation. First you define the sweep profile by selecting the edges to sweep, and then you select the path along which to sweep the selected edges (known as the sweep path). You can choose between two methods to define the sweep path:

- **Extrude along direction**
- **Sweep along edge**

These two methods are illustrated below.

1. From the main menu bar, select **Tools->Partition**.

   The **Create Partition** dialog box appears. Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also use the extrude/sweep method to partition cells using the tool, located with the partition cell tools in the module toolbox. For a diagram of the partition tools in the toolbox, see *Using the Partition toolset*.

2. From the **Type** radio buttons at the top of the dialog box, choose **Cell**.

   The **Method** list displays the methods that you can use to partition a cell.

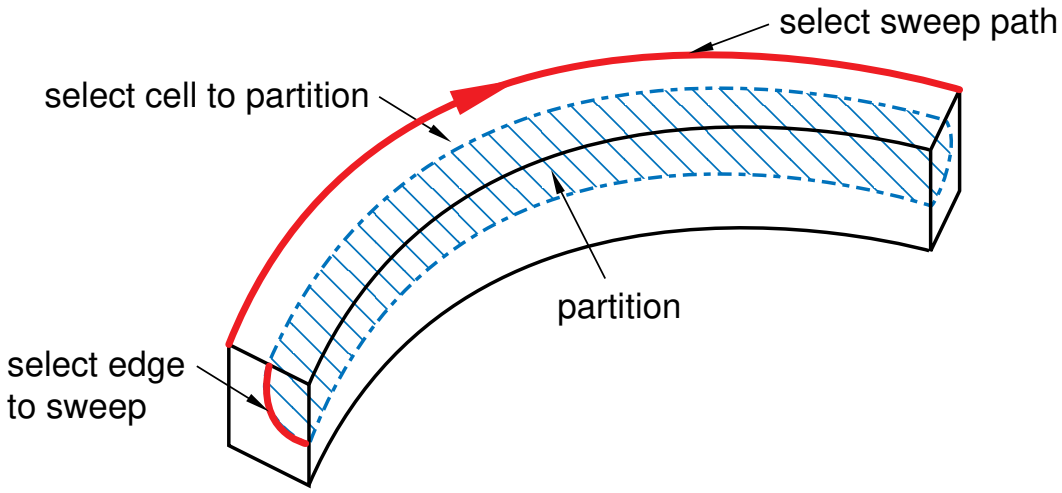
3. From the list of methods, select **Extrude/sweep edges**.
4. If the part or assembly contains more than one cell, select the cells to partition. You can use a combination of drag select, **[Shift] + Click**, and **[Ctrl] + Click** to select more than one cell to partition.

   Tip: If you are unable to select the desired cells, you can use the **Selection** toolbar to change the selection behavior. For more information, see *Using the selection options*.

   Abaqus/CAE highlights the selected cell.

5. To create the sweep profile, select the edges to sweep through the cells. The edges must all belong to the same part, lie on the same plane, and be connected to each other.

   Abaqus/CAE highlights the selected edges.



6. From the buttons in the prompt area, click on one of the following methods to define the sweep path:

   - Use the **Extrude along direction** method to partition a cell by extruding selected edges—the sweep profile—along a straight edge or datum axis—the sweep path—in a selected direction. The sweep path must be perpendicular to the plane containing the sweep profile. The partition extends infinitely in the selected direction through the selected cell. Extruding a sweep profile along a direction to partition a cell is illustrated in the following figure:

Abaqus/CAE highlights the sweep profile.

- Use the **Sweep along edge** method to partition a cell by sweeping selected edges—the sweep profile—along a straight or curved edge—the sweep path. The sweep path must begin in the plane containing the sweep profile, and its tangent must be perpendicular to that same plane. The resulting partition will extend only as far as the sweep path. Sweeping a sweep profile along an edge to partition a cell is illustrated in the following figure:

Abaqus/CAE highlights the sweep path.

7. In the prompt area, click **Create Partition**.
   Abaqus/CAE creates the partition.

Additional information

- *Partitioning techniques*
- *Methods for partitioning cells*

Using the N-sided patch method to partition a cell

You can partition a cell by creating a patch that divides the cell into regions. You can define the patch using either edges or corner points. If you select an edge, Abaqus/CAE searches for a continuous loop of connected edges that will define a viable patch. If you select corner points, you can select either three, four, or five points to define the partition. In contrast with the other cell partition tools, the partition that results from an N-sided patch does not extend beyond the patch. As a result, the N-sided patch method is useful for creating an isolated partition that does not extend into the rest of the cell.

If you select a curved edge or if you select two points connected by a curved edge, the corresponding edge of the resulting N-sided patch follows the contour of the edge. However, if you select points that are not connected by an edge, the patch simply connects the points; the patch will not follow the contour of the cell, and the partition may be incomplete.

1. From the main menu bar, select **Tools->Partition**.

   The **Create Partition** dialog box appears. Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also use the N-sided patch method to partition a cell using the  tool, located with the partition cell tools in the module toolbox. For a diagram of the partition tools in the toolbox, see *Using the Partition toolset*.

2. From the **Type** radio buttons at the top of the dialog box, choose **Cell**.

   The **Method** list displays the methods that you can use to partition a cell.

3. From the list of methods, select **N-sided patch**.
4. If the part or assembly contains more than one cell, select the cell to partition.

   Tip: If you are unable to select the desired cell, you can use the **Selection** toolbar to change the selection behavior. For more information, see *Using the selection options*.

   Abaqus/CAE highlights the selected cell.

   Tip: Use the **Previous** button () to undo the steps in a procedure.

5. From the buttons in the prompt area, select the method to define the N-sided patch:

   - Use the **Select Edges** method to partition a cell by defining an N-sided patch from a sequence of selected edges. Use the text field in the prompt area to select the method of choosing edges:

     ### Loop

     Select a single edge, and allow Abaqus/CAE to search for a continuous loop of connected edges that will partition the cell, as shown in the following figure:

     The edge that you select must be on the boundary of the cell being partitioned, and Abaqus/CAE must be able to form a closed loop from a series of connected edges. The resulting patch can have any number of edges. Abaqus/CAE highlights the loop that will form the patch.

Edges

Manually select the edges that will partition the cell. The edges that you select must be on the boundary of the cell being partitioned. You can select any number of edges, and the selected edges must form a closed loop.

- Use the **Select Corner Points** method to partition a cell by defining an N-sided patch using three to five selected points. Abaqus/CAE creates the patch by connecting the points in the order that you select them; consequently, the order in which you select the points is significant. The points can be vertices, midpoints, or datum points and must be on the boundary edges of the cell being partitioned. If a curved edge connects two of the points, the patch follows the contour of the curve, as shown in the following figure:

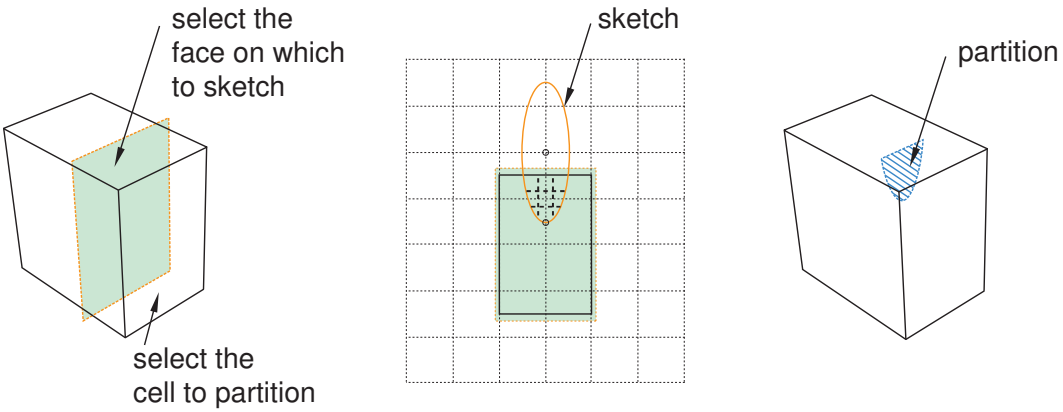
Abaqus/CAE highlights the selected points along with the edges that will form the patch.

6. Do one of the following:

   - If the highlighted edges indicate that Abaqus/CAE will create the desired partition, click **Create Partition** in the prompt area.

     Abaqus/CAE creates the partition.

   - To change the selection of edges, click the **Previous** button () to undo the previous step.



Additional information

- *Partitioning techniques*
- *Methods for partitioning cells*

Using the sketch planar partition method to partition a cell

You can partition a selected cell by sketching the geometry of a planar partition using the Sketcher. You use the Sketcher when you want to create a partition whose shape cannot be achieved with any of the other partition tools. A sketched partition is useful for creating a crack face that will be used in a fracture mechanics analysis.

You must sketch on a planar face. In most cases you will sketch the partition on a datum plane that intersects the selected cell. The following figure illustrates a sketched planar partition on a datum plane:

1. From the main menu bar, select **Tools->Partition**.

   The **Create Partition** dialog box appears. Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also use the sketch planar partition method to partition cells using the tool, located with the partition cell tools in the module toolbox. For a diagram of the partition tools in the toolbox, see *Using the Partition toolset*.

2. From the **Type** radio buttons at the top of the dialog box, choose **Cell**.

   The **Method** list displays the methods that you can use to partition a cell.

3. From the list of methods, select **Sketch planar partition**.

   If the part or assembly contains only one cell, Abaqus/CAE enters the Sketcher.

4. If the part or assembly contains more than one cell, select the cell to partition and click mouse button 2.

   Tip: If you are unable to select the desired cell, you can use the **Selection** toolbar to change the selection behavior. For more information, see *Using the selection options*.

5. Select the planar face on which to sketch. If no suitable face exists, you can select a datum plane.

   The selected face is highlighted in the viewport.

6. Select an edge and the orientation of the edge on the Sketcher grid. The edge must not be perpendicular to the sketch plane. By default, the selected edge will appear vertical and on the right side of the Sketcher grid. To choose a different orientation for the edge, click the arrow on the right side of the dialog box and choose an orientation from the list that appears.

Tip: If the part or assembly does not have an edge that will provide the desired orientation, you can create a datum axis. You can then select the datum axis to control the orientation of the part on the Sketcher grid.

- Abaqus/CAE highlights the selected edge, enters the Sketcher, and rotates the part until the selected planar face or datum plane aligns with the plane of the Sketcher grid and the selected edge aligns with the grid in the desired orientation. Abaqus/CAE highlights the selected faces.

7. Use the Sketcher to sketch the planar partition. From the main menu bar, click **Done** to indicate you have finished sketching the partition.
8. In the prompt area, click **Create Partition**.

   Abaqus/CAE creates the partition.

- *Methods for partitioning cells*

The Query toolset

The Query toolset allows you to obtain information about your model.

In this section:

- *Understanding the role of the Query toolset*
- *Querying the model*

Understanding the role of the Query toolset

The Query toolset allows you to obtain information about your model.

In most cases Abaqus/CAE displays the requested information in the message area, and the same information is written to the replay file. Select **Tools**->**Query** from the main menu bar to use the Query toolset, or select the query tool in the Query toolset.

The **Query** dialog box is split into two sections. The top section of the dialog box contains general queries that are available in each module except the Job module, where the Query toolset is not available at all. The bottom portion of the dialog box contains module-specific queries; as you switch between modules, Abaqus/CAE displays queries that are appropriate for the contents of the current module.

In this section:

- *General queries*
- *Module-specific queries*

General queries

You can always use the Query toolset to obtain general information about the model, regardless of which module you are using, although the Query toolset is not available in the Job module.
The **General Queries** in the Visualization module are similar to those in the other modules, but they are discussed separately in *Querying the model in the Visualization module* due to differences in some selection methods and the inclusion of undeformed and deformed model data in the results. For all other modules, the items under **General Queries** in the Query toolset provide the general information discussed below.

In most cases Abaqus/CAE displays the requested information in the message area, and the same information is written to the replay file. Select **Tools->Query** from the main menu bar to use the Query toolset, or select the  tool in the Query toolset.

The **Query** dialog box is split into two sections. The top section of the dialog box contains general queries that are available in each module except the Job module, where the Query toolset is not available at all. The bottom portion of the dialog box contains module-specific queries; as you switch between modules, Abaqus/CAE displays queries that are appropriate for the contents of the current module.

For tools that require meshes to be available, you can use the **View->Part Display Options** or **View->Assembly Display Options** menu items to display the native mesh.

Point/Node

Coordinates of a selected point or node. You can select a local CSYS in which to display the coordinates.

Distance

Distance between two selected points, nodes, edges, faces, or a combination of these objects. You can select a local CSYS in which to display the coordinates of the picked points and the components of the result.

Angle

The angle between two edges or faces, between an edge and a face, or between three points

Feature

For a selected feature:

- Feature name
- Description
- Status (if the feature is suppressed or if it failed to regenerate)
- Parent feature names
- Child feature names
- Parameters

Shell element normals

Display shell/membrane normal directions

Beam element tangents

Display beam/truss tangent directions

In addition, if the current viewport contains a mesh, the Query toolset provides the following information:

Mesh stack orientation

For hexahedral, wedge, and quadrilateral elements that you can use in a continuum shell, cohesive, cylindrical, or gasket mesh, Abaqus/CAE indicates the mesh stack orientation. For hexahedral and wedge elements, Abaqus/CAE colors the top face brown and the bottom face purple. For quadrilateral elements, arrows indicate the orientation of the elements. In addition, Abaqus/CAE highlights any element faces and edges that have inconsistent orientation.

Note:

The query results do not account for changes made in the mesh stack orientation while defining a solid composite layup or a composite shell layup in the Property module.

Mesh

For an assembly, part or part instance, geometric region, or element:

- The total number of nodes and elements in the selected area
- The number of elements for each element shape

By default, Abaqus/CAE displays mesh information in the message area, but you can display this information in tabular format in the **Mesh statistics** dialog box by toggling on **Display detailed report** in the prompt area. The **Mesh statistics** dialog box also enables you to display mesh information by part instance or by element type.

Element

For a selected element:

- Element label
- Element topology; for example, linear hexahedron
- Abaqus element name; for example, C3D8I
- Nodal connectivity

Mesh gaps/intersections

For a selected part or part instance:

- Display element edges of boundary faces with incompatible interfaces
- Display element edges of boundary faces with cracks or gaps
- Display element edges of boundary faces that intersect other faces

Mass properties

For an assembly, selected part or part instance, geometric region, solid element, shell, solid face, beam, or truss, Abaqus/CAE returns some or all of the following information:

- Surface area (displayed only for shell elements and for solid faces)
- Area centroid
- Volume
- Volume centroid
- Mass
- Center of mass
- Moments of inertia about the center of mass or about a specified point

For more information about this query, see *Querying mass properties*.

Geometry diagnostics

- Invalid, imprecise, or small geometry
- Topology

Sets

For a selected set:

- Geometry set: components, index, instance name, set name, set type, total number of components
- Element set: element label, element type, connectivity, instance name, set name, set type, total number of elements
- Node set: node label, nodal coordinates, elements sharing the node, instance name, set name, set type, total number of nodes

Surfaces

For a selected surface:

- Geometry surface: index, side, instance name, surface name, surface type, total number of surfaces
- Mesh surface: element label, element type, connectivity, side, instance name, surface name, surface type, total number of faces

Geometry face normal

The surface normal components in the global Cartesian coordinate system of a planar face or, for a curved surface, at a selected point on the face. You can select a local CSYS in which to display the normal. If typing coordinates of an evaluation point on a curved surface, you should enter the coordinates in the local CSYS, if selected.

Element face normal

The surface normal components in the global Cartesian coordinate system of the element face. You can select a local CSYS in which to display the normal.

Advanced distance

Whereas the regular distance query allows you to find the distance between two selected single entities, the advanced distance query allows you to find the minimum distance between groups of entities. These entities can be nodes, elements, vertices, edges, faces, or cells, and you can select them from the viewport or by set. You can select a local CSYS in which to display the coordinates of the closest points and the components of the result.

For more information, see *Obtaining general information about the model*.

- *Customizing mesh display*

Module-specific queries

In addition to general queries, you can query the model for information specific to the module you are using. Abaqus/CAE displays these module-specific queries at the bottom of the Query toolset under, "***Modulename*** **Module Queries**." The Query toolset can provide the following module-specific information:

Part module

The items under **Part Module Queries** provide the following module-specific information about the current part:

Part attributes

- Name
- Modeling space
- Type (deformable or rigid body)

Regeneration warnings

If any sets or surfaces in the selected part cannot be regenerated because their underlying geometry has been modified or deleted, Abaqus/CAE displays the set or surface name, the original number of faces, and the number of faces found during the query.

Substructure statistics

Abaqus/CAE displays the following information about the selected substructure part: the number of retained nodes, eigenmodes, and substructure loads in the part; the availability of the recovery matrix, gravity load vectors, reduced mass matrix, reduced structural damping matrix, and reduced viscous damping matrix in the substructure; and mass properties of the substructure.

For more information, see *Using the Query toolset in the Part module*.

Property module

The items under **Property Module Queries** provide the following module-specific information about the current part:

Section assignments

Sections assigned to a selected region

Regions missing sections

Regions that require a section assignment

Beam orientations

Beam orientations assigned to a selected wire region (Abaqus/CAE displays the ($\mathbf{n}_1$, $\mathbf{n}_2$, $\mathbf{t}$) axis system on the selected wire region)

Material orientations

Material orientations assigned to a selected region

Rebar orientations

Rebar reference orientations assigned to a selected region

Ply stack plot

Abaqus/CAE creates a new viewport and displays a graphical representation of a core sample through a region of a composite layup or composite section. The image shows the plies in the layup along with details of each ply, such as its fiber orientation, thickness, reference plane, and integration points.

Disjoint ply regions

Abaqus/CAE displays in the message area the names of the composite layups and the plies within them that contain disjoint regions.

For more information, see *Using the Query toolset to obtain assignment information*, and *Viewing a ply stack plot*.

Assembly module

The items under **Assembly Module Queries** provide the following module-specific information about a selected part instance:

Instance attributes

Name, type, and modeling space

Instance position

- Position of the origin relative to the global coordinate system
- Sum of the translations and rotations applied to the instance
- Number of translational and rotational constraints applied

For more information, see *Using the Query toolset to query the assembly*.

Step module

The Query toolset provides only general information in the Step module.

Interaction module

The item under **Interaction Module Queries** provides the following module-specific information about a selected wire:

- Connector assignment information

For more information, see *Using the Query toolset to obtain connector assignment information*.

Load module

The Query toolset provides only general information in the Load module.

Mesh module

The items under **Mesh Module Queries** provide the following module-specific information about a part or part instance:

- Free/Non-manifold edges
- Unmeshed regions
- Unassociated geometry

For more information, see *Obtaining mesh information*.

Job module

None of the Abaqus/CAE toolsets are available in the Job module.

Visualization module

The items under **Visualization Module Queries** provide the following module-specific information:

- Probe values. Abaqus/CAE displays information in the **Probe Values** dialog box as you move the cursor around the current viewport. Probing a model plot displays model data and analysis results; probing an *X*–*Y* plot displays *X*–*Y* curve data. For more information, see *Probing the model*.
- Stress linearization. Stress linearization is the separation of stresses through a section into constant membrane and linear bending stresses. Abaqus/CAE performs stress linearization calculations and displays the results in the form of an *X*–*Y* plot. For more information, see *Calculating linearized stresses*.
- Active elements or nodes. Abaqus/CAE displays the label numbers of all of the active nodes or active elements in the current viewport. For more information, see *Querying active node or element labels*.
- Ply stack plot. Abaqus/CAE creates a new viewport and displays a graphical representation of a core sample through a region of a composite layup or composite section. The image shows the plies in the layup along with details of each ply, such as its fiber orientation, thickness, reference plane, and integration points. For more information, see *Viewing a ply stack plot*.

Sketch module

The items under **Sketch Module Queries** provide the following information about a selected constraint or sketch:

Constraint

- Constraint type
- Constrained entity names

In addition, the constrained entities are highlighted in the sketch.

Detail

- Number of geometries

- Number of vertices
- Number of constraints
- Number of dimensions
- Number of unconstrained degrees of freedom

Querying the model

This section describes how you use the Query toolset to obtain information about your model.

In this section:

- *Using the Query toolset to query the model*
- *Obtaining general information about the model*
- *Querying mass properties*
- *Using the geometry diagnostic tools*

Using the Query toolset to query the model

You can use the Query toolset to obtain general information about the geometry of the model in the current viewport and the features that define the model.
In addition, you can obtain information specific to the module you are using; for example, if you are using the Mesh module, the Query toolset can provide information on the mesh, nodes, and elements.

1. From the main menu bar, select **Tools->Query**.

    **Tip:** You can also query the model by clicking the  tool in the Query toolset.

   Abaqus/CAE displays the **Query** dialog box.

2. From the **Query** dialog box, select one of the following:

   - **General Queries**
     - **Point/Node**
     - **Distance**
     - **Angle**
     - **Feature**
     - **Shell element normals**
     - **Beam element tangents**
     - **Mesh stack orientation**
     - **Mesh**
     - **Element**
     - **Mesh gaps/intersections**
     - **Mass properties**
     - **Geometry diagnostics**
     - **Sets**
     - **Surfaces**
     - **Geometry face normal**
     - **Element face normal**

     For more information, see *Obtaining general information about the model*.
   - Module-specific queries. For a complete list of the information available in each module, see *Understanding the role of the Query toolset*.

3. For shell normals, beam tangents, mesh gaps, and mesh stack orientation, Abaqus/CAE uses arrows and highlighting to display the requested information in the viewport.

   For all other queries, Abaqus/CAE displays prompts in the prompt area to guide you through the rest of the procedure. Abaqus/CAE displays the requested information in the message area. To resize the message area, drag the top edge; to see information that has scrolled out of the message area, use the scroll bar on the right side. The same information that appears in the message area is also written to the replay file.

4. Click the cancel button  in the prompt area when you have finished requesting information.

Additional information

- *Obtaining general information about the model*
- *Understanding the role of the Query toolset*

Obtaining general information about the model

You can use the Query toolset to obtain general information about your model including point/node coordinates; element labels, topology, and nodal connectivity; and mass properties.

To obtain general information about your model, select **Tools->Query** from the main menu or click the  tool in the Query toolset. For tools that require meshes to be available, you can use the **View->Part Display Options** or **View->Assembly Display Options** menu items to display the native mesh. Select one of the following from the **General Queries** field in the **Query** dialog box that appears:

Point/Node

Select a point or node. Abaqus/CAE displays the *X*-, *Y*-, and *Z*-coordinates of the point. You can select a local CSYS in which to display the coordinates.

Distance

Select two points or nodes. In the Part, Property, and Mesh modules you can select points, edges, or faces. You can select a local CSYS in which to display the coordinates of the picked points and the components of the result. Abaqus/CAE displays the following:

- The *X*-, *Y*-, and *Z*-coordinates of each entity.
- The absolute distance between the entities.
- The *X*-, *Y*-, and *Z*-components of the vector between the two entities.

The distance between non-point entities is always the shortest distance between two points within the entities.

Angle

Select **Face/Curve** or **3 Points** in the prompt area.

- If you selected **Face/Curve**, select two edges or two faces or select an edge and a face. Abaqus/CAE displays one of the following, depending on your selection:
  - The angle between the two edges.
  - The angle between the normals to the face.
  - The angle between the edge and the normal to the face.

  When you select an edge, Abaqus/CAE displays an arrow along the edge. When you select a face, Abaqus/CAE displays an arrow on the face that indicates the normal to the face. The angle is defined as the angle that must be swept by one edge or face to align the two arrows. The angle is always positive and less than or equal to 180°.
- If you selected **3 Points**, select three points/nodes or enter node labels.

Feature

Click mouse button 3 on a feature in the Model Tree, and select **Query** from the menu that appears. Abaqus/CAE displays the following information about the selected feature:

- Name and description; for example, solid extrude.
- Status, if the feature is suppressed or if it failed to regenerate.

- The name of its parent, if any.
- The names of its children, if any.
- The value of any parameters that define the feature.

Shell element normals

- For parts with shell regions, Abaqus/CAE displays the part or assembly using the shaded render style. The side of the shell where the surface normal coincides with the shell normal (top face) is colored brown; the opposite side (bottom face) is colored purple.
- For axisymmetric parts with wire regions, Abaqus/CAE displays cyan arrows indicating the directions of the normals.

You can use the **Assign** menu in the Property module or the **Mesh->Orientation->Normal** menu in the Mesh module to reverse the normal directions. For more information, see *Assigning shell/membrane normal directions*.

Beam element tangents

Abaqus/CAE displays cyan arrows indicating the directions of the beam tangents.

You can use the **Assign** menu in the Property module or the **Mesh->Orientation->Normal** menu in the Mesh module to reverse the tangent directions. For more information, see *Assigning beam/truss tangent directions*.

Mesh stack orientation

You can use this tool to query only hexahedral, wedge, and quadrilateral elements because these are the only elements that can be stacked to form a continuum shell, cohesive, cylindrical, or gasket mesh. For hexahedral and wedge elements, Abaqus/CAE colors the top face brown and the bottom face purple. Similarly, arrows indicate the orientation of quadrilateral elements. In addition, Abaqus/CAE highlights any element faces and edges that have inconsistent orientation. For more information, see *Creating a model with cohesive elements using geometry and mesh tools*, *Continuum shells*, *Swept meshing of cylindrical solids*, and *Gaskets*.

If the region is a native Abaqus mesh, you can change the mesh stack orientation by changing the direction of the sweep path. For solid regions, you can assign a new mesh stack orientation independent of the sweep path. If the region is an orphan mesh, you can use the Edit Mesh toolset to change the mesh stack orientation. For more information, see *Specifying the sweep path*, *Applying a mesh stack orientation*, and *Orienting the stack direction*, respectively.

Note:

The query results do not account for changes made in the mesh stack orientation while defining a solid composite layup or a composite shell layup in the Property module.

Mesh

For an assembly, part or part instance, geometric region, or element, Abaqus/CAE displays the following:

- The total number of nodes and elements in the selected area
- The number of elements for each element shape

By default, Abaqus/CAE displays mesh information in the message area, but you can display this information in tabular format in the **Mesh statistics** dialog box by toggling on **Display detailed report** in the prompt area.

The **Mesh statistics** dialog box also enables you to display mesh information by part instance or by element type.

Element

- Element label
- Element topology; for example, linear hexahedron
- Abaqus element name; for example, C3D8I
- Nodal connectivity.

Mesh gaps/intersections

Select the mesh parts or part instances, and enter the maximum distance between a node and an element face. Abaqus/CAE highlights element edges that intersect the boundary faces and element edges that are closer than the specified distance to boundary faces.

Mass properties

This query displays information about the surface area, area centroid, volume, volume centroid, mass, center of mass, and moments of inertia about the center of mass or about a specified point for your selection. For more information, see *Querying mass properties*.

Geometry diagnostics

- Invalid, imprecise, or small geometry
- Topology

Sets

Select a set from the list of sets provided. If desired, toggle on **Highlight set** to highlight the set in the viewport. Click **Done**.

Abaqus/CAE displays the following information about the selected set in the message area, depending on your selection:

- Geometry set: components, index, instance name, set name, set type, total number of components
- Element set: element label, element type, connectivity, instance name, set name, set type, total number of elements
- Node set: node label, nodal coordinates, elements sharing the node, instance name, set name, set type, total number of nodes

Surfaces

Select a surface from the list of surfaces provided. If desired, toggle on **Highlight surface** to highlight the surface in the viewport. Click **Done**.

Abaqus/CAE displays the following information about the selected surface in the message area, depending on your selection:

- Geometry surface: index, side, instance name, surface name, surface type, total number of surfaces
- Mesh surface: element label, element type, connectivity, side, instance name, surface name, surface type, total number of faces

Geometry face normal

Select a face. Select CSYS, if required. For a curved surface, you are prompted to select the point or enter the *X*-, *Y*-, and *Z*-coordinates of the point at which to evaluate the normal. If typing coordinates of an evaluation point on a curved surface, you should enter the coordinates in the local CSYS, if selected. You can select reference points, attachment points, or vertices. The surface normal components in the global Cartesian coordinate system appear in the message area. If you selected a CSYS, the normal is displayed in the given CSYS.

Element face normal

Select an element. Select CSYS, if required. The surface normal components in the global Cartesian coordinate system appear in the message area. If you selected a CSYS, the normal is displayed in the given CSYS.

Additional information

- *Using the Query toolset to query the model*
- *Understanding the role of the Query toolset*
- *Customizing mesh display*

Querying mass properties

The **Mass properties** query displays the surface area and area centroid, volume and volume centroid, mass and center of mass, and moments of inertia about the center of mass or about a specified point for your selection.
The data displayed depend on your selections. For example, if you select a single face of a solid part, Abaqus/CAE displays the surface area and area centroid of the face in the message area. If you select the entire part, Abaqus/CAE displays the volume and volume centroid, mass and center of mass, and its moments of inertia about the center of mass or about a specified point for the part. If the part is a shell, Abaqus/CAE also includes the surface area and area centroid of one side of the shell in the mass properties output.

The mass properties calculated in Abaqus/CAE account for mass being distributed in a continuum throughout the model, whereas the Abaqus solver calculates the mass properties according to the discretization of the model. When compared to the mass properties provided in the data (`.dat`) file of an Abaqus analysis, the values of the moments of inertia obtained in the mass properties query may be substantially different, especially for finite element models with coarse meshes.

In the Visualization module, the mass properties are always calculated based on model data (undeformed shape) even if the deformed shape is displayed in the viewport.

If the region that you query contains mesh occupying the space where geometry exists but that mesh is unassociated with any geometry, the volume/area will effectively be counted twice in the calculations. You should query unmeshed regions and/or unassociated geometry to avoid encountering this behavior.

You cannot query for the mass properties of a part to which an Eulerian section is assigned. However, you can query for the mass properties of an Eulerian part, provided it does not have an Eulerian section assignment.

You can query for the mass properties of a model even when portions of the model are not completely defined. For example, if your selection includes a part instance that does not have a section assignment, Abaqus/CAE includes the area of that part instance in mass properties calculations but excludes the part instance from calculations of volume, volume centroid, mass, center of mass, and moments of inertia. Abaqus/CAE also appends a warning message to the data indicating that the data are incomplete; in this example, the message would indicate that a portion of your selection was missing a section assignment. This approach enables you to investigate aspects of your model at various points during the modeling process without displaying misleading information about mass-related quantities.

Abaqus/CAE returns a warning message with the mass properties data in the following situations:

Geometry not considered by the mass properties query

Abaqus/CAE computes mass properties for shells, solids, trusses, and rotary inertia elements; and in modules other than the Visualization module. Abaqus/CAE does not compute mass properties for beam general section with a generalized section but it does compute mass properties for other profiles. Abaqus/CAE also includes point and nonstructural mass elements in its mass properties calculations. If your selection includes other geometry such as axisymmetric elements, springs, connectors, or gaskets (or, in the Visualization module, if your selection includes point and nonstructural mass elements), Abaqus/CAE excludes that geometry from its calculations. The exclusion of point and nonstructural mass elements from mass properties results in the Visualization module means that mass properties results may be different in the Visualization module than they are in other modules.

Ineligible thickness values

If your selection includes a section definition with a missing thickness value or a thickness value of zero, Abaqus/CAE excludes the selection from calculations of mass, center of mass, and moments of inertia. Similarly, Abaqus/CAE does not consider regions with a variable thickness (defined using a nodal thickness or field thickness) or regions using a thickness value that is not applicable to the corresponding sections specified.

Density not defined or improperly defined

If your selection includes a region in which a value for density is not available or is defined improperly, Abaqus/CAE excludes that region from all mass-related calculations in the mass properties query. The region's area and volume data are included in the final calculations.

Missing section assignment

If your selection includes a region that does not have a section assigned to it, Abaqus/CAE excludes that region from all mass-related calculations in the mass properties query. The region's area and volume data are included in the final calculations.

Inclusion of shell offsets or reinforcements

Abaqus/CAE does not consider shell offset values when calculating the center of volume or surface area, and Abaqus/CAE also excludes any reinforcements in your model from all mass property calculations. If your query includes shell offsets or reinforcements, Abaqus/CAE returns the query results with an appropriate warning message.

Composite sections

When your mass properties query selection includes a part or region with a composite section, Abaqus/CAE calculates mass- and volume-related values in the mass properties query using smeared properties located on the element.

Inclusion of nonstructural mass entities

Abaqus/CAE does not consider nonstructural mass on wires, such as mass-per-length values. In addition, when geometry is not meshed, Abaqus/CAE cannot compute center of mass and moment of inertia values as accurately as it can for meshed geometry.

1. Select **Tools->Query** from the main menu to use the Query toolset, or select the  tool in the Query toolset.
2. Click **Mass properties**.

   Additional options appear in the prompt area.
3. If desired, click **Options** to modify query options.
   a. In the **Mass Properties Query Options** dialog box, you can modify accuracy, density, thickness parameters, and the point about which the moment of inertia is computed. You can click **Reset** to return the options to the previously stored values.
   b. Click **OK** to save your changes and to close the dialog box.
4. If you include a native mesh in your selection, you can query for the mass properties of the geometry or of the native mesh. To query for the mass properties of the native mesh, click **Options** in the prompt area, then toggle on **Use mesh when available for accurate properties** in the dialog box that appears.
5. For selections that include complex geometry, Abaqus/CAE may take a long time to compute the volume properties. You can reduce the computation time by instructing Abaqus/CAE to stop the computation when a certain relative accuracy has been achieved. Click **Options** in the prompt area, then select a relative accuracy of **Low**, **Medium**, or **High** from the dialog box that appears. Higher relative accuracy yields a more accurate result but takes longer to calculate. Relative accuracy settings are available only for geometry selections, not for mesh selections.

6. If your selection includes regions in which thickness or density is either missing or improperly defined, you can supply values for the thickness or density of these regions for the mass properties calculations. Providing these values to the query does not change these values in the model itself.

   Click **Options** in the prompt area, then provide values greater than zero in the appropriate fields.

7. If you want to query mass properties for the entire assembly, select **Query entire assembly** and click **Done**.

   Abaqus/CAE displays the following information in the message area: the volume, volume centroid, mass, center of mass, and moments of inertia about the center of mass or about a specified point. If the assembly includes shell features, Abaqus/CAE reports the surface area and area centroid for one side of the shell faces as well.

8. If you want to query mass properties for the entire part (when the part is displayed in the Part module or Property module), select **Query entire part** and click **Done**.

   Abaqus/CAE displays in the message area the volume, volume centroid, mass, center of mass, and moments of inertia about the center of mass or about a specified point for the part. If the part includes shell features, Abaqus/CAE reports the surface area and area centroid for one side of the shell faces as well.

9. If you want to query mass properties for one or more part instances in an assembly, highlight **Select part instances**, highlight one or more part instances in the viewport, and click **Done**.

   Abaqus/CAE displays in the message area the volume, volume centroid, mass, center of mass, and moments of inertia about the center of mass or about a specified point for the part instance or instances. If the part instance or part instances you query include shell features, Abaqus/CAE reports the surface area and area centroid for one side of the shell faces as well.

10. If you want to query mass properties for one or more geometric regions in an assembly, part, or part instance, highlight **Select geometric regions**, highlight one or more regions in the viewport, and click **Done**.

    Abaqus/CAE displays in the message area the volume, volume centroid, mass, center of mass, and moments of inertia about the center of mass or about a specified point for the region or regions. If the region or regions you query include shell features, Abaqus/CAE reports the surface area and area centroid for one side of the shell faces as well.

11. If you want to query mass properties for one or more faces in an assembly, part, or part instance, highlight **Select geometric regions**, highlight one or more regions in the viewport, and click **Done**.

    a. From the prompt area, highlight **Select geometric regions**.
    b. From the **Selection** toolbar, select **Faces** from the list of object types.
    c. Select one or more faces from the viewport, and then click **Done**.

    Abaqus/CAE displays the total surface area of the selected faces. You can query for multiple shell surfaces or multiple faces, but you cannot perform a query for both shells and geometric faces.

12. If you want to query mass properties for one or more elements in an assembly, part, or part instance, highlight **Select elements**, highlight one or more elements in the viewport, and click **Done**.

    Abaqus/CAE displays in the message area the volume, volume centroid, mass, center of mass, and moments of inertia about the center of mass or about a specified point for the region or regions. If the region or regions you query include shell features, Abaqus/CAE reports the surface area and area centroid for one side of the shell faces as well.

13. If you want to query mass properties for one or more element faces in an assembly, part, or part instance, perform the following steps:

    a. From the prompt area, highlight **Select elements**.
    b. From the **Selection** toolbar, select **Element Faces** from the list of object types.
    c. Select one or more elements faces from the viewport, and then click **Done**.

Abaqus/CAE displays the total surface area of the selected element faces. You can query for multiple element faces and for element faces from multiple shell surfaces or multiple faces, but you cannot perform a query for element faces from both shells and geometric faces.

You can also use general queries, including querying mass properties, in the Visualization module. For more information, see *Querying the model in the Visualization module*.

Using the geometry diagnostic tools

This section describes how you can use the geometry diagnostic tools to locate the following in a part or part instance in the current viewport:

Geometry

- **Invalid entities**: Abaqus/CAE highlights the regions of the part or part instance that have invalid geometry.

  Toggle on **Update validity** to update the status of the selected part or part instance. If an invalid part has become valid, it is marked as valid in the Model Tree. If a valid part has become invalid, Abaqus/CAE displays a warning message that allows you to ignore the invalid status and continue using the part.
- **Imprecise entities**: Abaqus/CAE highlights the regions of the part that have imprecise geometry.

For more information on invalid geometry, see *What is a valid and precise part?*, and *Working with invalid parts*.

Topology

- **Free edges**: Abaqus/CAE highlights the free edges of the part or part instance, including shell and wire edges. A solid part should not contain any free edges.
- **Solid cells**: Abaqus/CAE highlights the solid cells of the part or part instance.
- **Shell faces**: Abaqus/CAE highlights the shell faces of the part or part instance.
- **Wire edges**: Abaqus/CAE highlights the wire edges of the part or part instance. Wire edges are wires, as opposed to edges of a solid or shell feature.

Small geometry

Small entities such as short edges, small faces, and faces with small face corner angles can affect the mesh quality. You can use the following tools to locate these regions:

- **Edges shorter than:**Abaqus/CAE highlights edges shorter than the specified length. The specified length must be 1×10^{-6} or greater.
- **Faces smaller than:**Abaqus/CAE highlights faces smaller than the specified area. The specified area must be 1×10^{-12} or greater.
- **Face corner angles less than:**Abaqus/CAE highlights faces where two edges meet at an angle less than the specified angle. The specified angle must be less than 90°. Abaqus/CAE meshes faces with small corner angles with elements that have a high aspect ratio that affect the mesh quality.

1. From the main menu bar, select **Tools->Query**, or click the  tool in the Query toolset to start the Query toolset.
2. From the **Query** dialog box, select **Geometry diagnostics**. If the viewport contains multiple part instances, select the one that you want to query.

   Abaqus/CAE displays the **Geometry Diagnostics** dialog box.
3. Toggle on the desired geometry diagnostic options and specify a new value, if desired.
4. + Click **Highlight**.

- Abaqus/CAE highlights any regions with the corresponding invalid, imprecise, or small geometry you selected. If the part size is relatively large, short edges and small faces, even though highlighted, may not be visible. To help you find these short edges and small faces, Abaqus/CAE displays markers around the highlighted regions.
- If you selected **Update validity**, Abaqus/CAE also checks and updates the validity status of the part or assembly. The validity checks can be computationally expensive for complex geometry.
- If no regions are found for a particular diagnostic tool, Abaqus/CAE displays a message in the message area.

5. If desired, click **Create Set** in the prompt area to create a geometry set containing the highlighted regions. In the dialog box that appears, enter a name for the set and + click **Continue**.

   The Geometry Edit toolset provides tools to repair regions that are invalid or imprecise. The Geometry Edit toolset allows you to specify a set when you select a region to repair.

   Note:

   You can view geometry diagnostics for the reference representation by toggling on **Apply to reference representation**. However, items from the reference representation will be excluded from created geometry sets because the reference representation cannot be repaired. For more information, see *Understanding the reference representation*.

The Reference Point toolset

This chapter describes the Reference Point toolset.

In this section:

- *What is a reference point?*
- *What is a reference point used for?*
- *Creating a reference point*

What is a reference point?

A reference point is a point that you create on a part. You can also create reference points on the assembly. You can position a reference point anywhere in space, and a reference point is useful for creating a point in your model where a vertex is not available; for example, at the center of a hole. In contrast to a vertex a reference point is ignored by the Mesh module when the mesh is generated.

You can use the Reference Point toolset in the Part module to create a reference point that is associated with a part by selecting **Tools->Reference Point** from the main menu bar. When you create the assembly, the reference point appears on each instance of the part in the assembly. A part can include only one reference point, and Abaqus/CAE labels the reference point **RP**. Abaqus/CAE asks you if you want to delete the original point if you try to assign a second point.

Alternatively, you can use the Reference Point toolset in the Assembly, Interaction, or Load modules to create a reference point on the assembly by selecting **Tools->Reference Point** from the main menu bar. In the Interaction module you can use the 

tool in the module toolbox to create a reference point. The assembly can include more than one reference point, and Abaqus/CAE labels them **RP-1**, **RP-2**, **RP-3**, etc. For more information, see *Creating a reference point*. If desired, you can turn off the display of the reference point symbol and the reference point label; for more information, see *Controlling reference point display*.

What is a reference point used for?

You can use a reference point for the following:

- If the part is a deformable planar part that is modeled with generalized plane strain elements, you must create a reference point to indicate the required reference node. For more information, see *Creating generalized plane strain sections*. For more information on generalized plane strain elements, see *Choosing the Element's Dimensionality*.
- If the part is a discrete or analytical rigid part, you use the reference point to indicate the rigid body reference point. Constraints or motion that you apply to the reference point are applied to the entire rigid part.

  The location of the rigid body reference point affects how you prescribe moments or motion; in addition, the location of the rigid body reference point affects the interpretation of moment reactions. If your model includes a dynamic analysis involving rotations, the rotary inertia specification of a rigid body must be made consistent with the location of its rigid body reference point.
- You must refer to a reference point on the assembly when you create a rigid body constraint in the Interaction module. A rigid body constraint constrains the motion of regions of the assembly to the motion of a reference point. You can create and name a set containing the reference point and refer to the set, or you can select the reference point directly from the current viewport. You can also apply loads and boundary conditions to a reference point in the Load module.
- In some cases you will want to position the reference point at the center of mass, which you can find using the Query toolset. You can use the Property module to assign mass and rotary inertia section properties to the reference point. The section can also include optional damping data.
- You can apply constraints to a reference point; for example, equation, coupling, and display body constraints.
- You can use a reference point when you create an assembly-level wire feature in the Assembly module or the Interaction module. A reference point is useful if you want to attach the connector to a point in space. You can create a reference point at the desired location and use a rigid body constraint to attach a part instance to the reference point. When you attach a connector to such a reference point, the connector is effectively attached to the part instance.

Creating a reference point

From the main menu bar, select **Tools->Reference Point** to create a reference point on a part or on the assembly. A part can include only one reference point, and the reference point appears on each instance of the part in the assembly. Alternatively, you can use the Assembly, Interaction, or Load modules to create multiple reference points on the assembly. For more information, see *What is a reference point?*.

1. From the main menu bar, select **Tools->Reference Point**.

   Tip: In the Interaction module you can create a reference point using the  tool in the module toolbox.

2. Select a point to act as the reference point. You can use either of the following techniques to position the reference point:

   - Select any existing vertex from the part, including datum points. If you want to move the reference point, you must edit the vertex or datum point. Alternatively, you can delete the reference point and select a new vertex or datum point.
   - Type the components of a vector representing the *X*-, *Y*-, and *Z*-coordinates of the reference point. If you want to move the reference point, you can use the Feature Manipulation toolset to edit its coordinates.

   Abaqus/CAE displays the reference point at the desired location along with its label. If you create the reference point on a part in the Part module, Abaqus/CAE labels it **RP**. If you create the reference point on the assembly, Abaqus/CAE labels it **RP-1**, **RP-2**, **RP-3**, etc. You can change the reference point label by clicking mouse button 3 on the feature in the Model Tree and selecting **Rename** from the menu that appears. If desired, you can turn off the display of the reference point symbol and the reference point label; for more information, see *Controlling reference point display*.

The Set and Surface toolsets

When you need to specify a region of your model (for example, to apply a load or to define contact), you can select the region from the viewport or you can define a set or a surface that contains the region. You use the Set and Surface toolsets to create and manage sets and surfaces.

The Set and Surface toolsets are available from the **Tools** menu in the main menu bar in all modules except the Visualization module.

In this section:

- *Understanding the role of the Set and Surface toolsets*
- *Understanding sets and surfaces*
- *Using the Set and Surface toolsets*

Understanding the role of the Set and Surface toolsets

The Set and Surface toolsets are collections of tools that allow you to create and manage sets and surfaces. You can use these tools to perform the following tasks:

Create

Create a set or surface by selecting a group of entities, such as faces and edges.

Edit

Modify a set or surface by selecting entities to add to it or to delete from it.

Rename

Replace the current name of an existing set or surface with a new name.

Delete

Delete a set or surface from the model.

In addition, you can use the Model Tree to merge a group of selected sets and surfaces into a new set or surface. For detailed instructions on creating and manipulating sets and surfaces, see the following sections:

- *Creating, editing, copying, renaming, and deleting sets and surfaces*
- *Creating sets*
- *Creating surfaces*
- *Performing Boolean operations on sets or surfaces*
- *Editing sets and surfaces*
- *Associating objects (such as loads and sections) with sets and surfaces*

Understanding sets and surfaces

This section describes basic concepts concerning sets and surfaces.

In this section:

- *What is a set?*
- *How do part sets and assembly sets differ?*
- *What is a surface?*
- *Regeneration of geometry sets and surfaces*
- *Specifying a particular side or end of a region*

What is a set?

A set is a named region or collection of entities on which you can perform various operations.

For example, once you create a set, you can use it to perform the following tasks:

- Assign section properties in the Property module.
- Create contact pairs with contact node sets and surfaces in the Interaction module.
- Define loads and boundary conditions in the Load module.
- Request output from specific regions of the model in the Step module.

You can create the following types of sets:

Geometry sets

A geometry set contains geometric objects (cells, faces, edges, and vertices) that you have selected from one of the following types of parts or from instances of these parts:

- Native parts (those created using the tools in the Part module)
- Parts that you imported from a file.

You select the entities to include in the set from the current viewport. Depending on the shape and modeling space of the part, you can include any combination of cells, faces, edges, and vertices in a set. However, some procedures can be performed only with certain types of objects. As a result, the set that you select must include only object types that are valid for the procedure. For example, concentrated forces can be applied only to vertices; therefore, the sets to which you apply concentrated forces can include only vertices.

Node and element sets

Node and element sets contain nodes and elements that you have selected. You can create node and element sets from native Abaqus nodes and elements on a part that you have meshed in the Mesh module, from orphan mesh nodes and elements, or from nodes and elements on any instances of parts. A set can include nodes or elements from a single part or from multiple part instances. Sets that you create using the Set toolset can include either nodes or elements but not both. However, you can create sets containing a mixture of nodes and elements by merging sets or by importing an output database or an input file containing multiple sets with the same name. Native nodes and elements within sets allow you to request output or add loads to specific areas without deleting the mesh and partitioning the geometry. However, any changes to the mesh—including regenerating it from replay or journal files—may invalidate or change the native portion of mesh sets.

For more information about mesh parts and orphan mesh nodes and elements, see *What kinds of files can be imported and exported from Abaqus/CAE?*, *Importing a model from an Abaqus input file*, *Importing a model from an output database*, and *Creating a mesh part*.

If you rename or delete a set, any objects associated with the set, such as sections or loads, become invalid. However, if you change the name of a renamed set back to its original name or if you recreate a deleted set using its original name, objects associated with that set are restored.

Additional information

• *Using the Set and Surface toolsets*

How do part sets and assembly sets differ?

Sets that you create from a part or sets that you create from a part instance in the assembly are used differently:

Part sets

Part sets are sets that you created in the part-related modules—Part or Property. The Mesh module also acts as a part-related module when you select the **Part** object from the context bar. When you import an orphan mesh from an output database, you also automatically import any sets as part sets. Part sets appear in the Model Tree in a **Set** container under the part with which they are associated. Only part sets are visible in the **Set Manager** in the Part and Property modules. You do not use part sets directly in the Part module; however, in the Property module you can assign sections to regions specified by part sets. If you assign a section to a region defined by a part set, Abaqus applies the section assignment to all instances of that part in the assembly.

When you instance a part in the Assembly module, you can refer to any part sets that you previously created; however, the assembly-related modules provide only read-only access to these sets, and you cannot access part sets from the **Set Manager** in assembly-related modules. Sets from an instanced part appear in the Model Tree under the assembly. You can select an eligible part set during a procedure (while applying a load or boundary condition, for example) by clicking the **Set** button on the far right side of the prompt area and selecting the set from the **Region Selection** dialog box that appears. Abaqus names the sets *part_instance_name.set_name*. You cannot access part sets from the **Set Manager** in an assembly-related module.

Assembly sets

Assembly sets are sets that you created in the assembly-related modules—Assembly, Step, Interaction, or Load. The Mesh module also acts as an assembly-related module when you select the **Assembly** object from the context bar. Assembly sets appear in the Model Tree in a **Set** container under the assembly along with any sets from an instanced part. Only assembly sets are visible in the **Set Manager** in the assembly-related modules. You can use assembly sets to indicate, for example, regions of the assembly where you would like to apply a load or boundary condition or to obtain output. Assembly sets can include regions from multiple part instances.

An assembly set refers to the assembly itself and not to the individual part instances. As a result, Abaqus/CAE does not delete an assembly set if you delete a part instance contained in the set. You must manually delete the assembly set.

A single part cannot contain a geometry set, a node set, or an element set with the same name as an existing set; however, different parts can contain sets with the same name. All assembly set names must be unique.

Additional information

- *What is a set?*
- *Using the Set and Surface toolsets*

What is a surface?

Surfaces are collections of faces and edges or collections of element faces and edges. You can select a surface when a procedure is expecting a face; for example, when you are applying distributed loads, such as pressure loads, and defining contact interactions. You can select an interior surface; for example, when you are using the solid offset mesh tool.

When you create a surface on a shell model, you must select which side of the surface is the desired face; you can also select both faces. Similarly, if you create a surface on a wire model, you must select which end of the wire is the desired face; you can also select the circumference of the wire. For more information, see *Specifying a particular side or end of a region*.

You can define a surface that includes edges of a shell or element edges. You can use edge-based surfaces in Abaqus/Explicit general contact interactions. You can also use edge-based surfaces to tie two shells along two edges or to tie two shells that intersect to form a "T."

You can create two different types of surfaces:

Geometry surfaces

Create a geometry surface by selecting geometric objects (faces and edges) from native or imported geometry. When the analysis input file is created, the surface definition in the input file specifies the element edges (in the case of axisymmetric part instances) or faces that are associated with the surface geometry.

Mesh surfaces

Create a mesh surface by selecting element faces (for three-dimensional regions) or edges (for two-dimensional regions) from meshes. Adding surfaces to the mesh allows you to request output or add loads to specific areas without deleting the mesh and partitioning the geometry. However, native element faces or edges within mesh surfaces may be invalidated or the content may change if you make any changes to the mesh—including regenerating the mesh from replay or journal files.

If you rename or delete a surface, any objects associated with the surface, such as loads or interactions, become invalid. However, if you change the name of a renamed surface back to its original name or if you recreate a deleted surface using its original name, objects associated with that surface are restored.

If you use the Virtual Topology toolset to create virtual faces and edges, you can select those virtual faces and edges when you create sets and surfaces. In addition, if an existing set or surface contains an edge or vertex that you ignored using the Virtual Topology toolset, the edge or vertex is removed from the set or surface. Similarly, if an existing set or surface contains faces or edges that you combined, Abaqus/CAE replaces the original faces and edges with the new combined faces and edges. This is true only if all of the faces and edges that you combined are members of the same set. For more information, see *What can I do with a part or a part instance containing virtual topology?*.

- *Defining Contact Pairs in Abaqus/Explicit*
- *Mechanical Contact Properties*

Regeneration of geometry sets and surfaces

Geometry sets and surfaces are regenerated automatically when you change the underlying geometry of the model. However, if you change the geometry of the model significantly, objects that you had previously included in sets or surfaces may be unidentifiable.

For example, if you delete or suppress a feature of a part, sets and surfaces associated with that feature are altered:

- If components of the feature were the only objects in a set or surface, the set or surface still appears in the **Set Manager** but is empty. You can edit the set so that it includes new geometry.
- If components of the feature were included with other objects in a set or surface, the set or surface no longer contains the components of the feature but continues to contain all of the other objects.
- If you suppress and then resume a feature, the sets and surfaces associated with that feature are also restored, as well as any objects assigned to those sets and surfaces, such as loads or interactions.

- *Using the Set and Surface toolsets*

Specifying a particular side or end of a region

When you create a surface definition from a shell, a wire, or an internal face of a three-dimensional part, you must specify which side of the part you want to include in the surface definition. When you select sides from a shell or face, Abaqus/CAE uses different colored faces to indicate the two sides and prompts you to select the color corresponding to the side that you want to select. During this procedure, the model display becomes translucent to make obstructed or interior sides visible. When you select sides of a wire, Abaqus/CAE uses different colored arrowheads to indicate the two sides of the part.

When you edit a surface definition, the sides are colored based on your previous selections as described below.

Selecting sides from a shell

To distinguish the sides of a shell, Abaqus/CAE colors one side of the shell brown and the other side purple. You select a specific side by clicking either the **Brown** or **Purple** button in the prompt area (see *Figure 1*).

Figure 1: Select the side of the surface.

You also have the option of selecting **Both sides**, which defines a double-sided surface that includes both the brown and the purple sides of the shell. Double-sided surfaces can be used only in the following situations:

- Contact interactions using three-dimensional shells, membranes, and rigid bodies in an Abaqus/Explicit analysis
- Contact interactions using the small-sliding, surface-to-surface contact formulation in an Abaqus/Standard analysis

Consider the conical shell in *Figure 2*.

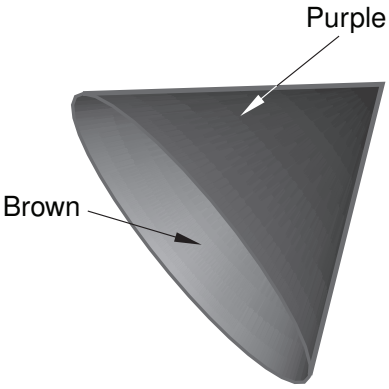

Figure 2: Colors indicate the side of a shell.

Abaqus/CAE displays the exterior side of the cone in purple and the interior side of the cone in brown. Therefore, to select the exterior of the cone, you would click **Purple** in the prompt area; to select the interior, you would click **Brown**.

If you select more than one shell face as part of a surface definition, you can control the color coding for each face individually. Abaqus/CAE includes a **Flip a surface** option that allows you to reverse the orientation of any individual face before creating the surface definition (see *Figure 3*).

Figure 3: The Flip a surface option becomes available for multi-faced shell surfaces.

Use this option to make all of the desired sides the same color, then select that color from the prompt area. If you select **Both Sides**, Abaqus/CAE selects both sides of all selected faces regardless of any surfaces that you previously flipped.

In the model in *Figure 4* both rounded ends are selected as part of the surface.

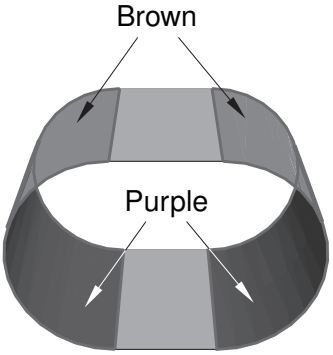

Figure 4: Two faces are included in the surface selection.

Initially, Abaqus/CAE colors the convex sides of both faces brown. However, the desired surface actually consists of one convex face and one concave face. To achieve this surface, click **Flip a surface**, and select the face on the right side of the model. Abaqus/CAE reverses the color-coding for only this face, as shown in *Figure 5*.

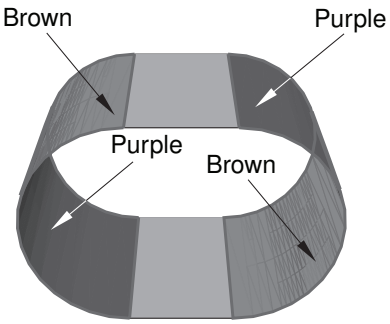

Figure 5: Flipping a surface.

Click **Brown** in the prompt area; Abaqus/CAE defines the surface on all of the brown face sides in the model.

When editing an existing surface definition, you can reselect sides by choosing either **Brown** or **Purple**. **Brown** indicates the side that you used to create the surface previously, and **Purple** indicates the other side. For example, if you selected the **Purple** side to create the surface previously, that side now appears as **Brown** during editing.

Selecting sides on interior surfaces

When you select an internal face to create a surface, the surface side is ambiguous. For example, the highlighted face in *Figure 6* could be either the right side of cell A or the left side of cell B.

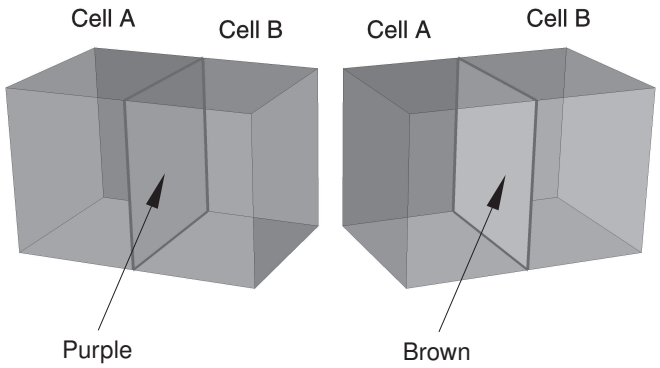

Figure 6: Defining a surface on an internal face.

Abaqus/CAE uses the same brown/purple color-coding interface discussed above to determine which side of the surface you intended to select. Click **Purple** to define a surface on the right side of cell A; click **Brown** to define a surface on the left side of cell B.

Selecting sides from a wire

If you are selecting a surface of a three-dimensional wire part instance, Abaqus/CAE displays the wire in red along with the arrowheads shown in *Figure 7*.

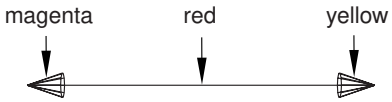

Figure 7: Arrows indicate the ends of a three-dimensional wire.

You can select the end with the magenta arrowhead, the end with the yellow arrowhead, or the circumferential surface of the part, which is indicated by the red wire (see *Figure 8*).

Figure 8: Select the end or the circumference of the surface.

If the wire part is two-dimensional, Abaqus/CAE distinguishes the two sides of the surface using the arrowheads shown in *Figure 9*.

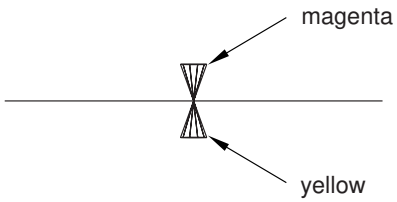

Figure 9: Arrows indicate the top and bottom surface of a two-dimensional wire.

You select an arrowhead color to determine the surface side, as shown in *Figure 10*.

Figure 10: Select the side of the surface.

If the part is an axisymmetric shell, the inside and the outside surface of the part are indicated with arrowheads (see *Figure 11*). The selection options are the same as in *Figure 10*.

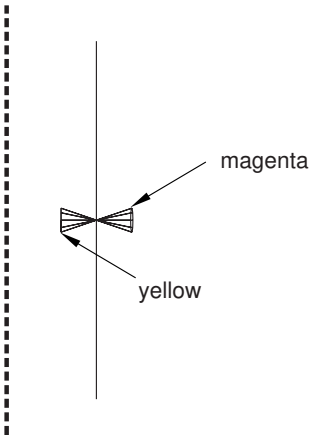

Figure 11: Arrows indicate the inside and the outside of an axisymmetric shell.

When editing an existing surface definition created on a wire, you can reselect sides by choosing either the **Magenta** or **Yellow** arrowheads. **Magenta** indicates the side that you used to create the surface previously, and **Yellow** indicates the other side. For example, if you selected the **Yellow** side to create the surface previously, that side now appears as **Magenta** during editing

- *Selecting interior surfaces*

Using the Set and Surface toolsets

This section outlines the various tasks you can perform with the Set and Surface toolsets and describes the procedures for each.

In this section:

- *Creating, editing, copying, renaming, and deleting sets and surfaces*
- *Creating sets*
- *Creating unsorted node sets*
- *Creating surfaces*
- *Performing Boolean operations on sets or surfaces*
- *Editing sets and surfaces*
- *Associating objects (such as loads and sections) with sets and surfaces*

Creating, editing, copying, renaming, and deleting sets and surfaces

You can create, edit, rename, and delete set or surface definitions.

To create, edit, rename, and delete set or surface definitions, use one of the following:

- The **Create**, **Edit**, **Copy**, **Rename**, and **Delete** items listed under the **Tools->Set** and **Tools->Surface** submenus in the main menu bar.

  The **Edit**, **Copy**, **Rename**, and **Delete** menu items contain submenus listing all of the sets or surfaces in the current model. The **Set** submenus vary depending on which module you are in; in the Part and Property modules, only part sets are listed. In the Mesh module, either part or assembly sets may be listed depending on whether a part or the assembly is selected in the context bar. In all other modules, only assembly sets are listed.
- The set and surface managers. These managers contain functions identical to those listed under the **Set** and **Surface** submenus but with convenient browsers that display sets and surfaces along with their type (such as geometry or mesh). The **Set Manager** displays part sets in the Part and Property modules, part or assembly sets—depending on the current object selection in the context bar—in the Mesh module, and assembly sets in all other modules.

  Note: Sets and surfaces that are empty as a result of feature or mesh modification will still appear in the lists. See *Regeneration of geometry sets and surfaces*, for more information.

  The Model Tree displays an exclamation point (!) next to the names of any empty sets or surfaces. You can also position the cursor over a set or surface name in the Model Tree to view a tooltip that includes the number of items it contains.

  To display a manager, select **Tools->Set->Manager** or **Tools->Surface->Manager** from the main menu bar.

  You can copy imported sets and surfaces through the Model Tree, but imported sets and surfaces cannot be copied through **Tools->Set** and **Tools->Surface** submenus or through set and surface managers.

Warning: When you delete a set or surface, any objects associated with that set or surface, such as loads or interactions, become invalid.

Additional information

• *Managing objects*

Creating sets

The Set toolset allows you to create geometry sets and node and element sets.

You create a geometry set when you are working on a native part created by Abaqus/CAE. You can create node and element sets from native Abaqus nodes and elements on a part that you have meshed in the Mesh module, from orphan mesh nodes and elements, or from nodes and elements on any instances of parts. For more information, see *What is a set?*.

In addition, you can create either a part set or an assembly set. You create a part set when you are working with a part in the Part module or the Property module. When you instance the part in the Assembly module, you can refer to any part sets that you previously created. Finally, you create an assembly set when you are working in the assembly-related modules—Assembly, Interaction, Load, and Mesh. For more information, see *How do part sets and assembly sets differ?*.

1. From the main menu bar, select **Tools->Set->Create**.

   Tip: You can also click **Create** in the **Set Manager**.

   The **Create Set** dialog box appears. The dialog box lists the types of sets that you can create based on the part or assembly displayed in the current viewport.

2. In the dialog box:
   a. Enter a name for the set. Part sets created on different parts can use the same name; however, assembly set names must be unique.
   b. If necessary, select the set type.

      By default, a node set is always sorted in the order of the node labels. You can toggle on **Make unsorted set** to create an unsorted node set and easily control the node set content. For more information, see *Creating unsorted node sets*.

   c. Click **Continue**.

   If you create a node or element set on a native part, Abaqus/CAE automatically displays the mesh if it is not already visible. If you create a node or element set on a part instance or on a part that contains both native and orphan mesh components, you must use the **Show native mesh** tool in the **Visible Objects** toolbar to display and select items from the native portion of the mesh.

3. Select the entities in the viewport that you want to include in your set.

   Tip: You can use the **Selection** toolbar to limit the types of entities that you can select in the viewport. For more information, see *Selecting objects within the viewport*.

   When you are finished selecting entities, click mouse button 2.

Additional information

- *What is a set?*
- *Selecting objects within the viewport*

Creating unsorted node sets

You can use the Set toolset to create unsorted node sets.
By default, a node set is always sorted in the order of the node labels. You can create an unsorted node set and easily control the node set content.

You can create unsorted node sets from native Abaqus nodes on a part that you have meshed in the Mesh module, from orphan mesh nodes, or from nodes on any instances of parts.

1. From the main menu bar, select **Tools->Set->Create**.

   Tip: You can also click **Create** in the **Set Manager**.

   The **Create Set** dialog box appears. The dialog box lists the types of sets that you can create based on the part or assembly displayed in the current viewport.

2. In the dialog box:
   a. Enter a name for the set. Part sets created on different parts can use the same name; however, assembly set names must be unique.
   b. Select **Node** as the set type, and toggle on **Make unsorted set**.
   c. Click **Continue**.

   If you create a node set on a native part, Abaqus/CAE automatically displays the mesh if it is not already visible. If you create a node set on a part instance or on a part that contains both native and orphan mesh components, you must use the **Show native mesh** tool in the **Visible Objects** toolbar to display and select items from the native portion of the mesh.

3. In the **Create Unsorted Node Set** dialog box that appears, specify the nodes for the set.

   Use either of the following techniques:

   Select the nodes from the viewport

   a. Select one of the following methods to insert selections in the set definition table:

      - Select **Individual** to select nodes individually.
      - Select **Along edges** to select nodes along a feature edge. Abaqus/CAE proposes a direction for the node selection (indicated by an arrow) and prompts you to confirm the direction. If necessary, you can flip the direction.
      - Select **Free** to select nodes using any of a variety of general selection methods as described in *Selecting objects within the current viewport*.

      Click **Add Before** or **Add After** to begin making selections.

   b. If desired, repeat the preceding step to add additional nodes.

      The **Add Before** and **Add After** buttons determine where your selections will be added in relation to the currently highlighted line in the set definition table.

   c. Click **Done** in the prompt area.

      Abaqus/CAE displays the **Create Unsorted Node Set** dialog box; the part instances and nodes in your set are listed in the set definition table.

   Enter the node labels directly into the table

   In the **Set Definition** table, use standard keyboard and mouse editing techniques to insert, modify, or delete part instance names and node label expressions. If you do not know the part instance names in the model, use the Query toolset to query nodes in the viewport. For special table editing options, press mouse button 3. (For more information, see *Entering tabular data*.) A node label expression is either of the following:

- A single node label; for example, 5.
- A range of nodes that you specify with a starting and ending node label optionally followed by an increment; for example, 5:10 or 5:10:2.

Select rows in the set definition table, and toggle on **Highlight nodes in selected row** to view node selections.

4. If desired, order some or all of the contents of the set definition table according to a sorting expression.
   a. Select one or more rows in the set definition table.
   b. Specify the following settings to order the contents of the selected rows:
      - **Sorting order**: select **Ascending** or **Descending**.
      - **Local system**: select or create a coordinate system, if desired.
      - An expression in the field provided. Any valid Python expression can be used, referencing one or more valid parameters: "Label", "X", "Y", "Z", "R", "Th", or "P". (The actual valid parameters depend on the local system selected, if any, and are indicated in the dialog.) For example, the simple expression "X" will sort the indicated nodes according to the X coordinate of each node. More complex examples include "X*Y" and "Z if Label < 1000 else Label".
   c. Click **Apply**. The contents of the selected rows are ordered according to the expression and sorting order. Rows themselves are not reordered; you can use the right mouse button menu in the table to move rows up or down as needed.
5. Click OK to commit the set definition.

Creating surfaces

The Surface toolset allows you to create geometry or mesh surfaces. Geometry surfaces can consist of geometric faces and edges; mesh surfaces can consist of element faces and edges.

1. From the main menu bar, select **Tools->Surface->Create**.

   Tip: You can also click **Create** in the **Surface Manager**.

   The **Create Surface** dialog box appears. The dialog box lists the type of surface you are creating.

2. In the dialog box:
   a. Enter a name for the surface. Surfaces created on different parts can use the same name; however, assembly surface names must be unique. For information on naming objects, see *Using basic dialog box components*.
   b. If necessary, select the surface type.
   c. Click **Continue**.

   If you create a mesh surface on a native part, Abaqus/CAE automatically displays the mesh if it is not already visible.

3. Select the entities in the viewport that you want to include in the surface. If you are creating a geometry surface, Abaqus/CAE allows you to select only faces and edges. Similarly, if you are creating a mesh surface, Abaqus/CAE allows you to select only element faces and element edges. You can select interior entities to include in the surface. For more information, see *Selecting interior surfaces*. To create an edge-based surface, you must select the edge of a shell or the edge of an element. For more information, see *What is a surface?*.
4. When you are finished selecting entities, click mouse button 2.
5. If you are creating a geometry surface from a native part, you must specify the side of the selected face or the end of the selected wire. For more information, see *Specifying a particular side or end of a region* and *Understanding the correspondence between geometric and physical objects*.

Additional information

- *What is a surface?*

- *Defining Contact Pairs in Abaqus/Explicit*
- *Mechanical Contact Properties*

Performing Boolean operations on sets or surfaces

You can select a group of sets or surfaces from the Model Tree and use Boolean operators to combine them into a single set or surface. The following operators are available:

Union

Use the **Union** operator to create a set or surface that merges the contents of your selections.

Intersection

Use the **Intersection** operator to create a set or surface containing the items common to all your selections.

Difference

Use the **Difference** operator to create a set or surface by subtraction. You must designate the "first" set or surface, and Abaqus/CAE subtracts the remaining selections from it.

For example, you can use the **Union** operator to combine all of the top faces from a linear pattern of part instances into a single surface.

1. From the Model Tree, expand the **Sets** or **Surfaces** container associated with a part or with the assembly.
2. Select all of the desired sets or surfaces. You can use a combination of drag-select, **[Shift] + Click**, and **[Ctrl] + Click** to select the desired sets or surfaces. You cannot combine sets with surfaces. For more information, see *Drag-selecting multiple objects*.
3. Click mouse button 3 over the Model Tree, and select **Boolean** from the menu that appears.

   Abaqus/CAE displays the **Sets Boolean** or **Surfaces Boolean** dialog box.
4. In the dialog box, enter the name of the new set or surface and select the desired operator.
5. If you selected the **Difference** operator, click the arrow to the right of the **First set** or **First surface** field and specify the set or surface from which Abaqus/CAE will subtract your remaining selections.
6. Click **OK**.

   Abaqus/CAE creates the new set or surface, and it appears in the Model Tree.

Additional information

- *Using the Set and Surface toolsets*
- *Selecting objects within the viewport*

Editing sets and surfaces

You can edit an existing set or surface by reselecting entities in the viewport.

1. From the main menu bar, select **Tools->Set->Edit->*set of your choice*** or **Tools->Surface->Edit->*surface of your choice***.

   Note:

   You can also click **Edit** in the **Set Manager** or in the **Surface Manager** after selecting the name of the set or surface of interest.

   The set or surface is highlighted in the viewport, and Abaqus/CAE prompts you to reselect the objects for the set.

2. In the viewport, reselect entities to include in the set or surface. Use **[Shift] + Click** and **[Ctrl] + Click** to change which entities are selected in the viewport.

   Tip: You can use the **Selection** toolbar to limit the types of entities that you can select in the viewport. For more information, see *Selecting objects within the viewport*."

   When you are finished selecting entities, click mouse button 2.

   If you are editing a geometry set, you can select only geometry for the set. Similarly, if you are editing a node or element set, you can select only nodes or elements, respectively. If you are editing a set imported from an output database or from an input file that contains both nodes and elements or a set created using the Boolean union operator that contains nodes, elements, and geometry, Abaqus/CAE prompts you to choose the type of entity that you will be reselecting. If you reselect the nodes, Abaqus/CAE retains any original elements and geometry in the set. Repeat this step as needed to edit each type of entity.

3. If necessary, specify the side or end of the regions that you want to include in the surface and then click mouse button 2. (For more information, see *Specifying a particular side or end of a region*.)

Additional information

- *Using the Set and Surface toolsets*
- *Selecting objects within the viewport*

Associating objects (such as loads and sections) with sets and surfaces

When you select the region to which to apply an object, such as a load or a section, you can choose between the following techniques:

Highlight selections in viewport

Click on the entities in the current viewport; for example, a face or a group of vertices. Use **[Shift] + Click** and **[Ctrl] + Click** to append entities to your selection.

Tip: You can use the **Selection** toolbar to limit the types of entities that you can select. For more information, see *Selecting objects within the viewport*.

Sets or Surfaces

Use an existing set or surface that you have created with the Set or Surface toolsets. If you choose to use an existing set or surface, the **Region Selection** dialog box appears. This dialog box contains a list of the sets or surfaces that are appropriate for the object you are applying.

Click the appropriate button in the prompt area to toggle between the two techniques. For more information, see *Using the Set and Surface toolsets*. You can also use selection groups to speed up your selection procedures. You can copy selected entities into selection groups, and you can paste entities from selection groups into your selection. For more information, see *What is a selection group?*.

The Stream toolset

A streamline is a curve that is instantaneously tangent to the velocity vector of the flow, and a stream is a set of streamlines that enable you to visualize the velocity or vorticity data in a fluid flow analysis. The Stream toolset is available only in the Visualization module.

This chapter explains how to use the Stream toolset to create, modify, and delete streams; display or hide them in the viewport; and customize several aspects of their appearance.

In this section:

- *Understanding stream display*
- *Creating a stream*
- *Displaying and hiding streams*
- *Customizing stream display*

Understanding stream display

A streamline traces the path tangent to a nodal vector field, and a stream is a set of streamlines that enable you to visualize data emanating from a particular location in a vector field. *Figure 1* shows a sample stream of 12 streamlines displaying velocity data in a fluid flow analysis.

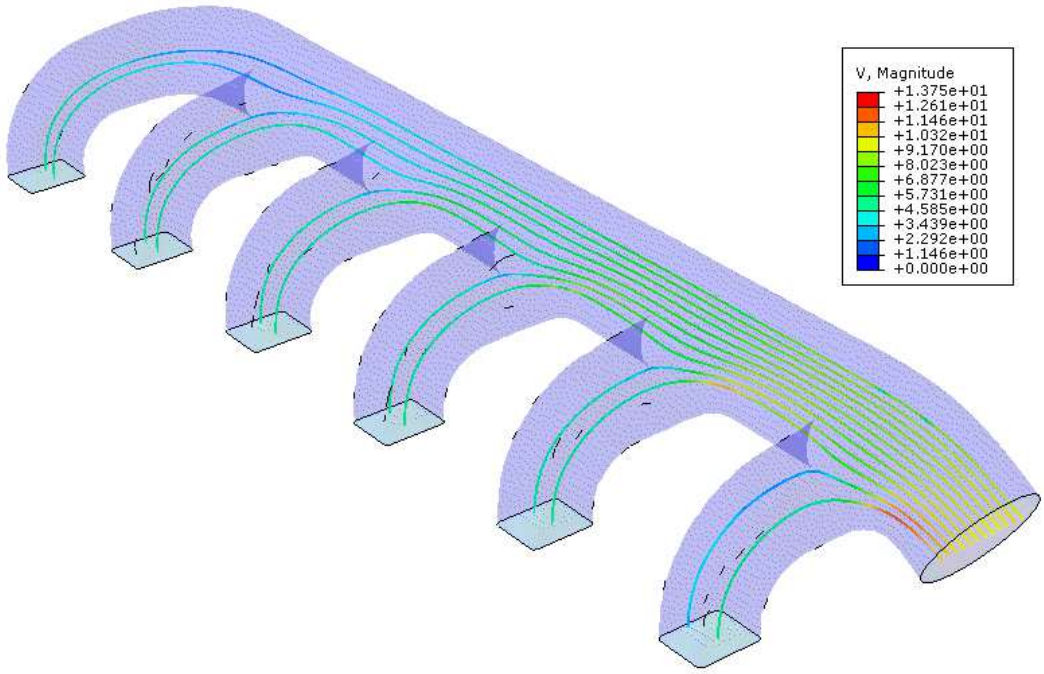

Figure 1: 12-pointed stream showing velocity data for a flow analysis through a manifold.

You can create streams by first defining a rake, which is a line segment with a series of points specified along its length that control the locations where Abaqus/CAE displays streamlines for a fluid flow analysis. Rakes are placed into an area of interest in the fluid flow; when you create and display the stream in the viewport, Abaqus/CAE displays a number of streamlines that corresponds to the number of points on the rake. Streamlines are evenly spaced along the rake, except for rakes defined using nontrivial path definitions; for more information about stream rake definition, see *Creating a stream*.

The streamline shape is driven by the currently selected stream variable, which is usually velocity or vorticity. To change the current stream variable, see *Selecting the stream field output variable*. The streamline color is driven by the currently selected primary variable. For more information on customizing streamline color options, see *Customizing stream colors*.

You must define separate stream rakes for each part instance for which you want to display flow data. Abaqus/CAE computes stream data for individual part instances only and does not display streamlines across separate part instances.

Creating a stream

A stream definition has two components: the location of the line segment or the path definition that you want to use as your “rake” for investigations of velocity or vorticity data, and the number of points along that rake for which you want to display streamlines of fluid flow data. You can specify the rake location by picking nodes from the viewport, by entering coordinates in the dialog box, or by selecting one of the path definitions in your session. Edge list paths cannot be used for stream definition.

You cannot save streams to the output database file. If you want to retain a stream that you have defined, record the process of defining that stream as a macro in Abaqus/CAE. For more information on macros, see *Managing macros*.

1. From the main menu bar in the Visualization module, select **Tools->Stream->Create**.

    **Tip:** You can also create a stream by using the  tool in the Visualization module toolbox.

   The **Create Stream** dialog box appears.
2. If desired, specify a custom name for the stream definition in the **Name** field.
3. If desired, increase or decrease the number of points specified in the **Number of points** field. By default, Abaqus/CAE creates a rake with five points.
4. From the **Specification** options, select **By nodes**, **By coordinates**, or **By path**.
5. To specify the location of the stream rake, do one of the following:

Select the nodes directly from the viewport

1. Click .

   Abaqus/CAE prompts you to select the first point.
2. Select the starting node for the rake.
3. Select the ending node for the rake.

Abaqus/CAE populates the **Start** and **End** fields with your selections.

Enter the coordinates into the dialog box

1. In the **Start (X, Y, Z)** field, enter the coordinates of the rake starting point.
2. In the **End (X, Y, Z)** field, enter the coordinates of the rake ending point.

Specify a path as the stream rake

From the **Path name** list, select the path that you want to use as a stream rake.

6. Click **OK**.

   Abaqus/CAE creates the stream definition and displays it in the viewport.

Additional information

- *Displaying and hiding streams*
- *Customizing stream display*

Displaying and hiding streams

You can display or hide streams individually in the current viewport by toggling their **Show** check boxes in the **Stream Manager**, and you can display or hide all of the streams in your session by clicking **Set All On** or **Set All Off**. The manager displays all streams defined in your session and indicates whether each one is currently displayed. In addition, you can display or hide the upstream or downstream component of each stream by toggling its **Upstream** or **Downstream** check boxes.

The **Stream Manager** also displays the number of points on the rake for each stream in your session. You can edit this number for a stream definition directly from the manager, except for streams defined on circular paths or streams defined using path definitions consisting of three or more points or nodes.

Customizing stream display

This section describes how you can customize the color, line style, and arrows of streamlines using settings in the **Stream Plot Options** dialog box.
You can open the **Stream Plot Options** dialog box by selecting **Options**->**Stream** from the main menu bar of the Visualization module of Abaqus/CAE.

The changes you make in the **Stream Plot Options** dialog box apply to all active streams in the current viewport only. Each viewport has separate stream options, which enables you to display streamlines differently in each viewport. For example, you can display streamlines using a uniform color in one viewport and display thicker streamlines that use banded contours based on the current primary variable in a different viewport.

You can also control the default settings that appear in the **Stream Plot Options** dialog box by editing the `onCaeStartup()` function in the Abaqus environment file (`abaqus_v6.env`). For more information, see *Using Abaqus Scripting Interface commands in your environment file*.

In this section:

- *Customizing stream colors*
- *Customizing streamline thickness and arrows*

Customizing stream colors

You can adjust the color that Abaqus/CAE uses to display streamlines for the active streams in the current viewport. The **Stream Plot Options** dialog box enables you to display streamlines with:

- a single, uniform color along their entire length,
- a continuous contour spectrum that varies along the length of the streamlines, or
- a banded contour spectrum that varies along the length of the streamlines.

Continuous contours display gradations without any solid bands of color, while banded contours display a number of contour intervals in which the color is constant. Contours for streamlines reflect values for the current primary variable and are subject to the contour settings specified in the **Contour Plot Options** dialog box. For more information about contour options, see *Customizing a contour plot*.

The color selected for uniform color display also determines the color with which Abaqus/CAE displays streamline arrows that indicate the direction of flow. For more information about toggling on arrow display, see *Customizing streamline thickness and arrows*.

1. Locate the **Color** options.

   Select **Options->Stream** from the main menu bar in the Visualization module. The **Color** options appear at the top of the page.
2. To specify the color option, choose **Uniform color**, **Continuous contour**, or **Banded contour**.
3. If you choose **Uniform color**, perform the following additional steps to select a color:

   1. Click the color sample ().

      Abaqus/CAE displays the **Select Color** dialog box.
   2. Use one of the methods in the **Select Color** dialog box to select a new color. For more information, see *Customizing colors*.
   3. Click **OK** to close the **Select Color** dialog box.

      The color sample and all streamlines in the viewport change to the selected color.
4. Click **OK** to implement your changes and to close the **Stream Plot Options** dialog box.

Customizing streamline thickness and arrows

You can adjust the display of streamlines in the current viewport by changing their thickness, adding directional arrows that indicate the direction of fluid flow, and by customizing the number of direction arrows when their display is enabled. Abaqus/CAE displays directional arrows using the uniform color selected in the **Color** options; for more information, see *Customizing stream colors*. Arrow sizes change as you increase or decrease streamline thickness.

1. Locate the **Style** options.

   Select **Options->Stream** from the main menu bar in the Visualization module. The **Style** options appear at the bottom of the dialog box.
2. Drag the **Line thickness** slider to make the streamlines thinner or thicker.
3. Toggle on **Uniform thickness across streams** to display all streamlines in the current viewport with a uniform thickness.
4. Toggle on **Show direction arrow** to display directional arrows along the streamlines.
5. Drag the **Approx. number of arrows on each streamline** slider to increase or decrease the number of directional arrows displayed on each streamline.
6. Click **OK** to implement your changes and to close the **Stream Plot Options** dialog box.

The Virtual Topology toolset

The Virtual Topology toolset allows you to ignore details, such as very small faces and edges, when you mesh a part or a part instance.

In this section:

- *What is virtual topology?*
- *What can I do with the Virtual Topology toolset?*
- *What can I do with a part or a part instance containing virtual topology?*
- *Why repair a part if I can use virtual topology?*
- *Creating virtual topology based on geometric parameters*
- *Using the Virtual Topology toolset*

What is virtual topology?

In some cases parts or part instances contain details such as very small faces and edges. These features can be important for the detailed machining and packaging design of the component; however, they may be redundant in the numerical analysis if they have little impact on the mechanics of the problem being studied. Indeed, these small details may unduly constrain the generation of the mesh, resulting in a poor mesh or a finer mesh density. In some circumstances small faces and edges can be significant if they occur in a region of interest where you need a fine mesh. However, in most cases the details add nothing to the analysis, and you want Abaqus/CAE to ignore them during the mesh generation process and during the analysis.

The topology of the model is its composition from faces, edges, and vertices. The Virtual Topology toolset allows you to manipulate this topology and create a simplified form for the purpose of meshing. This simplified form is different from the real model and is called “virtual topology.” The faces and edges that result from the manipulation are said to be “virtual.” Similarly, parts and part instances that contain virtual faces and edges are said to be “virtual.”

The Virtual Topology toolset allows you to remove small details by combining a small face with an adjacent face or by combining a small edge with an adjacent edge. The faces or edges to be combined can be specified directly, or you can choose the edges and vertices to ignore.

For example, *Figure 1* shows a piston that has some small details where the blended surfaces intersect. These details result in a dense mesh that includes some sliver-shaped elements. You can use virtual topology to ignore the small details, resulting in the more uniform mesh of better quality that is illustrated in *Figure 2*.

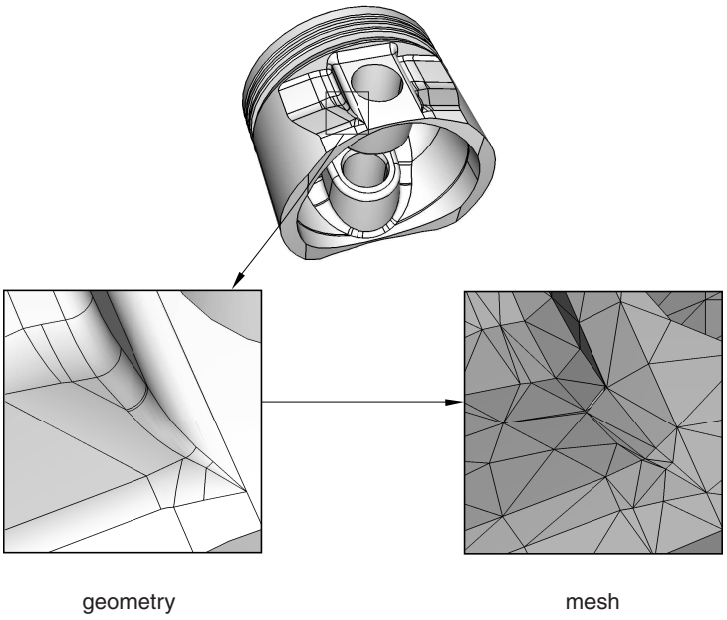

Figure 1: Small details result in a dense mesh of sliver-like elements.

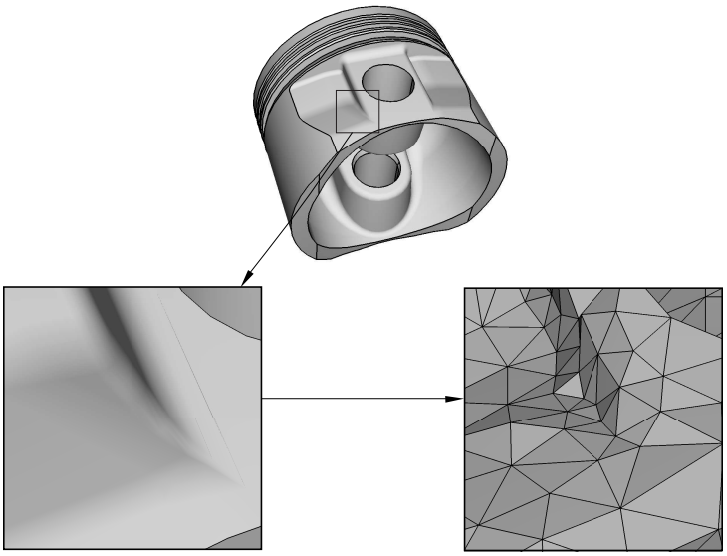

Figure 2: Using virtual topology to ignore small details results in a more uniform mesh of better quality.

Abaqus/CAE treats virtual topology in the same way that it treats standard geometry. For example, you can do the following:

- Partition virtual topology.
- Use the Geometry Edit toolset on virtual topology.
- Use Part module tools on virtual topology, such as extrude, sweep, and blend.

For example, *Figure 3* shows the piston containing virtual topology from *Figure 2* after it has been cut using the extruded cut tool in the Part module.

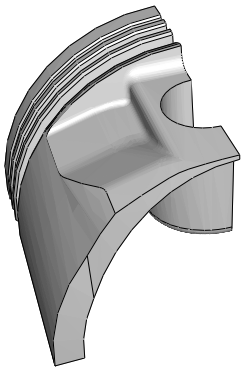

Figure 3: A part containing virtual topology is cut.

Note:

When you export a part containing virtual topology to an ACIS file, Abaqus/CAE removes the virtual topology from the part that is exported.

What can I do with the Virtual Topology toolset?

The Virtual Topology toolset is available only in the Mesh module. You can apply virtual topology to parts, or you can apply it to independent instances in the assembly. The Virtual Topology toolset allows you to do the following:

Combine faces or edges

You can select two or more faces or edges that Abaqus/CAE will combine into a single virtual face or virtual edge. If you combine two faces, any edges between the faces are ignored when Abaqus generates the mesh. Similarly, if you combine two edges, any vertices between the edges are ignored when the mesh is generated.

Ignore an edge or a vertex

You can select edges or vertices that Abaqus/CAE will ignore. Ignoring an edge between two faces is the equivalent of combining the faces. Similarly, ignoring a vertex between two edges is the equivalent of combining the edges; however, you will find the combine tools useful when you have a large number of faces and edges to combine. Using ignore to create virtual topology has the same effect as using combine to create virtual topology—ignored edges or vertices are not considered when Abaqus generates the mesh.

Automatically combine or ignore entities

You can specify a set of geometric parameters that Abaqus/CAE will use to create virtual topology. You can also select the area—faces, parts, part instances, or an entire assembly—to which Abaqus/CAE will apply the selected parameters. The virtual topology parameters are located in the **Create Virtual Topology** dialog box, which also includes tools that you can use to measure and highlight entities and preview the virtual topology. When you are finished, Abaqus/CAE creates a single virtual topology feature that contains all of the changes.

Restore entities

Rather than deleting or suppressing virtual topology features that may contain entities that you want to ignore along with some that you need to use, you can use the **Restore Entities** tool to highlight all entities that have been ignored and select the ones that you want to reactivate.

To preserve mesh quality, edges and faces to be combined should have shallow included angles that are close to 180°. The recommended angle is between 120° and 240°. You can use the angle method to choose only adjacent faces with shallow included angles. For more information, see *Using the angle and feature edge method to select multiple objects*. If the included angle at some edges or vertices lies outside this range, Abaqus/CAE displays a warning and allows you to remove those edges or vertices from your selection. If you choose to retain the sharp edges, the resulting mesh may not lie on a smooth surface. *Figure 1* illustrates a mesh on a virtual surface that is not smooth.

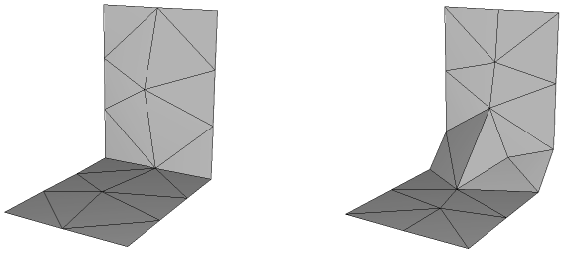

Figure 1: When you apply virtual topology to sharp edges and vertices, the resulting mesh can deviate substantially from the original surface.

You can ignore an edge only if that edge is shared by two adjacent faces or if it is embedded in a face. For example, you cannot ignore the free edge of a shell or an edge shared by three faces, as shown in *Figure 2*.

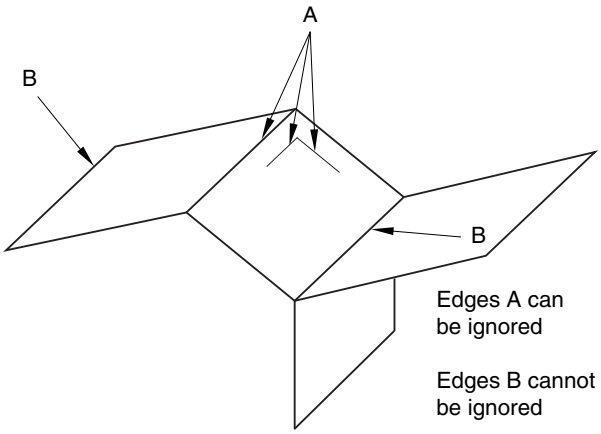

Figure 2: Some edges cannot be ignored.

Similarly, you can ignore a vertex only if that vertex is shared by two adjacent edges or embedded in a face. For example, you cannot ignore the vertex at the free end of a wire or where a wire intersects with a face, as shown in *Figure 3*.

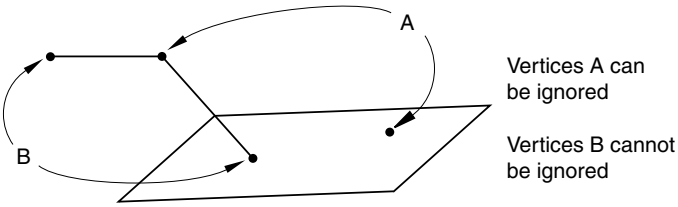

Figure 3: Some vertices cannot be ignored.

Abaqus/CAE does not support all of the meshing techniques on regions that contain virtual topology (combined faces or combined edges). Specifically, Abaqus/CAE does not support the following:

- Two-dimensional free meshing with quadrilateral or quadrilateral-dominated elements using the medial axis algorithm.
- Three-dimensional swept meshing using the medial axis algorithm.
- Two-dimensional structured meshing if the region to be meshed is not bounded by four corners.
- Three-dimensional structured meshing if the region to be meshed is not bounded by six sides.

If you need to apply virtual topology to a dependent instance, you can create a copy of the original part and then create an independent instance of the copy. You can then replace the dependent instance with the new independent instance and apply virtual topology to the replacement. For more information, see *What is the difference between a dependent and an independent part instance?*.

You may be able to make a part swept meshable by combining multiple faces on the target side into a single face; for more information, see *Swept meshing of three-dimensional solids*. However, if you combine many faces into a single face, the meshing procedure may be slower and the resulting mesh may not be acceptable. If you try to combine a large number of faces into a single face, Abaqus/CAE displays a warning and allows you to change your selection. Abaqus/CAE calculates the number of faces being combined from the cumulative number of faces in your selection. For example, if you try to combine two faces each of which already contains five combined faces, the cumulative number of faces will be ten.

What can I do with a part or a part instance containing virtual topology?

Abaqus/CAE stores virtual topology as features of the corresponding part or assembly. As a result, you can use the Model Tree to rename, suppress, resume, and delete virtual topology features. You cannot edit a virtual topology features. You can restore entities that have been ignored or combined using virtual topology. Restoring entities creates more new virtual topology features in the Model Tree—the original virtual topology features are unchanged.

You can create sets and surfaces that contain virtual faces and edges. In addition, if an existing set or surface contains an edge or vertex that you ignored, the edge or vertex is removed from the set or surface. Similarly, if an existing set or surface contains faces or edges that you combined, Abaqus/CAE replaces the original faces and edges with the new combined faces and edges. This is true only if all of the faces and edges that you combined are members of the same set.

Virtual topology is not exported; for example, if you export an assembly containing virtual topology to an ACIS file, Abaqus/CAE removes the virtual topology from the exported model. When you are creating the assembly in the Assembly module, you cannot merge or cut part instances that contain virtual topology.

Why repair a part if I can use virtual topology?

Introducing virtual topology is a convenient method for creating a clean, well-formed mesh. The emphasis is to ignore small geometric details that result in distorted elements in areas where the analysis results are not of significant interest. Virtual topology relaxes the need for the mesh to conform to every edge or vertex and allows you to obtain a simpler model with less detail. However, virtual topology does not change the underlying geometry of the part instance.

When you combine two faces to form a virtual face, Abaqus/CAE updates the display to reflect the ignored edge. However, to form a basis for the new virtual face, Abaqus/CAE maintains the underlying geometry of the faces that were combined. The nodes in the mesh will be placed on the underlying geometry. Therefore, a coarse mesh will interpolate across the virtual face, and a fine mesh will tend to converge to the geometry of the underlying combined faces. Virtual topology allows the mesh definition to be controlled by meshing parameters, such as seed size, and it helps to free meshing from constraints imposed by geometry, such as small faces.

In contrast, you use the Geometry Edit toolset to correct minor flaws that are typically introduced when a part is imported from a third-party application. You use the Geometry Edit toolset to correct the underlying geometry; for example, to stitch small gaps and to delete self-intersecting faces and recreate a valid replacement face. You also use the Geometry Edit toolset to remove redundant topology, such as superfluous vertices and edges. The Geometry Edit toolset modifies the actual geometry, and geometric restrictions limit how you can apply the repair tools; for example, you can remove redundant vertices only if the vertex lies on a curve that is common to both edges.

When you export a virtual part instance, the virtual topology is lost because the virtual face, edge, or vertex is not true geometry. For example, a virtual face is an abstracted reference to the underlying collection of combined faces. Therefore, you should use the Geometry Edit toolset if you need to remove small details from a part and want to export the part with the changes retained.

Creating virtual topology based on geometric parameters

You can use the controls in the **Create Virtual Topology** dialog box to automatically ignore unnecessary model details based on a set of geometric parameters. You can control the following parameters to determine which features Abaqus/CAE considers merging with surrounding geometry:

- Edge length
- Face size
- Face aspect ratio
- Face corner angle
- Thickness of faces representing small stair features
- Corner angle for combining adjacent edges or faces
- Angle and radius controls for combining blends (chamfered or rounded corners) with surrounding faces
- Redundant entities

Abaqus/CAE attempts to simplify the model by merging neighboring edges and faces when the selected parameters are exceeded.

The redundant entities parameter can only be toggled on or off—there are no other settings for this parameter. Redundant entities do not add to the geometry of the model. Redundant entities include:

- Edges that are interior to an existing face
- Edges that separate an otherwise continuous planar or curved face
- Vertices that are interior to a face
- Vertices that separate two straight edges or smooth curves without connecting a new edge

For example, *Figure 1* contains four redundant edges and one redundant vertex. Virtual topology will merge the edges with the surrounding faces and merge the vertex with the surrounding edges, leaving only the underlying box.

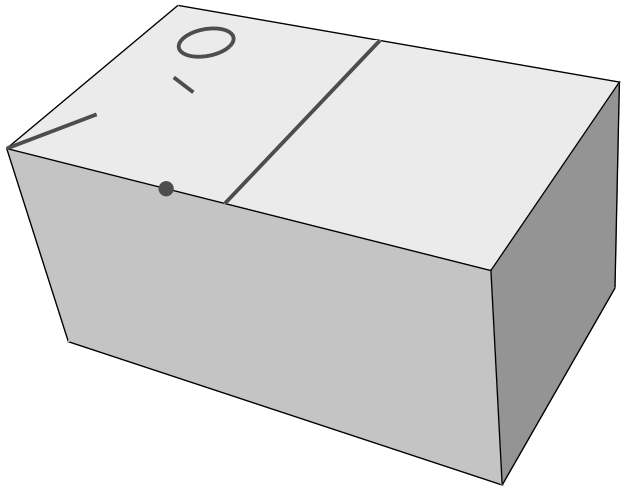

Figure 1: Redundant edges and vertices.

Keep in mind that redundant entities may define areas used by other tools within Abaqus/CAE. For example, the circular edge in *Figure 1* may define a face for the application of a pressure load. The controls in the **Create Virtual Topology** dialog box are based entirely on geometric parameters; you should carefully review the changes made using

virtual topology to make certain that none of the changed entities are required for other parts of the Abaqus/CAE model definition.

By default, all the virtual topology parameters in the dialog box are active, as shown in *Figure 2*. The default values for the edge length, face size, stair feature, and blend radius are calculated based on the size of the selected part or part instance; the other criteria are dimensionless and suitable default values are provided. You can toggle off the controls for entities that you want to be ignored by virtual topology. For example, if you have small faces that are a critical component of the model, toggle off **Faces smaller than**.

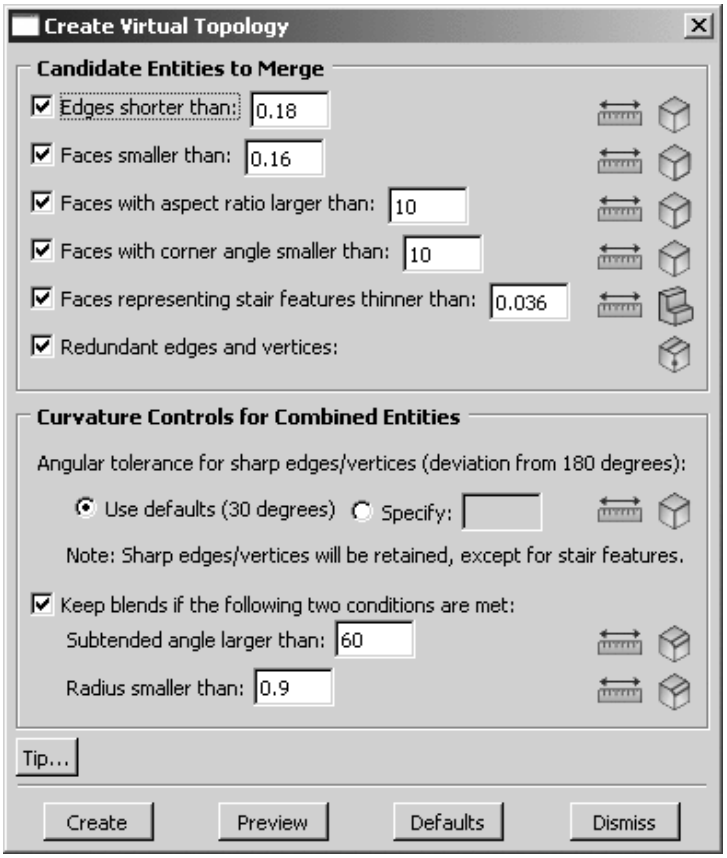

Figure 2: The Create Virtual Topology dialog box.

To help you review potential changes, each parameter in the dialog box contains tools that you can use to measure and highlight entities in the viewport that satisfy the corresponding geometric criteria. Items that are highlighted may not be changed if they conflict with other criteria or model requirements. To use the tools, click on the icons located to the right of each parameter in the **Create Virtual Topology** dialog box. The measure entities tools allow you to measure entities in the viewport. Abaqus/CAE displays the measured values in the message area; you can use the measurements to revise the parameter limits for your model. The highlight tools, such as **Highlight Short Edges**, indicate entities that satisfy the current parameter settings. For the **Candidate Entities to Merge** area of the **Create Virtual Topology** dialog box, the highlight tools indicate entities that may be merged with the surrounding geometry.

The highlight tools do not account for the combination of parameters or any other factors in the model that may prevent the highlighted features from being merged with surrounding geometry. For example, small stair features must satisfy two parameters for replacement using automatic virtual topology:

- The stair height or thickness must be less than the specified value.

- The opposing angles that separate the stair face from the surrounding faces must deviate from 180° by an angle larger than the specified angular tolerance for sharp edges/vertices (explained below with the curvature controls).

Figure 3 shows the angles and the face dimension that make up a stair feature. If you use the highlight tool to view potential faces, Abaqus/CAE does not consider the angle measurements when selecting the faces to highlight.

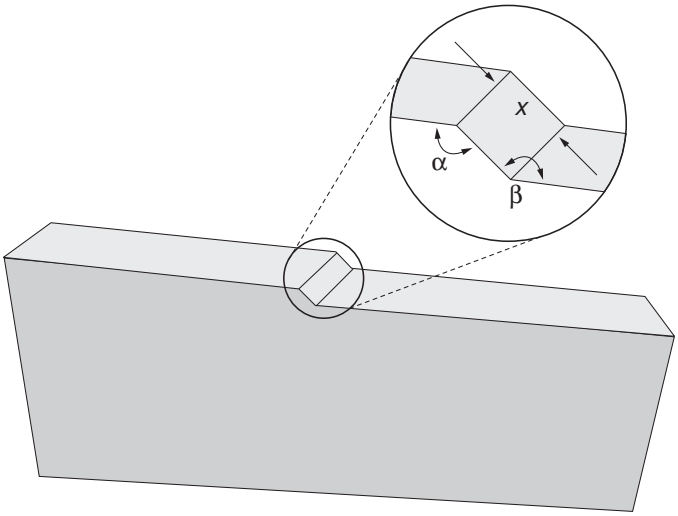

Figure 3: The face thickness (stair height), x, and the angles α and β create a stair feature.

The **Curvature Controls for Combined Entities** area of the **Create Virtual Topology** dialog box is used for combining corner angle and blend entities. The curvature control parameters and highlight tools indicate edges, vertices, or blends that will be retained—not replaced by virtual topology—using the current settings. The following examples explain how the curvature control parameters for corner angles and blends are interpreted by Abaqus/CAE.

Angular tolerance for sharp edges/vertices (deviation from 180 degrees)

Corner angles are the angles between any two adjacent faces or edges that create an edge or vertex, respectively, in the model. If a corner angle is close enough to 180° to be considered flat, Abaqus/CAE considers using virtual topology to ignore the associated edge or vertex. The default parameter setting considers angles flat if they deviate from 180° by less than 30°. *Figure 4* shows how merging faces effects the resulting mesh. The two upper images use a shallow angle so the resulting mesh is a close approximation of the geometry. Increasing the angle between the merged faces as shown in the lower images yields a progressively worse approximation. The corner angle parameter also applies to face corner angles between the edges of two-dimensional parts and to the angles that create small stair features.

Tip: To keep all corner angles, specify a deviation of 0°.

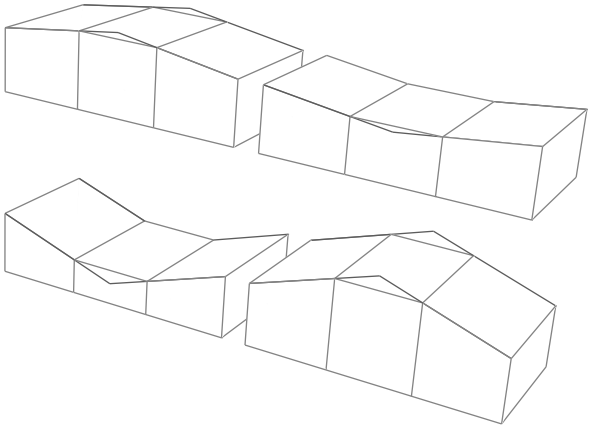

Figure 4: The correspondence between the mesh and the geometry decreases as the corner angles replaced by virtual topology (the peak and valley) deviate further from 180°.

Keep blends with a large subtended angle and a small radius

Blends—rounded or filleted corners—must satisfy two parameters to avoid consideration for virtual topology. This is due to the fact that either the subtended angle or the blend radius alone can create a feature that can be approximated well by the mesh, but combining a large angle with a small radius leads to a poor approximation. *Figure 5* illustrates how two different blend angles are approximated by the mesh if they are merged with the surrounding geometry. The blend radius is the same for both parts, but the larger subtended angle in the upper image results in a bumpy mesh at the corner.

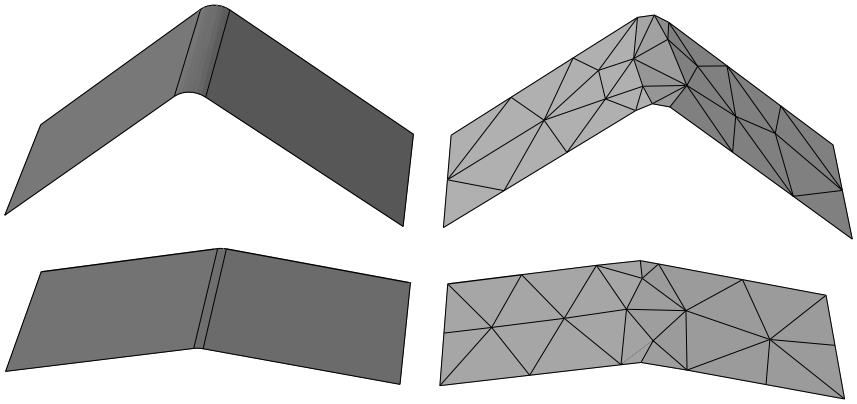

Figure 5: A large blend angle (upper image) may yield a bumpy mesh when it is replaced by virtual topology.

In *Figure 6* the subtended angle is the same for both parts, but the small blend radius in the upper image results in a poor quality mesh.

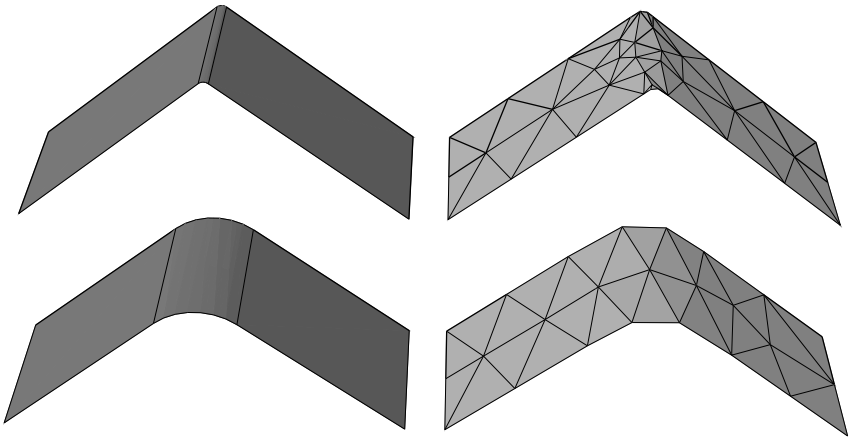

Figure 6: A small blend radius (upper image) may yield a poor quality mesh when it is replaced by virtual topology.

For detailed instructions on how to use the **Create Virtual Topology** dialog box, see *Creating virtual topology automatically*.

Using the Virtual Topology toolset

This section explains how to use the Virtual Topology toolset to remove small details from a part or a part instance prior to meshing and how to restore small details without deleting the virtual topology.

In this section:

- *Creating virtual topology automatically*
- *Combining faces*
- *Combining edges*
- *Ignoring edges and vertices*
- *Restoring entities that were replaced by virtual topology*

Creating virtual topology automatically

You can select **Tools->Virtual Topology->Automatic Create** from the main menu bar to open the **Create Virtual Topology** dialog box. Use the controls in the dialog box to combine faces, combine edges, or ignore entities in the model.

1. From the **Object** field in the context bar, select a part or the assembly.
2. From the main menu bar, select **Tools->Virtual Topology->Automatic Create**.

   Tip: You can also automatically create virtual topology using the  tool, located in the Mesh module toolbox.

3. Select the target regions to be considered for virtual topology.

   The default selection method is parts or part instances, depending on whether you selected a part or the assembly in Step 1. If desired, you can change the selection method in the prompt area to select faces.

   You can use a combination of drag-select, **[Shift] + Click**, and **[Ctrl] + Click** to select more than one part instance in an assembly or more than one face in a part or an assembly. You can also use the angle method or the face curvature method to select more than one face. For more information, see *Selecting objects within the current viewport*.

   Abaqus/CAE opens the **Create Virtual Topology** dialog box.

4. Toggle off any criteria that you do not want Abaqus/CAE to consider for virtual topology.
5. If desired, click the  tools, located next to each control that includes a size parameter, to measure entities in the viewport.

   Follow the instructions in the prompt area to make your selection. You can measure the length of multiple edges or the area of multiple faces in a single operation. When you are finished, click **Done** in the prompt area (if necessary).

   Abaqus/CAE displays the measured value in the message area. If you selected multiple entities, Abaqus/CAE displays the average, minimum, and maximum values. Use the measured values to verify or adjust the virtual topology controls in the dialog box.

6. Click on the highlight tools, located on the right side of the dialog box, to view entities that may be replaced by virtual topology according to the corresponding parameter. For example, the  tool highlights edges within your target region that are smaller than the current short edge length setting. Highlighted entities will not be replaced if they are an integral part of the model or if merging them violates the curvature control parameters.

   Note:

   The highlight tools for the curvature controls (corners and blends) indicate entities that will be *retained* according to the current settings.

7. When you are satisfied with the control settings, click **Preview** to highlight all the entities that will be replaced by virtual topology.

Note:

For large parts or assemblies, or any selection set that contains numerous items for replacement, the preview function may take some time. Instead, you can use the highlight tools as mentioned in Step 6 to quickly view entities that meet the parameter settings.

8. Click **Create** to create the virtual topology according to the selected parameter settings.

   Abaqus/CAE highlights any edges or vertices in the viewport that will become redundant using your current selections and prompts you to choose whether they should also be combined. Abaqus/CAE creates an **Auto virtual topology** feature in the Model Tree to combine or ignore the selected entities.

9. If the target regions selected in Step 3 are still valid, you can repeat Steps 4 through 8 to create more virtual topology on the same regions or click **Dismiss** to close the **Create Virtual Topology** dialog box.

   If the selected target regions are invalidated by the virtual topology, Abaqus/CAE closes the **Create Virtual Topology** dialog box and returns you to Step 3 to select new target regions.

You can use the Model Tree to restore the selected entities by deleting or suppressing the **Auto virtual topology** objects; you can use the **Restore Entities** tool to restore some entities while retaining the rest of the virtual topology feature. For more information on restoring individual entities, see *Restoring entities that were replaced by virtual topology*.

Combining faces

You can select **Tools->Virtual Topology->Combine Faces** from the main menu bar to combine selected faces. During mesh generation, Abaqus/CAE treats the combined faces as a single face and ignores any edges and vertices that were removed.

1. From the **Object** field in the context bar, select a part or the assembly.
2. From the main menu bar, select **Tools->Virtual Topology->Combine Faces**.

   Tip: You can also combine faces using the  tool, located in the Mesh module toolbox.

3. Select the faces that you want to combine.

   You can use a combination of drag-select, **[Shift] + Click**, **[Ctrl] + Click**, and the angle method to select more than one face to combine. For more information, see *Selecting objects within the current viewport*.

   Tip: If you are unable to select the desired face, you can use the **Selection** toolbar to change the selection behavior. For more information, see *Using the selection options*.

4. If the vertices at the end of any edges of the selected faces can also be ignored, Abaqus/CAE highlights the vertices and asks if you want to include them in your selection. Click **Yes** to ignore the highlighted vertices. Click **No** to keep the highlighted vertices.

   Abaqus/CAE combines the selected faces and vertices. You can use the Model Tree to restore the selected faces and vertices by deleting or suppressing the virtual topology feature; you can use the **Restore Entities** tool to choose faces and vertices to restore while retaining the rest of the virtual topology feature. For more information on restoring individual entities, see *Restoring entities that were replaced by virtual topology*.

Combining edges

You can select **Tools->Virtual Topology->Combine Edges** from the main menu bar to combine selected edges. During mesh generation, Abaqus/CAE treats the combined edges as a single edge and ignores any vertices that were removed.

1. From the **Object** field in the context bar, select a part or the assembly.
2. From the main menu bar, select **Tools->Virtual Topology->Combine Edges**.

   Tip: You can also combine edges using the  tool, located in the Mesh module toolbox.

3. Select the edges that you want to combine.

   You can use a combination of drag-select, **[Shift] + Click**, **[Ctrl] + Click**, and the angle method to select more than one edge to combine. For more information, see *Selecting objects within the current viewport*.

   Tip: If you are unable to select the desired edge, you can use the **Selection** toolbar to change the selection behavior. For more information, see *Using the selection options*.

   Abaqus/CAE combines the selected edges. You can use the Model Tree or the **Restore Entities** tool to restore the selected edges. For more information on restoring individual entities, see *Restoring entities that were replaced by virtual topology*.

Ignoring edges and vertices

You can select **Tools->Virtual Topology->Ignore Entities** from the main menu bar to ignore selected edges and vertices. Abaqus/CAE removes the selected entities from the assembly and ignores the entities when the mesh is generated.

1. From the **Object** field in the context bar, select a part or the assembly.
2. From the main menu bar, select **Tools->Virtual Topology->Ignore Entities**.

   Tip: You can also ignore edges and vertices using the  tool, located in the Mesh module toolbox.

3. Select the combination of edges and vertices that you want to ignore.

   You can use a combination of drag-select, **[Shift] + Click**, **[Ctrl] + Click**, and the angle method to select more than one edge or vertex to remove. For more information, see *Selecting objects within the current viewport*.

   Tip: If you are unable to select the desired edge or vertex, you can use the **Selection** toolbar to change the selection behavior. For more information, see *Using the selection options*.

4. If the vertices at the end of a selected edge can also be ignored, Abaqus/CAE highlights the vertices and asks if you want to include them in your selection. Click **Yes** to ignore the highlighted vertices. Click **No** to keep the highlighted vertices.

   Abaqus/CAE ignores the selected edges and vertices. You can use the Model Tree or the **Restore Entities** tool to restore the selected entities. For more information on restoring individual entities, see *Restoring entities that were replaced by virtual topology*.

Restoring entities that were replaced by virtual topology

You can select **Tools->Virtual Topology->Restore Entities** from the main menu bar to restore edges and vertices that were previously replaced by virtual topology. Using the restore tool allows you to select individual entities to restore rather than deleting or suppressing the virtual topology feature, which would bring back all of the entities.

1. From the **Object** field in the context bar, select a part or the assembly.
2. From the main menu bar, select **Tools->Virtual Topology->Restore Entities**.

   Tip: You can also restore entities using the tool, located in the Mesh module toolbox.

   Abaqus/CAE highlights in blue all entities that have been replaced by virtual topology.
3. Select the combination of entities that you want to restore.

   You can use a combination of drag-select, **[Shift] + Click**, and **[Ctrl] + Click** to select more than one entity to restore. For more information, see *Selecting objects within the current viewport*.
4. Click mouse button 2, or click **Done** in the prompt area.

   Abaqus/CAE creates a **Restore ignored geometry** feature in the Model Tree to restore the selected entities—the virtual topology features are not changed. If there are more entities that can be restored, Abaqus/CAE continues the selection procedure.
5. When you have finished restoring entities, click mouse button 2 or the cancel button in the prompt area.

Customizing model display

This part explains how you can customize your model display.

In this section:

- *Customizing geometry and mesh display*
- *Color coding geometry and mesh elements*
- *Using display groups to display subsets of your model*
- *Overlaying multiple plots*
- *Cutting through a model*

Customizing geometry and mesh display

This chapter explains how you can customize your geometry and mesh display.
The Visualization module has its own set of options to customize model appearance; for more information, see *Customizing plot display* and *Customizing viewport annotations*.

In this section:

- *Using geometry and mesh display options*
- *Choosing a render style*
- *Controlling edge visibility*
- *Controlling curve refinement*
- *Defining mesh feature edges*
- *Controlling translucency for substructure parts*
- *Controlling beam profile display*
- *Controlling shell thickness display*
- *Controlling datum display*
- *Controlling the display of individual coordinate systems*
- *Controlling reference point display*
- *Customizing mesh display*
- *Controlling model lighting*
- *Controlling instance visibility*
- *Controlling the display of attributes*
- *Saving your display options settings*

Using geometry and mesh display options

You can use the **Part Display Options**, **Assembly Display Options**, and **ODB Display Options** menus to customize geometry and mesh display.

Depending on the module you are using, Abaqus/CAE presents you with one of the following menu selections to customize geometry and mesh display:

View->Part Display Options

In geometry-related modules you can use this menu item to control your geometry render style, edge visibility, curve refinement, element and node labels, and the visibility of the various types of datum geometry.

View->Assembly Display Options

In assembly-related modules you can use this menu item to control your assembly render style, edge visibility, and the visibility of the various types of datum geometry. You can also use it to control the display of the mesh, element and node labels, part instances, loads, boundary conditions, and predefined fields in those same assembly-related modules.

View->ODB Display Options

This menu item is applicable only to the Visualization module. For more information, see *Customizing plot display*.

You can save the current display options and apply them to future Abaqus/CAE sessions by selecting **File->Save Options** from the main menu bar. For more information, see *Saving your display options settings*.

Choosing a render style

Render style is the style in which Abaqus/CAE displays your model.

You can use the **View->Part Display Options** and **View->Assembly Display Options** menu items to display your model in one of three render styles: wireframe, hidden, or shaded; these styles are shown in *Figure 1*. An explanation of these choices follows.

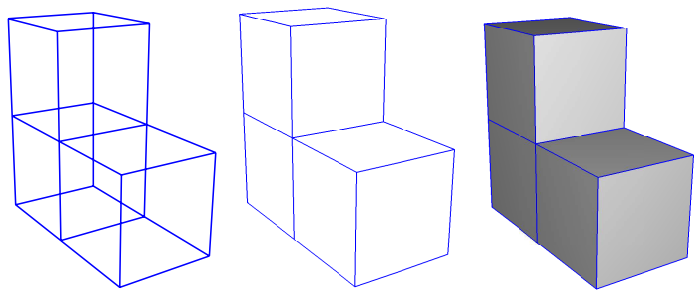

Figure 1: Model showing render style options. From left to right: the wireframe, hidden, and lightsource-shaded render styles.

Wireframe

Displays model edges; both interior and exterior edges are potentially visible. Wireframe plots produce a frame-like visual effect in which model faces are not displayed. Wireframe is the most rapidly drawn render style.

Hidden

Displays a wireframe plot in which edges obscured by the model are either not shown or are shown as dotted lines, depending on which option you select. (For more information on this option, see *Controlling edge visibility*.) Hidden plots produce a solid rather than frame-like appearance.

Shaded

Displays a filled plot in which a light source appears to be directed at the model. Shaded plots produce a highly three-dimensional visual effect. Edges attached to faces in shaded plots are always drawn in black.

1. Locate the **Render Style** options.

   From the main menu bar, select **View->Part Display Options** or **View->Assembly Display Options**. In the dialog box that appears, click the **General** tab.

2. From the top of the dialog box, click **Wireframe**, **Hidden**, or **Shaded** to select the style that you want.

   Tip: You can also select the render style using the wireframe , hidden , and shaded icons located in the Render Style toolbar.

3. + Click **OK** to implement your changes and to close the dialog box.

Abaqus/CAE renders the display in the selected style, and your changes are saved for the duration of the session.

Additional information

- *Customizing geometry and mesh display*
- *Choosing a render style*

Controlling edge visibility

You can control the visibility of geometry edges, reference representations, highlighted faces, and mesh edges.

Using the **View->Part Display Options** or **View->Assembly Display Options** menu items, you can control the visibility of the following:

Geometry edges

If a part or part instance is displayed with the hidden render style, Abaqus/CAE suppresses obscured geometry edges by default. Alternatively, if you toggle on the **Show dotted lines in hidden render style** option, Abaqus/CAE displays the obscured edges using a dotted line style.

If a part or part instance is displayed with the shaded render style, Abaqus/CAE displays the edges by default. Non-wire edges (edges attached to faces) are displayed in black. Alternatively, if you toggle off the **Show edges in shaded render style** option, Abaqus/CAE suppresses edge display.

If a three-dimensional part or part instance contains faces with curved edges, by default Abaqus/CAE displays gray "silhouette" edges originating from the faces, as shown in the hidden-line plot in *Figure 1*.

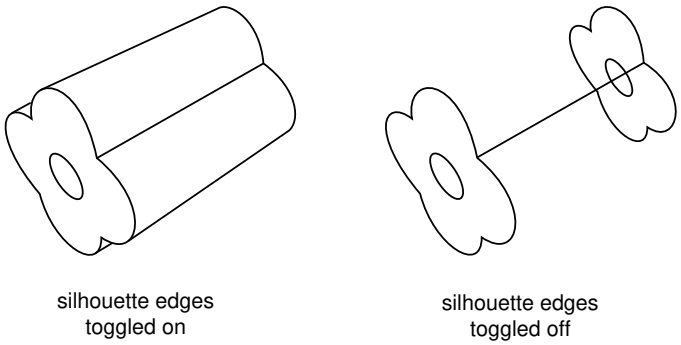

Figure 1: Hidden-line plot showing silhouette edges.

Unlike true edges, silhouette edges serve only as a visual aid; for example, you cannot select or partition a silhouette edge. Alternatively, if you toggle off the **Show silhouette edges** option, Abaqus/CAE displays only true edges.

Abaqus/CAE displays a curved part using a faceted representation of the part, and you use the **Curve refinement** option to specify the degree of faceting. For more information, see *Controlling curve refinement*.

Reference representation

If you are creating a midsurface model and have assigned midsurface regions to cells in the solid model, the geometry of the selected cells is contained in the reference representation. By default, Abaqus/CAE displays the reference representation in the Part module. However, you can use the **Show reference representation** option to toggle display of the reference representation in all modules where the part or assembly is displayed. Toggle off **Apply translucency** to display the reference representation as opaque instead of the default translucent appearance. For more information on the reference representation, see *Understanding the reference representation*.

Highlighted faces

You can control the style with which Abaqus/CAE displays the highlighted geometry faces of parts and assemblies. *Figure 2* shows three views of a sample part with its front face selected: the left figure uses stippling as the selection method, the middle figure shows an example of isolines, and the right figure displays facet selection.

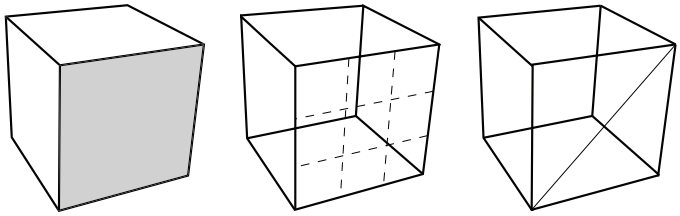

Figure 2: Highlighting faces with Stippling, Isolines, and Facets.

The stippling method offers a performance advantage, particularly for large, complex parts and assemblies. Using isolines can allow you to see a part or assembly more easily in wireframe mode than the stippling method. Finally, displaying all of a part or assembly's facets can help you debug a mesh more effectively, because meshing depends on the orientation of facets in a part or assembly.

Mesh edges

For mesh edges within a meshed part or a part imported from an output database, the visibility options are:

All edges

Displays all element edges. To see element edges on the interior of the model, you must also set the *render style* to wireframe.

Exterior edges

Displays only edges on the exterior of the model.

Feature edges

Displays only edges on the exterior of the model that are calculated to be feature edges. Feature edges lie between elements that have normals that differ by more than the “feature angle.” For more information on controlling the feature angle, see *Defining mesh feature edges*.

Free edges

Displays only edges that belong to a single element. Free edge display is particularly useful for locating potential holes or cracks in your mesh.

These options are shown in *Figure 3*.

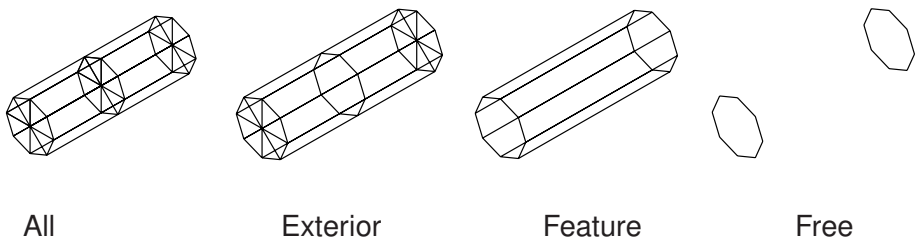

Figure 3: Model showing mesh edge display options.

If a mesh is displayed with the shaded render style, Abaqus/CAE displays the edges by default. Alternatively, if you toggle off the **Show edges in shaded render style** option, Abaqus/CAE suppresses edge display.

With the exception of showing hidden geometry edges as dotted lines, you cannot control the line style, color, or thickness of edges.

1. Locate the edge visibility options.

   From the main menu bar, select **View->Part Display Options** or **View->Assembly Display Options**. In the dialog box that appears, click the **General** tab.

2. Select the desired **Geometry** edge settings.
3. Select the desired **Mesh Edges** settings.
4. + Click **OK** to implement your changes and to close the dialog box.

   Your changes are saved for the duration of the session.

Additional information

- *Defining mesh feature edges*
- *Choosing a render style*
- *Customizing geometry and mesh display*

Controlling curve refinement

Abaqus/CAE uses a faceted representation of a curved face or a curved edge when displaying a part or part instance. When you are working in the Part module, you can use the **Curve refinement** option from the **Part Display Options** dialog box to specify the degree of this faceting applied to the current part. You can select one of five faceting levels between extra coarse and extra fine. Set the refinement to **Extra Coarse** to speed up display of a large model. Set the refinement to **Extra Fine** if you want to create a very accurate display for printing. Abaqus/CAE applies the curve refinement setting only to the part in the current viewport.

In addition, Abaqus/CAE uses the faceted representation of a part instance in the Assembly module when determining contact between part instances and when determining the position of attachment lines. You use the **Curve refinement** option to control the accuracy of the contact detection tool and to help display the part geometry more accurately.

1. Locate the **Curve refinement** options.

   From the main menu bar, select **View->Part Display Options**. In the dialog box that appears, click the **General** tab.
2. Select the desired curve refinement setting.
3. + Click **OK** to implement your changes and to close the dialog box.

   Abaqus/CAE applies the curve refinement setting only to the part in the current viewport.

Additional information

• *Customizing geometry and mesh display*

Defining mesh feature edges

You can specify that only the feature edges of a meshed part are visible.

You use feature edges to mask the detail provided by a mesh; feature edges are typically the physical edges of the part being meshed and do not include all the additional element edges. *Figure 1* shows a meshed part displayed at three different feature angles—0°, 5°, and 20°.

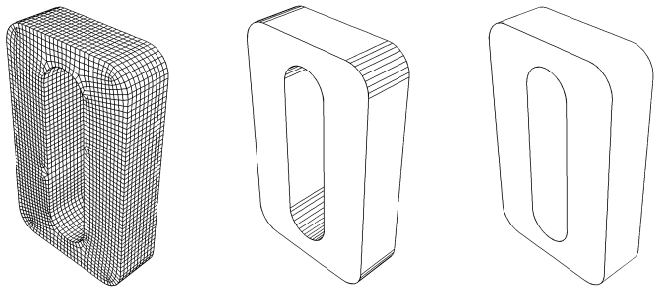

Figure 1: Plots showing feature angles of 0°, 5°, and 20°.

Feature edges are defined as adjacent edges with normals that differ by more than the "feature angle." You can customize the feature angle when you select **Feature** mesh edge visibility. Larger angles will reduce the number of feature edges; conversely, smaller angles will cause more edges to be visible. The default mesh feature angle is 20°.

1. Locate the feature angle option.

   From the main menu bar, select **View->Part Display Options** or **View->Assembly Display Options**. In the dialog box that appears, click the **General** tab.
2. From the bottom of the dialog box, select **Feature edges** from the list of mesh edges to show.

   Abaqus/CAE displays an **Angle** data field to the right of **Feature**.
3. Click the **Angle** data entry field, and enter the desired feature angle.
4. + Click **OK** to implement your changes and to close the dialog box.

   Your changes are saved for the duration of the session.

Additional information

- *Controlling edge visibility*
- *Customizing geometry and mesh display*

Controlling translucency for substructure parts

You can specify that the substructure parts and part instances in your model be displayed with or without translucency. If you want to control the level of translucency for part and assembly display, see *Changing the translucency*.

1. Locate the substructure translucency control option.

   From the main menu bar, select **View->Part Display Options** or **View->Assembly Display Options**. In the dialog box that appears, click the **General** tab.

2. From the middle of the dialog box, toggle on **Always show substructure with translucency** from the set of mesh-related options.

3. + Click **OK** to implement your changes and to close the dialog box.

   Your changes are saved for the duration of the session.

Additional information

• *Customizing geometry and mesh display*

Controlling beam profile display

If you use wire parts to model beams, you must create a beam section that refers to a beam profile, and you must assign the beam section to the wire part. In addition, you must assign a beam orientation to the wire part. You can then use the **View->Part Display Options** and the **View->Assembly Display Options** menu items to view a realistic display of the beam profile in parts and the assembly in the current viewport.

When beam profiles are displayed, Abaqus/CAE disables both view cuts and scaling and shrinking of the model. Displaying beam profiles is useful for checking that the correct profile has been assigned to a particular region and that the assigned beam orientation results in the expected orientation of the profile. For example, *Figure 1* shows the box beam profiles displayed on the light-service crane described in *Example: cargo crane*.

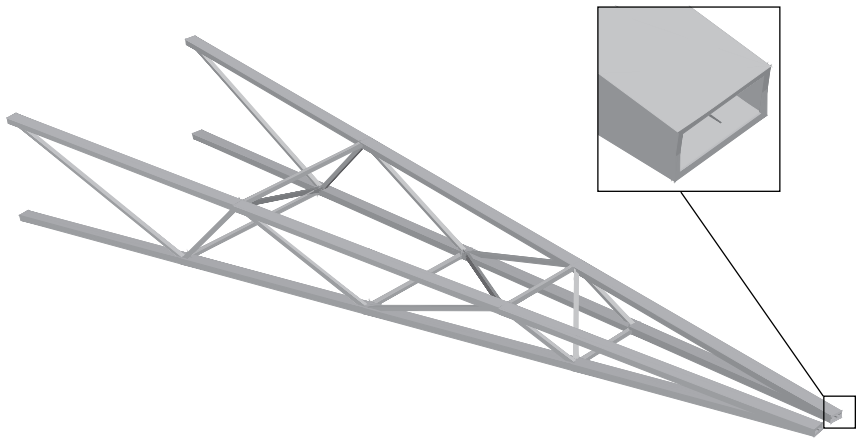

Figure 1: The cargo crane example with beam profiles displayed.

If you assign a general beam section to a wire, Abaqus/CAE displays the beam profile as an ellipse with a cross-sectional area and moments of inertia (I_{11} and I_{22}) that match the values you specified. If you assign a truss section to a wire, Abaqus/CAE displays the truss profile as a circle with a cross-sectional area that matches the value you specified.

Abaqus/CAE does not render the tapering of beam profiles along their length. If your model includes tapered beam sections, Abaqus/CAE renders these beams using the beam's starting profile along its entire length. For more information about tapered beams, see *Creating beam sections*.

Abaqus/CAE renders beam profiles according to the current settings for color coding and translucency. When these settings change, the color and translucency of the beam profiles change as well.

1. Locate the **Render beam profiles** option.

   From the main menu bar, select **View->Part Display Options** or **View->Assembly Display Options**. In the dialog box that appears, click the **General** tab.
2. From the bottom of the dialog box, toggle on **Render beam profiles** to display beam profiles.
3. If desired, apply a **Scale factor** to the beam profiles to increase or decrease their size. The default value is 1.
4. + Click **OK** to implement your changes and to close the dialog box.

   Abaqus/CAE displays the profile of the beam section with the appropriate dimensions and in the correct orientation. Your changes are saved for the duration of the session.

Additional information

• *Defining profiles*

- *Customizing geometry and mesh display*
- *Controlling beam profile display for postprocessing*

Controlling shell thickness display

Displaying shell thickness enables you to examine the thickness of shell geometry relative to the rest of the model. You can apply a scale factor to reduce or increase the display of shell thickness for your session.

If you use shell elements to model relatively thin components in your analysis, you can use the **View->Part Display Options** and the **View->Assembly Display Options** menu options to view the actual thickness of these shell elements in your model. *Figure 1* shows the effect of scale factor changes displayed on the stiffened plate model described in *Example: blast loading on a stiffened plate*.

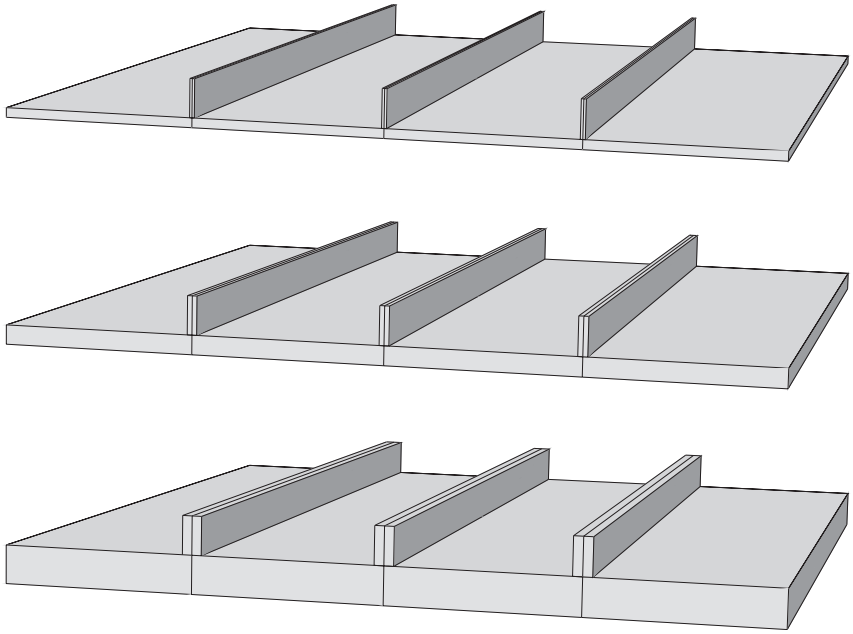

Figure 1: From top to bottom: shell thickness scale factor settings of 1 (default), 2, and 4.

Abaqus/CAE renders shell thickness for three-dimensional shell elements only; thickness is not displayed for axisymmetric shell elements, such as SAX1 elements. When shell thickness is displayed, Abaqus/CAE also renders the edges of shell geometry unless a view cut is displayed in the viewport. Abaqus/CAE renders shell thickness according to the current settings for color coding and translucency. When these settings change, the color and translucency of the shell thickness change as well.

If a discrete field has been used to define shell thicknesses or the shell offset, the **Render shell thickness** option has no effect. The shells are always displayed with zero thickness and no offset.

1. Locate the **Render shell thickness** option.

   From the main menu bar, select **View->Part Display Options** or **View->Assembly Display Options**. In the dialog box that appears, click the **General** tab.

2. From the bottom of the dialog box, toggle on **Render shell thickness** to display shell thicknesses for the shell sections in your model.
3. If desired, apply a **Scale factor** to the shell thicknesses to increase or decrease their thickness. The default value is 1, which produces a realistic rendering of the shell thickness settings.
4. + Click **OK** to implement your changes and to close the dialog box.

Abaqus/CAE displays the shell sections in the selected part or assembly with the appropriate thickness. Your changes are saved for the duration of the session.

Additional information

- *Defining sections*
- *Customizing geometry and mesh display*
- *Controlling shell thickness display for postprocessing*

Controlling datum display

You can use the **View->Part Display Options** and the **View->Assembly Display Options** menu items to control the display of datum geometry in parts and the assembly in the current viewport. You can control the display of each of the datum types—points, axes, planes, and coordinate systems—and you can toggle their display individually or all at once. Datum geometry that you choose not to display, although invisible, is still a feature of the part or assembly. For more information on datum geometry, see *The Datum toolset*. You can also control the display of reference points; for more information, see *The reference point*.

Datum geometry created on parts can be distracting when you are assembling instances of the part; turning off the display of datum geometry can result in a clearer display of the assembly. Similarly, turning off the display of datum geometry is useful for generating a clean printed image of a part or assembly.

1. Locate the **Datum** display options.

   From the main menu bar, select **View->Part Display Options** or **View->Assembly Display Options**. Click the **Datum** tab in the dialog box that appears.

2. Toggle the appropriate buttons to control the display of:

   - Datum points
   - Datum axes
   - Datum planes
   - Datum coordinate systems

   Alternatively, click **Show all datums** to display all datum geometry in the viewport, or click **Show no datums** to hide all datum geometry in the viewport.

3. Click **OK** to implement your changes and to close the dialog box.

   Your changes apply only to the current viewport and are saved for the duration of the session.

Additional information

- *Customizing geometry and mesh display*

Controlling the display of individual coordinate systems

You can highlight, display, and hide individual coordinate systems in the viewport. Abaqus/CAE provides the following display options during modeling and postprocessing:

Controlling display of datum coordinate systems during modeling

All datum geometry you create, including datum coordinate systems, are considered features of the part or assembly to which they apply. Abaqus/CAE provides shortcuts for datum coordinate systems and other features in the Model Tree under the **Features** container for the part or assembly. You can highlight an individual datum coordinate system by clicking its shortcut in the Model Tree; when highlighted, a coordinate system is rendered in red in the viewport and its title is displayed. To hide or display the coordinate system in the viewport, click mouse button 3 on the shortcut and select **Suppress** or **Resume**.

You can also control the display of individual datum coordinate systems by adding them to display groups. See *Managing display groups* for more information.

Controlling display of any coordinate system during postprocessing

In the Visualization module the available coordinate systems are divided into two groups: ODB coordinate systems, which are part of the output database file; and session coordinate systems, which are created during postprocessing. Session coordinate systems apply to one output database only and persist only for your Abaqus/CAE session, unless you move the session coordinate system to the output database. See *Saving a coordinate system to an output database file*.

You can highlight, display, or hide individual coordinate systems using either of the following techniques:

- All available coordinate systems have shortcuts in the Results Tree under the **ODB Coordinate Systems** and **Session Coordinate Systems** containers. You can click any shortcut to highlight that coordinate system in the viewport; when highlighted, a coordinate system is rendered in red in the viewport and its title is displayed. You can also display or hide any coordinate system by clicking mouse button 3 on the shortcut and selecting a Boolean operator from the list that appears.
- You can control the display of ODB coordinate systems and session coordinate systems by adding them to display groups, which can be displayed or hidden using the Boolean display options. See *Managing display groups* for more information.

The **Coordinate System Manager** also provides information about the ODB coordinate systems and session coordinate systems for the selected output database. You cannot change the display of coordinate systems from this manager, but you can rename or delete them. See *Creating coordinate systems during postprocessing*.

Additional information

- *Creating coordinate systems during postprocessing*
- *Creating datum coordinate systems*
- *Customizing geometry and mesh display*

Controlling reference point display

You can use the **View->Part Display Options** and the **View->Assembly Display Options** menu items to control the display of reference points in the current viewport on a part or on the assembly. Turning off the display of reference points is useful for generating a clean printed image of a part or the assembly. Even though you choose not to display reference points, they are still a feature of the part or assembly. For more information on reference points, see *The reference point*.

1. Locate the **Datum** display options.

   From the main menu bar, select **View->Part Display Options** or **View->Assembly Display Options**. Click the **Datum** tab in the dialog box that appears.

2. Toggle the appropriate buttons to control the display of:

   - Reference point labels
   - Reference point symbols

3. Click **OK** to implement your changes and to close the dialog box.

   Your changes apply only to the current viewport and are saved for the duration of the session.

Additional information

- *Customizing geometry and mesh display*

Customizing mesh display

You can use the **View->Part Display Options** and the **View->Assembly Display Options** menu items to specify whether or not node and element labels are displayed on a meshed part or assembly. You can choose to display or suppress your native mesh and, if displayed, to do so only in the Mesh module or in all part-related or all assembly-related modules. If you display the native mesh, you can choose to also display the geometry of bottom-up meshed sections, non-bottom-up sections, or both along with the mesh. Displaying the geometry provides a visual indication of how well the mesh conforms to the geometry.

1. Locate the mesh display options.

   From the main menu bar, select **View->Part Display Options** or **View->Assembly Display Options**. In the dialog box that appears, click the **Mesh** tab.

2. Toggle **Show native mesh** to display or suppress the native mesh.

   When **Show native mesh** is on, you can also control the following options:

   a. Select one or both of the following options to display geometry with the native mesh:

      - Toggle on **Show bottom-up geometry** to display the geometry of regions that have been assigned the bottom-up meshing technique. This option is on by default.
      - Toggle on **Show non-bottom-up geometry** to display the geometry of regions assigned all other meshing techniques. This option is off by default.

   b. Select one of the following options to control the modules in which you can display the native mesh:

      - Choose **In the Mesh module only** to display your native mesh only in the Mesh module.
      - Choose **In all part-related modules** from the **Part Display Options** dialog box or **In all assembly-related modules** from the **Assembly Display Options** dialog box to display your native mesh in all modules that support the display of the part or assembly, respectively.

3. Toggle **Show node labels** and **Show element labels** to affect the display of these items.
4. + Click **OK** to implement your changes and to close the dialog box.

   Your changes are saved for the duration of the session.

Additional information

• *Customizing geometry and mesh display*

Controlling model lighting

You can use the **View->Light Options** menu item to control the lighting of your model. Lights affect the appearance of your model in the current viewport when the **Shaded** render style is used. You can control the intensity of the **Ambient** light and the **Shininess** of the model surface. You can also control the locations and intensities of up to eight additional positional lights. The combined effects of the light settings can be used to simulate different surface finishes and light conditions on your model. The default settings provide good contrast for viewing all features in most models.

The default settings provide good contrast for viewing all features in most models. Using the default settings is particularly important for tessellated, banded contour plots, for which intense light can fade the colors in the facets of the contour plot and display misleading results that do not match the colors in the plot legend. These changes to contour colors can also appear in printouts of banded contour plots if you print to file in EPS, PostScript, or SVG formats, because these three formats use tessellated contours by default. To print a banded contour plot to any of these formats without creating misleading contour colors, turn off shading before printing.

Global settings

Ambient light is applied evenly to the entire scene and brightens a model from all directions. Low intensity ambient light allows the positional lighting to create shading that distinguish small features and surface contours from the rest of the model. High intensity ambient light removes shading and may make some model features difficult to see.

If your computer's graphics card supports OpenGL shading language (GLSL), Abaqus/CAE also reveals the global **Shading** options, from which you can enable Phong shading for your session. Phong shading renders more realistic shading on three-dimensional surfaces than the default option, Gouraud shading, but it can cause a noticeable performance impact on some systems. This performance impact occurs only when the mesh is hidden; if the mesh is displayed (either during modeling or postprocessing), Abaqus/CAE renders Phong lighting with no noticeable performance impact.

Shininess is the reflectivity of the model surface and is used to control the size of specular highlights from the positional lights. A very shiny surface reflects light like a mirror—the light reflects in one direction based on the incident angle of the light source. Therefore, a surface must be positioned correctly with respect to the light source to reflect light to your viewpoint. Surfaces that are less shiny reflect light more randomly, so a wider range of surface angles can reflect light to your viewpoint. Like high intensity ambient lighting, low shininess can obscure small features and contours of your model from view.

The **Viewpoint** option controls how specular lighting effects are calculated. An **Infinite** viewpoint assumes a constant vector for the direction from the camera to each point when calculating reflections and specular highlights at a point. A **Local** viewpoint calculates a separate direction vector for each point based on its position in the viewport. A **Local** viewpoint creates more realistic lighting effects but can decrease overall performance.

Positional light settings

Positional lights provide a light bulb effect. A positional light is projected onto the model from the specified location, and its effects change as you rotate your model view. Positional lights work in conjunction with shininess to determine how your model reflects light.

The distance of the light from the model is equal to the distance from the camera to the model. You can position the lights by specifying their **Latitude** and **Longitude** on a hemisphere around the model. You can also specify the **Type** of light source being used. A **Directional** light is a planar light source; the angle of incident light on the model will be equivalent for all parallel surfaces. A **Point** light is a point light source; the angle of incident light depends on the location of the surface or point relative to the light. A **Point** light creates more realistic lighting effects but can decrease overall performance.

You can control two different qualities for positional lights: **Diffuse** intensity and **Specular** intensity. The **Diffuse** setting controls the intensity of a positional light. Unlike ambient light, surfaces that face toward the light position

will brighten more readily than other surfaces in the model when increasing the diffuse intensity of a positional light. The **Specular** setting controls the brightness of those surfaces that are reflecting from the light toward the viewpoint. You should first set the position and diffuse intensity of the positional light to achieve the shading you desire. Then you can adjust the brightness of reflected light with the **Specular** slider.

1. Locate the lighting options.

   From the main menu bar, select **View->Light Options**.
2. If the **Shading** options are displayed, select **Gouraud** or **Phong** shading.
3. From the **Viewpoint** field, select **Infinite** or **Local** to define the viewpoint type.
4. Use the slider to set the desired **Ambient** light intensity.
5. Use the slider to set the desired **Shininess** for the model surface. A higher number corresponds to a shinier surface.
6. Toggle on a number in the **Lights** field to add a positional light to the scene.
7. To change the settings for a positional light, click the associated number tab in the **Lights** field.
   - From the **Type** field, select **Directional** or **Point** to define the light type.
   - Use the sliders to set the desired **Latitude** and **Longitude** for the light's position.
   - Use the slider to set the desired **Diffuse** intensity.
   - Use the slider to set the desired **Specular** intensity.
8. Click **Defaults** to revert all lighting to the default settings.
9. Click **Dismiss** to close the dialog box.

   Your changes are saved for the duration of the session. To save the settings for future sessions, select **File->Save Options** from the main menu bar (see *Saving your display options settings*).

Additional information

• *Customizing geometry and mesh display*

Controlling instance visibility

By default, Abaqus/CAE displays all part instances included in the assembly. You can turn the display of all instances on or off, or you can toggle the display of individual instances. Part instances that you have suppressed or that do not belong to the current display group cannot be made visible using this dialog box; you must use the Feature Manipulation toolset or the Display Group toolset instead. For more information, see *The Assembly module* or *Using display groups to display subsets of your model*.

This section describes how to control instance visibility from the **Assembly Display Options** dialog box. You can also change instance visibility from the Model Tree or the viewport: from the Model Tree, highlight the part instances that you want to display or hide, click mouse button 3, and select **Hide** or **Show**; from the viewport, highlight the instances you want to hide, click mouse button 3, and select **Hide Instance** from the menu that appears.

1. Locate the **Instance** display options.

   From the main menu bar, select **View->Assembly Display Options**. Click the **Instance** tab in the dialog box that appears. The **Instance** options become available; each part instance in the assembly is listed.

2. To control instance visibility, do any of the following:

   - Click **Set All On** to make all (except suppressed) instances visible.
   - Click **Set All Off** to turn off the display of all instances.
   - Click individual instance names to toggle their appearance.

3. Click **OK** to implement your changes and to close the dialog box.

   Your changes apply only to the current viewport and are saved for the duration of the session.

Additional information

• *Customizing geometry and mesh display*

Controlling the display of attributes

The **Attribute** display options in the **Assembly Display Options** dialog box allow you to control the display of symbols representing

- interactions, constraints, and connectors that you create in the Interaction module,
- loads, boundary conditions, and predefined fields that you create in the Load module,
- engineering features that you create in the Property module and Interaction module, and
- optimization attributes that you create in the Optimization module.

You can control when and how these attributes are displayed, and you can click **Set all on** or **Set all off** to display or hide all attributes, respectively. For information on the symbols representing each attribute, see *Special graphical symbols*.

For information on controlling the display of boundary conditions, coupling constraints, connectors, and point elements in the Visualization module, see *Controlling the display of model entities*.

1. Locate the **Attribute** display options.

   From the main menu bar, select **View->Assembly Display Options**. Click the **Attribute** tab in the dialog box that appears. The **Attribute** options become available.

2. Click the **Main** tab to specify which attributes you want to display and in which modules you want them to appear.

   a. Select the **Show attribute in** option.

      - Select **Module in which it was created** to display attributes only in the modules in which they are created. For example, loads would appear only in the Load module and interactions only in the Interaction module.
      - Select **All assembly-related modules** to display attributes in all modules that support the display of the assembly.

   b. From the **Show** list, select the attributes that you want to display. Only those attributes that you select will appear in the viewport; for example, if you toggle on **Loads** and **BCs**, only load and boundary condition symbols will appear in the viewport. You can also select all categories and all types within each category by clicking **Set all on**, or you can deselect all categories and all types within each category by clicking **Set all off**.

3. Click the **Symbol** tab to control the size and density of attribute symbols. You can also reduce the number of attribute symbols displayed on orphan mesh regions to a fraction of the maximum allowable number.

   a. Specify your **Size** preferences. The higher the size setting, the larger the symbols appear in the viewport.

      - Drag the **Arrows** slider to specify the size of arrow symbols.
      - Drag the **Other symbols** slider to specify the size of all symbols other than arrows.
      - Toggle off **Scale symbols based on analytical field value** to remove the symbol scaling for attributes that specify analytical fields. For more information, see *Displaying symbols for interactions and prescribed conditions that use analytical fields*.

   b. If you are working with geometry, specify the desired density of the attribute symbols. The higher the density setting, the more symbols Abaqus uses to represent each attribute.

      - Drag the **Face density** slider to control the density of symbols that appear on faces.

- Drag the **Edge density** slider to control the density of symbols that appear on edges.

The effect of changing a symbol density setting may vary depending on the size of the region in the viewport.

c. If you want to reduce the density of attribute symbols displayed on orphan mesh regions, enter a value between 0 and 1 in the **Fraction of symbols displayed on orphan mesh regions** field. The higher the fraction value, the more symbols Abaqus/CAE uses to represent each attribute. Choosing the default density of 1 prompts Abaqus/CAE to draw symbols on every mesh entity within the region.

4. Click the tab of the attribute of interest to specify which particular attribute categories and types you want to appear in the viewport.

For example, if you click the **Load** tab, a list of load categories appears. If you click the arrow next to one of the categories, a list of all the load types within that category appears.

Use the following techniques to specify the attribute categories and types that you want to display:

- Click the arrow next to the category of interest. From the list of types that appear, select those types that you want to display.
- Toggle the desired category. This action selects or deselects all types within that category.
- Click **Set All On** to select all categories and all types within each category.
- Click **Set All Off** to deselect all categories and all types within each category.

The check box next to a category label becomes a black check mark on a white background when all types in that category are selected. The check box becomes light gray and the check mark becomes dark gray if only some of the types within that category are selected.

Note:

The attribute categories and types that you specify only appear in the viewport if you toggled on that attribute in Step 2.

5. Repeat the previous step as necessary to display specific categories and types of other attributes of interest.

6. At the bottom of the **Assembly Display Options** dialog box, click **OK** to implement your display settings in the current viewport and to close the dialog box.

Additional information

- *Customizing geometry and mesh display*
- *Special graphical symbols*

Saving your display options settings

If you change your display options settings (for example, if you change the render style or turn off the display of datum planes), you can store the new settings for future sessions. Abaqus/CAE saves your settings in a file called `abaqus_2026.gpr`. For more information, see *Working with abaqus_2026.gpr files*.

From the main menu bar, select **File->Save Display Options** to save all the current display options settings. The **Save Display Options** dialog box appears and allows you to save the options in the current directory or in your home directory.

You can edit the `abaqus_2026.gpr` file using API commands in the Abaqus Scripting Interface; for more information, see *Editing display preferences and GUI settings*. You can also delete the file to restore the default GUI and display options settings, and you can copy the file to other directories on your computer or transfer the file to a different computer. When you save your settings from `abaqus_2026.gpr`, Abaqus/CAE always saves all the current settings and always overwrites all the settings that were previously saved. You cannot save only selected settings. You can use the **noSavedOptions** command line option to start Abaqus/CAE without loading the settings in `abaqus_2026.gpr`. For more information, see *Starting Abaqus/CAE (or Abaqus/Viewer)*.

Abaqus/CAE saves the following display options settings in `abaqus_2026.gpr`:

- Part and assembly display options; for example, render style, the visibility of the various types of datum geometry and simulation attributes, and the display of mesh, element, and node labels.

  Note:

  The settings in the **Main** tab of the **Assembly Display Options** dialog box are not saved in `abaqus_2026.gpr`; however, the settings for the simulation attribute categories and types specified on other tabs (such as **Interaction** and **Load**) are saved in `abaqus_2026.gpr`. For more information, see *Controlling the display of attributes*.

- Graphics options and viewport annotation options. Abaqus/CAE also saves the perspective setting.
- Print options.
- Display options in the Visualization module; for example, the contour type for contour plots and the render style and fill color in the common plot options.
- Animation options in the Visualization module.
- Other options in the Visualization module, such as probe, field report, *X*–*Y* plot, and *X*–*Y* report options.
- Options selected in the **Linked Viewports Manager**.

Color coding geometry and mesh elements

This section explains how you can apply color coding to viewable geometry and mesh elements.

In this section:

- *Understanding color coding*
- *Changing the initial color*
- *Changing the translucency*
- *Coloring geometry and mesh elements*
- *Coloring all geometry in the Visualization module*
- *Coloring nodes or elements in the Visualization module*
- *Coloring constraints in the Visualization module*
- *Customizing the display color of individual objects*
- *Displaying multiple color mappings*
- *Editing the colors in the Auto-Color List*
- *Saving and restoring custom color mappings*

Understanding color coding

This section discusses how to use color coding to distinguish between components in your model or output database.

In this section:

- *Color coding concepts*
- *Color coding in the Visualization module*

Color coding concepts

You can distinguish between components in your model or output database by color coding the viewable geometry and mesh elements in the current viewport. Abaqus/CAE applies color coding according to **Color Mappings** that specify the colors assigned to each item for a particular type of object, such as parts, section assignments, boundary conditions, or display groups. In the example shown in *Figure 1* the color mapping is by parts, and each row describes the color assigned to one of the three part definitions in this model. The **Color Code** dialog box thus provides a legend that describes all of the color coding currently displayed in the current viewport.

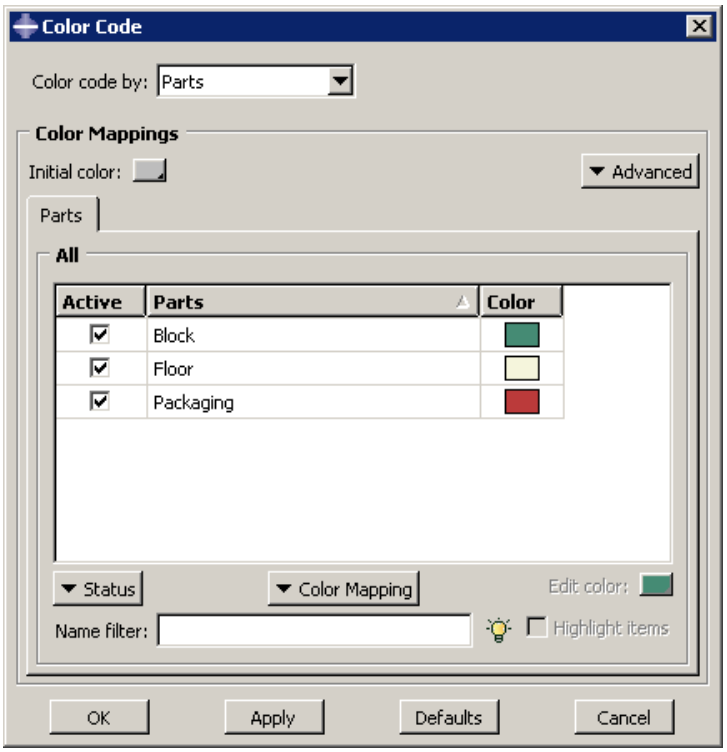

Figure 1: The Color Code dialog box.

Color coding is applied in two layers. All geometry and mesh elements are first colored with the **Initial color**, a customizable setting that is grey by default. (See *Changing the initial color*, for more information.) Abaqus/CAE then applies color coding on top of the initial color according to the colors and objects in the color mapping that you select. Areas will remain visible in the initial color if you apply a color mapping such as Boundary conditions, Loads, or Sets, for which Abaqus/CAE usually color codes only distinct points or surfaces in the model.

Abaqus/CAE automatically creates color mappings for all items in your model by associating the name of each item with a color in the **Auto-Color List**. The colors are selected by matching the **Auto-Color List** with an alphabetical listing of item names; thus, in the **Parts** example in *Figure 1***Block** is color coded with the first color in the **Auto-Color List**, **Floor** is color coded with the second color, and so on. Color assignments depend on the item name only; therefore, resorting these items in the **Color Code** dialog box does not change the color assignments.

Note:

If a region is shared by two or more items in the model, such as when a skin section is assigned to the surface and a solid section is assigned to the entire block, the common region will be colored with the color definition for the item whose name appears later in the alphabetical list. Abaqus/CAE overwrites the first color mapping color definition as each color assignment is displayed in the viewport.

Because each color mapping is a set of links between item names and color definitions, color mappings persist between modules in Abaqus/CAE and between a model database and its output databases. However, because Abaqus/CAE relies on object names for color coding, you cannot retain the color coding associated with an object when you rename that object. By contrast, Abaqus/CAE usually deletes an object's color definition when you delete the object definition from your model; the two exceptions are material and section definitions, whose color coding persists in the viewport even after you delete the definition. To refresh the color coding in the current viewport after you delete a material or section definition, you must either apply a color mapping or switch to a different module.

Abaqus/CAE also provides a default color mapping for each module. For example, when you display the **Mesh defaults** color mapping in the Mesh module, Abaqus/CAE color codes items in the viewport according to their meshability. Each module's default color mapping is available only in that module; you cannot color code objects in the Property module using the assignments in the **Mesh defaults** color mapping. Module default mappings cannot be edited, and the module default mappings correspond to the default colors that Abaqus/CAE uses if no color coding is applied.

Color mappings are viewport-specific and, in some cases, they persist between modules. Persistence of color coding between modules depends on whether you have the default color mapping displayed for your current module:

- If the default color mapping for your module is selected, Abaqus/CAE automatically changes the color mapping as you switch modules. For example, if you select the **Assembly defaults** color mapping in the Assembly module and then switch to the Mesh module, Abaqus/CAE automatically applies the **Mesh defaults** color mapping.
- If a non-default color mapping is selected, Abaqus/CAE retains the color mapping as you switch modules. For example, if you select the **Part instances** color mapping in the Assembly module and then switch to the Mesh module, Abaqus/CAE continues to color code by part instance name rather than by meshability.

When you change the color mapping, Abaqus/CAE refreshes color coding only in the current viewport while retaining any color coding in other inactive, visible viewports. When you add a new viewport to your session, the new viewport inherits the color mappings of the previously current viewport.

Once color mappings are created, you can customize any color mapping (except the module defaults) by changing the colors assigned to any of its individual objects. You can also toggle the active status of individual objects in the color mapping, which controls whether an individual object is color coded in the current viewport. Objects whose color coding is inactive are rendered with the initial color. The **Color Code** dialog box also provides sorting and filtering tools that you can use to display a subset of the objects in a color mapping. These tools can help you focus your display when a color mapping has many objects.

Color coding in the Visualization module

The color coding process is slightly different in the Visualization module than in other Abaqus/CAE modules. You control the overall edge and fill colors of your model using the **Color & Style** options in the **Common Plot Options** or **Superimpose Plot Options** dialog box. Using these options, you select a single color for all element and surface edges and a separate color for all element faces and surfaces. The colors you select apply uniformly to the entire model.

You can also control the colors of individual elements and part instances using the **Color Code** options. The **Color Code** dialog box allows you to select separate colors for individual items. You must use the **Color Code** options to execute any complex, nonuniform color scheme.

By default, individual item colors override the overall common or superimposed *edge color* and *fill color*. You can change this behavior by using the **Color & Style** options in the **Common Plot Options** or **Superimpose Plot Options** dialog box to specify whether individual or overall item colors should take precedence. (Individual item colors do not apply to contour plots.)

The Visualization module offers a smaller subset of color mappings than are available in the other modules. When an output database is displayed in the current viewport, the available color mappings for color coding are part instances, elements, nodes, constraints, materials, sections, display groups, averaging regions, internal sets, layups, and plies; when a model in the current model database is displayed, the only available color mapping is by part instance. However, you can control both the edge and fill colors when you customize colors for the individual objects in the current viewport, and you can choose to apply color coding to the entire model or to its nodes or elements only. In addition, settings in the Visualization module depend upon other options; when you specify an individual item color in the **Color Code** dialog box, Abaqus/CAE applies the color based on two characteristics of the current plot:

Color precedence setting

Abaqus/CAE applies the color if, on the **Color & Style** page of the **Common Plot Options** or **Superimpose Plot Options** dialog box, **Allow color code selections to override options in this dialog** is toggled on.

Render style

In the wireframe and hidden render styles, Abaqus/CAE displays only element edges. If the current plot uses the wireframe or hidden render style, Abaqus/CAE applies the individual item color to those edges.

In the filled and shaded render styles, Abaqus/CAE displays element faces as well as element edges. If the current plot uses the filled or shaded render style, Abaqus/CAE applies the individual item fill color to the element faces and the individual item edge color to the element edges.

In the filled and shaded render styles, line-type elements (such as beams) are treated as if their lines are faces. In the filled and shaded render styles, Abaqus/CAE applies the individual item fill color to the lines representing such an element.

Changing the initial color

Abaqus/CAE begins the color coding process by applying an **Initial color** to the viewable geometry and mesh elements in the current viewport. By default, this initial color is grey, but you can customize the initial color by selecting one of the following from the **Initial color** field:

- You can select the current color, which prompts Abaqus/CAE to retain the current colors displayed in the viewport. Selecting this option does not change any colors; therefore, this option is most useful when you do not want to change a geometry or mesh element color that you have already applied in the viewport.
- You can set the initial color to display the default color mappings for your selected module. This option is useful for resetting individual selections to their default colors without removing all color changes from the viewport. For example, when you choose this option in the Assembly module, Abaqus/CAE color codes components of the assembly according to the assembly module default settings: **Display body**, **Geometry**, **Native mesh**, and **Orphan mesh**.
- You can select a custom color as the initial color.

If you are working in any module other than the Visualization module, you can use the translucency tool in the **Color Code** toolbar to make the initial color translucent and to select a level of translucency. For more information, see *Changing the translucency*.

Note:

In the Visualization module, you control translucency from the **Other** page of the **Common plot options** or **Superimpose plot options** dialog box. See *Customizing render style, translucency, and fill color*, for more information.

1. Click the  tool in the Color Code toolbar.
   Abaqus/CAE displays the **Color Code** dialog box.
2. Click and hold the **Initial color** sample, and then select one of the following choices from the list that appears:
   - Select the equal sign (=) to select the current color.
   - Select the asterisk (*) to select the default color mapping for the module.
   - Select the color sample () to select a custom color. Choosing the color sample symbol opens the **Select Color** dialog box for you to choose a new color. (For more information, see *Customizing colors*.)
3. Click **Apply**.
   Abaqus/CAE displays the new initial color selection in the current viewport.

Changing the translucency

By default, Abaqus/CAE displays geometry and mesh elements in the shaded render style using opaque colors. Interior features and features that are “behind” other objects in the viewport are not visible.

In some cases, Abaqus/CAE applies translucency to the model to help you select interior or hidden entities during a procedure. You can also use the  tool in the **Color Code** toolbar to toggle translucency on and off when it is not required by a procedure.

To set the percentage of translucency that Abaqus/CAE uses, click the arrow to the right of the  tool. Abaqus/CAE displays a vertical slider. Drag the slider up to make the display colors more opaque or down to make them more transparent.

Note:

In the Visualization module, you control translucency from the **Other** page of the **Common plot options** or **Superimpose plot options** dialog box. See *Customizing render style, translucency, and fill color* for more information.

Coloring geometry and mesh elements

You can apply color coding to geometry and mesh elements from any module other than the Visualization module. If you want to apply color coding in the Visualization module, see either *Coloring all geometry in the Visualization module*, or *Coloring nodes or elements in the Visualization module*.

Abaqus/CAE applies color coding to the current viewport according to color mappings for specific types of objects, such as part instances, materials, sections, or display groups. This section describes how to examine the assignments in a particular color mapping and how to apply the assignments in a color mapping to the current viewport.

Abaqus/CAE provides two methods that you can use to apply color coding to predefined object types in the current viewport. You can quickly select a color mapping by choosing its name from the list immediately to the right of the  tool in the Color Code toolbar. Abaqus/CAE refreshes the current viewport with the color coding specified in that color mapping. Alternatively, you can select the color mapping from the **Color Code** dialog box. You must use the dialog box if you want to customize the color mapping. See *Customizing the display color of individual objects*, for a description of the options provided for changing the colors assigned to individual objects.

Additional information

- *Changing the initial color*
- *Coloring nodes or elements in the Visualization module*
- *Customizing the display color of individual objects*

Apply a color mapping using the toolbar list

1. Locate the list of color mappings.

   The list resides immediately to the right of the  tool in the Color Code toolbar.

2. Select a color mapping from the list.

   Abaqus/CAE color codes the geometry and mesh settings according to the colors displayed in the **Color Code** dialog box.

Apply a color mapping using the Color Code dialog box

1. Click the  tool in the Color Code toolbar.

   Abaqus/CAE displays the **Color Code** dialog box, which displays the default color mappings for the current module.

2. If you are color coding geometry or mesh elements, select a color mapping from the **Color Code by** list. (If you are performing a different color coding operation, refer to either *Coloring all geometry in the Visualization module*, or *Coloring nodes or elements in the Visualization module*.)

   Abaqus/CAE displays the selected color mapping in the **Color Mapping** portion of the dialog box.

3. Click **Apply**.

   Abaqus/CAE color codes the current viewport according to the colors displayed in the **Color Code** dialog box.

Coloring all geometry in the Visualization module

This section describes how to apply color coding to all viewable geometry in the current viewport when you are working in the Visualization module. To apply color coding to geometry and mesh elements from any of the other Abaqus/CAE modules, see *Coloring geometry and mesh elements*. To color code by selected nodes or elements in the Visualization module instead of the entire geometry, see *Coloring nodes or elements in the Visualization module*.

When an output database is selected in the Visualization module, you can select any of the following color mappings when you apply color coding to all of the geometry:

- **Part instances**
- **Element sets**
- **Materials**
- **Sections**
- **Element types**
- **Averaging regions**
- **Internal sets**
- **Composite layups**
- **Composite plies**

When a model in the current model database is selected in the Visualization module, only the **Part instances** color coding option is available.

Abaqus/CAE lists all the items for the current selection method in the **Color Mappings** table. Once you select a color mapping in the **Color Code** dialog box, you can also customize the display color of its individual items. See *Selecting multiple items from lists and tables*, for more information. You make your selections directly from the table, and you can select multiple cells; for more information, see *Selecting multiple items from lists and tables*.

1. Click the  tool in the Color Code toolbar.

   Abaqus/CAE displays the **Color Code** dialog box, which displays the default color mappings for the current module.
2. From the **Color Code** list, select **All**.
3. From the **By** list, select the name of the color mapping that you want to apply.
4. Click **Apply**.

   Abaqus/CAE color codes the current viewport according to the colors displayed in the **Color Code** dialog box.

Coloring nodes or elements in the Visualization module

When an output database is selected in the current viewport, you can color code selected **Nodes** and **Elements** to customize the display of your results in a viewport. For step-by-step instructions on using the **Color Code** dialog box, see *Coloring geometry and mesh elements*. To color code by selected item attributes instead of nodes or elements, see *Customizing the display color of individual objects*.

For the **Element** and **Node** item types, your item choices vary with the method that you select from the **By** list at the top of the **Color Code** dialog box. Some selection methods require you to complete the information in the **Color Mappings** table. Regardless of whether the **Color Mappings** table is completed by Abaqus/CAE or by you, once it is complete, you can select multiple cells to change node and element colors, node symbol shapes, and node symbol sizes (see *Selecting multiple items from lists and tables* for more information).

When you change node and element colors, you must select the colors you want from the **Select Color** dialog box. Abaqus/CAE does not support automatic color coding for nodes and elements. In addition, the columns in the **Color Mappings** table are not sortable when you examine color mappings for **Nodes** and **Elements**; consider using the filter if you need to find node or element names from a large list.

The **Color Code** dialog box does not retain node and element color selections when you close the dialog box or switch viewports. You should consider saving color macros frequently when you change node and element colors; see *Saving and restoring custom color mappings*, for more information.

Choose from the following selection methods to color elements and nodes in your model:

Pick from viewport

Select **Pick from viewport** to specify elements or nodes by picking them directly from the viewport. Click **Edit Selection** or **Add Selection**, respectively, to edit an existing row or to add a new row to the **Color Mappings** table. Abaqus/CAE automatically enters pick mode, and **Select *items* for color coding** appears in the prompt area. See *Selecting objects within the viewport* for more information on picking items in the viewport. Click **Delete Selection** to delete a highlighted row from the table.

Element labels (Node labels)

Select **Element labels** or **Node labels** to specify elements or nodes by number. For each row in the **Color Mappings** table, select the name of the part instance to which the nodes or elements belong from the list in the **Part instance** column and type a list of element or node numbers separated by commas or a range of numbers such as `1:4` into the **Labels** field. If desired, you can specify a range using a number other than `1` as the operator; for example, `1:21:5` selects items labeled `1`, `6`, `11`, `16`, and `21`.

Result value

Select **Result value** to specify elements or nodes containing results within a given range of values.

The output variable to be considered is displayed at the bottom of the **Color Mappings** table, to the right of the **Field Output** button. To select a new result variable, click **Field Output**; see *Selecting the field output to display* for more information on the **Field Output** dialog box. Choose from the filtering methods in the **Type** cell; the symbols represent results below , inside , outside , or above  the selected value or range. Enter the required value or values in the **Min value** and **Max value** cells to specify the range for the filter type that you selected. You can add rows to the table and select different filtering methods and result ranges, but all rows refer to the same field output variable. Every element (or node) in the model is used in the filtering process, regardless of the current active display group in the model.

Note:

The bounds for filtering based on element or nodal output variables are always based on the values of a variable at the nodes. Therefore, element-based output quantities are extrapolated and averaged at the nodes before comparing them against the user-defined bounds. The averaging settings in the **Result Options** dialog box determine how element-based variables are calculated at the nodes. For example, consider a case where elements are filtered based on Mises stress using the default averaging threshold of 75%. After extrapolation to the nodes, the values are averaged according to this threshold. This conditional averaging may result in several distinct values of Mises stress at the node based on contributions from the various elements to which the node belongs. Any element whose Mises stress contribution falls within the user-defined bounds is included in the color coding selection.

All elements (All nodes)

Select **All elements** or **All nodes** to select all items of the specified type in your model. No further item specification is necessary.

Node sets

Select **Node sets** to specify a new color for node sets saved in your model. The **Color Mappings** table lists all the available set names. You can select element sets by using the **All** item type.

Internal sets

Select **Internal sets** to specify internal (created by Abaqus/CAE) node or element sets. The **Color Mappings** table lists all the available set names.

Display groups

Select **Display groups** to specify a saved display group. The **Color Mappings** table lists all the available display group names.

Part instances

Select **Part instances** to specify a new color for all nodes in the selected part instance. The **Color Mappings** table lists all part instances in the model.

To select all the elements in a part instance, use the **Part instances** method for the **All** item type.

Additional information

- *Coloring geometry and mesh elements*
- *Customizing the display color of individual objects*

Coloring constraints in the Visualization module

You can apply color coding to constraints displayed in the current viewport when you are working in the Visualization module and when an output database is selected.
To color code all geometry in the Visualization module, see *Coloring all geometry in the Visualization module*.

1. Click the  tool in the Color Code toolbar.

   Abaqus/CAE displays the **Color Code** dialog box, which displays the default color mappings for the current module.
2. From the **Color Code** list, select **Constraints**.
3. In the **Constraint Types** list, edit any of the assigned colors.
4. Click **Apply**.

   Abaqus/CAE color codes the current viewport according to the selections in the **Color Code** dialog box.

Customizing the display color of individual objects

This section describes how to customize the display of individual objects; these examples apply throughout Abaqus/CAE, including in the Visualization module. Once Abaqus/CAE creates the automatic color mappings for your viewport, you can customize the color display by changing any of the colors assigned to individual objects in the color mapping. The **Color Code** dialog box displays each object and its assigned color on the same row in the **Color Mappings** table. For each object, you can select a different color, activate or deactivate its display, and set (or revert to) the default colors for the selected objects. The **Color Code** dialog box also provides options that support the management of colors for each object: you can filter by object name, sort table columns, and highlight the selected object.

In the Visualization module, you can apply color coding to the entire viewport or to the nodes or the elements only. You cannot color code nodes or elements in a model database in the other Abaqus/CAE modules.

The following options are available for customizing the display color of individual objects:

Changing the fill color for an individual item

The **Color** column displays the fill color assigned to each object. To choose a different color, either double-click the color sample  in that row or highlight the color sample and click the **Edit color** color sample. Abaqus/CAE opens the **Select Color** dialog box, from which you can select a new fill color. (For more information about selecting custom colors, see *Customizing colors*.) When you click **Apply**, Abaqus/CAE refreshes the current viewport with your new fill color.

Changing the edge color for an individual item (Visualization module only)

When you open the **Color Code** dialog box from the Visualization module, the dialog box includes the **Edge** column, which displays the edge color assigned to each object. You cannot customize the edge color in any other module.

To change the edge color for an individual item, either double-click the color sample  in that row or highlight the color sample and click and hold the **Edit color** symbol (=, *, or ). Abaqus/CAE opens the **Select Color** dialog box, from which you can select a new edge color. (For more information about selecting custom colors, see *Customizing colors*.) When you click **Apply**, Abaqus/CAE refreshes the current viewport with your new edge color.

Activating and deactivating table rows

Abaqus/CAE displays color coding for active objects only; inactive objects are rendered with the initial color. Deactivating color coding for several objects in a color mapping can simplify your display and help you examine or debug a model.

Note:

You cannot deactivate color coding for objects in the module default color mappings.

To toggle the activation status of color coding for an object, click **Status** and choose an activation or deactivation option from the list that appears. If you select **Activate all** or **Deactivate all**, Abaqus/CAE toggles the status of the **Active** column for all rows in the **Color Mappings** table. If you select **Activate selected** or **Deactivate selected**, Abaqus/CAE toggles the status of the **Active** column for the highlighted rows only. You can also select and deselect the checkboxes in the **Active** column to toggle the status of color coding for the objects in those rows. When you click **Apply** in the **Color Code** dialog box, Abaqus/CAE applies color coding to the current viewport for active rows only.

Highlighting selected objects

Select the **Highlight items** checkbox to display a highlighted border around any items whose rows are selected in the **Color Mappings** table. Abaqus/CAE enables highlighting only for the following color mappings: **Part instances**, **Sets**, **Surfaces**, **Internal sets**, and **Internal surfaces**. You cannot highlight objects when you apply color coding to nodes or elements.

Reverting to default colors and setting new defaults

After you make changes to the display color of individual objects, you can revert to the default color settings for the current color mapping by clicking **Color Mapping**, and then selecting **Restore Defaults** from the list that appears. Alternatively, if you want your changes to become the new default color mappings for your session, select **Set As Defaults** from the same list.

Auto-coloring individual objects

You can apply auto-coloring to selected objects in a color mapping. Select the individual objects that you want to change, then select **Auto-color Selected** from the **Color Mapping** list. Abaqus/CAE applies color coding from the auto-color list according to the alphabetical order of the names in the selected rows.

Sorting by columns

Click the column headings in the **Color Mappings** table to sort the table by the contents of the selected column. Click the same heading a second time to reverse the sorting order.

Note:

You cannot sort by columns when you color code nodes or elements.

Changing the sort order of the objects in the **Color Mappings** table is for navigation only; their order in the dialog box has no effect on the colors that are selected for color coding. Abaqus/CAE assigns colors from the auto-color list to model definitions in alphabetical order, based on the names of the items in the color mapping.

Filtering rows by name

If your selected color mapping contains many rows, you can use the **Name filter** to reduce the number of rows displayed. Click  next to the **Name filter** field to see examples of valid filtering syntax.

Displaying multiple color mappings

You can apply color coding for two or three different color mappings to the viewport at the same time. Displaying multiple color mappings can reveal interactions between aspects of the model that might not be apparent when you display the color mappings separately. For example, you might want to display color mappings for both **Boundary conditions** and **Loads** in the same viewport.

To add another color mapping to the **Color Mappings** portion of the dialog box, click **Advanced** and select **Add Mapping** from the list that appears. Abaqus/CAE adds another tabbed color mapping to the dialog box, in which you can display any color mapping by selecting the mapping from the **Color Code by** list. *Figure 1* shows the **Color Code** dialog box with the **Boundary conditions** and **Loads** color mappings displayed.

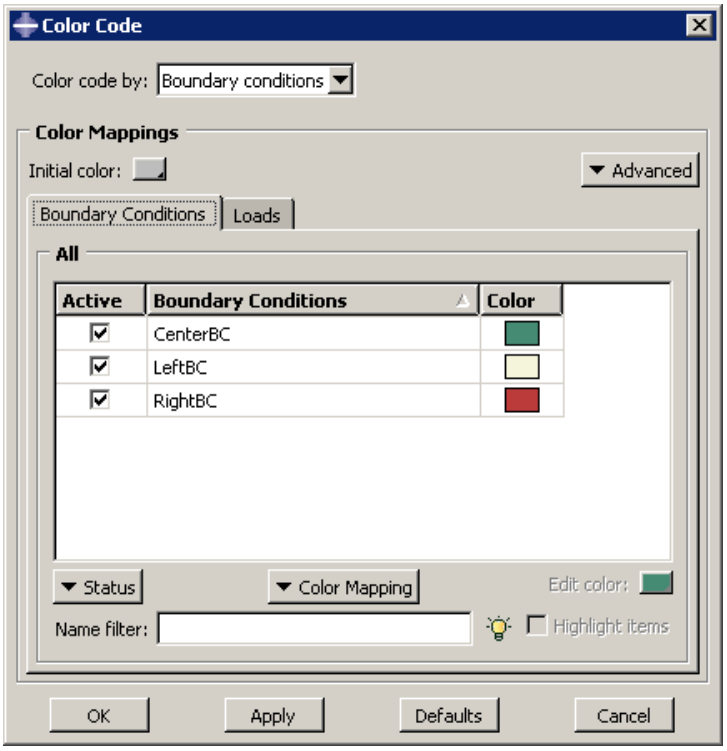

Figure 1: The Color Code dialog box with multiple color mappings.

You can also remove a color mapping from the dialog box by clicking its tab and selecting **Remove Current Mapping** from the **Advanced** list.

When multiple color mappings are open, Abaqus/CAE applies color mappings for the leftmost color mapping first, before proceeding to the mapping or mappings to its right. You can display up to three color mappings at a time, but Abaqus/CAE does not permit you to reorder the tables. If you want to color code attributes in a different order, you must close each color mapping and then add the color mappings in the order in which you want Abaqus/CAE to display them in the viewport.

Editing the colors in the Auto-Color List

When you create color mappings, Abaqus/CAE assigns colors to objects by referring to the color definitions in the **Auto-Color List**. You can modify the contents of this list by adding, removing, rearranging, and changing the colors.

Unlike color mappings, the Auto-Color List is common for all viewports.

1. Click the  tool in the Color Code toolbar.

   Abaqus/CAE displays the **Color Code** dialog box.
2. Click **Advanced**, and select **Edit Auto-colors** from the list that appears.

   Abaqus/CAE displays the **Edit Auto-Colors** dialog box.
3. To insert a new color into the Auto-Color list:

   1. Highlight the color in the Auto-Color list that you want to precede or follow the color that you add.
   2. Click **Insert Before** or **Insert After** to add a new color in the indicated location in the Auto-Color list.

      The **Select Color** dialog box opens.
   3. Choose a color, and click **OK** to close the **Select Color** dialog box.

   Abaqus/CAE adds the new color in the selected location.
4. To change one of the colors in the Auto-Color list, double-click the color and select a new color from the **Select Color** dialog box that appears.
5. To move a color within the Auto-Color list, highlight the color and click either **Move Up** or **Move Down** to move the color one step in the selected direction.
6. To delete a color from the Auto-Color list, highlight the color and click **Delete**.
7. Continue adding, changing, moving, and deleting colors until the Auto-Color list contains the colors you want in the desired order.
8. Click **OK**.

   Abaqus/CAE uses the revised Auto-Color list for any subsequent color coding.

Saving and restoring custom color mappings

Color mappings are session-specific settings that are not saved to the model database or output database by default. Abaqus/CAE provides two methods you can use to save your custom color coding definitions.

- You can save your color mapping definitions as session options. Session options can be saved to the model database, to an output database, or to an XML file. When you save color mappings using this process, Abaqus/CAE records only the color mappings for the item currently selected in the **Color Code** dialog box. For example, when color mappings for part instances are displayed, those color mapping definitions are the only ones written to the selected file.
- You can create a color macro or write the selected color mapping to an ASCII file. A color macro records all of the color mappings and your initial color selection, and an ASCII file records the current color mapping only. You can run a color macro as you would any other macro; see *Managing macros*. Color macros record all of the color mappings you select, rather than just the ones currently displayed in the **Color Code** dialog box.

This section describes the macro-based method for saving color mapping definitions. For more information about saving color mappings as a session option, see *Managing session objects and session options*.

Additional information

• *Managing macros*

Save a color macro

1. Click the  tool in the Color Code toolbar.
   Abaqus/CAE displays the **Color Code** dialog box.
2. Click **Advanced**, and select **Save Color Macro** from the list that appears.
   Abaqus/CAE displays the **Create Macro** dialog box, which indicates the location where the macro will be saved.
3. Enter a **Name** for this macro, and click **OK**.
   Abaqus/CAE saves the macro, making it available for you to run from the **Macro Manager** dialog box.

Read or write an ASCII file for a color mapping

1. Click the  tool in the Color Code toolbar.
   Abaqus/CAE displays the **Color Code** dialog box.
2. Click mouse button 3 with the cursor positioned over the **Color Mappings** table, then select one of the following choices from the list that appears:
   - Select **Write to File** to select a file name and to save the current color mapping.
   - Select **Read from File** to select a file name and to read the contents of a saved color mapping.

Using display groups to display subsets of your model

By default, Abaqus/CAE displays your entire model; however, you can choose to display subsets of your model by creating display groups.
These subsets can contain combinations of part instances, geometry (cells, faces, or edges), datum geometry (points, axes, planes, or coordinate systems), elements, nodes, and surfaces from the current model or output database. This chapter explains the concept of display groups and how you can manage them.

In this section:

- *Understanding display groups*
- *Managing display groups*

Understanding display groups

A display group is a collection of selected model components and can contain the entire model or combinations of part instances, geometry (cells, faces, or edges), datum geometry (points, axes, planes, or coordinate systems), elements, nodes, surfaces, constraints, and output database coordinate systems.
Display groups allow you to reduce clutter on your screen and focus on areas of interest within your model, to access "hidden" components in complex models, and to decrease the amount of time needed to refresh the display in the current viewport. For example, you can use display groups to show contact surfaces but suppress elements or to produce a contour plot showing elements in the interior of your model that would otherwise be obscured. You can plot, save, edit, copy, rename, and delete display groups.

In the Visualization module you can plot more than one display group in the same viewport, and you can customize the plot options for each display group independently.

In this section:

- *Understanding how to create display groups*
- *Understanding display group Boolean operations*

Understanding how to create display groups

A display group can contain combinations of model components: part instances, geometry (cells, faces, or edges), datum geometry (points, axes, planes, or coordinate systems), elements, nodes, surfaces, constraints, output database coordinate systems, or the entire model. In addition, you can create a display group by operating on previously saved display groups. However, while creating a display group, you can perform operations on only one type of model component at a time. Creating a display group containing selected components of more than one type is an incremental process. The model components that can be used to create a display group depend on the module in which you are working, as shown in *Table 1* and *Table 2*.

Table 1: Model components that can be used to create display groups in the Part- and Assembly-related modules and in the Visualization module.

Modules	Available Model Components
Part-related (Part, Property)	Geometry (cells, faces, or edges)
	Datum geometry (points, axes, planes, or coordinate systems)
	Elements
	Nodes
	Reference points
	Sets (geometry, element, or node)
	Display groups
Assembly-related (Assembly, Step, Interaction, Load, Mesh)	Part instances
	Geometry (cells, faces, or edges)
	Datum geometry (points, axes, planes, or coordinate systems)
	Assembly wires (connector wires)
	Elements
	Nodes
	Reference points
	Sets (geometry, element, or node)
	Surfaces
	Display groups
Visualization module	Part instances
	Elements
	Nodes
	Surfaces
	Display groups

Table 2: Model components that can be used to create display groups for output databases in the Visualization module.

Module	Available Model Components
Visualization	Part instances
	Elements

Module	Available Model Components
	Nodes
	Surfaces
	Display groups
	Coordinate systems
	Tie constraints
	Shell-to-solid coupling constraints
	Distributing coupling constraints
	Kinematic coupling constraints
	Rigid body constraints

To create a display group, you first select the particular items of interest. You can then perform a Boolean operation on your selection and the contents of the current viewport. This sequence can be repeated as necessary to create the desired group. In addition, you can create a new display group by editing (for example, performing additional Boolean operations on) the contents of a previously saved display group.

You can save either the selection in the dialog box or the contents of the current viewport as a display group. By default, a display group persists only for the duration of the session. If you want to retain a display group for use in subsequent sessions, save it to an XML file, to the model database, or to an output database; for more information, see *Managing session objects and session options*. You can access a display group only in modules of the same type as the one in which it was created (see *Table 1* and *Table 2*). For example, if you create and save a display group in the Part module, you will be able to access this display group only in the Part and Property modules.

A display group named `All` that contains all objects in the current part, assembly, or output database is created automatically by Abaqus/CAE. This display group appears in the display group manager for the current module and cannot be edited, copied, renamed, or deleted. It is not associated with a particular part, assembly, or output database. You can use this display group to quickly return to a plot of the entire part or model after performing Boolean operations.

Additional information

- *Creating or editing a display group*
- *Controlling the display of constraints in the Visualization module*

Understanding display group Boolean operations

To create or edit a display group, you can perform Boolean operations on selected model components and the contents of the current viewport. Abaqus/CAE offers the following Boolean operations in the Display Group toolset: **Replace**, **Add**, **Remove**, **Intersect**, and **Either**.

As an example of a simple Boolean operation, assume the current viewport shows the entire model. If you select a single element set and then apply the **Remove** operation, that element set is eliminated from the display in the current viewport.

For each Boolean operation you perform to create or edit a display group, you can select only one type of model component: part instances, geometry (cells, faces, or edges), datum geometry (points, axes, planes, or coordinate systems), elements, nodes, surfaces, previously saved display groups, or the entire model. For a given display group, Abaqus/CAE initially assumes that you want to include all nodes connected to all elements in the group. However, if you select particular nodes, all subsequent operations on that display group include only the nodes you have selected.

An explanation of each of the Boolean operations follows. In the icons below, the circle on the left represents the items in the current viewport; the circle on the right represents your selection. The shaded portion represents the resulting display group. All of these Boolean operations except the last one, **Replace All**, are available in the **Create Display Group** dialog box; the Display Group toolbar provides access to the **Replace**, **Remove**, **Either**, and **Replace All** Boolean operations, as well as **Undo** and **Redo** operations.

 Replace

Use the **Replace** operator to replace the current viewport contents with your selection.

 Add

Use the **Add** operator to add your selection to the current viewport contents.

 Remove

Use the **Remove** operator to remove your selection from the current viewport contents. If your selection includes one or more elements or surfaces, the nodes connected to those items are also removed, provided that you have not specifically operated to include those nodes in the display group.

 Intersect

Use the **Intersect** operator to display only those items common to your selection and the display in the current viewport.

 Either

Use the **Either** operator to display only model components that are either in your selection or in the current viewport but not in both.

Note: From the Display Group toolbar, click **Invert Display**  to hide all the model components that are displayed in the current display group or to display all the model components that are hidden. This

operation is equivalent to selecting all the objects in the **Create Display Group** or **Edit Display Group** dialog box and clicking the **Either** button.

Replace All

Use the **Replace All** operator to replace your display group and display all entities in the current viewport. This operator is available in the toolbar only.

When you select the  (**Replace Selected**) or  (**Remove Selected**) operators from the toolbar, Abaqus/CAE displays a list of model components in the prompt area. Select the type of model component that you want to replace or remove from the selected display group, then click one or more model components in the viewport to change the contents of the display group.

Note:

The **Replace Selected** and **Remove Selected** operators perform the same actions as the **Replace** and **Remove** operators in the display group dialog boxes. The toolbar operators have different names to indicate that you must select model components from the viewport before using these operators to change the current display.

Additional information

• *Creating or editing a display group*

Managing display groups

The display group managers allow you to create a display group and to plot, edit, copy, rename, or delete a previously saved display group.
The display group manager for the current module lists only the display groups that you have saved in modules of the same type during the current session. The **Part Display Group Manager** in the part-related modules lists the model and part to which each display group belongs; the **Assembly Display Group Manager** in the assembly-related modules lists the model to which each display group belongs.

In the Visualization module you can plot multiple display groups in the same viewport. The **ODB Display Group Manager** in the Visualization module allows you to lock and unlock plotted display groups to selectively customize plot options. In addition, you can synchronize all plotted display groups to use the same plot options.

In this section:

- *Creating or editing a display group*
- *Selection methods for creating or editing a display group*
- *Copying, renaming, and deleting a display group*
- *Plotting display groups*
- *Customizing display groups in the Visualization module*
- *Applying display groups to multiple viewports and models*

Creating or editing a display group

To create a display group, you first select the particular items of interest. You can then perform Boolean operations on your selection and the contents of the current viewport. When you create a display group, you can choose at any time to save either the contents of the current viewport or the items selected in the dialog box (if applicable). You must save a display group to do any of the following:

- Plot the display group later in the session.
- Apply the display group to a different model or to a different viewport.
- Edit, copy, or rename the display group.
- Plot multiple display groups in the same viewport in the Visualization module.

Saved display groups are available only during the current session and only when you are in modules of the same type as the module in which you created the display group.

Note:

Saved display groups are not updated to reflect changes made to the model, such as adding, deleting, or suppressing features or partitioning a part; such changes may invalidate display groups created with respect to the original model.

You can edit the combination of model components in a previously saved display group. Editing a display group is similar to creating a display group: in both cases you can select model components and then apply Boolean operations on your selection and the contents of the current viewport. When you select a display group to edit, the contents of the current viewport update to show the selected display group. You use the display in the current viewport to determine the model components in the group you are editing; you cannot list the model components. When you are finished editing, all viewports that use the display group will be updated.

1. Locate the options for creating or editing a display group.

   - To create a display group, select **Tools->Display Group->Create** from the main menu bar.

     Tip: You can also create a display group by clicking the  tool in the Display Group toolbar.

     The **Create Display Group** dialog box appears.

   - To edit a previously saved display group, select **Tools->Display Group->Edit** from the main menu bar. From the menu that appears, select the display group you want to edit.

     The **Edit Display Group** dialog box appears.

   Tip: You can also use the display group manager to create or edit a display group. From the main menu bar, select **Tools->Display Group->Manager** to display the manager for the current module. To create a display group, click **Create**. To edit a display group, select it from the list and double-click on it or click **Edit**.

2. From the **Item** list at the top left of the dialog box, select the type of model component to use for the display group (as available for the current module): **Cells**, **Faces**, **Edges**, **Datums**, **Assembly wires**, **Reference points**, **Elements**, **Nodes**, **Sets**, **Surfaces**, **Part instances**, **Display groups**, **Internal Sets**, **Internal Surfaces**, **Coordinate systems**, **Ties**, **Shell-to-solid couplings**, **Distributing couplings**, **Kinematic couplings**, or **Rigid bodies**. You can select **All** to specify all objects in the current part, assembly, or output database when you are creating a new display group.

Abaqus/CAE refreshes the **Method** list and the right side of the dialog box. If you select **All**, these fields are empty and no further item specification is necessary. If the item that you select has only one selection method, Abaqus/CAE immediately enters the required selection mode. For example, if you select **Cells**, Abaqus/CAE immediately enters the viewport selection mode.

3. Choose a selection method from the **Method** list; and/or select the specific items for the display group by picking from the viewport, selecting items from the list that appears on the right side of the dialog box, or entering data in the right side of the dialog box. See *Selection methods for creating or editing a display group*, for more detailed information.

   Tip: If your model contains many items of a particular type, you can use the filter to reduce the number of item names displayed on the right side of the **Create Display Group** dialog box. Click the **Tip** button next to the **Filter** field to see examples of valid filtering syntax.

   Certain items can be highlighted in the viewport to verify your selection. Toggle **Highlight items in viewport** if available.

   Toggle **Show common list between linked viewports** to display items common to all linked viewports in the **Method** list. For **Part instances**, viewports containing model databases or output databases are considered; for other model components, only viewports containing output databases are considered.

4. From the icons in the bottom portion of the dialog box, click the desired Boolean operation (see *Understanding display group Boolean operations*, for more information).

   Abaqus/CAE carries out the selected Boolean operation on the model components you have selected in the dialog box and the contents of the current viewport.

5. Repeat steps beginning with Step 2 as needed to produce the desired display group.
6. If you are creating a new display group, you can choose to save it at any time.
   a. To save the contents of the current viewport as a display group, click **Save As**; then enter a name for the display group in the dialog box that appears, and click **OK**.

      Abaqus/CAE saves the contents of the current viewport (regardless of what is selected in the dialog box) as a display group.

   b. If model components are selected in the **Create Display Group** dialog box, you can save the selected components as a display group. Click **Save Selection As**; then enter a name for the display group in the dialog box that appears, and click **OK**.

      Abaqus/CAE saves only the components selected in the dialog box (regardless of what is displayed in the current viewport) as a display group.

7. Click **Dismiss** to close the **Create Display Group** dialog box or **OK** to close the **Edit Display Group** dialog box.

Additional information

- *Choosing background colors*
- *Controlling the display of constraints in the Visualization module*

Selection methods for creating or editing a display group

You can use the following selection methods to specify the items that will be contained in a display group:

- To specify geometry (cells, faces, or edges), assembly wires, or reference points by picking them directly from the viewport, select them from the **Item** list. (For datums, elements, and nodes, you must also select **Pick from viewport** from the **Method** list.) Abaqus/CAE automatically enters the pick mode, and **Select *items* for the display group** appears in the prompt area. See *Selecting objects within the viewport* for more information on picking items in the viewport.

  Click **Done** in the prompt area when you have finished picking items in the viewport.

  Click **Edit selection**, **Add selection**, or **Delete selection** in the dialog box to further modify your viewport selections.
- To specify elements or nodes by number, select **Element labels** or **Node labels** from the **Method** list. Select the name of the part instance to which the nodes or elements belong from the list in the **Part instance** field on the right side of the **Create Display Group** dialog box. Type into the **Labels** field a list of element or node numbers separated by commas or a range of numbers optionally followed by an increment; for example, 1:10 or 1:10:2.
- To specify elements in the Visualization module by type, select **Element type** from the **Method** list. A list of the available element types in your model appears on the right side of the **Create Display Group** dialog box. Select one or more element types from this list (see *Selecting multiple items from lists and tables* for more information).
- To specify elements in the Visualization module by material or section, select **Material assignment** or **Section assignment** from the **Method** list. A list of the available materials or sections in your model appears on the right side of the **Create Display Group** dialog box. Select one or more materials or sections from this list (see *Selecting multiple items from lists and tables* for more information).
- To specify elements in the Visualization module by layups or plies, select **Composite Layups** or **Composite Plies** from the **Method** list. A list of the available composite layups or plies in your model appears on the right side of the **Create Display Group** dialog box. Select one or more layups or plies from this list (see *Selecting multiple items from lists and tables* for more information).
- To specify geometry, element, or node sets in part- and assembly-related modules or surfaces in assembly-related modules, select **Set names** or **Surface names** from the **Method** list. A list of the available set or surface names in your model appears on the right side of the **Create Display Group** dialog box. Select one or more set names from this list (see *Selecting multiple items from lists and tables* for more information).
- To specify internal (created by Abaqus/CAE) sets in part- and assembly-related modules or internal surfaces in assembly-related modules, select **Internal sets** or **Internal surfaces** from the **Item** list. A list of the available set or surface names in your model appears on the right side of the **Create Display Group** dialog box. Select one or more set names from this list (see *Selecting multiple items from lists and tables* for more information).
- To specify element, node, surface, or internal (created by Abaqus/CAE) sets in the Visualization module, select **Element sets**, **Node sets**, **Surface sets**, or **Internal sets** from the **Method** list. A list of the available set names in your model appears on the right side of the **Create Display Group** dialog box. Select one or more set names from this list (see *Selecting multiple items from lists and tables* for more information).
- To select all items of the specified type in your model, select **All elements**, **All nodes**, or **All surfaces** from the **Method** list. No further item specification is necessary.
- If you selected **Part instances** or **Display groups** from the **Item** list, a list of the available part instances or display groups in your model appears on the right side of the **Create Display Group** dialog box. Select one or more part instance or display group names from this list (see *Selecting multiple items from lists and tables* for more information).

  Note:

  In assembly-related modules you can also display a subset of the part instances in your model using the visibility options in the **Instance** tabbed page of the **Assembly Display Options** dialog box (see *Controlling*

instance visibility). Part instances that have been toggled off in the **Assembly Display Options** dialog box cannot be made visible using display groups.

- To specify elements, nodes, or surfaces containing results within a given range of values in the Visualization module, select **Result value**.

  The output variable to be considered is displayed at the top right side of the dialog box. To select a new result variable, click **Field Output**; see *Selecting the field output to display* for more information on the **Field Output** dialog box. Choose from the filtering methods in the **Type** field.

  - If you select  (inside) or  (outside), enter values for the upper and lower bounds of the range of results in the **Min value** and **Max value** fields, respectively.
  - If you select , enter a value above which the results should fall in the **Min value** field.
  - If you select , enter a value below which the results should fall in the **Max value** field.

  Every element (or node or surface) in the model is used in the filtering process, regardless of the current active display group in the model. If you choose a range of values for which no elements (or nodes or surfaces) exist, you will create an empty display group.

  You can achieve better performance in time history animations using the *status field output variable* rather than the result-based display group functionality. The status field output variable allows you to remove elements that meet a specified result-based failure criteria from your model plots; see *Selecting the status field output variable* for more information.

  Note:

  The bounds for filtering based on element, nodal, or surface output variables are always based on the values of a variable at the nodes. Therefore, element- and surface-based output quantities are extrapolated and averaged at the nodes before comparing them against the user-defined bounds. The averaging settings in the **Result Options** dialog box determine how element- and surface-based variables are calculated at the nodes. For example, consider a case where elements are filtered based on Mises stress using the default averaging threshold of 75%. After extrapolation to the nodes, the values are averaged according to this threshold. This conditional averaging may result in several distinct values of Mises stress at the node based on contributions from the various elements to which the node belongs. Any element whose Mises stress contribution falls within the user-defined bounds is included in the display group.

- To specify coordinate systems in the Visualization module, select **Coordinate systems** from the **Item** list, then select one of the following:

  - To specify coordinate systems that are part of the output database, select **Odb systems** from the **Method** list. A list of the output database coordinate systems appears in the right side of the **Create Display Group** dialog box.
  - To specify coordinate systems that have been created during your session, select **User systems** from the **Method** list. A list of the user-defined coordinate systems appears in the right side of the **Create Display Group** dialog box.
  - To specify coordinate systems from the output database and the session, select **All** from the **Method** list. A list of the output database coordinate systems and user-defined coordinate systems appears in the right side of the **Create Display Group** dialog box.

  Select one or more coordinate systems from the list that appears (see *Selecting multiple items from lists and tables* for more information).

- To specify analysis constraints in the Visualization module, select one of the following constraint types in the **Item** list: **Ties**, **Shell-to-solid couplings**, **Distributing couplings**, **Kinematic couplings**, or **Rigid bodies**.

Additional information

- *Creating or editing a display group*

Copying, renaming, and deleting a display group

To copy, rename, or delete a display group, use one of the following:

- The **Copy**, **Rename**, and **Delete** items listed under the **Tools->Display Group** menu on the main menu bar.

  The **Copy**, **Rename**, and **Delete** items contain submenus listing all the display groups you have saved in modules of the same type as the current module during the session.
- The display group manager dialog box for the current module. The display group manager dialog boxes contain functions identical to those listed under the **Tools->Display Group** menu on the main menu bar but with a convenient browser that lists all the display groups for the current module and session. To display the display group manager dialog box for the current module, select **Tools->Display Group->Manager** from the main menu bar.

Note:

If you try to delete a display group that is shown in multiple viewports, Abaqus/CAE warns that the display groups in those viewports will be reset to the entire model.

Additional information

• *Managing display groups*

Plotting display groups

You can plot a display group for the model in the current viewport. In the Visualization module you can plot more than one display group in the same viewport.
Abaqus/CAE plots only the components in each display group that are valid for the current model. For example, if a display group references an element set called `Fixture`, the model in the current viewport should also contain an element set called `Fixture`. Abaqus/CAE ignores model components that are not valid.

Additional information

• *Managing display groups*

Plot a single display group in any module

1. From the main menu bar, select **Tools->Display Group->Plot**.
2. From the menu that appears, select the display group that you want to plot.

   Tip: You can also use the display group manager for the current module to plot a display group. From the main menu bar, select **Tools->Display Group->Manager**. Select the display group you want to plot, and click **Plot** from the buttons on the right side of the manager.

   The model plot in the current viewport changes to show only the selected display group.

Plot one or more display groups in the Visualization module

1. From the main menu bar, select **Tools->Display Group->Manager**.

   The **ODB Display Group Manager** appears with a list at the top of all display groups saved in the current session.

2. Select one or more display groups from the list (see *Selecting multiple items from lists and tables*, for more information), and click **Plot** from the buttons on the right side of the manager.

   The model plot in the current viewport changes to show only the selected display groups, and the plotted display groups appear in the list of display group instances at the bottom of the **ODB Display Group Manager**.

3. To add one or more display groups to the plot in the current viewport, select them from the list of saved display groups at the top of the **ODB Display Group Manager**, and click **Add** from the buttons on the right side of the manager.

   The selected display groups are added to the model plot in the current viewport and to the list of display group instances at the bottom of the **ODB Display Group Manager**.

4. To remove a display group from the plot in the current viewport, select the instance from the list at the bottom of the **ODB Display Group Manager**, and click **Remove** from the buttons at the bottom of the manager.

   The selected display group is removed from the model plot in the current viewport and from the list of display group instances.

5. You can customize plot state–dependent and independent options separately for each display group in the current viewport. For more information, see *Customizing display groups in the Visualization module*.

Customizing display groups in the Visualization module

The **ODB Display Group Manager** in the Visualization module allows you to lock and unlock plotted display groups to selectively customize plot options. In addition, you can synchronize all plotted display groups to use the same plot options. For example, you can display a particular group of elements in the shaded render style with translucency and display the remainder of the model in the wireframe render style. *Figure 1* shows another example of two display groups plotted in the same viewport using different plot states and plot options.

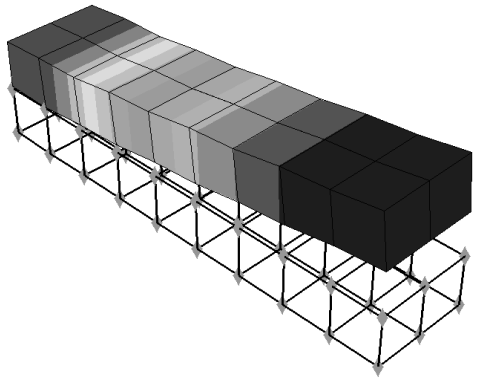

Figure 1: Multiple customized display groups in one viewport.

When you plot a display group in the Visualization module, the display group appears (along with its current plot states) in the list of display group instances at the bottom of the **ODB Display Group Manager**. Plot state–dependent and independent options that you specify apply to all unlocked display group instances. You can lock a display group instance that you do not want to be affected by plot options.

Changing the plot state will not affect locked display group instances in the viewport. However, view manipulations and changes to the color coding will affect all display group instances, both locked and unlocked. In addition, the contents of a locked display group can be edited.

Display groups are plotted in the viewport in the order in which they appear in the list of display group instances; the first instance in the list is the topmost instance in the viewport. Therefore, if two display group instances contain the same components and those components overlap in the viewport, the plot options for the first instance in the list take precedence. You can rearrange the order of the instances in the list to control which plot options will be displayed.

1. Follow the procedure described in *Plotting display groups*, to plot multiple display groups in the same viewport.
2. In the list of display group instances in the **ODB Display Group Manager**, click in the **Lock** column next to the display group name to lock the instances that you do not want to customize.

   Locked display groups are indicated by a check mark in the **Lock** column.
3. Customize the plot options for the unlocked display group instance or instances as desired. (See *Customizing plot display*," for more information.)
4. When you have finished customizing the plot options for a display group instance, click in the **Lock** column next to the display group name to prevent your settings from being modified.
5. Repeat Steps 3 and 4 as needed until you obtain the desired display in the viewport.
6. If you want all display group instances to use the same plot state and plot options, select the instance that reflects the desired plot state and plot options, and click **Sync Options** from the buttons at the bottom of the manager.

   All other unlocked display group instances will be synchronized to the selected display group's plot state and plot options.

7. To rearrange the order in which the display groups are plotted in the viewport, select an instance from the list at the bottom of the **ODB Display Group Manager** and click **Move Up** to move the instance up in the list or **Move Down** to move the instance down in the list.

   The display in the current viewport is updated to reflect your change.

Additional information

• *Managing display groups*

Applying display groups to multiple viewports and models

You can use a single display group to view the same subset of different models, and you can view a display group in multiple viewports.

A single display group can apply to different models as long as the display group is valid for each model. For example, *Figure 1* shows a single display group applied to two different models shown in two different viewports.

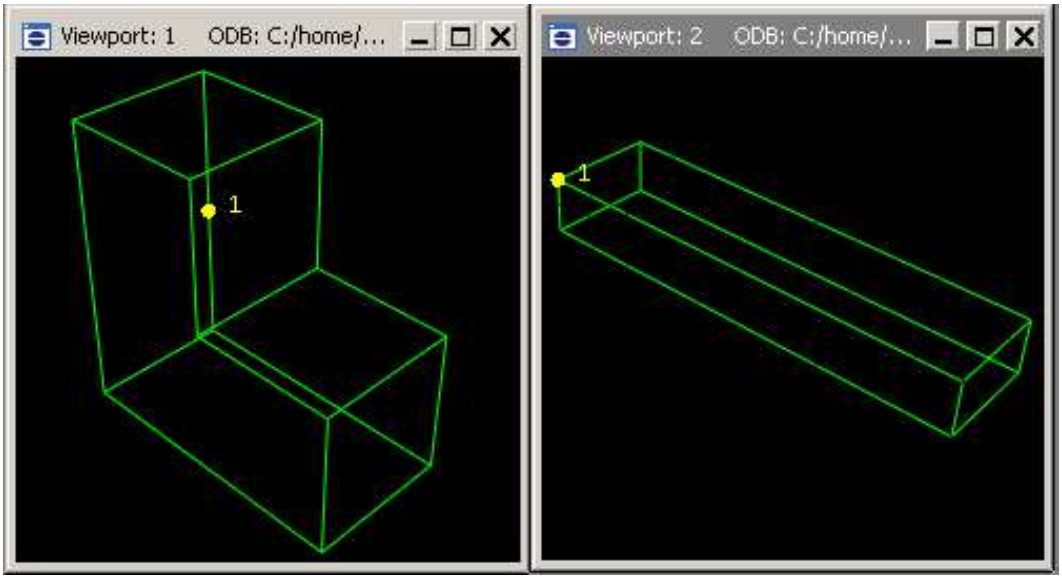

Figure 1: A display group applied to two different models.

Additional information

• *Managing display groups*

Plot a previously saved display group in any viewport

1. Click on the viewport border to make the viewport current.
2. From the main menu bar, select **Tools->Display Group->Plot**. Select the display group to plot from the menu that appears.

   Abaqus plots the display group in the current viewport. Abaqus plots only the components in the display group that are valid for the current model.

Edit a previously saved display group in any viewport where it is displayed

1. Click on the viewport border to make the viewport current.
2. From the main menu bar, select **Tools->Display Group->Edit**. Select the display group to edit from the menu that appears.

   The **Edit Display Group** dialog box appears.
3. Select the desired model components, and apply the desired Boolean operations.

   During the editing process, the results of any Boolean operations appear only in the current viewport.
4. Click **OK** to close the **Edit Display Group** dialog box.

   Your editing changes are applied to all viewports that reference the selected display group. If the modified display group becomes invalid for one of the models (for example, by the inclusion of a node not contained in that model), Abaqus warns that part of the display group is now invalid.

Overlaying multiple plots

This chapter explains the concept of overlaying plots and how you can create and manage such plots.
By default, Abaqus/CAE displays only one plot at a time in the current viewport. A plot may display multiple plot states, such as the contours and material orientations of the same model. However, a single plot cannot display data from more than one output database nor can it display both the model and an *X*–*Y* plot in the same viewport. If you want to display data in this fashion, you must overlay individual plots in the same viewport.

In this section:

- *Understanding how to overlay plots*
- *Producing and modifying overlay plots*

Understanding how to overlay plots

You can create a display that contains multiple plots in one viewport. For example, you may want to do any of the following:

- combine a contour plot and an *X*–*Y* plot
- compare the deformed plot shapes from two different output database files in the same viewport
- combine a time history animation with an animated *X*–*Y* plot displaying the change in several variables in the model over time

Overlay plots are useful, for example, for displaying data from both output databases in a co-simulation in the same viewport.

Overlay plots are composed of layers; each layer contains one plot, and the layers are stacked on top of each other to create the combined plot. *Figure 1* shows a plot containing the deformed shape plots at four different increments of an analysis as well as an *X*–*Y* plot of the strain energy in the model versus time.

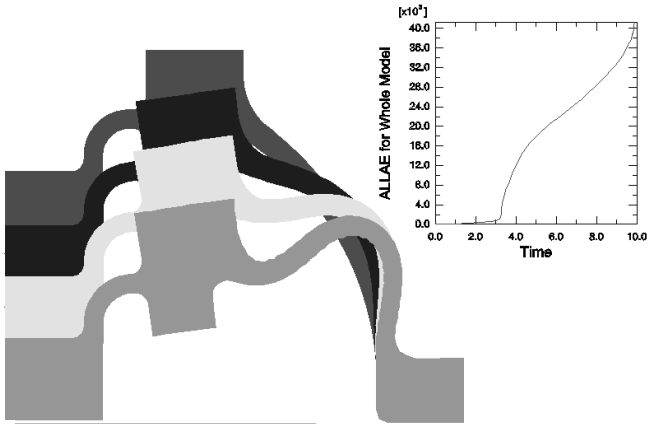

Figure 1: Overlay plot.

By default, the viewport does not contain any layers; only one plot at a time is displayed. To overlay multiple plots, you create a layer for each individual plot as you interact with Abaqus/CAE. You then choose the layers to display in the current viewport. You can create as many layers as you would like; any number of layers can be displayed in the same viewport. In addition, you can open multiple output databases and automatically display the combined contents in an overlay plot in a single viewport.

Use the **Overlay Plot Layer Manager** to create, display, position, and delete layers. To access the manager, select **View->Overlay Plot** from the main menu bar or click the **Overlay Plot Layer Manager** tool in the toolbox.

When you create a layer, it contains everything that is visible in the current viewport. You can change the contents of a layer, manipulate its view, reorder the layer with respect to the other layers in the overlay plot, and change the various display options that are applied to the contents. By default, layers are plotted directly on top of one another. Sometimes lines that appear directly on top of one another can create undesirable visual effects. You can offset the layers with respect to each other to avoid such display anomalies.

The settings in the **Overlay Plot Layer Manager** are applied to the contents of the current viewport only when you click **Plot Overlay**. Abaqus/CAE then enters the overlay plot state; when you click **Plot Single** in the **Overlay Plot Layer Manager**, the overlay plot disappears from the viewport and the display reverts back to the previous plot state.

You can also click the tool in the toolbox to switch between the single plot and overlay plot state at any time.

When you are in the overlay plot state, Abaqus/CAE displays your plots relative to an overlay plot coordinate system. As you create a layer, Abaqus/CAE assigns the view in which the layer was created to the overlay plot front (1–2) view. You can modify what is displayed in the overlay plot front view by manipulating the view for each individual layer, as described in *Manipulating the view for an overlay plot*. User-specified views defined in the overlay plot state are relative to the overlay plot coordinate system.

Columns in the **Overlay Plot Layer Manager** display the following information about each layer:

Visible

A check mark in this column indicates that the layer is visible in the viewport when you are in the overlay plot state.

Current

A check mark in this column indicates that the layer is current. Only one layer can be current at a time, although each layer can contain multiple plot states (for more information, see *Displaying multiple plot states*). Plot options are applied to only the current layer when you are in the overlay plot state; you can choose whether view manipulation options are applied to all existing layers or to only the current layer. The current layer is not necessarily the foremost layer in the viewport.

Name

The name of the layer.

Object

The name of the object contained in the layer; for example, an output database or an *X*–*Y* plot.

Producing and modifying overlay plots

This section explains how to overlay multiple plots by creating layers and plotting them in the same viewport and how to modify an overlay plot once you have created it.
Each layer in an overlay plot is completely independent. You can change the output database, the plot state (or plot states), reorder the layers with respect to each other, manipulate the view for each individual layer, and change the various display options that are applied to the contents.

In this section:

- *Producing an overlay plot*
- *Reordering the layers in an overlay plot*
- *Manipulating the view for an overlay plot*
- *Editing the layers in an overlay plot*

Producing an overlay plot

An overlay plot is a display that contains multiple plots in one viewport.
Overlay plots are composed of layers; you can open multiple output databases and create the layers automatically, or you can use the **Overlay Plot Layer Manager** to create layers manually.

You also use the **Overlay Plot Layer Manager** to configure your overlay plots.

Tip: You can also plot any combination of deformed and undeformed models shapes with or without contours, symbols, or materials orientations for a single output database by using the **Allow Multiple Plot States**  tool. Since all the plot states are created on a single layer, the **Allow Multiple Plot States** tool is limited to displaying data from a single output database, step, and frame. For more information, see *Displaying multiple plot states*.

1. Determine the method to use for producing the overlay plot:
   - Create layers automatically by opening multiple output databases.
   - Create layers manually.

2. To create layers automatically, do the following:
   a. Select **File->Open** from the main menu bar.
   b. From the **Open Database** dialog box that appears, select **Output Database (*.odb*)** as the **File Filter**.
   c. Select the output databases to open, toggle on **Append to layers**, and click **OK**. For more details, see *Opening a model database or an output database*.

      An overlay plot containing the combined contents of the output databases is automatically created in a viewport, and each output database is assigned to a separate layer. You can select **View->Overlay Plot** from the main menu bar to display the **Overlay Plot Layer Manager** and view the layers.

3. To create layers manually, do the following:
   a. Create the first plot that you want to include in the display.
   b. Open the **Overlay Plot Layer Manager** by selecting **View->Overlay Plot** from the main menu bar.

      Tip: You can also open the manager by clicking the **Overlay Plot Layer Manager**  tool in the toolbox.

   c. Click **Create** to create a layer that contains the plot shown in the current viewport.

      The **Create Viewport Layer** dialog box appears.

   d. Enter a name for the layer, and click **OK**.

      The new layer appears in the **Overlay Plot Layer Manager**, with check marks in both the **Visible** and **Current** columns.

   e. Create a new plot in the current viewport.
   f. Repeat Step c through Step e to create as many layers as you would like to include in the plot. In the **Create Viewport Layer** dialog box for all layers after the first one, you can choose to copy the view from an existing layer by toggling on **Copy view from** and selecting a layer from the list.

      The new layers appear in the **Overlay Plot Layer Manager** as you create them; the most recently created layer will have a check mark in the **Current** column.

g. Check that the layers you want to include in the plot have a check mark in the **Visible** column, and click **Plot Overlay**.

   The layers appear stacked on top of each other in the current viewport in the order in which they are listed in the **Overlay Plot Layer Manager**.

4. From the **Overlay Plot Layer Manager**, you can delete a layer by clicking in the **Name** or **Object** column to select the layer and clicking **Delete**.
5. With the overlay plot displayed in the viewport, you can click **Plot Single** in the **Overlay Plot Layer Manager** to exit the overlay plot state.

   The overlay plot disappears from the viewport, and the display returns to the previous plot state; but the **Overlay Plot Layer Manager** remains open. Click **Dismiss** to close the **Overlay Plot Layer Manager**.

Tip: You can also click the  tool in the toolbox to switch between the single plot and overlay plot state at any time.

Additional information

- *Understanding how to overlay plots*
- *Producing and modifying overlay plots*

Reordering the layers in an overlay plot

Layers are plotted in the viewport in the order in which they are listed in the **Overlay Plot Layer Manager**. By default, the layers are plotted directly on top of one another, which can sometimes result in undesirable visual effects where the plots appear to overlap.

You can rearrange the order in which the layers are plotted, and you can apply a small offset to all the layers in the screen *Z*-direction (perpendicular to the plane of the screen) to separate them in the display and eliminate any undesirable visual effects. If you apply a positive offset, the layers are drawn in the viewport in the order shown in the **Overlay Plot Layer Manager** (the last layer in the manager is the topmost layer in the viewport). If you apply a negative offset, the drawing order is reversed. *Figure 1* shows an example of an overlay plot with different offset values applied.

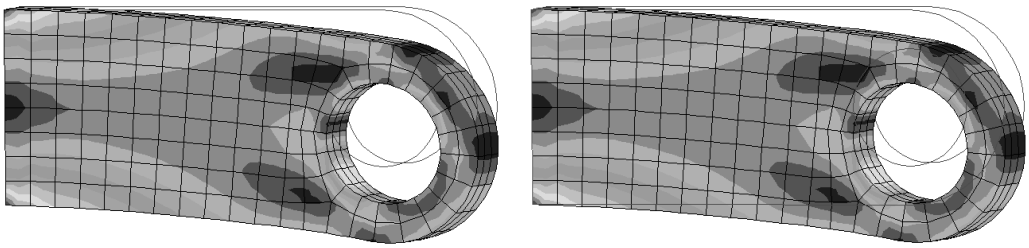

Figure 1: Overlay of undeformed and contour plots: positive offset on left, negative offset on right.

1. Create an overlay plot using the procedure described in *Producing an overlay plot*.
2. Reorder the layers using one of the following methods:
   - Select the layer you wish to reorder by clicking in the **Name** or **Object** column in the **Overlay Plot Layer Manager**. Click **Move Up** to move the layer up in the manager; click **Move Down** to move the layer down in the manager.
   - Drag the **Layer offset** slider to a positive or negative value to shift the layers in the positive or negative screen *Z*-direction. You may have to experiment with the offset values to achieve your desired display.

   Abaqus/CAE applies your settings to the overlay plot in the current viewport.
3. With the overlay plot displayed in the viewport, you can click **Plot Single** in the **Overlay Plot Layer Manager** to exit the overlay plot state.

   The overlay plot disappears from the viewport, and the display returns to the previous plot state; but the **Overlay Plot Layer Manager** remains open. Click **Dismiss** to close the **Overlay Plot Layer Manager**.

Tip: You can also click the  tool in the toolbox to switch between the single plot and overlay plot state at any time.

Additional information

- *Understanding how to overlay plots*
- *Producing and modifying overlay plots*

Manipulating the view for an overlay plot

While you are in the overlay plot state, you can choose whether view manipulations are applied to all existing layers or to only the current layer.

1. Create an overlay plot using the procedure described in *Producing an overlay plot*.
2. In the **Overlay Plot Layer Manager**, toggle **All** or **Current** next to **View manipulation layer** to specify whether you want the view manipulations that you apply to affect all the layers or only the current layer.
3. Use the view manipulation tools to position, orient, and magnify the objects in the viewport. (See *Manipulating the view and controlling perspective*," for information on the view manipulation tools.)

   The view manipulations will be applied either to all the visible layers or to only the current layer, depending on your selection in Step 2. The 3D compass can be used only to manipulate all of the visible layers; it is not available when you are manipulating only the current layer.
4. With the overlay plot displayed in the viewport, you can click **Plot Single** in the **Overlay Plot Layer Manager** to exit the overlay plot state.

   The overlay plot disappears from the viewport, and the display returns to the previous plot state; but the **Overlay Plot Layer Manager** remains open. Click **Dismiss** to close the **Overlay Plot Layer Manager**.

Tip: You can also click the  tool in the toolbox to switch between the single plot and overlay plot state at any time.

Additional information

- *Understanding how to overlay plots*
- *Producing and modifying overlay plots*

Editing the layers in an overlay plot

You can change the model, plot state, plot options, animation controls, or field output variable options for each layer in an overlay plot.

1. Create an overlay plot using the procedure described in *Producing an overlay plot*.
2. Click in the **Current** column next to the layer that you want to modify.
3. To change the model, open a new output database. (For more information, see *Opening a model database or an output database*.)
4. To change the plot type, select a new plot type from the **Plot** menu or from the plot tools in the toolbox.
5. To change the plot state-independent or plot state-dependent customization options, select new options from any of the following dialog boxes:

   - **Viewport Annotation Options**
   - **ODB Display Options**
   - **Result Options**
   - **Common Plot Options**
   - **Superimpose Plot Options**
   - **Contour Plot Options**
   - **Symbol Plot Options**
   - **Material Orientation Plot Options**

   For more information, see *Using viewport annotation options*, *Selecting result options*, or *Customizing plot display*."

   Click **OK** or **Apply** in each dialog box to implement your changes in the current layer of the overlay plot.

6. You can synchronize the visible layers by clicking any of the  icons under **Layer Options** in the **Overlay Plot Layer Manager**: **View manipulation layer**, **Plot state layer**, or **Plot options layer**.
7. Change any of the animation options desired. For more information, see *Object-based animation*, and *Controlling animation playback*.
8. Change the field output variable options desired. For more information, see *Selecting field output variables*.
9. You can synchronize the field output variable options of the visible layers by clicking the  icon next to **Field Output layer**.
10. Repeat Step 2 through Step 8 for each layer that you wish to modify.
11. With the overlay plot displayed in the viewport, you can click **Plot Single** in the **Overlay Plot Layer Manager** to exit the overlay plot state.

    The overlay plot disappears from the viewport, and the display returns to the previous plot state; but the **Overlay Plot Layer Manager** remains open. Click **Dismiss** to close the **Overlay Plot Layer Manager**.

Tip: You can also click the  tool in the toolbox to switch between the single plot and overlay plot state at any time.

Cutting through a model

View cuts allow you to cut through a model so that you can visualize the interior or selected sections of the model and, for results data in the Visualization module, display its resultant forces and moments.

In this section:

- *Understanding view cuts*
- *Managing view cuts*

Understanding view cuts

View cuts allow you to cut planar or deformable sections through a model to see the interior of the model. You can define and use view cuts during both modeling and postprocessing activities, though some aspects of view cut functionality are available only for one of these activities. This section describes the view cut functionality; unless otherwise noted, the view cut functionality described is available for both modeling and postprocessing.

Figure 1 shows how a planar view cut can be used to cut through a contour plot of a gearbox model in the Visualization module.

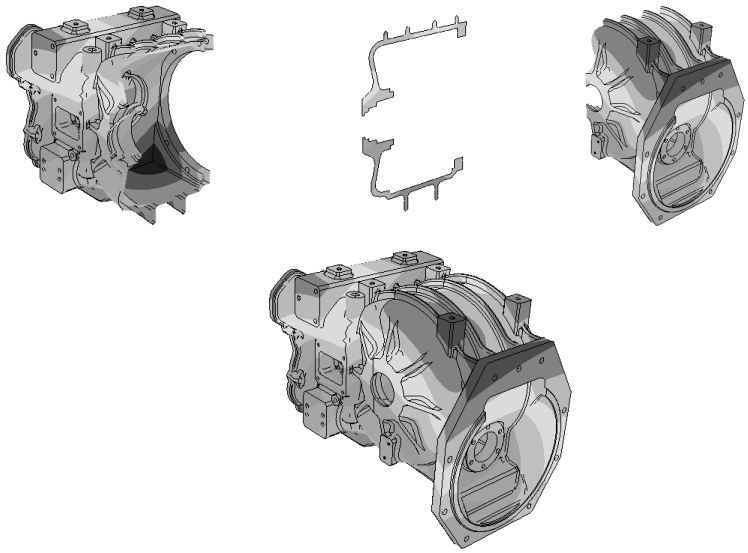

Figure 1: Planar view cut through a contour plot of a gearbox model. Top, left to right: the model below the cut, on the cut, and above the cut; bottom: the entire model.

View cut shapes

You can create view cuts based on a plane. In the Visualization module you can also create view cuts based on the following shapes:

- a cylinder,
- a sphere, or
- an isosurface corresponding to a constant value of a field variable or model attribute.

The types of shapes for view cut creation are illustrated in *Figure 2*.

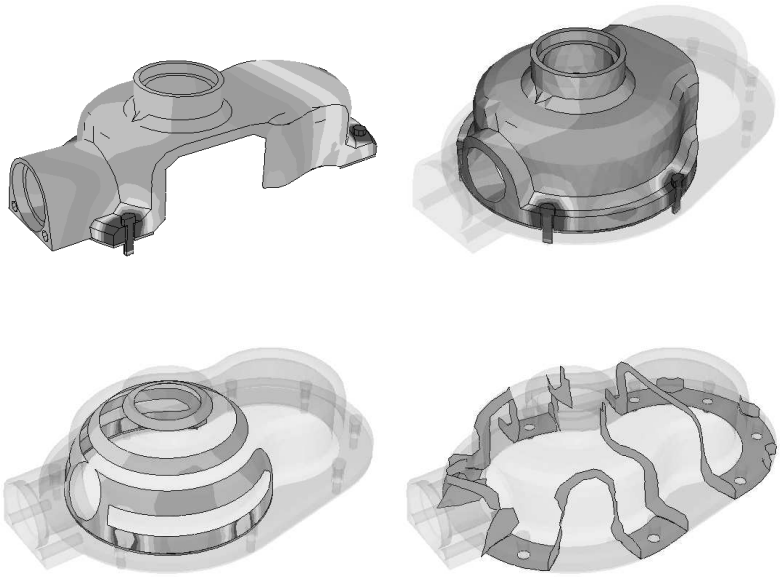

Figure 2: View cuts based on planar, cylindrical, spherical, and isosurface shapes.

For isosurface cuts the result values are computed as described in *Understanding how contour values are computed*, for line- and banded-type contours. By default, Abaqus/CAE applies an averaging threshold of 100% for isosurface cuts to insure the continuous display of results at the cut location. You can apply an averaging threshold less than 100% by toggling off **Override primary variable averaging** when you create the isosurface cut. Abaqus/CAE then applies the averaging threshold specified in the **Averaging** options in the **Result Options** dialog box; for more information, see *Controlling result averaging*. Cuts along the *X*-, *Y*-, and *Z*-planes are created by default.

Note:

Isosurface view cuts offer slightly different functionality and behavior than isosurface-type contour plots. An isosurface view cut always reflects the results of the primary variable that was active when the view cut was created; you cannot change the variable for which an isosurface view cut displays results. By contrast, isosurface-type contour plots always display data from the currently selected primary variable for your session. Because each isosurface view cut is tied to a single variable, you can investigate the locations where two isosurface view cuts intersect if you display multiple isosurface view cuts that are based on different output variables.

Displaying the cut section

To display the cut section of your model, you activate a cut and choose whether to display the model on the cut, above the cut, and/or below the cut, as illustrated in *Figure 1*. The cut itself is never visible. For planar cuts the portion of the model below the cut is defined as that part located on the negative side of the plane (relative to the orientation of the normal to the plane). For cylindrical and spherical cuts the portion of the model below the cut is defined as that part located at radii less than the radius of the cut shape. For an isosurface cut the portion of the model below the cut is defined as that part located at isovalues less than the specified isovalue. By default, Abaqus/CAE displays the model on and below the cut. In the Visualization module, you can display the model above the cut and the model below the cut at the same time; in all other modules, only one of these display options is available at a time.

Plot options

You can select different plot options for the portions of the model below the cut, on the cut, and above the cut; for example, in *Figure 2* some portions of the model are displayed with translucency activated, while others are displayed with no translucency.

Displaying multiple view cuts (Visualization module only)

Only one cut can be active (used to display the model in the current viewport) at a time in modules other than the Visualization module; in the Visualization module, however, you can display multiple view cuts at once. In addition, in the Visualization module you can activate view cuts on undeformed, deformed, contour (texture-mapped only), symbol, or material orientation plots. For symbol and material orientation plots, Abaqus/CAE displays symbols and material orientation triads at all integration points for each element included in the view, even if the element is partially cut.

Animation of view cuts (results data only)

Plots with an active view cut can be animated for output database data in the Visualization module; the view cut will be updated for each animation frame. View cuts cannot be activated on tessellated contour plots; swept, shrunk, or extruded plots; or highly refined plots (medium, fine, or extra fine).

Results caching

By default, Abaqus/CAE caches the result values used to generate images of a cut model in memory to improve performance. However, you can disable results caching for cut fields to decrease memory usage if necessary; see *Controlling results caching*, for more information.

Following the deformation

For plots of the deformed model, you can choose to have the cut follow the deformation; i.e., the cut surface will be calculated relative to a reference frame, and the cut deformation will match the deformation of the model.

Repositioning view cuts

You can reposition cuts on your model: planar cuts can be rotated or translated, while the other cut shapes can only be translated.

View Cut Manager

You can select a cut (either active or inactive) in the **View Cut Manager** to position, edit, copy, rename, or delete it. Selecting a cut in the manager is not the same as activating the cut. A cut can be both selected and active, unselected and active, or selected and inactive; and you can display or hide a free body cut for the currently displayed view cut if it is active. You can specify free body options that are common to all view cuts or that are specific to a particular view cut. *Figure 3* shows an example of the information displayed in the view cut manager in the Visualization module; in other modules, the free body display and cut-specific options are not included in this dialog box.

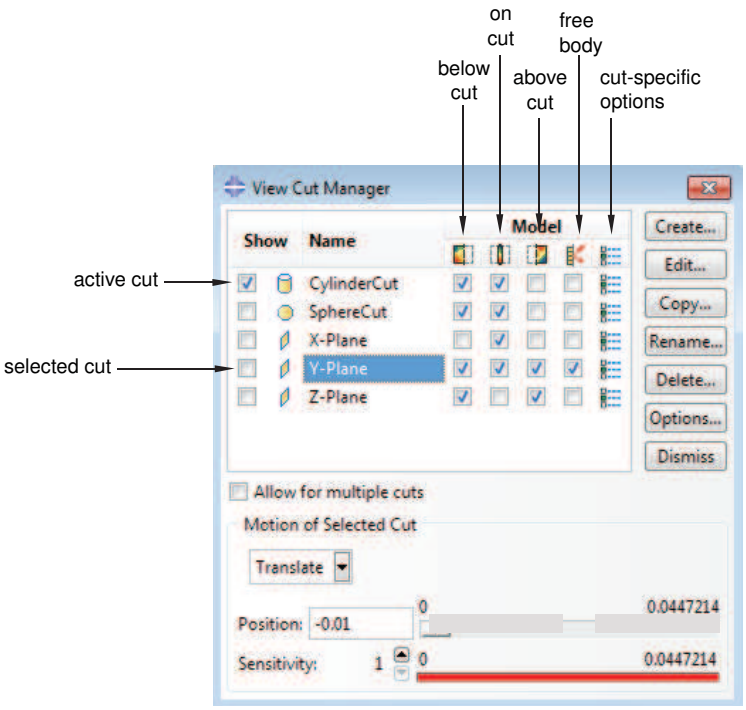

Figure 3: The View Cut Manager dialog box in the Visualization module.

Resultant forces and moments on view cuts (results data only)

For view cuts of output database data in the Visualization module you can also display the resultant forces and moments, and you can compute these values based on a display group, an element set, or the entire model. You can display the resultant force and moment on a view cut only for solid geometry, composite solid sections, shell sections, or beam sections. For resultant forces and moments to be displayed, the output database must include element force nodal output (NFORC) for composite solid sections and section force (SF) and section moment (SM) output for shell sections and beam sections. Abaqus/CAE does not support display of resultant forces and moments on view cuts for axisymmetric models. You can display the resultant force and moment on a view cut for any of the displayed view cuts in your session. Abaqus/CAE updates the resultant force and moment vectors and summation point as you reposition the view cut or animate the model.

You may observe different values for the resultant forces and moments if you compare the values in the deformed and undeformed shape plots. These differences can occur because view cut–based free body force computations integrate the stress field over the area, and, if you toggle the plot state, the elements that are part of the view cut can change or the elemental deformations can change the area of the cross section.

By default, Abaqus/CAE displays vectors on the view cut only, showing the resultant force and moment across the view cut. However, you can also display a series of vectors that show resultant force and moment data at regular intervals in your model. This series of resultant force and moment vectors can run through the entirety of your model or within a user-specified region.

XFEM-based view cut components (results data only)

Abaqus/CAE automatically creates and displays a view cut when you open an output database containing a crack calculated by the extended finite element method (XFEM). The view cut displays the model at the isosurface where the value of the signed distance function is zero, which corresponds with the surface of the XFEM crack. Boundary conditions are not displayed while an XFEM crack view cut is active.

The tools in the **View Cut Manager** operate as follows for XFEM cracks:

- The below cut  check box displays the entire model, except for the XFEM crack.
- The on cut  check box displays the isosurface where the value of the signed distance function is zero, which corresponds with the surface of an XFEM crack.
- The above cut  check box is not used by an XFEM crack.

Optimization-based view cut components (results data only)

Abaqus/CAE automatically creates and displays a view cut when you open an output database created by an optimization process, for both topology and shape optimizations. By default, the view cut displays the model at the isosurface where the value of the material property is zero, which corresponds with elements that have a density and stiffness close to zero and consequently play an insignificant role in the strength of the model. Boundary conditions are not displayed while an optimization view cut is active.

The tools in the **View Cut Manager** operate as follows for optimizations:

- The below cut  check box displays the material that has a property less than the value of the slider. By default, this is the material that is not contributing to the strength of the model.
- The on cut  check box displays the isosurface where the material has a property equal to the value of the slider.
- The above cut  check box displays the material that has a property greater than the value of the slider. By default, this is the material that continues to contribute to the strength of the model.

Consideration for small faces

A view cut may display inconsistent results if the area of one or more faces of the part is less than 1E–6 because faceting of such small faces is not possible.

Managing view cuts

The view cut manager allows you to create a view cut and to activate, reposition, edit, copy, rename, delete, or customize a previously created view cut.
When you display view cuts for output database data in the Visualization module, the manager also enables you to activate and deactivate display of the resultant forces and moments for the displayed view cut. This section describes how to create and manage view cuts and, for results data in the Visualization module, the display of their associated resultant force and moment vectors.

In this section:

- *Creating or editing a view cut*
- *Displaying a cut section and its resultant force and moment vectors*
- *Allowing for multiple free body cuts*
- *Repositioning a view cut*
- *Copying, renaming, and deleting a view cut*
- *Customizing the cap color for a view cut*
- *Customizing the cut model display in the Visualization module*
- *Customizing display and calculation of resultant force and moment on the active view cuts*
- *Customizing slicing options*

Creating or editing a view cut

You can create view cuts based on a plane. In addition, in the Visualization module, you can create view cuts based on a cylinder, a sphere, or an isosurface corresponding to a constant value of any contour variable. Cuts along the *X*-, *Y*-, and *Z*-planes are created by default.

When you edit an isosurface view cut, Abaqus/CAE updates its definition so that it reflects the current result options and variable selection.

1. Locate the options for creating or editing a view cut.

   - To create a view cut, select **Tools->View Cut->Create** from the main menu bar.

     The **Create Cut** dialog box appears.

   - To edit a previously created view cut, select **Tools->View Cut->Edit** from the main menu bar. From the menu that appears, select the view cut you want to edit.

     The **Edit Cut** dialog box appears.

   Tip: You can also use the view cut manager to create or edit a view cut. From the main menu bar, select **Tools->View Cut->Manager**. To create a view cut, click **Create**. To edit a view cut, select it from the list and double-click on it or click **Edit**.

2. Type a name for the view cut. For more information on naming objects, see *Using basic dialog box components*. You cannot change the name in the **Edit Cut** dialog box, but you can rename a view cut (see *Copying, renaming, and deleting a view cut*).
3. If the **Shape** text field appears in the editor, select the cut shape. Click the arrow next to the **Shape** text field, and select a shape from the list that appears: **Plane**, **Cylinder**, **Sphere**, or **Isosurface**. The shape cannot be changed once the cut has been created.

   The **Shape** text field can be edited only for view cuts created in the Visualization module.
4. If you select **Isosurface** as the cut shape, the cut will be created on a constant value of the current primary field output variable. Toggle on **Override primary variable averaging** to apply a variable averaging threshold of 100% for the selected view cut, or toggle off this option to use the variable averaging threshold specified in the **Averaging** options in the **Result Options** dialog box; for more information, see *Controlling result averaging*

   Isosurface cuts cannot be created for variables stored on surfaces, since no information is available for the interior of the model. See *Selecting the primary field output variable*, for information on changing the primary field output variable.
5. By default, the cut is defined on the displayed frame, and the structure moves through the cut as it deforms. Toggle on **Follow model deformation** to define a Lagrangian cut; i.e., the cut is defined on a reference frame and deforms with the model when you display a different frame. Choose the **Reference frame** to be the **First**, **Last**, or **Current** frame of the analysis.

   The **Follow model deformation** option is available only for view cuts in the Visualization module.
6. For planar, cylindrical, or spherical view cuts in the Visualization module, toggle on the method you wish to use to define the view cut values: **Key-in** or **From CSYS** (the latter option is available only if the output database contains a coordinate system or if you have created a coordinate system in the current session).

   a. If you select the **Key-in** method, enter the coordinates for the following points, depending on the cut shape:

- For **Plane** cuts, enter the coordinates for the origin; the normal axis; and, optionally, axis 2. Axis 2 is an axis lying in the plane; the view cut can be rotated about this axis or about Axis 3, defined as the axis orthogonal to the normal axis and to Axis 2. See *Repositioning a view cut*.
- For **Cylinder** cuts, enter the coordinates for the origin and the cylinder axis.
- For **Sphere** cuts, enter the coordinates for the origin.

b. If you select the **From CSYS** method, choose a coordinate system from the list that appears (systems designated with an asterisk have been saved to the current output database), and select the following, depending on the cut shape:

- For **Plane** cuts, select **Axis 1**, **Axis 2**, or **Axis 3** of the coordinate system to be the normal axis. The cut can be rotated about either of the other two coordinate system axes; see *Repositioning a view cut*.
- For **Cylinder** cuts, select **Axis 1**, **Axis 2**, or **Axis 3** of the coordinate system to be the cylinder axis.
- For **Sphere** cuts, the origin of the coordinate system will be the origin of the cut; you do not need to select anything else.

The **From CSYS** option is available only for view cuts in the Visualization module.

7. Click **OK** to close the **Create Cut** or **Edit Cut** dialog box.

When you create a new view cut, it is activated automatically (i.e., used to display the model in the current viewport). By default, the cut is positioned halfway through the model.

By default, view cuts persist only for the duration of your session. If you want to retain a view cut that you have defined to make it available in subsequent sessions, you can save it to an XML file, to the model database, or to an output database. For more information, see *Managing session objects and session options*.

Additional information

- *Creating coordinate systems during postprocessing*
- *Understanding view cuts*

Displaying a cut section and its resultant force and moment vectors

To display the cut section of your model, you activate a view cut and choose whether to display the model on the cut, below the cut, and/or above the cut. The cut itself is not visible. In the Visualization module you can display the model both below the cut and above the cut; in all other modules, you can display one view or the other.

In the Visualization module you can activate multiple view cuts; in all other modules, only one view cut can be active at a time. For each view cut in the Visualization module, you can also display the resultant force and moment based on a display group, an element set, or the entire model. You can specify free body options that are common to all view cuts or that are specific to a particular view cut.

For view cuts displaying data from an output database, you can also display the resultant force and moment vectors at regular intervals through the model for the selected view cut. For more information, see *Customizing display and calculation of resultant force and moment on the active view cuts*.

The activation status of each view cut persists only for the duration of your session. If you want to retain this view cut activation status for subsequent sessions, you can save these data to an XML file, to the model database, or to an output database. For more information, see *Managing session objects and session options*.

1. From the main menu bar, select **Tools->View Cut->Manager**.

   The **View Cut Manager** appears with a list of all the view cuts that have been created during the current session. A check mark appears in the **Show** column to the left of the active view cut.

2. Click the check box in the **Show** column to the left of the view cut you wish to activate or deactivate.

   The active view cut is used to cut through the model in the current viewport.

   Tip: You can also activate or deactivate a view cut using one of the following methods:

   - In any module other than the Visualization module, click the tool in the View Cut toolbar.
   - In the Visualization module, click the tool in the toolbox.

   If no view cut is active, selecting either of these tools will activate the first view cut in the list in the **View Cut Manager** (usually the default *X*-plane cut). If a view cut is active, selecting this tool will deactivate the cut.

3. Click the check boxes in the **Model** columns to the right of the view cut to display the model below , on , and/or above the cut (these positions are not mutually exclusive).

   The selected portion of the model is displayed in the viewport.

4. If you are working in the Visualization module, click the check box under the icon in the **Model** columns for the active view cut to display the resultant force and moment along that view cut, acting on the visible component. For example, you will see equal and opposite resultant force and moment vectors when you switch from the “Show below cut” option to the “Show above cut” option.

   To specify free body options for a particular view cut, click the icon to the right of the view cut for which you want to specify options.

   Note:

   The **View Cut Options** (common to all view cuts or specific to a particular view cut) enable you to control three aspects of the resultant force and moment display on view cuts. You can

compute the resultant force and moment based on a display group, an element set, or the whole model; and you can adjust the summation point and component resolution. You can enable display of the resultant force and moment on a view cut for solid geometry, composite solid sections, shell sections, or beam sections. For resultant forces and moments to be displayed, the output database must include element force nodal output (NFORC) for composite solid sections and section force (SF) and section moment (SM) output for shell sections and beam sections. For more information, see *Customizing display and calculation of resultant force and moment on the active view cuts*.

5. In the Visualization module, toggle on **Allow for multiple cuts** to enable the display of multiple view cuts.

Additional information

- *Using the extended finite element method to model fracture mechanics*
- *Creating or editing a view cut*

Allowing for multiple free body cuts

In the Visualization module you can display multiple view cuts on your model at the same time by toggling on **Allow for multiple cuts**. When you select this option, Abaqus/CAE displays the cutting surface for all view cuts in your session for which the **Show** checkbox is selected. You can reposition only the active view cut. In practice, you might want to activate and reposition each view cut in turn to place them in the locations you want to investigate. In addition, the cuts you display do not interact; for example, you cannot display only the portion of your model that lies between two parallel planar view cuts.

Note:

Abaqus/CAE does not support display of multiple XFEM-based view cut components at the same time.

1. From the main menu bar, select **Tools->View Cut->Manager**.

   The **View Cut Manager** appears with a list of all the view cuts that have been created during the current session. A check mark appears in the **Show** column to the left of the active view cut.

2. Toggle on **Allow for multiple cuts**.

   Abaqus/CAE displays the on-cut position for every view cut for which the **Show** checkbox is selected, and Abaqus/CAE hides all free body cuts and disables the check boxes under the  icon in the **Model** columns. You can show or hide individual view cuts from the current display by toggling their **Show** checkboxes.

Additional information

- *Using the extended finite element method to model fracture mechanics*
- *Creating or editing a view cut*

Repositioning a view cut

By default, when a view cut is first activated, Abaqus/CAE positions it halfway through the model. You can use the view cut manager to reposition cuts on the model. You can translate plane cuts along the normal axis or rotate them about the other two axes. You can redefine the radius of cylindrical or spherical cuts and the contour value used for isosurface cuts to reposition where they cut through the model. The positioning options in the view cut manager apply only to the selected cut, which may be different from the currently active cut.

In all modules except the Visualization module, Abaqus/CAE repositions the cutting plane back to the halfway point if you modify the model.

1. From the main menu bar, select **Tools->View Cut->Manager**.

   The **View Cut Manager** appears with a list of all the view cuts that have been created during the current session.

2. Select a view cut in the manager by clicking on its name.

   The selected view cut is highlighted in the manager.

3. To translate a **Plane** view cut:

   1. Select **Translate** from the menu at the bottom of the view cut manager.
   2. Reposition the view cut using one of the following methods:

      - Enter a value for the **Position** along the normal axis.
      - Drag the **Position** slider to select a value. The slider is available only if the view cut is currently active.
      - Increase the **Sensitivity** of the slider for fine control over view cut repositioning. Each sensitivity increment focuses the slider's range of motion by a factor of 10, so a sensitivity setting of 100 enables you to reposition a view cut within 1/100 of the model.

        Alternatively, you can double-click a location in the **Sensitivity** bar to reposition the view cut to a general location, then drag the **Position** slider to select a value.

      The selected cut is translated by the specified value.

4. To rotate a **Plane** view cut:

   1. Select **Rotate** from the menu at the bottom of the view cut manager.
   2. Select the axis of rotation (the 2- or 3-axis for a cut defined by the **Key-in** method or either of the two non-normal axes for a cut defined by the **From CSYS** method; see *Creating or editing a view cut*); and enter a value for the **Angle** of rotation, or use the slider to select a value.

      The selected cut is rotated about the origin of the axis of rotation by the specified angle. Any translations applied to the view cut are ignored.

5. To reposition a **Cylinder**, **Sphere**, or **Isosurface** view cut, enter a value in the available text field, or use the slider to select a value. The slider is available only if the view cut is currently active; you can increase the slider's sensitivity for greater precision.

   - For **Cylinder** cuts enter a value for the **Radius** of the cylinder.
   - For **Sphere** cuts enter a value for the **Radius** of the sphere.
   - For **Isosurface** cuts enter a value for the contour **Value** to which the cut should correspond.

The selected cut is repositioned as specified.

Additional information

• *Creating or editing a view cut*

Copying, renaming, and deleting a view cut

You can copy, rename, or delete a view cut using commands from the main menu bar or the view cut manager.

To copy, rename, or delete a view cut, use one of the following:

- The **Copy**, **Rename**, and **Delete** items listed under the **Tools->View Cut** menu on the main menu bar.

  The **Copy**, **Rename**, and **Delete** items contain submenus listing all the view cuts you have created.
- The view cut manager dialog box. The view cut manager contains functions identical to those listed under the **Tools->View Cut** menu on the main menu bar but with a convenient browser that lists all the view cuts. To display the view cut manager dialog box, select **Tools->View Cut->Manager** from the main menu bar.

Note:

Abaqus/CAE creates a view cut when you open a model containing a crack calculated by the extended finite element method (XFEM) and when you open a model created by an optimization process. You cannot create, delete, or edit an XFEM view cut or an optimization view cut.

Additional information

• *Creating or editing a view cut*

Customizing the cap color for a view cut

In modules other than the Visualization module, you can customize the “cap” that appears when you display the portion of the cutting plane on the view cut.

The **Cap Color** options provide two choices for customizing the cap color:

- Select **Specify** and click  to display the entire cap with a fixed color. Abaqus/CAE displays that color for all components on the cutting plane and does not change the color as you move the plane or change the color coding selections.
- Select **Use body color** to display the current colors of each component in the model on the cutting plane. Abaqus/CAE changes the coloring of the model components on the cutting plane dynamically as you reposition the plane or change the color coding selections.

Note:

Abaqus/CAE displays different cap colors for different parts; however, Abaqus/CAE does not display a different cap color for different sections, materials, mesh defaults, etc., in the same part.

Abaqus/CAE hides the cap from the viewport if you toggle on translucency for your session; for more information, see *Changing the translucency*. In addition, Abaqus/CAE might hide the cap when you save or export the contents of the viewport, depending on the file format you select.

- If you save a viewport image to a file and select a vector-based file format, Abaqus/CAE hides the cap in the resulting file. Abaqus/CAE creates a vector-based file when you save the image in **SVG** format or when you save the image in **PS** or **EPS** format and specify **Vector** as the **Image format** from the **PS Options** dialog box or the **EPS Options** dialog box.
- If you export viewport data in either VRML or 3DXML format, Abaqus/CAE hides the cap in the exported file. The cap is included in the exported file for all other export formats.

1. From the main menu bar, select **Tools->View Cut->Manager**.

   The **View Cut Manager** dialog box appears.
2. Click **Options**.

   The **View Cut Options** dialog box appears.
3. From the list of **Cap Color** options, select one of the following:

   - Select **Specify** and click , then select a cap color from the **Select Color** dialog box that appears to display the selected color for the entire portion of the model displayed on the cut. For more information about selecting a new color, see *Customizing colors*.
   - Select **Use body color** to color the cap using the current color coding settings for each component that intersects the view cut.
4. Click **OK**.

Additional information

- *Controlling the destination and appearance of printed images*
- *Exporting geometry, model, and mesh data*

Customizing the cut model display in the Visualization module

You can use the view cut options to customize the appearance of a cut model in the Visualization module. You can select different options for the portions of the model below the cut, on the cut, and above the cut.

You can choose to apply the view cut options to the model or to use the current plot options. View cut options related to the cut model display are associated with the viewport rather than with an individual view cut; therefore, if the view cut options are applied to the model, any active cut will use them. *Figure 1* illustrates how the view cut options can be used to customize the model on the cut plane.

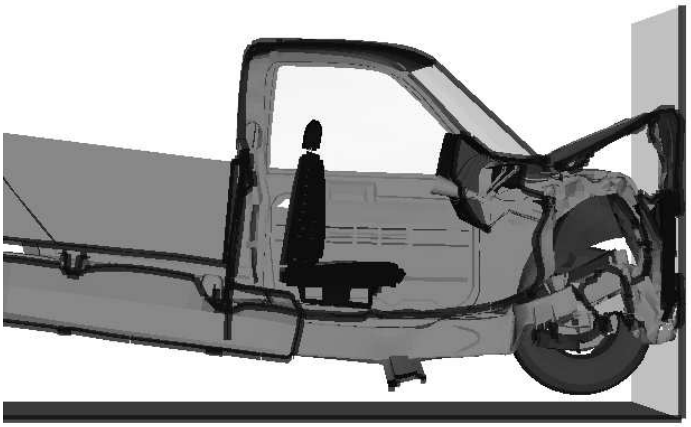

Figure 1: Longitudinal view cut through a truck model with customized plot options on the cut plane.

1. From the main menu bar in the Visualization module, select **Options->View Cut**.
   The **View Cut Options** dialog box appears.

   Tip: You can also use the view cut manager to customize the cut options. From the main menu bar, select **Tools->View Cut->Manager**, and click **Options** in the view cut manager.

2. Select the portion of the model that you wish to customize by clicking one of the following tabs: **Below Cut**, **On Cut**, **Above Cut**.
3. Toggle on **Use these options** to apply the view cut options to the selected portion of the model. Alternatively, toggle on **Use current plot options** to apply the common plot options or, if applicable, superimposed plot options to the selected portion of the model.
4. Click the following tabs to customize the appearance of view cuts in the current viewport:
   - **Basic**: Choose render style and edge visibility.
   - **Color & Style**: Control model edge color and style and model face color.
   - **Other**: The **Other** page contains the following tab:
     - **Translucency**: Control shaded render style translucency.

   To learn how to customize the render style and other display characteristics of your view cut, see *Customizing plot display*.

Customizing display and calculation of resultant force and moment on the active view cuts

You can use the free body options for view cuts in the Visualization module to customize how the resultant force and moment displayed on the active view cut are calculated and to customize the summation point and coordinate system transformation.

You can specify free body options that are common to all view cuts or that are specific to a particular view cut. Abaqus/CAE can calculate the resultant force and moment by cutting through a display group, an element set, or the whole model. You can also customize the content and appearance of all free body cuts in the current viewport; see *Customizing general display options for free body cuts*.

Display of resultant force and moment data is available for view cuts of output databases only. You cannot display this data for view cuts when a model from the current model database is displayed in the Visualization module.

You may observe different values for the resultant forces and moments if you compare the values in the deformed and undeformed shape plots. These differences can occur because view cut–based free body force computations integrate the stress field over the area, and, if you toggle the plot state, the elements that are part of the view cut can change or the elemental deformations can change the area of the cross section.

By default, Abaqus/CAE displays the resultant force and moment only once for each view cut for which you toggle on display of the resultant force and moment. If desired, you can also display a series of vectors that show the resultant force and moment data at regular intervals through the entire model or through a portion of the model.

1. From the main menu in the Visualization module, select **Options->View Cut**.

   The **View Cut Options** dialog box appears.

   Tip: You can also use the view cut manager to customize the cut options using one of the following methods:

   - To specify options common to all view cuts, select **Tools->View Cut->Manager** from the main menu bar, and click **Options**.
   - To specify options for a particular view cut, select **Tools->View Cut->Manager** from the main menu bar, and click the  icon to the right of the view cut for which you want to specify options.

2. Click the **Free Body** tab.
3. If you are defining cut-specific options, select **Use these options**.
4. From the **Computation based on** options:

   - Select **Cutting through a display group** and select a display group to compute the resultant force and moment based on a view cut through the selected display group. By default, the current display group is selected.
   - Select **Cutting through an element set** and select an element set in the output database to compute the resultant force and moment based on a view cut through the selected set.
   - Select **Cutting through the whole model** to compute the resultant force and moment based on a view cut through the entire model.

5. If desired, customize the summation point or the coordinate system transformation options for the resultant force and moment vectors arising from view cuts.

   a. From the **Summation point** options, select the three-dimensional location from which the resultant force and moment vectors originate.

      - Select **Centroid of cut** to place the summation point automatically at the centroid of the surface of the view cut.

Note:

When the view cut cuts through a shell, the centroid is based on the length times the shell thickness.

When the view cut cuts through a beam, the centroid is at the nodal connectivity line.

- Select **User-defined**, and specify a custom three-dimensional location in space or click to select the summation point from the viewport. The summation point is highlighted in the viewport.

b. From the **Component resolution** options, you can specify the coordinate system transformation that takes place when vectors are displayed in component form. (See *Customizing general display options for free body cuts*, for more information about displaying force and moment vectors in component form.)

- Select **Normal and tangential** to orient the component vectors with the normal and the tangent of the surface you select.

  If desired, specify the *Y*-axis value of the tangent for the component vectors. This option enables you to enforce a uniform direction for the tangent vector when you display a series of free body cuts on view cut slices.

- Select **CSYS** and a coordinate system to transform the component vectors to a custom coordinate system. Alternatively, you can click **Create** to create a new datum coordinate system.

The **Component resolution** options affect the display of resultant forces and moments only when component vector display is selected in the **Free Body Plot Options** dialog box.

6. Toggle on **Show heat flow rate if available** to display the heat flow rate in terms of energy per time across the view cut.
7. If you want to customize the content and appearance of the free body cut displayed on the active view cut and those created using the Free Body toolset, click to access the **Free Body Plot Options**; this option is unavailable if you are defining cut-specific options. See *Customizing general display options for free body cuts*.
8. Click **OK**.

   By default, view cuts persist only for the duration of your session. If you want to retain a view cut that you have defined to make it available in subsequent sessions, you can save it to an XML file, to a model database, or to an output database. For more information, see *Managing session objects and session options*.
9. Click **Apply** to implement your changes.

   The view cuts change to reflect your specifications.

   By default, your changes are saved for the duration of the session and will affect all subsequent view cuts in that viewport. If you want to retain your changes for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

Customizing slicing options

View cut slices are similar to the on-cut portion of a view cut, but they are displayed at a series of intervals along the range of the active view cut, rather than on just the cutting plane itself.
You can use the settings on the **Slicing** tabbed page in the Visualization module to display a series of view cut slices along the range of the active view cut. You can display view cut slices at regular intervals along the range of the active view cut, or you can display the slices along a predefined path in your session. When you enable slicing, you can also display the resultant force and moment at that location of the model.

You can specify slicing options that are common to all view cuts or that are specific to a particular view cut. View cut slicing can be enabled only when a single view cut is active and only in the Visualization module. However, if you define cut-specific slicing options and obtain reports for multiple active view cuts, the slicing options are considered in the free body computations. You can display slices for both translational and rotational view cut display. Slices are displayed along the entire range of the active view cut regardless of any repositioning of the view cut in the **Motion of Selected Cut** options in the **View Cut Manager**. For rotational view cuts, you can also rotate the slices and change their axis of rotation.

If you enable view cut slicing along a path in a model that has a great deal of folding or curvature, the cutting surfaces of the slices can sometimes cross different parts of your model at the same time. You can limit or eliminate this behavior by focusing on a subset of your model: either use a display group to hide a portion of your model or change the path definition so that slicing is displayed only along some of the curved parts.

1. From the main menu bar in the Visualization module, select **Options->View Cut**.

   The **View Cut Options** dialog box appears.

   Tip: You can also use the view cut manager to customize the cut options using one of the following methods:

   - To specify options common to all view cuts, select **Tools->View Cut->Manager** from the main menu bar, and click **Options**.
   - To specify options for a particular view cut, select **Tools->View Cut->Manager** from the main menu bar, and click the  icon to the right of the view cut for which you want to specify options.

2. Click the **Slicing** tab.
3. If you are defining cut-specific options, select **Use these options**.
4. Toggle on **Display slicing** to enable slicing for view cuts in your session.
5. If you want to display view cut slices along the entire range of the view cut, select **Step through the active view cut's range**. If you display view cut slices or free body cuts in multiple locations for the selected view cut, you can also customize the minimum and maximum values of the line segment within which Abaqus/CAE will display the resultant forces and moments. By default, the minimum and maximum values are set to allow for distribution of slices throughout the entire model.
6. If you want to display view cut slices along a predefined path, select **Step along a predefined path**, then do the following:
   a. Select the path.
   b. Specify the locations where you want to display view cut slices using the **Display slices at path nodes** option:
      - Toggle on this option to place the view cut slices at the nodes that comprise the path definition.
      - Toggle off this option to place the view cut slices at a number of regular intervals along the path. Specify the number of slices from the field and slider at the bottom of the dialog box.

c. Specify the location of the summation point for the resultant forces and moments using the **Set free body summation point on the path** option:

- Toggle on this option to place the summation point for the resultant forces and moments on the selected path.
- Toggle off this option to place the summation point for the resultant forces and moments at the location about which resultant moments are taken.

7. Click **Apply** to implement your changes.

The view cuts change to reflect your specifications.

By default, your changes are saved for the duration of the session and will affect all subsequent view cuts in that viewport. If you want to retain your changes for subsequent sessions, save them to a file. For more information, see *Saving customizations for use in subsequent sessions*.

Using plug-ins

This part of the guide describes how you can use plug-ins and the Plug-in toolset to extend the capabilities of Abaqus/CAE.

In this section:

- *The Plug-in toolset*
- *Abaqus plug-ins*

The Plug-in toolset

The Plug-in toolset loads plug-in files into Abaqus/CAE.

In this section:

- *What is a plug-in?*
- *Where can I get plug-ins?*
- *How can I get information about a plug-in?*
- *An example of a Python module and a function*
- *What can I do with a GUI plug-in?*
- *How do I make a plug-in available from Abaqus/CAE?*
- *How are kernel plug-ins executed?*
- *Overwriting plug-ins*
- *How are GUI plug-ins executed?*
- *Hiding a plug-in's source code*
- *Displaying exceptions for imported plug-ins at startup*
- *Abaqus/CAE modules and plug-ins*
- *How can I provide information about a plug-in?*

What is a plug-in?

A plug-in is a piece of software that installs itself into another application to extend the capabilities of that application. Abaqus plug-ins execute Abaqus Scripting Interface and Abaqus GUI Toolkit commands, and they provide a way to customize Abaqus/CAE for your particular needs or preferences. For example, a simple plug-in could automatically print the contents of the current viewport according to some predefined options. A more complex plug-in could provide a graphical user interface to a specialized postprocessing routine that you have written.

There are two types of plug-ins: kernel and GUI. A kernel plug-in consists of functions written using the Abaqus Scripting Interface. In contrast to a kernel plug-in, a GUI plug-in is written using the Abaqus GUI Toolkit and contains commands that create graphical user interfaces, which in turn send commands to the kernel. Both kernel and GUI plug-ins are available from the **Plug-ins** menu on the main menu bar or from a plug-ins toolbox.

By default, several kernel and GUI example plug-ins are available from the **Plug-ins** menu on the main menu bar. You can use these examples to see how plug-ins are created and to learn how plug-ins interact with Abaqus/CAE. In addition, you can access two example plug-ins from a plug-ins toolbox. When you select **Plug-ins->Toolboxes->Examples** from the main menu bar, Abaqus/CAE displays the **Examples** toolbox. You can click an icon in the toolbox to start a plug-in. *Figure 1* shows the **Toolboxes** menu and the **Examples** toolbox.

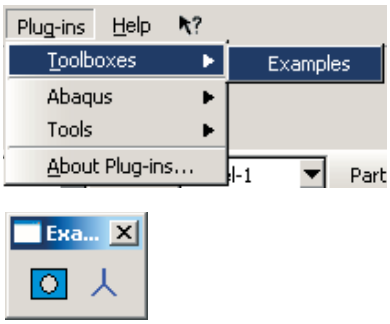

Figure 1: The Toolboxes menu and the Examples plug-in toolbox.

Where can I get plug-ins?

Several plug-ins are provided with the Abaqus installation.
You can view these plug-ins by selecting **Plug-ins->Abaqus** or **Tools** from the main menu bar.

For information on how to view a document that describes the plug-in and its usage, see *How can I get information about a plug-in?*.

Additional plug-ins are available in the SIMULIA Community (*SIMUILA Community > Learning Resources > 3DEXPERIENCE and Traditional Products > Abaqus > Plug-ins/Scripts*), which provides example plug-ins as well as access to a community of users that fosters the advance of the Abaqus Scripting Interface and the Abaqus GUI Toolkit. Click **Blog** and filter by **Process Automation** to browse plug-in examples in this community. You can also write your own plug-ins, as described in this section.

How can I get information about a plug-in?

The **Plug-ins** menu that appears in the Abaqus/CAE main menu bar contains an **About Plug-ins** item that displays the **About Plug-ins** dialog box. This dialog box lists all the plug-ins that are currently installed. As you click on each plug-in in the tree list, Abaqus/CAE displays information about that plug-in, such as the author and the version. In addition, you can click **View** in the **About Plug-ins** dialog box to view a document that describes the plug-in. For more information, see *How can I provide information about a plug-in?*.

This information is specified as optional arguments to the plug-in registration command. As a result, if the author of the plug-in chose not to supply some of these optional arguments, the corresponding information will not be available in the **About Plug-ins** dialog box.

An example of a Python module and a function

A kernel plug-in associates a Python module and a function with a menu item or a toolbox icon. For example, the kernel plug-in shown below is a simple function defined in the file `myUtils.py` that prints the current viewport to a PNG file. The file `myUtils.py` is a Python module.

```
def printCurrentVp():

    from abaqus import session, getInputs
    from abaqusConstants import PNG
    name = getInputs( (('File name:', ''),),
        'Print current viewport to PNG file')[0]
    vp = session.viewports[session.currentViewportName]
    session.printToFile(
        fileName=name, format=PNG, canvasObjects=(vp, ))
```

The first line of the example (`def printCurrentVp():`) is a function definition that contains the indented commands. A plug-in requires a function definition. As a result, if you want to create a kernel plug-in by extracting the commands written to the `abaqus.rpy` replay file, you must first wrap the commands in a function definition. For more details on writing kernel scripts and creating function definitions, refer to the *Abaqus Scripting User's Guide* and to the *Abaqus Scripting Reference Guide*.

After you have written a kernel plug-in, you can execute it from the **Plug-ins** menu in the Abaqus/CAE main menu bar after you register it with the Plug-in toolset. For more information, see *How do I make a plug-in available from Abaqus/CAE?*.

What can I do with a GUI plug-in?

A GUI plug-in is written using the Abaqus GUI Toolkit. For more details on writing GUI scripts, refer to the *Abaqus GUI Toolkit User's Guide* and to the *Abaqus GUI Toolkit Reference Guide*. In addition to GUI commands, a GUI plug-in usually contains a kernel module that defines the function that will be executed when the GUI issues the command to the kernel. For example, you could write a GUI plug-in that presents the user with a dialog box for entering the dimensions of a plate, as shown in *Figure 1*.

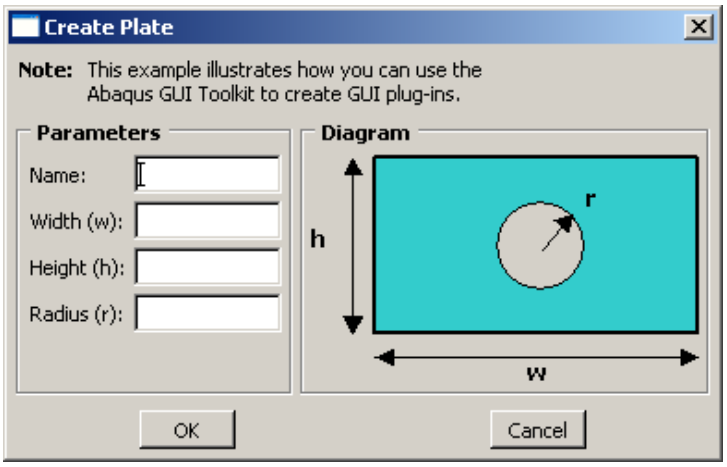

Figure 1: A dialog box for entering the dimensions of a plate.

When the user clicks the **OK** button to close the dialog box, the GUI plug-in constructs a command that is sent to the kernel for execution. The kernel function builds a part using the dimensions entered in the dialog box.

A GUI plug-in is similar to a kernel plug-in in that you must register it with the Plug-in toolset before you can execute it from the **Plug-ins** menu in the Abaqus/CAE main menu bar.

How do I make a plug-in available from Abaqus/CAE?

To make a plug-in available from Abaqus/CAE, you must place specially named files containing registration commands in one of the directories that Abaqus/CAE searches for plug-ins.
The registration commands can make a plug-in available from the **Plug-ins** menu in the main menu bar, from a separate plug-in toolbox, or from both. This section describes how you make a plug-in available from Abaqus/CAE.

In this section:

- *Where are plug-in files stored?*
- *What are the kernel and GUI registration commands?*
- *An example of adding a kernel plug-in to the Plug-ins menu*
- *An example of adding a kernel plug-in to a plug-ins toolbox*
- *An example of adding a GUI plug-in to the Plug-ins menu*

Where are plug-in files stored?

Abaqus plug-ins can be stored in several locations.
Native Abaqus/CAE plug-ins are included with the Abaqus/CAE installation. External plug-ins (any plug-in installed after the Abaqus/CAE installation) should not be placed inside the Abaqus/CAE installation.

Instead, you should install external plug-ins in any of the following locations:

- *home_dir*`\abaqus_plugins`, where *home_dir* is your home directory.
- *current_dir*`\abaqus_plugins`, where *current_dir* is the current directory.
- **plugin_central_dir** is an Abaqus environment parameter used to define one or more specific directories where plug-ins are stored. This is typically a central location accessed by all users at your site if the directory is mounted on a file system that all users can access. **plugin_central_dir** can be defined in the `abaqus_v6.env` file or the Abaqus solver `custom_v6.env` file. For example,

  ```
  plugin_central_dir = "C:\\Program
  Files\\SIMULIA\\CAE\\plugins;U:\\shared\\CAE\\plugins"
  ```

  Directories are separated by a semicolon on Windows systems or by a colon on Linux systems. For more information, see *Using the Abaqus environment files*.

Abaqus/CAE will import any files in these directories that match the naming convention `*_plugin.py`. These files must contain registration commands. The name of the file must follow the rules described in *Standard Abaqus Scripting Interface exceptions*.

What are the kernel and GUI registration commands?

The plug-in registration commands are located in the Plug-in toolset, which you can access from the main menu bar of Abaqus/CAE. To access the registration commands, your script should start with the following statements:

```
from abaqusGui import getAFXApp
toolset=getAFXApp().getAFXMainWindow().getPluginToolset()
```

You can use the `toolset` variable to do the following:

Add an item to the Plug-ins menu

The following statements add a kernel and a GUI plug-in to the **Plug-ins** menu:

```
toolset.registerKernelMenuButton()
toolset.registerGuiMenuButton()
```

Add an icon to a plug-ins toolbox

The following statements add a kernel and a GUI plug-in to a plug-ins toolbox:

```
toolset.registerKernelToolButton()
toolset.registerGuiToolButton()
```

The registration commands are described in *Plug-in registration commands*.

An example of adding a kernel plug-in to the Plug-ins menu

You use the `registerKernelMenuButton()` command to make a kernel plug-in available from the **Plug-ins** menu. The following example illustrates how you associate the simple function described in *An example of a Python module and a function*, with a **Print Current Viewport** item in the **Plug-ins** menu. (The function prints the current viewport to a PNG file.) The registration command references the kernel function `printCurrentVP` that is located in the Python module `myUtils`:

```
from abaqusGui import getAFXApp
toolset = getAFXApp().getAFXMainWindow().getPluginToolset()
toolset.registerKernelMenuButton(
    buttonText='Print Current Viewport',
    moduleName='myUtils', functionName='printCurrentVp()' )
```

The first two lines in the example provide access to the commands in the Plug-in toolset. The next line inserts a **Print Current Viewport** menu item under the **Plug-ins** menu in the main menu bar. When the user clicks **Print Current Viewport**, Abaqus/CAE issues the following command to the kernel:

```
myUtils.printCurrentVp()
```

The `buttonText` argument accepts a pipe-separated (|) list of words. The pipe separates submenu names from the menu button name. This allows you to group several plug-ins under one menu. For example, if you have defined more functions in `myUtils.py`, you can use the following version of `myUtils_plugin.py` to register them under a cascading menu:

```
from abaqusGui import getAFXApp
toolset = getAFXApp().getAFXMainWindow().getPluginToolset()
toolset.registerKernelMenuButton(
    buttonText='My Utils|Print Current Viewport',
    moduleName='myUtils', functionName='printCurrentVp()' )

toolset.registerKernelMenuButton(
    buttonText='My Utils|Print Sections',
    moduleName='myUtils', functionName='printSections()' )

toolset.registerKernelMenuButton(
    buttonText='My Utils|Print Materials',
    moduleName='myUtils', functionName='printMaterials()' )
```

The previous example results in the menu structure shown in *Figure 1*:

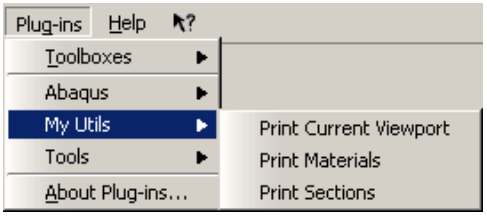

Figure 1: The effect of registering plug-ins under a cascading menu.

An example of adding a kernel plug-in to a plug-ins toolbox

You use the `registerKernelToolButton()` command to make a kernel plug-in available from a plug-ins toolbox. When you add a plug-in to a toolbox, an item appears in the **Plug-ins->Toolboxes** menu. When you select this item, Abaqus/CAE displays a plug-ins toolbox. Although you can display text in a toolbox, you will probably want to supply an icon instead and not use text (for more information on creating icons, see *Icons*).

The `registerKernelToolButton` registration command uses the same arguments as the `registerKernelMenuButton` command; however, it also requires a toolbox name. You can use the `buttonText` argument to specify only a tooltip by preceding the tip text with "\t" as shown in the following version of `myUtils_plugin.py`:

```
from abaqusGui import getAFXApp, FXXPMIcon
from myIcons import vpIconData
vpIcon = FXXPMIcon(getAFXApp(), vpIconData)

toolset = getAFXApp().getAFXMainWindow().getPluginToolset()
toolset.registerKernelToolButton(toolboxName='My Utils',
    buttonText='\tPrint Current Viewport', icon=vpIcon,
    moduleName='myUtils', functionName='printCurrentVp()' )
```

This example creates a **My Utils** item under the **Plug-ins->Toolboxes** menu. When a user clicks **My Utils**, Abaqus/CAE displays a toolbox with **My Utils** shown in its title bar. When you click the icon in the toolbox, Abaqus/CAE sends the following command to the kernel:

```
myUtils.printCurrentVp()
```

The same command would be sent to the kernel if you registered the plug-in in the **Plug-ins** menu.

The **Toolboxes** item, if it exists, always appears first in the **Plug-ins** menu; and the **About Plug-ins** item always appears last. Other items in the **Plug-ins** menu are listed alphabetically.

An example of adding a GUI plug-in to the Plug-ins menu

You use the `registerGuiMenuButton()` command to make a GUI plug-in available from the **Plug-ins** menu. The following example shows how you can use registration commands to add a GUI plug-in that creates a form that posts a dialog box prompting the user for input. When the user selects **Plug-ins->My Utility**, Abaqus/CAE activates the form.

Registration commands for kernel plug-ins must reside in a file separate from the kernel plug-in code. In contrast, registration commands for GUI plug-ins can reside in a separate file or in the GUI plug-in file itself. This example shows how you can combine the registration commands and the GUI plug-in code into a single file.

```
from abaqusGui import AFXForm, getAFXApp

class MyForm(AFXForm):

    form code goes here

toolset = getAFXApp().getAFXMainWindow().getPluginToolset()
toolset.registerGuiMenuButton(buttonText='My Utility',
    object=MyForm(toolset) )
```

When you make a GUI plug-in available from the **Plug-ins** menu or from a toolbox, the registration command references a GUI object that receives a message when the plug-in is selected. The selector of the message is generated by combining the message ID that you specify together with the `SEL_COMMAND` message type. In most cases you will supply a form or procedure as the GUI object and use `ID_ACTIVATE` (the default) for the message ID. Forms and procedures prompt the user for input, in most cases using a dialog box or the prompt line. After receiving input from the user, forms and procedures then issue commands to the kernel. For details on creating forms, procedures, and dialog boxes, see *Modes* and *Dialog boxes*. You can also create simple dialog boxes using the **Really Simple GUI Builder** plug-in; for more information, see *Creating dialog boxes with the Really Simple GUI (RSG) Dialog Builder*.

How are kernel plug-ins executed?

Abaqus executes a kernel plug-in by issuing a command to the kernel of the form *moduleName.functionName*. The module name and the function name are the names that you supplied in the registration command for that plug-in.

When Abaqus/CAE starts and imports a plug-in, the directory in which the plug-in is located is stored by Abaqus/CAE. The first time that the plug-in is invoked, Abaqus/CAE updates the kernel's *sys.path* list with that plug-in's directory. The next time that plug-in is invoked, Abaqus/CAE issues the commands inside the plug-in but does not update the *sys.path*.

For example, consider the `myUtils_plugin.py` and `myUtils.py` files described in previous sections. Assume that you stored these two files in a subdirectory called `myPlugins` in the `abaqus_plugins` directory in your home directory. The first time that you click **Print Current Viewport** in the **Plug-ins** menu, Abaqus/CAE sends the following commands to the kernel:

```
import sys
sys.path.append('path to your home dir/abaqus_plugins/myPlugins')
import myUtils
myUtils.printCurrentViewport()
```

The next time you click **Print Current Viewport** in the **Plug-ins** menu, Abaqus/CAE sends only the following command to the kernel:

```
myUtils.printCurrentViewport()
```

Since Abaqus/CAE updates the *sys.path* list, your plug-in code does not need to perform this task to import modules that it needs. This assumes that those modules are located in the same directory as the plug-in. If you have to import modules that are not located in the same directory, you must augment the *sys.path* list. If you need to augment the *sys.path* list, you should use functions that determine the file locations automatically, rather than hard-coding the path to the plug-ins in your file. This makes it easy to move plug-ins to different locations without having to modify their code. The following example of `myUtils.py` illustrates an example of augmenting the *sys.path* list:

```
import sys, os

# Full path (with name) to this file
absPath = os.path.abspath(__file__)

# Full directory specification
absDir = os.path.dirname(absPath)

# Full subdirectory specification
subDir = os.path.join(absDir, 'mySubDir')
sys.path.append(subDir)

# myModule is located in subDir
import myModule

rest of module code
```

Overwriting plug-ins

Upon startup, Abaqus/CAE searches for plug-ins in the Abaqus/CAE installation, your home directory, the current directory, and the directories specified by the **plugin_central_dir** Abaqus environment parameter. If Abaqus/CAE finds a plug-in with the same name and case in multiple directories, the plug-in found later in the search will overwrite one found earlier in the search.
Plug-in names are case sensitive. For example, a plug-in named `myPlugin` is different from a plug-in named `MyPlugin`. The overwriting approach enables you to use a customized version of a plug-in that resides only in your home directory or current directory; however, in most cases you should avoid naming conflicts with plug-ins.

Python searches for modules according to the order specified in the *sys.path* list and stops searching as soon as it finds a match for the module name. For example, if you have a utility module called `myUtils.py` stored in two different plug-in directories and these directories contain different code, both plug-ins will reference the same module—the one found first in the *sys.path* list.

You can use Python's package style for storing and referencing your modules to avoid unintentional overwriting of plug-ins or accessing of the wrong module. Start by creating a directory with a detailed name that is unlikely to be duplicated by others, and store your `_plugin.py` file in that directory. Create another directory of the same name within the first directory, and place your other plug-in files in the newer directory with an empty file named `__init__.py`, so that the directory structure looks as follows:

```
torqueCalculator
   torqueCalculator_plugin.py
   torqueCalculator
      __init__.py
      torqueUtils.py
      torqueForm.py
      torqueDB.py
```

When you import files in your code, use the package name to qualify the import. For example, inside `torqueForm.py`, you can qualify the import with the following statement:

```
from torqueCalculator.torqueDB import TorqueDB
```

How are GUI plug-ins executed?

Abaqus/CAE executes a GUI plug-in by sending a message to the GUI object specified in the registration command for that plug-in. As with the kernel plug-ins, the first time that a GUI plug-in is invoked, Abaqus/CAE updates the kernel's *sys.path* list with that plug-in's directory. In addition, Abaqus/CAE sends the plug-in's `kernelInitString` to the kernel and updates the GUI's *sys.path* list to include that plug-in's directory. You can use the `kernelInitString` to initialize the kernel for commands that will be sent by the plug-in's GUI. The next time that plug-in is invoked, only the message will be sent to the GUI object.

If you need to import files into the GUI that are not located in the same directory as the plug-in, you must augment the *sys.path* list as shown in the previous example. In addition, if you need to augment the kernel's *sys.path* list, you should supply code similar to the following in the plug-in's `kernelInitString`, in this example the name of the file containing the plug-in is `myForm_plugin.py`:

```
from abaqusGui import AFXForm, getAFXApp

class MyForm(AFXForm):

    form code goes here

import os

# Full path (with name) to this file
absPath = os.path.abspath(__file__)

# Full directory specification
absDir = os.path.dirname(absPath)

# Full subdirectory specification
subDir = os.path.join(absDir, 'mySubDir')
initString  = "sys.path.append('%s')\n" % subDir

# myModule is located in subDir
initString += 'import myModule'
toolset = getAFXApp().getAFXMainWindow().getPluginToolset()
toolset.registerGuiMenuButton(buttonText='My Utility',
    object=MyForm(toolset), kernelInitString=initString )
```

Hiding a plug-in's source code

If you do not want other users to see the source code of your plug-in, you can supply the compiled version of the plug-in instead of supplying the source code version. When Abaqus/CAE imports the source code version of a plug-in, Abaqus/CAE first parses the plug-in and then compiles it into a executable version of the file (called *filename*`.pyc`) before it executes the file. If the source code has not changed since the last time the plug-in was compiled, Abaqus/CAE executes the compiled version directly and bypasses the compilation step. Abaqus/CAE will still import the plug-in if you delete the file containing its source code but retain the compiled version of the plug-in.

If you have only compiled versions of some plug-ins, you may want to store them in a directory under the `abaqus_plugins` directory. This will avoid confusion by keeping compiled versions of plug-ins that do not have source code separate from the compiled versions of plug-ins that still have the source code.

Displaying exceptions for imported plug-ins at startup

By default, Abaqus/CAE does not display the exceptions associated with the import of plug-ins when you start the application. If you want to expose these exceptions for debugging purposes, set the environment variable `ABQ_PLUGIN_DEBUG` to 1 at a command prompt before launching Abaqus/CAE. When this environment variable is set, Abaqus/CAE provides more trackback information about plug-ins upon startup, including the location and nature of any failures that occur.

Abaqus/CAE modules and plug-ins

By default, a plug-in appears in all Abaqus/CAE modules. However, you can use the `applicableModules` argument of the registration commands to specify individual modules in which a plug-in is available. If a plug-in is not applicable to the current module, its menu item will be hidden in the **Plug-ins** menu. For example, if you specify that a plug-in is available only in the Part module, you will not see that menu item under the **Plug-ins** menu unless you are in the Part module. The following registration command makes the plug-in available in only the Part and Assembly modules:

```
toolset.registerKernelMenuButton(
    buttonText='Print Materials',
    moduleName='myUtils', functionName='printMaterials()',
    applicableModules=('Part','Assembly'))
```

Abaqus/CAE uses similar functionality to hide items in the **Tools** menu as you move between modules. For a full description of the arguments to the kernel and GUI registration commands, see *Plug-in registration commands*.

How can I provide information about a plug-in?

When you create a plug-in, you can supply the following arguments to the registration command:

author

A string specifying the author's name.

version

A string specifying the version of the plug-in.

description

A string specifying a brief description of the plug-in.

helpUrl

A string specifying a path to a URL that provides information about your plug-in.

For a full description of the arguments to the kernel and GUI registration commands, see *Plug-in registration commands*.

The `helpUrl` argument can be any valid web browser URL. In most cases the URL will point to an HTML file, but the URL can also point to a plain text file or to an external website. If you provide a help file with your plug-in that will be referenced by the `helpUrl` argument, you should avoid hard-coding directory names by constructing the path to the help file using the techniques shown in previous examples. The following example of `myUtils_plugin.py` shows how you can provide information about the plug-in and construct the relative path to the `helpUrl` argument:

```
from abaqusGui import getAFXApp
toolset = getAFXApp().getAFXMainWindow().getPluginToolset()

import os
helpUrl = os.path.join(os.getcwd(), 'bridgeHelp.htm')

toolset.registerKernelMenuButton(
    buttonText='Print Current Viewport',
    moduleName='myUtils', functionName='printCurrentVp()',
    author='SIMULIA', version='1.0'
    description='Print current viewport to a PNG file', helpUrl=helpUrl)
```

Abaqus plug-ins

This section describes the plug-ins that are provided with Abaqus/CAE and appear in the **Plug-ins** menu. Select **Plug-ins->About Plug-ins** to display a **View** button that displays help on each plug-in.

In this section:

- *Running the Getting Started with Abaqus examples*
- *Creating a GUI plug-in*
- *Creating a kernel plug-in*
- *Creating dialog boxes with the Really Simple GUI (RSG) Dialog Builder*
- *Upgrading a script*
- *Displaying modal contribution factors*
- *Displaying the history of the adaptive remeshing error indicator*
- *Generating a report of postprocessing results*
- *Exchanging data between Abaqus/CAE and Microsoft Excel*
- *Importing a model from a file in stereolithography (STL) format*
- *Exporting a part or assembly in stereolithography (STL) format*
- *Plotting amplitude data*
- *Combining data from multiple output databases*
- *Finding the nearest node to a point*
- *Finding the average temperature of a set of elements*
- *Creating a planar constraint*
- *Resetting midside nodes*
- *ODB Reducer/Builder*
- *Additive manufacturing*
- *View cut along a path*

Running the Getting Started with Abaqus examples

This plug-in allows you to run the examples described in *Getting Started with Abaqus/CAE*. The plug-in creates a model that reproduces each example. The plug-in also creates a job associated with the model; however, the plug-in does not submit the job for analysis. If desired, you can go to the Job module and submit the job for analysis. You can then can go to the Visualization module to view the results of the analysis.

The plug-in fetches files associated with the examples and places those files in the current directory. You can run the following examples from the plug-in:

- *Example: creating a model of an overhead hoist*
- *Example: connecting lug*
- *Example: skew plate*
- *Example: cargo crane*
- *Example: cargo crane under dynamic loading*
- *Example: skew plate*
- *Example: stress wave propagation in a bar*
- *Example: connecting lug*
- *Example: blast loading on a stiffened plate*
- *Example: axisymmetric mount*
- *Example: vibration of a piping system*
- *Abaqus/Standard 3D example: shearing of a lap joint*
- *Abaqus/Explicit example: circuit board drop test*
- *Example: forming a channel in Abaqus/Explicit*

Creating a GUI plug-in

This plug-in illustrates how you can use the Abaqus GUI Toolkit to create GUI plug-ins. The plug-in displays a dialog box that prompts you for the name and the dimensions of a part. When you click **OK**, the plug-in creates the part. The plug-in also creates a toolbox icon that is displayed when you click **Plug-ins->Toolboxes->Examples**.

Creating a kernel plug-in

This plug-in illustrates how you can use the Abaqus Scripting Interface to create a plug-in that executes kernel commands. The plug-in toggles the visibility of the view triad in the current viewport. The plug-in also creates a toolbox icon that is displayed when you click **Plug-ins->Toolboxes->Examples**.

Creating dialog boxes with the Really Simple GUI (RSG) Dialog Builder

Using the RSG dialog builder is an alternative to using the Abaqus GUI Toolkit commands and a text editor to create dialog boxes.

The **Really Simple GUI (RSG) Dialog Builder** plug-in enables you to create dialog boxes and connect them to kernel commands without writing any code. You select items from a toolbox to add them to an empty dialog box and edit their properties.

The RSG dialog builder provides access to a subset of the commands in the Abaqus GUI Toolkit, but it requires no programming experience to produce a working dialog box. The dialog boxes that you create become new plug-ins to Abaqus/CAE. You can save them as either RSG plug-ins or standard plug-ins, but you can only edit RSG plug-ins with the RSG dialog builder. You must use a text editor to edit standard plug-ins. However, saving an RSG dialog box as a standard plug-in allows an experienced programmer to extend the dialog's functionality by selecting from the complete set of Abaqus GUI Toolkit commands.

The RSG dialog builder plug-in includes a “Five minute tour” that describes and shows some of the basic functions that you can use to build a custom dialog box. The tour icon  is located at the upper left corner of the **GUI** tabbed page in the **RSG Dialog Builder**.

Upgrading a script

The upgrade script plug-in allows you to upgrade a script from a previous release of Abaqus.

In this section:

- *Introduction*
- *Using the upgrade script plug-in*

Introduction

The upgrade script plug-in allows you to upgrade a script from a previous release of Abaqus to the current release of Abaqus. The plug-in allows you to do the following:

- Upgrade across several releases of Abaqus.
- Choose both the release of the original script and the release of the resulting upgraded script.
- Upgrade a single script or all the scripts in a specified directory.
- Preview the changes to your script that resulted from the upgrade process, and, if the changes are acceptable, proceed with the upgrade.

For more information, see *Upgrade script commands*. You can access the plug-in from the **Plug-ins** menu in any module.

Using the upgrade script plug-in

Start the plug-in by selecting **Plug-ins->Abaqus->Upgrade Scripts** from the main menu bar. Enter the following in the **Upgrade Scripts** dialog box:

- Do one of the following to choose the files to upgrade:
  - Choose **Files**, and enter the names of the files to upgrade.
  - Choose **Directory**, and enter the name of the directory to upgrade. Abaqus/CAE upgrades all of the scripts in the directory and any subdirectories.
- Toggle on **Create backups** to keep copies of the original scripts in their original directory.
- Do one of the following to choose the type of the commands to upgrade:
  - Choose **Kernel** to upgrade only Abaqus Scripting Interface commands.
  - Choose **GUI** to upgrade only Abaqus GUI Toolkit commands.
  - Choose **Both** to upgrade both Abaqus Scripting Interface and Abaqus GUI Toolkit commands.

  In most cases you should choose to upgrade both types of commands.
- Enter the name of the log file. The file will contain a log of the upgrade commands that are issued along with a list of the changes to the script and any errors or warnings that are issued. Abaqus/CAE stores the log file in the current directory and displays its contents on the screen during the upgrade process.
- Select the release of the original script and the release to which you would like to upgrade. If you are not sure when the script was created, you should choose the earliest release available. The default release for the original script is three releases before the current release.
- Do one of the following to select the application that displays a preview of the updated script when you click **Preview Changes**:
  - Choose **Use web browser** to preview your changes in the default web browser.
  - Choose **Use specified executable** and enter the path to the executable file that will display the differences between the script and the upgraded script; for example, `windiff`.

From the buttons at the bottom of the dialog box, do the following:

- Click **Preview Changes** to use the selected application to preview the changes to the script.
- If the changes are acceptable, click **Upgrade Scripts** to perform the upgrade and to close the **Upgrade Scripts** dialog box.

Displaying modal contribution factors

The modal contribution factors (MCF) plug-ins are a noise, vibration, and harshness (NVH) application that allows you to compute the output from a modal frequency response analysis and to study the contribution of each mode to the total structural or acoustic response.

In this section:

- *Introduction*
- *Preparing the structural and/or acoustic data*
- *An overview of the MCF plug-in*
- *Computing the modal contribution factors*
- *Displaying modal contribution factors*
- *Ranking criterion for modal contribution factors*

Introduction

When a modal frequency response analysis is performed in Abaqus/Standard, the response is calculated from a linear combination of mode shapes and the corresponding modal amplitudes. For a typical structural-acoustic or structural analysis, the number of modes being studied can number in the hundreds. The designer needs to closely examine these individual modes and find or rank the dominant modes (the modes with major contributions to the total response). The contribution of each mode to the total structural or acoustic response is called the Modal Contribution Factor (MCF).

The NVH application requires two plug-ins that you can access from the **Plug-ins** menu in the Visualization module. The first computes the modal contribution factors, and the second allows you to view the modal contribution factors.

Preparing the structural and/or acoustic data

A typical Abaqus/Standard modal frequency response analysis uses a frequency step followed by multiple steady-state dynamic steps (for multiple load cases) for each base state. The plug-in reads the following variables from the output database generated by the analysis:

- The field output from each frequency step must include the nodal displacement (U). In addition, if you are performing a coupled structural-acoustic analysis, the field output from each frequency step must include the nodal pore or acoustic pressure (POR).
- After each frequency step, there must be at least one modal steady-state dynamic step (not steady-state dynamic, direct or steady-state dynamic, subspace).
- In each modal steady-state dynamic step the history output must include the generalized displacements (GU) and the phase angle of the generalized displacements (GPU) for at least one mode.

You can find sample input files for a modal steady-state dynamic analysis in *Analysis of a rotating fan using substructures and cyclic symmetry* and *Coupled acoustic-structural analysis of a pick-up truck*.

An overview of the MCF plug-in

The modal frequency response, such as the sound pressure or displacement, can be expressed as

$$P(\overline{x};\Omega) = \sum_{\alpha=1}^{N} p_\alpha(\overline{x};\Omega) = \sum_{\alpha=1}^{N} \phi_\alpha(\overline{x})\, q_\alpha(\Omega).$$

The first plug-in uses a script to recover the fluid-structure coupled MCF ($\phi_{\alpha m} q_\alpha$ for each mode α at a response point m for a range of frequencies) based on the mode shapes, ϕ_α, (from the frequency step) and the modal amplitudes, q_α, (from the steady-state dynamic step with modal output requested) in the output database. The plug-in sums these partial pressures and compares them against the Abaqus total. In addition, the script creates a ranking criterion based on a sensitivity analysis.

The second plug-in uses a script that displays polar or vector plots or bar graphs that allow you to identify the most significant modes at each excitation frequency.

Computing the modal contribution factors

The first plug-in computes all the requested quantities (MCFs) and then adds them to the output database as history output. The plug-in is available only from the Visualization module. Enter the Visualization module and start the plug-in by selecting **Plug-ins->NVH->Compute modal Contribution Factors** from the main menu bar.

The plug-in displays the **Open ODB** dialog box, and you enter the name of the output database generated by the Abaqus/Standard analysis described in *Preparing the structural and/or acoustic data*. The plug-in adds the computed values of the modal contribution factors back to the same output database; you must have write access to the output database.

After you enter the output database name, the plug-in displays the **Compute MCF** dialog box, as shown in *Figure 1*:

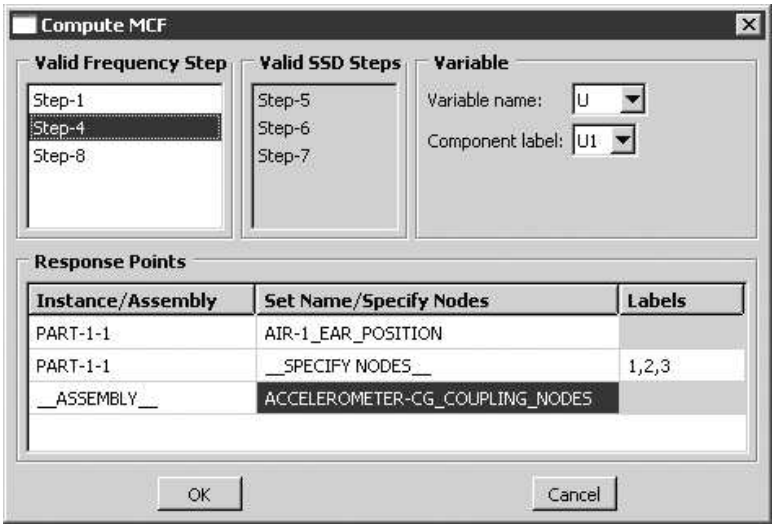

Figure 1: The Compute MCF dialog box.

You must select one of the valid frequency steps from the **Compute MCF** dialog box. A valid frequency step is one that is followed by a modal steady-state dynamic step (not steady-state dynamic, direct or steady-state dynamic, subspace). In addition, a valid frequency step includes GU and GPU output for at least one mode. The valid modal steady-state dynamic steps for each frequency step that you select are shown in the list of **Valid SSD Steps**.

The **Compute MCF** dialog box also asks for the **Response Points**. You can select any combination of the following formats:

- A part instance name followed by a list of node labels
- A part instance name followed by a list of instance-level node sets
- Assembly-level node sets

Finally, you must select the field output variable, which can be any one of the following: acoustic Pressure (POR), displacement (U), velocity (V), or acceleration (A).You can request only U or POR from the frequency step. For all output variables other than POR, you must also request the corresponding component label. For example, if you request U, you must also request either U1, U2, or U3.

After you click **OK** to close the **Compute MCF** dialog box, the plug-in processes all of the valid modal steady-state dynamic steps for the selected frequency step along with all of the specified response points and all of the modes in the frequency step.

Displaying modal contribution factors

After the first plug-in has analyzed the data and written the results back to the output database, you can view the modal contribution factors. Start the second plug-in by selecting **Plug-ins->NVH->Plot modal Contribution Factors** from the main menu bar in the Visualization module. The plug-in displays the **Open ODB** dialog box, and you enter the name of the output database from which to read. The plug-in then displays the **Select Steps** dialog box, as shown in *Figure 1*:

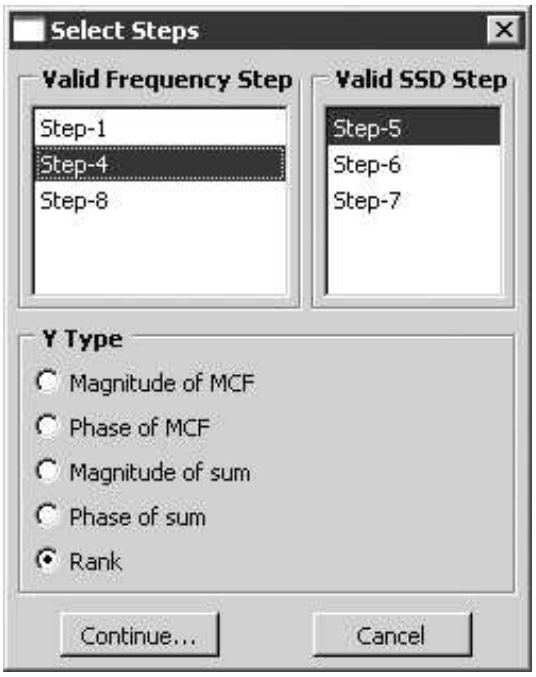

Figure 1: The Select Steps dialog box.

You must select the **Valid Frequency Step** and the **Valid SSD Step** from which you will generate plots. In addition, you must choose one of the following types of variables to plot:

- Magnitude of MCF
- Phase of MCF
- Magnitude of sum
- Phase of sum
- Rank

The magnitude or the phase of the sum indicates the summation of modal contribution factors over all the modes. This is same as the Abaqus output variable (POR, U, V, or A).

When you click **Continue**, the plug-in displays the **Plot MCF** dialog box. Click the **Frequency Step/SSD Step** button to select different frequency and steady-state dynamic step.

Click the **Selection** tab to select the following:

- The response point.
- The frequency of interest, if you are plotting a bar graph, a polar plot, or a vector plot.
- Any number of **Y** components to plot. You add a **Y** component by clicking **>**; you remove a **Y** component by clicking **<**. You can add or remove all of the **Y** components by clicking the **>>** or **<<** buttons respectively.

The **Selection** tabbed page is shown in *Figure 2*:

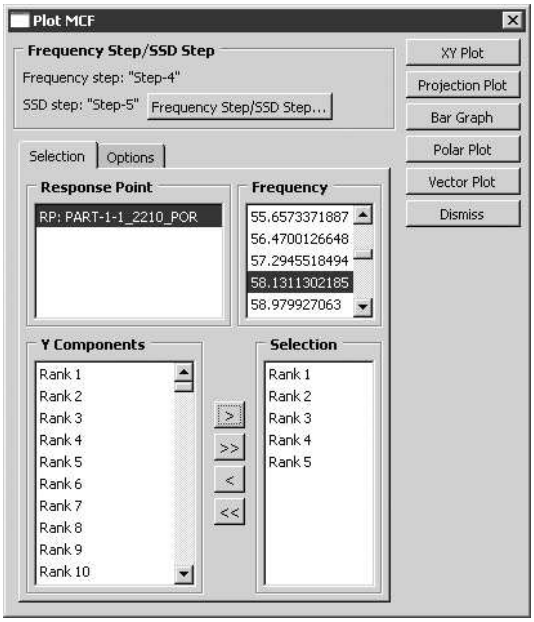

Figure 2: The Selection tabbed page.

Click the **Options** tab to select the general plot options. In addition, if you select POR-based results, you can select the **P Reference** value for XY and projection plots. From the buttons on the right side of the **Plot MCF** dialog box, select the type of plot to create.

- Click **XY Plot** to generate the spectrum for the magnitude or phase of MCF. For mode-ranking selection, the plug-in creates *X–Y* plots for the modes corresponding to the specified ranks.
- Click **Projection Plot** to plot the projection of the selected MCF onto the corresponding total sound pressure level across the spectrum. You can use this plot to view the contribution of a mode (positive or negative) to the total sound pressure level.
- Click **Bar Graph** to plot a bar graph of the MCF of each mode.
- Click **Polar Graph** to plot a polar graph of the MCF of each mode. The polar plot shows both the magnitude and phase information of each individual MCF on the complex plane for each frequency. When plotted with the total sound pressure vector, you can readily identify the modes that dominate the contribution to the total sound pressure.
- Click **Vector Graph** to plot a vector graph of the MCF of each mode. The vector for each mode is drawn in sequence. As more and more modes are plotted, the vector graph tends towards the magnitude of the total sound pressure vector.

The **Options** tabbed page is shown in *Figure 3*:

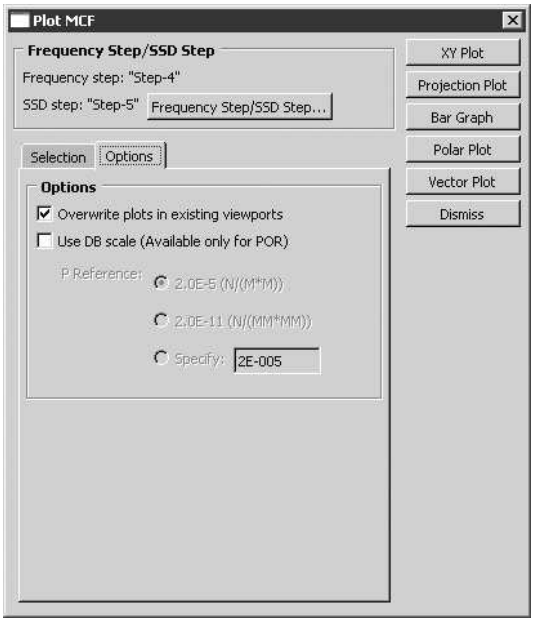

Figure 3: The Options tabbed page.

The plug-in creates each type of plot in a separate viewport and names the viewport accordingly. As a result, you can select **Viewport->Tile Vertically** from the main menu bar to view all the plots at the same time. The following figures were created by the plug-in using the output database generated by a modified version of *Coupled acoustic-structural analysis of a pick-up truck*. The variable selected was POR, and the bar graph, polar graph, and vector graph and the ranks were generated for a frequency of 35 Hz. The analysis examined the first five ranked modes (out of 180):

Figure 4 shows the model that was analyzed. The bar graph indicates that Mode 36 is the significant mode at this frequency.

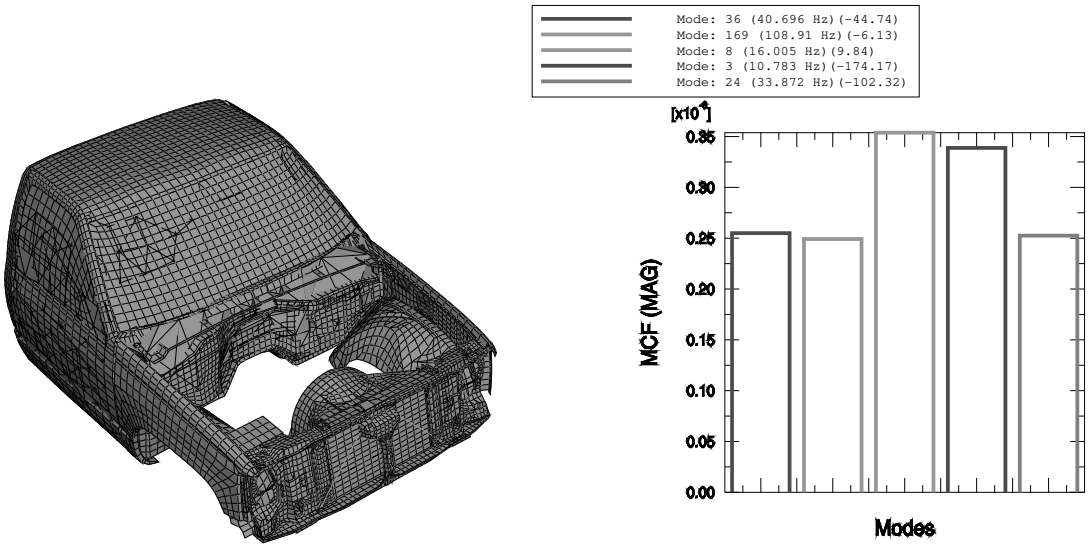

Figure 4: Bar graph of MCF for the coupled acoustic-structural analysis of a pick-up truck.

Figure 5 shows the *X–Y* plot and the projection plot. The *X–Y* plot shows the magnitude of the modal contribution factor at all frequencies. The projection plot shows the projection of the modal contribution factor on the total response at all frequencies. For example, mode 169 becomes more significant at 110 Hz.

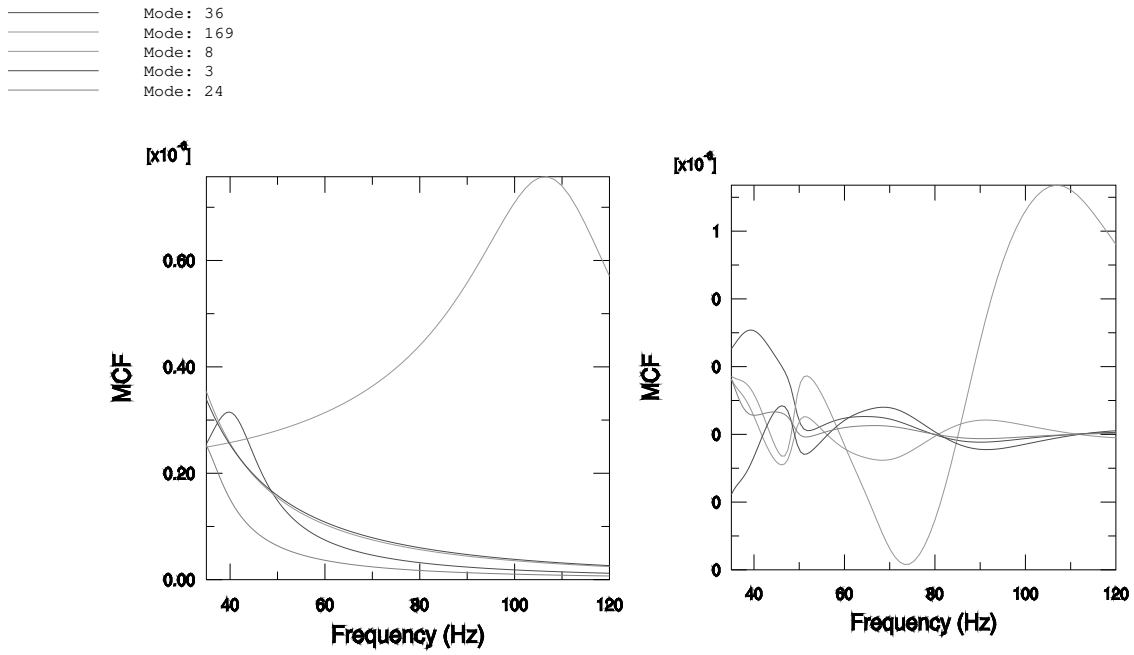

Figure 5: *X–Y* and projection plots of MCF for the coupled acoustic-structural analysis of a pick-up truck.

Figure 6 shows the polar graph and the vector graph. The bar graph shows that the magnitude of mode 36 is less than the magnitude of mode 8; however, the polar plot shows that mode 36 is more in phase with the total response (the vector sum of all the modal contributions). As a result, mode 36 contributes more to the total magnitude than mode 8 at 35 Hz and consequently ranks higher.

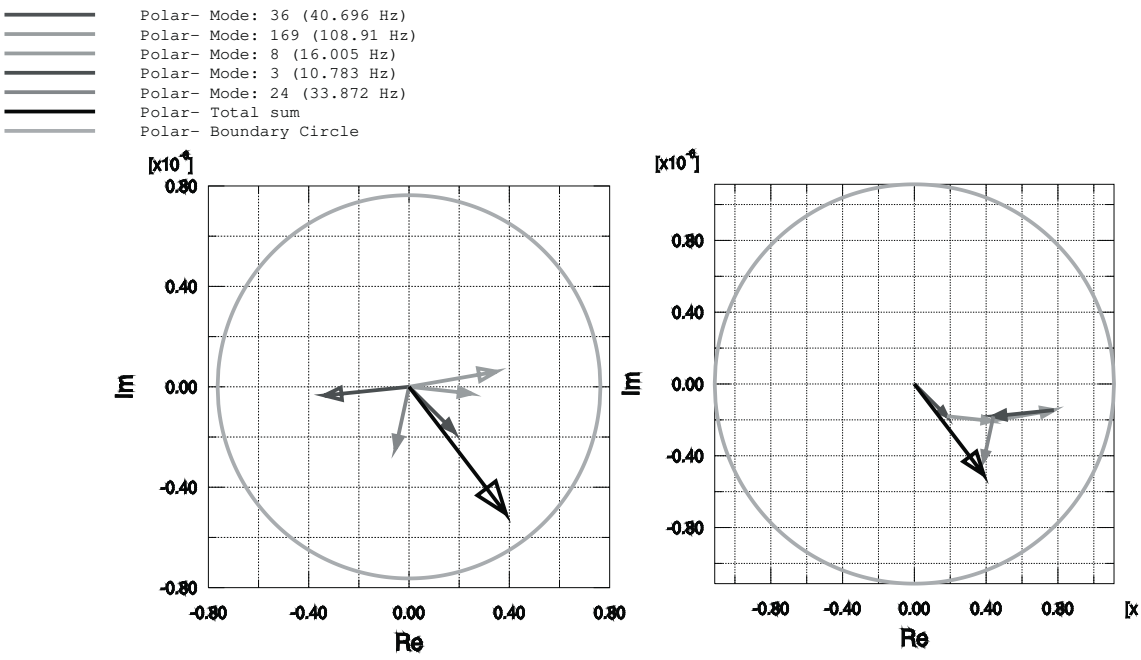

Figure 6: Polar and vector graphs of MCF for the coupled acoustic-structural analysis of a pick-up truck.

Ranking criterion for modal contribution factors

If you select **Rank** as the variable to plot, the plots generated by the plug-in allow you to identify and rank significant modes based on the change in total response magnitude that would result from a fixed percentage increase in the real and imaginary components of the MCF (or partial response). The plug-in implements the ranking criterion as follows:

- α = mode number
- P_α = partial response for mode α
- $P_{\alpha R}$ = real portion of partial response for mode α
- $P_{\alpha I}$ = imaginary portion of partial response for mode α
- $P_{\alpha M}$ = magnitude of partial response for mode α
- $P_{\alpha P}$ = phase of partial response for mode α
- T = total response P
- $TR = \sum_\alpha P_{\alpha R}$ = real portion of total response
- $TI = \sum_\alpha P_{\alpha I}$ = imaginary portion of total response
- $TM = \sqrt{TR^2 + TI^2}$ magnitude of total response
- $TP =$ phase of total response
- $\delta_\alpha = \sqrt{(TR + 0.1^* p_{\alpha R})^2 + (TI + 0.1^* p_{\alpha I})^2} - TM$ = delta in total response magnitude for 10% increase in any given partial response (i.e. sensitivity)

You can determine the top n modes based on the absolute value of δ_α and output $p_{\alpha M}$ and $p_{\alpha P}$ for these modes.

Displaying the history of the adaptive remeshing error indicator

The adaptivity plotter plug-in allows you to review the history of selected error indicators and the element count in a sequence of adaptive remeshing jobs.

In this section:

- *Introduction*
- *Using the adaptivity plotter plug-in*

Introduction

When you execute an adaptivity analysis, Abaqus/CAE submits a succession of Abaqus/Standard jobs as it attempts to reduce the mesh discretization error in your model. This error is characterized by error indicator measures calculated by Abaqus/Standard. Global norms of these indicators are calculated by Abaqus/CAE, and you can use these norms to evaluate the performance and effectiveness of the adaptive remeshing process. For more information, see *Selection of Error Indicators Influencing Adaptive Remeshing*.

The adaptivity plotter plug-in enables you to plot these error indicator norms and to view a graphical representation of the effectiveness of the adaptive remeshing process. You can access the plug-in from the **Plug-ins** menu in any module. The plug-in reads the model database (`.cae`) file associated with the adaptive remeshing jobs; therefore, the file must be available.

Using the adaptivity plotter plug-in

Start the plug-in by selecting **Plug-ins->Tools->Adaptivity Plotter** from the main menu bar. When you start the adaptivity plotter plug-in, it reads the current model database and displays the **Adaptivity Plotter** dialog box. Enter the following in the **Adaptivity Plotter** dialog box:

- Select the desired adaptivity process from the model database.
- Toggle on the remeshing rules that you want to plot. Where applicable, you can choose the following:
  - The error indicators generated by the remeshing rule.
  - The global norms of these error indicators.
- Toggle on **Plot in separate viewport** to create a new viewport for the *X–Y* plot. If you leave this option toggled off, the plug-in will create the *X–Y* plot in the current viewport.
- Toggle on **Show element count** to plot the element count, totaled over all the active remeshing rules.
- Toggle on **Show remeshing rule targets** to plot the target error indicator norm for each rule.
- Click **Plot** to create the *X–Y* plot, or click **Export** to create a table of the error indicator norms in HTML format. An example of an *X–Y* plot created by the plug-in is shown in *Figure 1*.

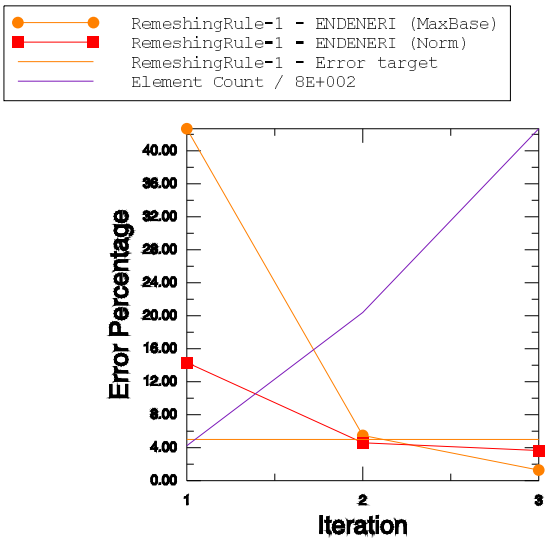

Figure 1: An *X–Y* plot created by the Adaptivity Plotter plug-in.

The following four values are plotted in *Figure 1*:

- The **MaxBase** norm for the error indicator ENDENERI for **RemeshingRule-1**. This norm represents the error indicator value at the location of maximum energy density, normalized by that density.
- The **global Norm** for the error indicator ENDENERI for **RemeshingRule-1**. This norm represents a normalized average of the error indicator over the entire remeshing rule domain.
- The error target, which is the target set when you create the remeshing rule. In this example the target is fixed at 5%.
- The element count, representing the sum of elements in each of the active remeshing rule regions. The *Y*-axis scale is percent, which is used by the plots of error indicator and error target. To determine the error count, you

must multiply the scaling factor indicated in the legend, 800 in this example, by the percent value on the *Y*-axis. For example, the element count at iteration 2 is approximately 20 × 800, or 16000 elements.

Generating a report of postprocessing results

The **Report Generator** plug-in enables you to create an HTML report using the model data and results data in an Abaqus output database (`.odb`) file. You can adjust the settings in the plug-in to select the content that you want to include in the report and to customize the appearance of the report. You can also save your commonly used report settings into a report options file, which can be loaded for use in another session or for another output database.

You can launch the **Report Generator** by selecting **Plug-ins->Tools->Report Generator** from the main menu bar in the Visualization module. Once you select the content that you want to include and click **Generate**, Abaqus/CAE generates the report and opens it automatically in your default browser.

By default, Abaqus/CAE generates report output in the current working directory, but you can specify a different location. When you generate a report, Abaqus/CAE overwrites any report content in the output directory that you select. If you want to retain a report, you should move all of the report files to a secure location where you are not likely to overwrite their contents. All of the files included in an HTML report are listed in the **File Summary** section of the report.

Many of the options in the **Report Generator** control the types of graphical data that you add to the report. You can include the following types of figures in a report:

- 3D XML figures: Toggle on **Include 3DXML** to include a figure in 3D XML format, a file format that enables you to manipulate a three-dimensional rendition of your assembly directly in the report. If your report includes content in 3D XML format, you must use a supported browser and the 3D XML Player to display the report properly. You can download the 3D XML Player from the Dassault Systèmes website at *http://www.3ds.com*.
- Two-dimensional custom views: Toggle on one or more of the **View Options** settings to generate figures that display the assembly from one or more of the predefined views or user-defined views in Abaqus/CAE.
- Additional figures: Use the **Save Current Viewport** plug-in to create a custom, named figure of the current viewport, which you can then include in a report by selecting it from one of the **Additional figures** lists in the **Report Generator** plug-in. Each **Additional figures** list displays only the custom figures that were created in the corresponding module; for example, the **Material Information** section of the report can include additional figures only when they were created in Property module.

  You can launch the **Save Current Viewport** plug-in by selecting **Plug-ins->Tools->Save Current Viewport**. This plug-in is available in the Property module, the Assembly module, the Load module, the Interaction module, and the Visualization module.

The options in the **Report Generator** are organized into tabbed pages that correspond, in general, to the sections in the HTML report. The following options are available:

General

You can select the directory in which the HTML report files will be generated, change the title that appears at the top of the report, and change the user name that appears in the report. You can also display all of the images in the report at full size or display thumbnail images in the report that link to full-sized versions.

Additional options allow you to include or exclude the top-level components of the report, while settings on other pages in this dialog box allow you to select the specific contents to include in each section. For example, toggling on **Include results** on the **General** page prompts Abaqus/CAE to include results data in the HTML report; the options on the **Results** page enable you to control the specific results data included in the report, such as results from individual output variables or selected *X*–*Y* plots.

Materials

You can include figures and a 3D XML–format file that display the assembly with its contents color coded to highlight the material data. Figures can be displayed in any of the default views or user-defined views in

Abaqus/CAE. You can also include any additional viewport images saved in the Property module using the **Save Current Viewport** plug-in.

You can also append a table of materials to the material figures in the HTML report. By default, the table of materials describes the material properties for the materials defined in the assembly and provides a color key to indicate which materials correspond to each color in the figures. You can include full descriptions of each hyperelastic and plastic material in the model; these descriptions are part of the material definition.

Instances

You can include figures and a 3D XML–format file that display the assembly with its contents color coded to highlight the part instances. You select the part instances that you want to display from a list and display the part instances together in a single image or individually in separate images. Figures can be displayed in any of the default views or user-defined views in Abaqus/CAE. You can also include any additional viewport images saved in the Assembly module using the **Save Current Viewport** plug-in.

You can append a table of part instances to the part instance figures in the HTML report. The table of part instances describes the part definition for the instances included in the assembly and provides a color key to indicate which part instances correspond to each color in the figures.

Loads

If you saved any viewport figures in the Load module using the **Save Current Viewport** plug-in, you can include any of those figures in the **Load Information** section of the report.

Interactions

If you saved any viewport figures in the Interaction module using the **Save Current Viewport** plug-in, you can include any of those figures in the **Interaction Information** section of the report.

Results

You can include figures and a 3D XML–format file that display contour plots of the assembly for a single step and increment in the analysis for the field output variables that you select. Figures can be displayed in any of the default views or user-defined views in Abaqus/CAE. You can also include any additional viewport images saved in the Visualization module using the **Save Current Viewport** plug-in. To select the field output variables for which you want to create contour plots, click **Populate**, then select variables and figure options from the dialog box that appears.

You can also include *X*–*Y* plots from the current output database or the current session in the report.

Format

You can customize the appearance of the report by generating the report using a custom style sheet and by displaying an image such as a company logo in the report.

Exchanging data between Abaqus/CAE and Microsoft Excel

The **Excel Utilities** plug-in enables you to import amplitude data or *X*–*Y* data from a Microsoft Excel workbook and to export either type of data from Abaqus/CAE to a Microsoft Excel workbook.

Note:

The **Excel Utilities** plug-in is available only for Windows.

Start the plug-in by selecting **Plug-ins->Tools->Excel Utilities** from the main menu bar. Enter the following in the **Excel Utilities** dialog box:

Object

Choose **XY Data** to transfer an *X*–*Y* data object, or choose **Amplitude** to transfer an amplitude definition.

Transfer Direction

Choose **From Abaqus/CAE to Excel** to export data from Abaqus/CAE to Microsoft Excel, or choose **From Excel to Abaqus/CAE** to import data from a Microsoft Excel spreadsheet into the current session or one of the open model databases.

Options for data import from Excel

To import amplitude data or *X*–*Y* data from Microsoft Excel, specify the name of the Excel file from which you want to import data, select one of the worksheets within the file, and identify the starting location of the data you want to import. By default, the plug-in imports only two columns of data—the data in the column you select and the data in the column immediately to its right—but if you toggle on **Import multiple curves** while importing *X*–*Y* data, the plug-in imports data in pairs of columns, creating an amplitude definition or an *X*–*Y* data object for each pair. If you are importing amplitude data, specify whether the amplitude data object you create should be a tabular or smooth step amplitude.

Amplitude objects are saved into the current model, while *X*–*Y* data objects are made available to the current session.

Options for data export to Excel

To export amplitude data to Microsoft Excel, select the model in which the data resides, then select one or more amplitude definitions and click **OK**. Abaqus/CAE creates a new Excel file and displays the exported data in a worksheet. If you are exporting a single amplitude object, Abaqus/CAE also plots the data in a chart; a chart is not created if you export multiple amplitude objects. Only tabular or smooth step amplitude definitions are available for export.

To export *X*–*Y* data to Microsoft Excel, select one or more *X*–*Y* data objects and click **OK**. Abaqus/CAE creates a new Excel file and displays the exported data in a worksheet. If you export a single *X*–*Y* data object, Abaqus/CAE also plots the data in a chart; a chart is not created if you export multiple *X*–*Y* data objects. You can export any *X*–*Y* data object in your session, including any temporary objects or the data that are currently displayed in the viewport.

Importing a model from a file in stereolithography (STL) format

Select **Plug-ins->Tools->STL Import** from the main menu bar to import a part from an external file in stereolithography (STL) format (`*.stl`) into Abaqus/CAE. The **STL Import** plug-in converts all part definitions and model data into Abaqus format, creating a new Abaqus/CAE model and a new Abaqus input file.

In practice, you might want to add the STL model data that you import to an existing Abaqus/CAE model. To add the STL parts or part instances to an existing Abaqus/CAE model after import, copy these objects from the newly created model to any other Abaqus/CAE model using the **Copy Objects** dialog box. For more information about copying model objects, see *Copying objects between models*.

You can import an STL file saved in ASCII format on Windows or Linux platforms. You can import an STL file saved in binary format only on Windows platforms.

1. From the main menu bar, select **Plug-ins->Tools->STL Import**.

   The **STL Import** dialog box appears.
2. Specify the name of the STL file from which you want to import model data.

   Abaqus/CAE populates the **Model name** field with the name of the STL file you selected.
3. If desired, edit the default model name specified in the **Model name** field for the new Abaqus/CAE model and the new Abaqus input file that will be created.
4. If desired, specify a node merge tolerance value. This tolerance must be positive.
5. Click **OK** to import the model data.

   The plug-in converts the model data in the stereolithography file and creates an Abaqus/CAE model in the current model database and an Abaqus input file in your current working directory. If any STL data cannot be converted, the plug-in records errors or warnings about unconverted data in the log file.

Exporting a part or assembly in stereolithography (STL) format

Select **Plug-ins->Tools->STL Export** from the main menu bar to export a part or assembly from an Abaqus/CAE model to a file in stereolithography (STL) format (`*.stl`). You can export data from either a single part or from the entire assembly, and you can export either the geometry or mesh data from your selection.

To export geometry data, perform the STL export from the Part module or the Assembly module. The plug-in converts any solid parts in your selection to shell geometry during the conversion to STL format. In addition, the plug-in uses the faceted representation of the part to create a mesh for the exported geometry. The accuracy of the generated mesh is dependent on the degree of faceting, which you can control using the **Curve refinement** option. For more information, see *Controlling curve refinement*.

To export mesh data, perform the STL export from the Mesh module or the Visualization module. During the conversion to STL format, the plug-in divides quadratic elements at their midside nodes to create linear elements and splits any quadrilateral elements into triangular elements. When you export assembly data from the Visualization module, the plug-in exports data according to the plot state in the current viewport.

You can export STL files in ASCII format or in binary format.

1. Switch to the Part module or the Mesh module to export part data; or switch to the Assembly module or the Visualization module to assembly data.
2. Display the part or assembly that you want to export in the current viewport.
3. From the main menu bar, select **Plug-ins->Tools->STL Export**.

   The **STL Export** dialog box appears.
4. From the **STL file name** options, specify the name of the STL format file you want to create and the location where you want to create it. If you do not specify a location, the plug-in creates the file in the current working directory.
5. From the **STL file type** options, specify whether you want to create an STL format file in **ASCII** or **Binary** format.
6. Click **OK** to export the model data.

   The plug-in converts the model data in the selected part or assembly and creates a new STL format file in the location that you specified. If any Abaqus data cannot be converted to STL format, the plug-in records errors or warnings about unconverted data in the log file.

Plotting amplitude data

The **Amplitude Plotter** plug-in enables you to create *X–Y* plots that provide a graphical display of the data from one or more of the amplitude definitions in your model. You can plot data from the following types of amplitude objects:

- Tabular
- Equally spaced
- Periodic
- Modulated
- Decay
- Smooth step

For more information about defining and using these amplitude types in Abaqus/CAE, see *The Amplitude toolset*.

You can launch the **Amplitude Plotter** by selecting **Plug-ins->Tools->Amplitude Plotter** from the main menu bar in the Interaction module or the Load module. To plot amplitude data, select one or more amplitude rows in the top half of the dialog box and click **Plot**. Multiple amplitude objects can be included in the same *X–Y* plot if they are of the same amplitude type.

By default, the **Amplitude Plotter** creates an *X–Y* plot that is sized to include all the data in your selected amplitude or amplitudes. You can zoom in on a particular area in the amplitude data when you create your *X–Y* plot by specifying a custom minimum or maximum value using the **Min X Value** or **Max X Value** options. As with any *X–Y* plot in Abaqus/CAE, you can also customize the plot, its axes, or the plot legend by double-clicking these components of the plot; see *Customizing X–Y plot appearance*, for more information about these customization options. The **Amplitude Plotter** also includes a **Display plot legend** option that you can toggle to display or hide the plot legend as you plot amplitude objects.

Toggle on the **Save XY Data** option to create named *X–Y* data objects for the amplitude objects you include in the *X–Y* plot. You can customize the names for the *X–Y* data objects you create; Abaqus/CAE displays these names in the plot legend, and the *X–Y* data objects will be saved as session objects and will be available for use in the Visualization module. The *X–Y* data objects generated by the **Amplitude Plotter** are session-specific and cannot be saved to the model database.

Combining data from multiple output databases

The **Combine ODBs** plug-in enables you to combine model data and results data from two or more Abaqus output database (`.odb`) files into a new output database. You can use this utility to combine any output database files, including those with model data and results from the following:

- Output from different substructures in the same model.
- Output from two different analysis products such as Abaqus/Standard and Abaqus/Explicit, as part of a co-simulation.

If you want to experiment with different combinations of output databases without creating a new combined output database, you can first attempt to display data from different output databases together by using an overlay plot. Data in an overlay plot cannot be saved, but plotting results data from different output databases together can help you decide which data you want to include in a combine operation. For more information about overlay plots, see *Overlaying multiple plots*."

All model data from the selected output databases are included in the output database. However, for results data you can choose to include a subset of the data from the output databases that you specify. Abaqus/CAE determines which results data are included in the combined output database based on two factors: the filtering options you specify and your selection of primary output database.

Filters

You can filter the data that the plug-in includes in the combined output database to include results only from selected steps or frames, from selected output variables, or from a combination of these options. For example, a filter can enable you to include results data only from the last step and the last frame of the specified output databases, and the same filter can dictate that only Mises stress results are included in the combined output database. You can also establish multiple filters if you want to set up different filtering conditions in different steps.

The **Combine ODBs** plug-in also provides two levels of filtering: output database–specific filters, which filter results from only a single output database, and default filters, which apply to the entire job. The output database–specific filters take precedence over the default filters, so Abaqus/CAE employs the settings in the default filters only when the default filter you define does not conflict with filters for one of the individual output databases.

The filtering syntax is flexible enough to allow you to specify multiple steps, frames, or output variable values. You can specify multiple step names in a comma-separated list, such as `Step-1, Step-2, Step-4`. For frames you can include ranges or individual values; for example, entering `1, 3, 5, 7:9` returns frames 1, 3, 5, 7, 8, and 9 to the combined output database.

You can also use the symbolic constants `"ALL"`, `"FIRST"`, and `"LAST"` as shortcuts to specify the data you want to include. These options enable you to include results data from all steps or frames and data from all output variables rather than one or more selected variables.

Primary output database

You designate one output database in every combine operation as the primary output database. **Combine ODBs** first transfers all results data, subject to filtering selections, from the primary output database to the combined output database. The plug-in then locates results data from matching steps and frames in the subsequent output databases and copies only those data into the combined output database. This strategy provides a more coherent structure for the combined results data.

Note:

Each time you combine output databases using the plug-in, Abaqus/CAE records your output database and filtering selections in XML format in a configuration file. You can upload this file into the plug-in for subsequent combine operations.

The **Combine ODBs** plug-in excludes the following types of data from the combined output database:

- History data
- Surface data
- Analytical rigid part instances
- Local coordinate systems associated with field output data

1. From the main menu bar in the Visualization module, select **Plug-ins->Tools->Combine ODBs**.

   The **Combine ODBs** dialog box appears.
2. In the **Job name** field, specify a name for the combine job.
3. If you want to specify your combine options using data in an XML configuration file, do the following:
   a. Click mouse button 3 anywhere in the dialog box, and select **Read from XML File** from the list that appears.

      The **Select XML File** dialog box appears.
   b. Navigate to the XML configuration file you want to use, and click **OK**. For more information, see *Using file selection dialog boxes*.

      Abaqus/CAE populates the table in the dialog box with the output database files and filtering selections specified in the configuration file. You can customize any of these settings further before running the combine operation.
4. Do the following to specify the primary output database:
   a. Click mouse button 3 anywhere in the dialog box, and select **Select Primary ODB** from the list that appears.

      The **Select Primary ODB** dialog box appears.
   b. Navigate to the output database you want to use, and click **OK**. For more information, see *Using file selection dialog boxes*.
5. If you want to add output databases to the combine operation one at a time, do the following:
   a. Click mouse button 3 anywhere in the table, and select **Add ODB** from the list that appears.

      Abaqus/CAE adds a row labeled **ODB** to the table and displays the **Select ODB** dialog box.
   b. Navigate to the output database you want to include, and click **OK**. For more information, see *Using file selection dialog boxes*.

      Abaqus/CAE adds the output database to the selected row.
   c. Repeat these steps for each output database you want to add to the combine operation.
6. If you want to add multiple output databases to the combine operation at once, do the following:
   a. Double-click the **Name** heading.

      The **Select ODBs** dialog box appears.
   b. Navigate to the folder containing the output databases you want to include, select the output database files, and click **OK**. For more information, see *Using file selection dialog boxes*.

      Abaqus/CAE adds the selected output databases in new **ODB** rows to the **Combine ODBs** dialog box.

7. If desired, define filtering options to specify the steps, frames, and output variables to be included in the combined output database.

   - Define a single step, frame, or output variable filter for all output databases:

     1. Double-click the **Step**, **Frame**, or **Variable** heading.
     2. Specify the filtering criteria in the **Set Values** dialog box.

        If you specify the symbolic constants `"ALL"`, `"FIRST"`, and `"LAST"`, you must include the surrounding quotes.
     3. Click **OK**.

     Abaqus/CAE adds the selected criteria to the **Step**, **Frame**, or **Variable** column for the default filters and for every output variable included in the dialog box.

   - Define default filtering options or filtering options for a single output database:

     1. In the **Default** row, **Primary** row, or in one of the **ODB** rows, specify the step, frame, and output variable filters that you want to use as default filters or filters for the selected output database only.
     2. If desired, add more default filters or output database–specific filters by clicking mouse button 3 in the appropriate row, selecting **Add filter** from the menu that appears, and populating the new row with additional filtering criteria.

8. Toggle on **Open the combined ODB after job completion** to display the combined output database in the viewport when the job completes.
9. Click **OK**.

   Abaqus/CAE opens the **Odb Combine Log Message** dialog box, which displays the progress of the combine job and displays any errors that may arise. If any of the output databases you select are from an earlier release, Abaqus/CAE upgrades the output databases, saves the upgraded copy as a new file, and uses the new file in the combine job. If you selected **Open the combined ODB after job completion** and the combine job completes without errors, Abaqus/CAE opens the combined output database in the viewport after the combine job is complete.

Finding the nearest node to a point

The **Find Nearest Node** plug-in lets you locate the node that is nearest to a given point in a meshed model or undeformed plot. You enter the *x*-, *y*-, and *z*-coordinates of any point, and Abaqus/CAE shows you the closest node in your meshed model or undeformed plot. In addition, you can optionally limit the search to a particular region of the model, which is useful in large models.

This plug-in can be used with a model database (`.cae`) file or with the undeformed plot of an output database (`.odb`) file. It cannot be used in a deformed plot.

1. From the main menu bar in the Mesh module or the Visualization module, select **Plug-ins->Tools->Find Nearest Node**.

   The **Find Nearest Node** dialog box appears.

2. Enter the *x*-, *y*-, and *z*-coordinates of the desired point, and click **Find**.

   Abaqus/CAE adds an annotation in the viewport, with an arrow pointing to the nearest node in the mesh. The node number and coordinates are also given in the message area at the bottom of the window; for example:
   ```
   Node 15 of Instance Hinge-solid-1 is nearest to the defined
   point (1,1,1) Coordinates of node are
   (0.104999999665,0.999999977648,0.04), distance from defined point is
   1.64399665481
   ```

3. If you have a large model and want to restrict the search to a smaller region, click **Select Nodes for Reduced Search**. Follow the prompts to pick any subset of nodes in the viewport, either individually, by angle, or by feature edge. See *Selecting objects within the current viewport*, for instructions. See *Using the angle and feature edge method to select multiple objects*, for details about selecting by angle or feature edge.

   Click **Complete** when you are done selecting nodes.

   Note:

   If there are multiple part instances in the assembly, you may only select nodes for reduced search on one instance.

Finding the average temperature of a set of elements

The **Volume Weighted Average Temperature** plug-in lets you calculate the average temperature for all elements or any subset of elements in an analysis. The elements can be picked in the viewport or selected from a predefined named set. If there are multiple part instances in the assembly, you can select elements on only one instance. Results can be requested at the current time for the model displayed in the viewport or as an *X–Y* time curve over all steps in the analysis.

This plug-in can be used only with an output database (`.odb`) file. The field output variables IVOL and TEMP must be available in the output database for the whole model.

1. From the main menu bar in the Visualization module, select **Plug-ins->Tools->Volume Weighted Average Temperature**.

   The **Volume Weighted Average Temperature** dialog box appears.

2. Choose the time for which the average temperature will be calculated:

   - Choose **Current step/frame** to find the temperature only during the step and frame currently displayed in the viewport.
   - Choose **All steps** to calculate and plot the temperature over the course of the entire analysis.

3. Select the elements in which the average temperature will be calculated. You can select all of the model's elements or a subset.

   - Click **Select From Viewport**, and follow the prompts to pick the elements either individually, by angle, or by feature edge. See *Selecting objects within the current viewport*, for instructions. See *Using the angle and feature edge method to select multiple objects*, for details about selecting by angle or feature edge.
   - Click **Select Element Sets** to choose from a list of predefined element sets.

   Click **Complete** when you are done selecting elements.

4. Calculate the average temperature.

   - Click **Calculate** if you selected **Current step/frame**.

     The result is given in the message area at the bottom of the window, for example:

     ```
     Number of elements picked from viewport: 80 **Volume weighted
     average temperature for the selected elements No. of elements used
     in calculation: 80 Step: Step-1, Frame: 15, Current time: 15.0
     WtAvTemp: 199.883326817 Volume: 1575.0
     ```

   - Click **Plot** if you selected **All steps**.

     A time history *X–Y* plot is displayed in the current viewport. If desired, you can change the default curve name for the history plot.

Creating a planar constraint

The **Plane Remains Plane** plug-in lets you constrain a planar face on a solid body using one or more of the following techniques:

- **Create Planar Constraint**—a constraint is generated that causes the planar face to remain planar throughout an analysis. The plane can rotate and expand, but all nodes on the face will remain in-plane. This constraint is enforced using an analytical rigid surface that is placed in contact with the face with zero friction. A distributed coupling is also created between the analytical rigid surface reference node and all nodes on the face to constrain the rigid body motion of the analytical surface.
- **Create Parallel Planar Constraint**—in addition to the analytical rigid surface constraint described above, a constraint is generated that forces the planar face to remain parallel to its original configuration.
- **Create Beam Element Normal to Plane**—a beam element of any length is generated normal to the planar face and attached to the analytical rigid surface reference node through a kinematic coupling. This technique requires that you first create either of the constraints described above.

The plug-in has the following limitations:

- If picking multiple planes to constrain, you must pick planes that are parallel. There is no automatic check that multiple planes are parallel.
- When applying temperature fields, separate fields must be created for the solid and beam regions.
- The analytical rigid surface will be sized to cover the entire plane in most cases, but there can be cases in which the size is insufficient. You should visually confirm the size of the analytical rigid surface; if the surface is too small, you will have to edit its dimensions in the Part module.
- If the solid body is edited, the constraints must be deleted and redefined.

1. From the main menu bar in the Interaction module, select **Plug-ins->Tools->Plane Remains Plane->Create Planar Constraint** or **Create Parallel Planar Constraint**.
2. Follow the prompts to select the surface that is to remain planar. Select the surfaces either individually, by face angle, or by face curvature. See *Selecting objects within the current viewport*, for instructions.

   Click **Done** when you are finished selecting surfaces.
3. In the **Scaling Factor for ARS Plane** dialog box, enter your desired scaling factor for the analytical rigid surface, and click **OK**.
4. If desired, select **Plug-ins->Tools->Plane Remains Plane->Create Beam Element Normal to Plane** to add a beam element normal to the plane. Follow the prompts to select an analytical rigid surface (to define the beam direction), specify the end point of the beam, and enter the length of the beam.

Resetting midside nodes

Abaqus/CAE automatically projects midside nodes onto the geometry during meshing. In cases where the element quality is adversely affected, you can use the **Reset Midside Nodes** plug-in to reset the midside nodes of quadratic elements to the average position of the edge end nodes. You can define the region containing the nodes to reset by selecting from the geometry, mesh, sets, or surfaces. You can access the plug-in only from the Mesh module.

1. From the main menu bar in the Mesh module, select **Plug-ins->Tools->Reset Midside Nodes**.

   The **Reset Midside Nodes** dialog box appears.

2. Select one of the following methods to define the region containing the nodes to reset:

   - **Pick from viewport**
   - **Select sets**
   - **Select surfaces**

3. If you selected **Pick from viewport**, select regions from the viewport and click **Done**.

   Abaqus/CAE resets the midside nodes of the quadratic elements in the selected region to the average position of the edge end nodes.

4. If you are selecting sets or surfaces, select existing sets or surfaces from the **Region Selection** dialog box that appears, and click **OK**. To limit the lists for easier selection, type a filter pattern into the **Name filter** field, and press the **[Enter]** key to apply the filter.

   Tip: Toggle on **Highlight selections in viewport** to preview the selected sets or surfaces.

   Abaqus/CAE resets the midside nodes of the quadratic elements in the selected region to the average position of the edge end nodes.

5. You can undo and redo multiple changes that you make resetting the midside nodes.
6. Click **Dismiss** to close the **Reset Midside Nodes** dialog box.

ODB Reducer/Builder

The **ODB Reducer/Builder** plug-in provides a method to take portions of an Abaqus output database (`.odb`) file and put them into a new Abaqus output database.
The ability to choose among many options for data to include in a new output database makes this tool useful for a number of applications, including:

- Sharing portions of results files with downstream engineers, other teams, and external partners.
- Decreasing database load times.
- Reducing storage footprint by paring down the output database files to store only certain relevant results.

The plug-in offers control of the data to include in the new output database in several categories.

Mesh

Choose which elements and nodes are included in the new database.

Model features

Choose which set or surface definitions, sections, materials, profiles, and datums to include in the new database.

Results features

Choose which steps and frames (and which field output from those steps and frames) to include in the new database. Choose whether or not history output is included.

Note: Characters such as ':' and ';' are not allowed in step names within the ODB.

1. From the main menu in the Visualization module, select **Plug-ins->Tools->ODB Reducer/Builder**.
   The **ODB Reducer/Builder** dialog box appears.
2. From the **Model Features** frame, toggle off **Sets** to disable the **Sets** tab and exclude all the element, node, and surface set definitions from the resulting database. Toggle on **Sets** to access the options in the **Sets** tab.
3. From the **Model Features** frame, toggle off **Properties** to disable the **Properties** tab and exclude all section, material, and profile data from the resulting database. Toggle on **Properties** to access the options in the **Properties** tab.
4. From the **Model Features** frame, toggle off **Datums** to disable the **Datums** tab and exclude all the datums in the resulting database. Toggle on **Datums** to access the options in the **Datums** tab.
5. From the **Results Features** frame, toggle off **Steps/Frames** to disable the **Steps/Frames** tab and exclude all the steps/frames from the resulting database. Toggle on **Steps/Frames** to access the options in the **Steps/Frames** tab.

   Note: Because field output and history output are dependent on steps/frames, field and history output data will not be available in the resulting output database when **Steps/Frames** is toggled off.

6. From the **Results Features** frame, toggle off **Field outputs** to disable the **Field Outputs** tab and exclude all the field outputs from the resulting database. Toggle on **Field outputs** to access the options in the **Field Outputs** tab.

7. From the **Results Features** frame, toggle off **History outputs** to disable the **History** tab and exclude all the history outputs from the resulting database. Toggle on **History outputs** to include all the history outputs in the resulting database.

    **Note:** There are no filters for history outputs.

8. Use the **Mesh** tab to select which regions of the model to include in the new output database.
   a. Select **Currently displayed** to include areas of the mesh that are currently displayed in the current viewport.
   b. Select **From session file** to load a display group from a file. In the **Session file** text field, use the file selector or type in the name of an `.xml` file and type in the name of the display group in the **Display Group Name** text field.
   c. Select **Bounding box** to include the mesh within or outside a specified box. Specify numerical values for **x Min**, **x Max**, **y Min**, **y Max**, **z Min**, and **z Max** in their corresponding text fields. Choose **Inside** or **Outside** from the list to include the mesh lying within the bounding box or outside it.
   d. Select **Bounding cylinder** to include the mesh within or outside a specified cylinder. Enter three comma-separated numerical values for **Origin point** and **Axis vector** and a single numerical value for **Radius** in their corresponding text fields. Choose **Inside** or **Outside** from the list to include the mesh lying within the bounding cylinder or outside it.
   e. Select **Bounding sphere** to include the mesh within or outside a specified sphere. Enter three comma-separated numerical values for **Origin point** and a single numerical value for **Radius** in their corresponding text fields. Choose **Inside** or **Outside** from the list to include the mesh lying within the bounding sphere or outside it.
   f. Select **Instances**, and use the selection box to include the mesh only from the specified part instances.
   g. Select **Sets**, and use the selection box to include the mesh from the specified sets.

    **Note:** Use the **Mesh Preview Toggle** button to preview the selection.

9. When the **Sets** tab is enabled,
   a. Toggle on **Node sets** to write node set definitions to the new output database. Select **All** to include all the node sets, or use **Select** to specify a list of node sets add to the new database.
   b. Toggle on **Element sets** to write element set definitions to the new output database. Select **All** to include all the element sets, or use **Select** to specify a list of element sets to add to the new database.
   c. Toggle on **Surface sets** to write surface set definitions to the new output database. Select **All** to include all the surface sets, or use **Select** to specify a list of surface sets to add to the new database.

10. When the **Properties** tab is enabled,
    a. Toggle on **Sections** to write section data to the new output database. Select **Keep all data** to retain all the information. **Nullify All** and **Nullify selected** create the empty containers without data. Use these options to create section names without the section properties.
    b. Toggle on **Materials** to write material data to the new output database. Select **Keep all data** to retain all the information. **Nullify All** and **Nullify selected** create the empty containers without data. Use these options to create material names without the material properties.
    c. Toggle on **Profiles** to write profile data to the new output database. Select **Keep all data** to retain all the information. **Nullify All** and **Nullify selected** create the empty containers without data. Use these options to create profile names without the profile properties.

11. When the **Datums** tab is enabled, select **All** to include all the datums, or **Select** a list of datums from the selection box.

12. When the **Steps/Frames** tab is enabled,

a. Select **Match field requests** to use the list of steps and frames from the **Field Outputs** tab.
b. Select **Last frame of last step** to include only the last frame of the last step in the output database.
c. Select **Last frame of each step** to include the last frame of all the steps in the output database.
d. Use **Select below** to activate the **Steps** and **Frames** selection tables and buttons. After selecting the required frames for a particular step, click **Update Frame Selection** to include the selected frame in the output database. Repeat this process for each step. Use **Remove Selected Step** or **Remove All Steps** to exclude all or the selected step from the previously made choices.

Note: A preview of selected steps/frames is shown in the **Current individually selected steps/frames** box below.

13. When the **Field Outputs** tab is enabled,
    a. Select **All fields** to include all the field outputs in the output database.
    b. Use **Select below** to activate the **Steps**, **Frames**, and **Fields** selection tables and buttons. After selecting the required field outputs for a particular step and frame combination, click **Update Output Selection** to include the selected field outputs in the output database. Repeat this process for each step/frame combination. Click **Apply To Step** to include the selected field outputs in all the frames within the selected step. Click **All Steps/Frames** to include the selected field outputs in all the steps and frames. Use **Remove Selected** or **Remove All** under the **Steps** selection table to exclude all field outputs for all the steps or the selected step from the previously made choices. Use **Remove Selected** or **Remove All** under the **Frames** selection table to exclude all field outputs for all the frames or the selected frame from the previously made choices.

Note: A preview of selected field outputs is shown in the **Current individually selected field outputs** box below.

14. If desired, save the settings to a file by clicking **Save Settings** after specifying a filename in the **File** text field in the **Controls** box. You can load the settings later by clicking **Load Settings** after specifying the filename in the **File** text field.
15. Use the **ODB name append** text field to specify the name of the generated output database. The new database is saved to the same location as the currently open output database, using the original file name but with the specified text appended before the `.odb` extension.
16. Click **Generate ODB (and close)** to generate the output database and close the plug-in. Click **Generate ODB (and stay)** to generate the output database and keep the dialog box open.

    Check the Abaqus/CAE message area and the replay file for more information about the output database generation. Abaqus/CAE automatically opens the new output database after the process is completed.

Additive manufacturing

The additive manufacturing plug-in offers a comprehensive and scalable software solution that minimizes the risk of making mistakes when modeling the additive manufacturing process using Abaqus.

You activate the plug-in by selecting **AM Modeler (Show/Hide)** in the **Plug-ins** menu. The **AM Modeler** tab appears with the **Models** and **Results** tabs in the Model Tree area of the main window.

To create an additive manufacturing model, click mouse button 3 and select **Create AM Model** from the menu.

You must select the analysis type and the process type according to the additive manufacturing process you want to simulate. There are two analysis types available: eigenstrain and thermomechanical.

For the eigenstrain analysis type, you can choose between the trajectory-based or pattern-based process type.

For the thermomechanical analysis type, you can choose between four process types:

- Trajectory-based powder bed fabrication
- Pattern-based powder bed fabrication
- Laser direct energy deposition
- Fusion deposition modeling

In this section:

- *Trajectory-based thermomechanical process*
- *Pattern-based thermomechanical process*
- *Trajectory-based eigenstrain process*
- *Pattern-based eigenstrain process*
- *Event series*

Trajectory-based thermomechanical process

You can use the additive manufacturing plug-in to simulate a trajectory-based thermomechanical analysis.

1. In the **Create AM Model** dialog box, select **Thermo-Mechanical** as the analysis type.
2. For the process type, select **Trajectory-based powder bed fabrication**, **Laser direct energy deposition**, or **Fusion deposition modeling**.
3. Specify the thermal and structural models for the simulation, and click **OK**.

   A new AM model appears in the AM Modeler tree. If you expand the node for the AM model, four subnodes display: **Material Input**, **Moving Heat Source**, **Cooling**, and **Event Series**.
4. From the **Event Series** subnode, select **Create/Edit** from the mouse button 3 menu to specify any kind of trajectory or path of the tools (such as laser beam or roller) used in the additive manufacturing process.

   See *Event series* for more information.
5. From the **Material Input** subnode, select **Create** from the mouse button 3 menu to specify all the structural inputs for modeling the additive manufacturing process.

   Abaqus/CAE populates the field with default values. Enter your desired values, and click **OK**.
6. From the **Moving Heat Source** subnode, select **Create** from the mouse button 3 menu to specify all the thermal inputs for modeling the additive manufacturing process.

   Abaqus/CAE populates the field with default values. Enter your desired values, and click **OK**.
7. From the **Cooling** subnode, select **Create** from the mouse button 3 menu to specify thermal interactions (such as radiation and convection) on the model.

   Abaqus/CAE populates the field with default values. You can define radiation and convection cooling interaction. Enter your desired values, and click **OK**.

Pattern-based thermomechanical process

You can use the additive manufacturing plug-in to simulate a pattern-based thermomechanical analysis.

1. In the **Create AM Model** dialog box, select **Thermo-Mechanical** as the analysis type.
2. For the process type, select **Pattern-based powder bed fabrication**.
3. Specify the thermal and structural models for the simulation, and click **OK**.

   A new AM model appears in the AM Modeler tree. If you expand the node for the AM model, four subnodes display: **Material Input**, **Moving Heat Source**, **Cooling**, and **Event Series**.
4. From the **Event Series** subnode, select **Create/Edit** from the mouse button 3 menu to specify any kind of trajectory or path of the tools (such as laser beam or roller) used in the additive manufacturing process.

   See *Event series* for more information.
5. From the **Material Input** subnode, select **Create** from the mouse button 3 menu to specify all the structural inputs for modeling the additive manufacturing process.

   Abaqus/CAE populates the field with default values. Enter your desired values, and click **OK**.
6. From the **Moving Heat Source** subnode, select **Create** from the mouse button 3 menu to specify all the thermal inputs for modeling the additive manufacturing process.

   Abaqus/CAE populates the field with default values. Enter your desired values, and click **OK**.
7. From the **Cooling** subnode, select **Create** from the mouse button 3 menu to specify thermal interactions (such as radiation and convection) on the model.

   Abaqus/CAE populates the field with default values. You can define radiation and convection cooling interaction. Enter your desired values, and click **OK**.

Trajectory-based eigenstrain process

You can use the additive manufacturing plug-in to simulate a trajectory-based eigenstrain analysis.

1. In the **Create AM Model** dialog box, select **Eigenstrain** as the analysis type.
2. For the process type, select **Trajectory based**.
3. Specify the structural model for the simulation, and click **OK**.

   A new AM model appears in the AM Modeler tree. If you expand the node for the AM model, two subnodes display: **Material Input** and **Event Series**.
4. From the **Event Series** subnode, select **Create/Edit** from the mouse button 3 menu to specify any kind of trajectory or path of the tools (such as laser beam or roller) used in the additive manufacturing process.

   See *Event series* for more information.
5. From the **Material Input** subnode, select **Create** from the mouse button 3 menu to specify all the structural inputs for modeling the additive manufacturing process.

   Abaqus/CAE populates the field with default values. Enter your desired values, and click **OK**.

Pattern-based eigenstrain process

You can use the additive manufacturing plug-in to simulate a pattern-based eigenstrain analysis.

1. In the **Create AM Model** dialog box, select **Eigenstrain** as the analysis type.
2. For the process type, select **Pattern based**.
3. Specify the structural model for the simulation, and click **OK**.

   A new AM model appears in the AM Modeler tree. If you expand the node for the AM model, the **Material Input** subnode displays.
4. From the **Material Input** subnode, select **Create** from the mouse button 3 menu to specify all the structural inputs for modeling the additive manufacturing process.

   Abaqus/CAE populates the field with default values.
5. Enter your desired values, and click **OK**.

Event series

You can use the additive manufacturing plug-in to define an event series.

1. In the **AM Modeler** tab, select **Event Series->Create/Edit**.
2. Select the model in the **Model** box.
3. Select **Event Series Type**.

   Abaqus/CAE populates some default built-in **Event Series Types** for the additive manufacturing process.
4. **Optional:** You can select **Custom** in the **Event Series Type** box and define your own type.

   A new **Event Series Structure** tab appears. Specify the name of the **Event Series Type**, **fields number**, and **fields names**. The fields described below appear on the new **Event Series Data** tab.
5. Specify the **Event series name**.
6. Specify the time span as either **Step time** or **Total time**.
7. Specify the field values.

   You can specify field values through a `SIM`, `INP`, or `CSV` file or enter the values directly in a table. Select the appropriate entry from the **Data** source list, and specify the file or the table entries.
8. To define additional event series, create additional tabs by clicking the **+** symbol.

   Repeat the above step for each event series.
9. Click **OK** to finish defining the event series.

View cut along a path

View Cut Along a Path plug-in is used to move a cut plane through the model along a user defied point-list or node-list path. You can access the plug-in only from the the Visualization module.

1. From the main menu bar in the the Visualization module, select **Plug-ins->View Cut Along a Path**.

   The **View Cut Along a Path** dialog box appears.

2. Select a path from the **Choose Path:** combo box.

   Tip: Click the path icon to create a new path.

3. Toggle on **Display free body forces** from **Options** to view free body forces at the point on the path as cut plane moves along.
4. Slide the **Move along a path** slider to move the cut plane along the path from **Start** to **End** of the path.

   The cut plane is positioned so that the point on the path corresponding to the slider movement lies on the cut plane and the tangent to the spline fitted through the path points is normal to the plane.

5. Slide the **Axis-2** and **Axis-3** sliders to rotate the cut plane along orthogonal axes at the given position on the path from **-90** to **90** degrees.

   The orthogonal axes **Axis-2** and **Axis-3** are Normal and Bi-normal of the Frenet–Serret frame at the given point of the spline fitted through the path points.

6. Click **Reset Rotations** to reset **Axis-2** and **Axis-3** rotations to zero.
7. Click **OK** to close the **View Cut Along a Path** dialog box retaining current view cut.
8. Click **Cancel** to close the **View Cut Along a Path** dialog box.

Appendix

The following sections provide information about the use of keywords, special element types, graphical symbols, and element and output variables in Abaqus/CAE.

In this section:

- *Abaqus keyword browser table*
- *Keyword support from the input file reader*
- *Special element types*
- *Special graphical symbols*
- *Element and output variable support*

Abaqus keyword browser table

Use the following table to determine which Abaqus/CAE module (or toolset) contains the functionality associated with a particular Abaqus keyword. To view documentation for the module (or toolset), click the module (or toolset) name shown in the table. Most currently unsupported keywords can be added to your model using the Keywords Editor.

To see keywords beginning with a particular letter of the alphabet, click that letter in the table below.

A	*B*	*C*	*D*	*E*	*F*	*G*	*H*	*I*	*J*	*K*	*L*	*M*
N	*O*	*P*	Q	*R*	*S*	*T*	*U*	*V*	*W*	X	Y	Z

Table 38: Keyword browser table.

Keyword	Purpose	Module	Products
**ACOUSTIC CONTRIBUTION*	Request the computation of the acoustic contribution factors for the linear, eigenmode-based, steady-state dynamic procedure.	Unsupported	Abaqus/Standard
**ACOUSTIC FLOW VELOCITY*	Specify flow velocities as a predefined field for acoustic elements.	Unsupported	Abaqus/Standard
**ACOUSTIC MEDIUM*	Specify an acoustic medium.	*Property module*	Abaqus/Standard Abaqus/Explicit
**ACOUSTIC WAVE FORMULATION*	Specify the type of formulation in acoustic problems with incident wave loading.	*Model attribute*	Abaqus/Standard Abaqus/Explicit
**ACTIVATE ELEMENTS*	Activate elements within a step.	Unsupported	Abaqus/Standard
**ADAPTIVE MESH*	Define an adaptive mesh domain.	Supported in the *Step module*; only one adaptive mesh domain can be defined per step.	Abaqus/Standard Abaqus/Explicit
**ADAPTIVE MESH CONSTRAINT*	Specify constraints on the motion of the mesh for an adaptive mesh domain.	Displacement and velocity adaptive mesh constraints are supported in the *Step module*.	Abaqus/Standard Abaqus/Explicit
**ADAPTIVE MESH CONTROLS*	Specify controls for the adaptive meshing and advection algorithms.	*Step module*	Abaqus/Standard Abaqus/Explicit
**ADAPTIVE MESH REFINEMENT*	Activate adaptive mesh refinement in an Eulerian domain.	Unsupported	Abaqus/Explicit
**ADAPTIVE REMESH*	Specify an adaptive remesh domain	Unsupported	Abaqus/Standard
**ADAPTIVE REMESH RETAIN*	Specify mesh or mesh geometry entities that need to be	Unsupported	Abaqus/Standard

Keyword	Purpose	Module	Products
	reconstructed in the adaptive domain.		
**ADJUST*	Adjust user-specified nodal coordinates to lie on a given surface or to make adjustments based on a user-specified distribution.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**ALLOWABLE STRESS*	Specify the allowable stress of a composite at the initiation of damage in a multiscale material.	Unsupported	Abaqus/Standard
**AMPLITUDE*	Define an amplitude curve.	*Amplitude toolset*; bubble loading is not supported. Similar functionality is available in the *Interaction module*.	Abaqus/Standard Abaqus/Explicit
**ANISOTROPIC HYPERELASTIC*	Specify anisotropic hyperelastic properties for approximately incompressible materials.	*Property module*	Abaqus/Standard Abaqus/Explicit
**ANNEAL*	Anneal the structure.	*Step module*	Abaqus/Explicit
**ANNEAL TEMPERATURE*	Specify material properties for modeling annealing or melting.	*Property module*	Abaqus/Standard Abaqus/Explicit
**AQUA*	Define fluid variables for use in loading immersed beam-type structures.	Unsupported	Abaqus/Aqua
**ASSEMBLY*	Begin an assembly definition.	*Assembly module*	Abaqus/Standard Abaqus/Explicit
**ASYMMETRIC-AXISYMMETRIC*	Define areas of integration for contact elements used with CAXA*n* or SAXA*n* elements.	Unsupported	Abaqus/Standard
**AXIAL*	Used to define the axial behavior of beams.	Unsupported	Abaqus/Standard Abaqus/Explicit
**BASE MOTION*	Define the base motion for linear, eigenmode-based, dynamic procedures.	Unsupported	Abaqus/Standard
**BASELINE CORRECTION*	Include baseline correction.	*Amplitude toolset*	Abaqus/Standard
**BEAM ADDED INERTIA*	Define additional beam inertia.	Unsupported	Abaqus/Standard Abaqus/Explicit
**BEAM FLUID INERTIA*	Define additional beam inertia due to immersion in a fluid.	*Property module*	Abaqus/Standard Abaqus/Explicit

Keyword	Purpose	Module	Products
**BEAM GENERAL SECTION*	Specify a beam section when numerical integration over the section is not required.	General beam sections with linear response are supported in the *Property module*.	Abaqus/Standard Abaqus/Explicit
**BEAM SECTION*	Specify a beam section when numerical integration over the section is required.	*Property module*	Abaqus/Standard Abaqus/Explicit
**BEAM SECTION GENERATE*	Generate beam section properties for a meshed cross-section.	Unsupported	Abaqus/Standard
**BEAM SECTION OFFSET*	Define an offset for the beam cross-section origin.	*Property module*	Abaqus/Standard Abaqus/Explicit
**BIAXIAL TEST DATA*	Used to provide biaxial test data (compression and/or tension).	*Property module*	Abaqus/Standard Abaqus/Explicit
**BLOCKAGE*	Control contacting surfaces for blockage.	Unsupported	Abaqus/Explicit
**BOUNDARY*	Specify boundary conditions.	*Load module*; fluid cavity pressure and generalized plane strain boundary conditions are not supported.	Abaqus/Standard Abaqus/Explicit
**BRITTLE CRACKING*	Define brittle cracking properties.	*Property module*	Abaqus/Explicit
**BRITTLE FAILURE*	Specify brittle failure criterion.	*Property module*	Abaqus/Explicit
**BRITTLE SHEAR*	Define the postcracking shear behavior of a material used with the brittle cracking model.	*Property module*	Abaqus/Explicit
**BUCKLE*	Obtain eigenvalue buckling estimates.	*Step module*	Abaqus/Standard
**BUCKLING ENVELOPE*	Define a nondefault buckling envelope for buckling strut response of frame elements with PIPE sections.	Unsupported	Abaqus/Standard
**BUCKLING LENGTH*	Define buckling length data for buckling strut response of frame elements with PIPE sections.	Unsupported	Abaqus/Standard
**BUCKLING REDUCTION FACTORS*	Define buckling reduction factors for buckling strut response of frame elements with PIPE sections.	Unsupported	Abaqus/Standard
**BULK VISCOSITY*	Modify bulk viscosity parameters.	*Step module*	Abaqus/Explicit
**C ADDED MASS*	Specify concentrated added mass in a *FREQUENCY step.	Unsupported	Abaqus/Aqua

Keyword	Purpose	Module	Products
**CAP CREEP*	Specify a cap creep law and material properties.	*Property module*	Abaqus/Standard
**CAP HARDENING*	Specify Drucker-Prager/Cap plasticity hardening.	*Property module*	Abaqus/Standard Abaqus/Explicit
**CAP PLASTICITY*	Specify the Modified Drucker-Prager/Cap plasticity model.	*Property module*	Abaqus/Standard Abaqus/Explicit
**CAPACITY*	Define the molar heat capacity at constant pressure for an ideal gas species.	*Interaction module*	Abaqus/Explicit
**CAST IRON COMPRESSION HARDENING*	Specify hardening in compression for the gray cast iron plasticity model.	*Property module*	Abaqus/Standard Abaqus/Explicit
**CAST IRON PLASTICITY*	Specify plastic material properties for gray cast iron.	*Property module*	Abaqus/Standard Abaqus/Explicit
**CAST IRON TENSION HARDENING*	Specify hardening in tension for the gray cast iron plasticity model.	*Property module*	Abaqus/Standard Abaqus/Explicit
**CAVITY DEFINITION*	Define a cavity for thermal radiation.	*Interaction module*	Abaqus/Standard
**CECHARGE*	Specify concentrated electric charges in piezoelectric analysis.	*Load module*	Abaqus/Standard
**CECURRENT*	Specify concentrated current in an electric conduction analysis.	*Load module*	Abaqus/Standard
**CENTROID*	Define the position of the centroid of the beam section.	*Property module*	Abaqus/Standard Abaqus/Explicit
**CFILM*	Define film coefficients and associated sink temperatures at one or more nodes or vertices.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**CFLOW*	Specify concentrated fluid flow.	*Load module*	Abaqus/Standard
**CFLUX*	Specify concentrated fluxes in heat transfer, mass diffusion, or electrochemical analyses.	*Load module*	Abaqus/Standard Abaqus/Explicit
**CHANGE FRICTION*	Change friction properties.	*Interaction module*	Abaqus/Standard
**CHARACTERISTIC LENGTH*	Define characteristic element length at a material point.	Unsupported	Abaqus/Explicit
**CLAY HARDENING*	Specify hardening for the clay plasticity model.	*Property module*	Abaqus/Standard Abaqus/Explicit

Keyword	Purpose	Module	Products
**CLAY PLASTICITY*	Specify the extended Cam-clay plasticity model.	*Property module*	Abaqus/Standard Abaqus/Explicit
**CLEARANCE*	Specify a particular initial clearance value and a contact direction for the secondary nodes on a surface.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**CLOAD*	Specify concentrated forces and moments.	*Load module*	Abaqus/Standard Abaqus/Explicit Abaqus/Aqua
**CLUSTER MASS INERTIA TABLE*	Specify mass and inertia discrete particle clusters.	Unsupported	Abaqus/Explicit
**COHESIVE BEHAVIOR*	Specify contact cohesive behavior properties.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**COHESIVE SECTION*	Specify element properties for cohesive elements.	*Property module*	Abaqus/Standard Abaqus/Explicit
**COMBINATORIAL RULE*	Define controls associated with combinatorial rules to derive interaction properties from surface properties.	Unsupported	Abaqus/Explicit
**COMBINED TEST DATA*	Specify simultaneously the normalized shear and bulk compliances or relaxation moduli as functions of time.	*Property module*	Abaqus/Standard Abaqus/Explicit
**COMPLEX FREQUENCY*	Extract complex eigenvalues and modal vectors.	*Step module*	Abaqus/Standard
**COMPOSITE MODAL DAMPING*	Specify composite modal damping for modal analyses based on the SIM architecture.	Unsupported	Abaqus/Standard
**CONCENTRATION TENSOR*	Define the concentration tensor for an inclusion in the aggregate.	Unsupported	Abaqus/Standard
**CONCRETE*	Define concrete properties beyond the elastic range.	*Property module*	Abaqus/Standard
**CONCRETE COMPRESSION DAMAGE*	Define compression damage properties for the concrete damaged plasticity model.	*Property module*	Abaqus/Standard Abaqus/Explicit
**CONCRETE COMPRESSION HARDENING*	Define hardening in compression for the concrete damaged plasticity model.	*Property module*	Abaqus/Standard Abaqus/Explicit
**CONCRETE DAMAGED PLASTICITY*	Define flow potential, yield surface, and viscosity parameters	*Property module*	Abaqus/Standard Abaqus/Explicit

Keyword	Purpose	Module	Products
	for the concrete damaged plasticity model.		
**CONCRETE FAILURE*	Specify material failure criteria and allow element deletion for the concrete damaged plasticity material model.	Unsupported	Abaqus/Explicit
**CONCRETE TENSION DAMAGE*	Define postcracking damage properties for the concrete damaged plasticity model.	*Property module*	Abaqus/Standard Abaqus/Explicit
**CONCRETE TENSION STIFFENING*	Define postcracking properties for the concrete damaged plasticity model.	*Property module*	Abaqus/Standard Abaqus/Explicit
**CONDUCTIVITY*	Specify thermal conductivity.	*Property module*	Abaqus/Standard Abaqus/Explicit
**CONNECTOR BEHAVIOR*	Begin the specification of a connector behavior.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**CONNECTOR CONSTITUTIVE REFERENCE*	Define reference lengths and angles to be used in specifying connector constitutive behavior.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**CONNECTOR DAMAGE EVOLUTION*	Specify connector damage evolution for connector elements.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**CONNECTOR DAMAGE INITIATION*	Specify connector damage initiation criteria for connector elements.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**CONNECTOR DAMPING*	Define connector damping behavior.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**CONNECTOR DERIVED COMPONENT*	Specify user-defined components in connector elements.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**CONNECTOR ELASTICITY*	Define connector elastic behavior.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**CONNECTOR FAILURE*	Define a failure criterion for connector elements.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**CONNECTOR FRICTION*	Define friction forces and moments in connector elements.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**CONNECTOR HARDENING*	Define the plasticity initial yield value and hardening behavior in connector elements.	*Interaction module*	Abaqus/Standard Abaqus/Explicit

Keyword	Purpose	Module	Products
**CONNECTOR LOAD*	Specify loads for available components of relative motion in connector elements.	*Load module*	Abaqus/Standard Abaqus/Explicit
**CONNECTOR LOCK*	Define a locking criterion for connector elements.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**CONNECTOR MOTION*	Specify the motion of available components of relative motion in connector elements.	*Load module*	Abaqus/Standard Abaqus/Explicit
**CONNECTOR PLASTICITY*	Define plasticity behavior in connector elements.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**CONNECTOR POTENTIAL*	Specify user-defined potentials in connector elements.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**CONNECTOR SECTION*	Specify connector attributes for connector elements.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**CONNECTOR STOP*	Specify connector stops for connector elements.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**CONNECTOR UNIAXIAL BEHAVIOR*	Define uniaxial behavior in connector elements.	*Interaction module*	Abaqus/Explicit
**CONSTITUENT*	Define a constituent in the multiscale material.	Unsupported	Abaqus/Standard Abaqus/Explicit
**CONSTRAINT CONTROLS*	Reset overconstraint checking controls.	Unsupported	Abaqus/Standard
**CONTACT*	Begin the definition of general contact.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**CONTACT CLEARANCE*	Define contact clearance properties.	Unsupported	Abaqus/Explicit
**CONTACT CLEARANCE ASSIGNMENT*	Assign contact clearances between surfaces in the general contact domain.	Unsupported	Abaqus/Explicit
**CONTACT CONTROLS*	Specify additional controls for contact.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**CONTACT CONTROLS ASSIGNMENT*	Assign contact controls for the general contact algorithm.	Unsupported	Abaqus/Standard Abaqus/Explicit
**CONTACT DAMPING*	Define viscous damping between contacting surfaces.	*Interaction module*	Abaqus/Standard Abaqus/Explicit

Keyword	Purpose	Module	Products
**CONTACT EXCLUSIONS*	Specify self-contact surfaces or surface pairings to exclude from the general contact domain.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**CONTACT FILE*	Define results file requests for contact variables.	Unsupported; Abaqus/CAE reads output from the output database file only.	Abaqus/Standard
**CONTACT FORMULATION*	Specify a nondefault contact formulation for the general contact algorithm.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**CONTACT INCLUSIONS*	Specify self-contact surfaces or surface pairings to include in the general contact domain.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**CONTACT INITIALIZATION ASSIGNMENT*	Assign contact initialization methods for general contact.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**CONTACT INITIALIZATION DATA*	Define contact initialization methods for general contact.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**CONTACT INTERFERENCE*	Prescribe time-dependent allowable interferences of contact pairs and contact elements.	*Interaction module*	Abaqus/Standard
**CONTACT MASS SCALING*	Specify contact mass scaling during the step.	*Interaction module*	Abaqus/Explicit
**CONTACT OUTPUT*	Specify contact variables to be written to the output database.	*Step module*	Abaqus/Standard Abaqus/Explicit
**CONTACT PAIR*	Define surfaces that contact each other.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**CONTACT PERMEABILITY*	Specify fluid permeability contact property.	Unsupported	Abaqus/Standard
**CONTACT PRINT*	Define print requests for contact variables.	Unsupported	Abaqus/Standard
**CONTACT PROPERTY ASSIGNMENT*	Assign contact properties for the general contact algorithm.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**CONTACT RESPONSE*	Define contact responses for design sensitivity analysis.	Unsupported	Abaqus/Design
**CONTACT STABILIZATION*	Define contact stabilization controls for general contact.	*Interaction module*	Abaqus/Standard
**CONTOUR INTEGRAL*	Provide contour integral estimates.	*Interaction module*	Abaqus/Standard
**CONTROLS*	Reset solution controls.	*Step module*	Abaqus/Standard

Keyword	Purpose	Module	Products
**CONWEP CHARGE PROPERTY*	Define a CONWEP charge for incident waves.	Unsupported	Abaqus/Explicit
**CORRELATION*	Define cross-correlation properties for random response loading.	Unsupported	Abaqus/Standard
**CO-SIMULATION*	Identify that the current step is a co-simulation step in Abaqus.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**CO-SIMULATION REGION*	Identify the interface regions in the Abaqus model and specify the fields to be exchanged during co-simulation.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**COUPLED CONSTITUTIVE RESPONSE*	This option is used to introduce a user-defined constitutive behavior involving multiple physics fields.	Unsupported	Abaqus/Standard
**COUPLED TEMPERATURE-DISPLACEMENT*	Fully coupled, simultaneous heat transfer and stress analysis.	*Step module*	Abaqus/Standard
**COUPLED THERMAL-ELECTRICAL*	Fully coupled, simultaneous heat transfer and electrical analysis.	*Step module*	Abaqus/Standard
**COUPLED THERMAL-ELECTROCHEMICAL*	Define a coupled thermal-electrochemical analysis.	*Step module*	Abaqus/Standard
**COUPLING*	Define a surface-based coupling constraint.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**CRADIATE*	Specify radiation conditions and associated sink temperatures at one or more nodes or vertices.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**CREEP*	Define a creep law.	*Property module*	Abaqus/Standard
**CREEP STRAIN RATE CONTROL*	Control loadings based on the maximum equivalent creep strain rate.	Unsupported	Abaqus/Standard
**CRUSH STRESS*	Define the crush stress of a material.	Unsupported	Abaqus/Explicit
**CRUSH STRESS VELOCITY FACTOR*	Define how the approach velocity at a crushing interface influences a material's resistance to crushing.	Unsupported	Abaqus/Explicit
**CRUSHABLE FOAM*	Specify the crushable foam plasticity model.	*Property module*	Abaqus/Standard Abaqus/Explicit
**CRUSHABLE FOAM HARDENING*	Specify hardening for the crushable foam plasticity model.	*Property module*	Abaqus/Standard Abaqus/Explicit

Keyword	Purpose	Module	Products
**CURE GLASS TRANSITION TEMPERATURE*	This option is used to specify the glass transition temperature as a function of the degree of cure.	Unsupported	Abaqus/Standard
**CURE HEAT GENERATION*	Define the specific heat of the reaction for cure modeling capabilities.	Unsupported	Abaqus/Standard
**CURE KINETICS*	Define the reaction kinetics for cure modeling capabilities.	Unsupported	Abaqus/Standard
**CURE MAX CONVERSION*	Define the maximum value of the degree of conversion for cure modeling capabilities.	Unsupported	Abaqus/Standard
**CURE SHRINKAGE*	Define the cure shrinkage coefficients for cure modeling capabilities.	Unsupported	Abaqus/Standard
**CYCLED PLASTIC*	Specify cycled yield stress data for the *ORNL model.	*Property module*	Abaqus/Standard
**CYCLIC*	Define cyclic symmetry for a cavity radiation heat transfer analysis.	*Interaction module*	Abaqus/Standard
**CYCLIC HARDENING*	Specify the size of the elastic range for the combined hardening model.	*Property module*	Abaqus/Standard Abaqus/Explicit
**CYCLIC SYMMETRY MODEL*	Define the number of sectors and the axis of symmetry for a cyclic symmetric structure.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**D ADDED MASS*	Specify distributed added mass in a *FREQUENCY step.	Unsupported	Abaqus/Aqua
**D EM POTENTIAL*	Specify distributed surface magnetic vector potential.	*Load module*	Abaqus/Standard
**DAMAGE EVOLUTION*	Specify material properties to define the evolution of damage.	*Property module*	Abaqus/Standard Abaqus/Explicit
**DAMAGE INITIATION*	Specify material and contact properties to define the initiation of damage.	*Property module*	Abaqus/Standard Abaqus/Explicit
**DAMAGE STABILIZATION*	Specify viscosity coefficients for the damage model for fiber-reinforced materials, surface-based cohesive behavior or cohesive behavior in enriched elements.	*Property module*	Abaqus/Standard Abaqus/Explicit
**DAMPING*	Specify material damping.	*Property module*	Abaqus/Standard Abaqus/Explicit

Keyword	Purpose	Module	Products
**DAMPING CONTROLS*	Specify damping controls.	Supported in the *Step module* only for substructure generation.	Abaqus/Standard
**DASHPOT*	Define dashpot behavior.	*Property module* and *Interaction module*; supported only for linear behavior independent of field variables. For nonlinear behavior or to include field variables, model connectors in the *Interaction module.*	Abaqus/Standard Abaqus/Explicit
**DEBOND*	Activate crack propagation capability and specify debonding amplitude curve.	Unsupported	Abaqus/Standard
**DECHARGE*	Input distributed electric charges for piezoelectric analysis.	*Load module*	Abaqus/Standard
**DECURRENT*	Specify distributed current densities in an electromagnetic analysis.	*Load module*	Abaqus/Standard
**DEFORMATION PLASTICITY*	Specify the deformation plasticity model.	*Property module*	Abaqus/Standard
**DENSITY*	Specify material mass density.	*Property module*	Abaqus/Standard Abaqus/Explicit
**DEPVAR*	Specify solution-dependent state variables.	*Property module*	Abaqus/Standard Abaqus/Explicit
**DESIGN GRADIENT*	Directly specify design gradients for design sensitivity analysis.	Unsupported	Abaqus/Design
**DESIGN PARAMETER*	Specify design parameters with respect to which sensitivities are calculated.	Unsupported	Abaqus/Design
**DESIGN RESPONSE*	Specify responses for design sensitivity analysis.	Unsupported	Abaqus/Standard Abaqus/Design
**DETONATION POINT*	Define detonation points for a JWL explosive equation of state.	*Property module*	Abaqus/Standard Abaqus/Explicit
**DFLOW*	Specify distributed seepage flows for consolidation analysis.	*Load module*	Abaqus/Standard
**DFLUX*	Specify distributed fluxes in a mass diffusion or electrochemical analysis, and specify distributed fluxes and nonuniform distributed fluxes in a heat transfer analysis.	*Load module*	Abaqus/Standard Abaqus/Explicit
**DIAGNOSTICS*	Control diagnostic messages.	Unsupported	Abaqus/Standard Abaqus/Explicit

Keyword	Purpose	Module	Products
**DIELECTRIC*	Specify dielectric material properties.	*Property module*	Abaqus/Standard
**DIFFUSIVITY*	Specify mass diffusivity or slurry concentration diffusivity.	*Property module*	Abaqus/Standard
**DIRECT CYCLIC*	Obtain the stabilized cyclic response of a structure directly.	*Step module*	Abaqus/Standard
**DISCRETE ELASTICITY*	Specify effective elastic material properties for discrete particles.	Unsupported	Abaqus/Explicit
**DISCRETE SECTION*	Specify element properties for discrete elements.	Unsupported	Abaqus/Explicit
**DISPLAY BODY*	Define a part instance that will be used for display only.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**DISTRIBUTING*	Define a distributing coupling constraint.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**DISTRIBUTING COUPLING*	Specify nodes and weighting for distributing coupling elements.	Unsupported; this option has been superseded by coupling constraints used in conjunction with the distributing option.	Abaqus/Standard
**DISTRIBUTION*	Define spatial distributions.	*Property module*	Abaqus/Standard Abaqus/Explicit
**DISTRIBUTION TABLE*	Define a distribution table.	*Property module*	Abaqus/Standard Abaqus/Explicit
**DLOAD*	Specify distributed loads.	*Load module*	Abaqus/Standard Abaqus/Explicit Abaqus/Aqua
**DOMAIN DECOMPOSITION*	Define a region for domain decomposition and/or define constraints on the domain decomposition.	Unsupported	Abaqus/Explicit
**DRAG CHAIN*	Specify parameters for drag chain elements.	Unsupported	Abaqus/Standard
**DRUCKER PRAGER*	Specify the extended Drucker-Prager plasticity model.	*Property module*	Abaqus/Standard Abaqus/Explicit
**DRUCKER PRAGER CREEP*	Specify a Drucker-Prager creep law and material properties.	*Property module*	Abaqus/Standard
**DRUCKER PRAGER HARDENING*	Specify hardening for Drucker-Prager plasticity models.	*Property module*	Abaqus/Standard Abaqus/Explicit

Keyword	Purpose	Module	Products
**DSA CONTROLS*	Set DSA solution controls.	Unsupported	Abaqus/Design
**DSECHARGE*	Input distributed electric surface charges for piezoelectric analysis.	*Load module*	Abaqus/Standard
**DSECURRENT*	Specify distributed current densities over a surface in an electromagnetic, fully coupled electrical, or fully coupled electrochemical analysis.	*Load module*	Abaqus/Standard
**DSFLOW*	Specify distributed seepage flows normal to a surface.	*Load module*	Abaqus/Standard
**DSFLUX*	Specify distributed surface fluxes for heat transfer analysis.	*Load module*	Abaqus/Standard Abaqus/Explicit
**DSLOAD*	Specify distributed surface loads.	*Load module*	Abaqus/Standard Abaqus/Explicit
**DYNAMIC*	Dynamic stress/displacement analysis.	*Step module*	Abaqus/Standard Abaqus/Explicit
**DYNAMIC TEMPERATURE-DISPLACEMENT*	Dynamic coupled thermal-stress analysis using explicit integration.	*Step module*	Abaqus/Explicit
**EIGENSTRAIN*	Define your eigenstrain based on different physics.	Unsupported	Abaqus/Standard
**EL FILE*	Define results file requests for element variables.	Unsupported; Abaqus/CAE reads output from the output database file only.	Abaqus/Standard Abaqus/Explicit
**EL PRINT*	Define data file requests for element variables.	Unsupported	Abaqus/Standard
**ELASTIC*	Specify elastic material properties.	*Property module*	Abaqus/Standard Abaqus/Explicit
**ELCOPY*	Create elements by copying from an existing element set.	Not applicable; copying portions of sketches and instancing of parts serve similar purposes.	Abaqus/Standard Abaqus/Explicit
**ELECTRIC MACHINE LOAD*	Define electromagnetic forces loads for an electric machine.	Unsupported	Abaqus/Standard
**ELECTRIC MACHINE PROPERTY*	Define electric machine properties (or parameters) needed to apply electric machine loads.	*Property module*	Abaqus/Standard
**ELECTRICAL CONDUCTIVITY*	Specify electrical conductivity.	*Property module*	Abaqus/Standard
**ELECTRICAL RESISTIVITY*	Specify electrical resistivity.	Unsupported	Abaqus/Standard

Keyword	Purpose	Module	Products
**ELECTROMAGNETIC*	Electromagnetic response.	*Step module*	Abaqus/Standard
**ELEMENT*	Define elements by giving their nodes.	*Mesh module*	Abaqus/Standard Abaqus/Explicit
**ELEMENT MATRIX OUTPUT*	Write element stiffness matrices and mass matrices to a file.	Unsupported	Abaqus/Standard
**ELEMENT OPERATOR OUTPUT*	Write element operator output to a SIM document.	Unsupported	Abaqus/Standard
**ELEMENT OUTPUT*	Define output database requests for element variables.	*Step module*	Abaqus/Standard Abaqus/Explicit
**ELEMENT PROGRESSIVE ACTIVATION*	Define the progressive element activation feature and its properties.	Unsupported	Abaqus/Standard
**ELEMENT RECOVERY MATRIX*	Generate modal recovery matrices for a substructure.	Unsupported	Abaqus/Standard
**ELEMENT RESPONSE*	Define element responses for design sensitivity analysis.	Unsupported	Abaqus/Standard Abaqus/Design
**ELEMENT SOLUTION-DEPENDENT VARIABLES*	Allocate space for element solution-dependent variables, and specify optional output names and descriptions for some or all variables allocated.	Unsupported	Abaqus/Standard
**ELEMENT USER OUTPUT VARIABLES*	Specify the number of user-defined element output variables.	Unsupported	Abaqus/Standard
**ELGEN*	Incremental element generation.	Not applicable; elements are generated when you *mesh*the model.	Abaqus/Standard Abaqus/Explicit
**ELSET*	Assign elements to an element set.	*Set toolset*	Abaqus/Standard Abaqus/Explicit
**EMBEDDED ELEMENT*	Specify an element or a group of elements that lie embedded in a group of “host” elements in a model.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**EMISSIVITY*	Specify surface emissivity.	*Interaction module*	Abaqus/Standard
**END ASSEMBLY*	End the definition of an assembly.	*Assembly module*	Abaqus/Standard Abaqus/Explicit
**END INSTANCE*	End the definition of an instance.	*Assembly module* for part instances not imported from a previous analysis; *Load module*	Abaqus/Standard Abaqus/Explicit

Keyword	Purpose	Module	Products
		for part instances imported from a previous analysis	
**END LOAD CASE*	End the definition of a load case for multiple load case analysis.	*Load module*	Abaqus/Standard
**END PART*	End the definition of a part.	*Part module*	Abaqus/Standard Abaqus/Explicit
**END STEP*	End the definition of a step.	*Step module*	Abaqus/Standard Abaqus/Explicit
**ENERGY FILE*	Write energy output to the results file.	Unsupported; Abaqus/CAE reads output from the output database file only.	Abaqus/Standard Abaqus/Explicit
**ENERGY OUTPUT*	Define output database requests for whole model or element set energy data.	*Step module*	Abaqus/Standard Abaqus/Explicit
**ENERGY PRINT*	Print a summary of the total energies.	Unsupported	Abaqus/Standard
**ENRICHMENT*	Specify an enriched feature and the properties of the enrichment.	*Interaction module*	Abaqus/Standard
**ENRICHMENT ACTIVATION*	Activate or deactivate an enriched feature.	*Interaction module*	Abaqus/Standard
**EOS*	Specify an equation of state model.	*Property module*	Abaqus/Explicit
**EOS COMPACTION*	Specify plastic compaction behavior for an equation of state model.	*Property module*	Abaqus/Standard Abaqus/Explicit
**EPJOINT*	Define properties for elastic-plastic joint elements.	Unsupported	Abaqus/Standard
**EQUATION*	Define linear multi-point constraints.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**EQUIVALENT RADIATED SURFACE PROPERTIES*	Specify radiated surface properties.	*Property module*	Abaqus/Standard
**EULERIAN BOUNDARY*	Define inflow and outflow conditions at Eulerian mesh boundaries.	*Load module*	Abaqus/Explicit
**EULERIAN MESH MOTION*	Define the motion of an Eulerian mesh.	*Load module*	Abaqus/Explicit
**EULERIAN SECTION*	Specify element properties for Eulerian elements.	*Property module*	Abaqus/Explicit

Keyword	Purpose	Module	Products
**EVENT SERIES*	Define the event series data.	Unsupported	Abaqus/Standard
**EVENT SERIES TYPE*	Define the type of an event series.	Unsupported	Abaqus/Standard
**EXPANSION*	Specify thermal or field expansion.	*Property module*	Abaqus/Standard Abaqus/Explicit
**EXTERNAL FIELD*	Import external fields to define distributions, initial conditions, and history-dependent fields or to perform a submodel analysis.	Unsupported	Abaqus/Standard Abaqus/Explicit
**EXTREME ELEMENT VALUE*	Define element variables to be monitored.	Unsupported	Abaqus/Explicit
**EXTREME NODE VALUE*	Define nodal variables to be monitored.	Unsupported	Abaqus/Explicit
**EXTREME VALUE*	Define element and nodal variables to be monitored.	Unsupported	Abaqus/Explicit
**FABRIC*	Specify the in-plane response of a fabric material.	Unsupported	Abaqus/Explicit
**FAIL STRAIN*	Define parameters for strain-based failure measures.	*Property module*	Abaqus/Standard Abaqus/Explicit
**FAIL STRESS*	Define parameters for stress-based failure measures.	*Property module*	Abaqus/Standard Abaqus/Explicit
**FAILURE RATIOS*	Define the shape of the failure surface for a *CONCRETE model.	*Property module*	Abaqus/Standard
**FASTENER*	Define mesh-independent fasteners.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**FASTENER PROPERTY*	Prescribe mesh-independent fastener properties.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**FATIGUE*	Define a fatigue crack growth analysis in bulk brittle materials and in brittle material interfaces.	Unsupported	Abaqus/Standard
**FIBER DISPERSION*	Define the second-order orientation tensor of fiber in a composite material.	Unsupported	Abaqus/Standard Abaqus/Explicit
**FIELD*	Specify predefined field variable values.	*Load module*	Abaqus/Standard Abaqus/Explicit
**FIELD IMPORT*	Import external fields to apply over an analysis step in a	Unsupported	Abaqus/Standard Abaqus/Explicit

Keyword	Purpose	Module	Products
	sequentially coupled multiphysics analysis.		
**FIELD MAPPER CONTROLS*	Define controls for the mapper.	Unsupported	Abaqus/Standard Abaqus/Explicit
**FIELD OPERATIONS*	Define optional field operations to perform when importing a predefined field.	Unsupported	Abaqus/Standard Abaqus/Explicit
**FILE FORMAT*	Specify format for results file output and invoke zero-increment results file output.	Unsupported; Abaqus/CAE does not use the results file.	Abaqus/Standard
**FILE OUTPUT*	Define output written to the results file.	Unsupported; Abaqus/CAE reads output from the output database file only.	Abaqus/Explicit
**FILM*	Define film coefficients and associated sink temperatures.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**FILM PROPERTY*	Define a film coefficient as a function of temperature and field variables.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**FILTER*	Define a filter and/or operator for output filtering and/or operating.	*Filter toolset*	Abaqus/Explicit
**FIXED MASS SCALING*	Specify mass scaling at the beginning of the step.	*Step module*	Abaqus/Explicit
**FLEXIBLE BODY*	Generate a flexible body from an Abaqus/Standard substructure or a natural frequency extraction.	Unsupported	Abaqus/Standard
**FLOW*	Define seepage coefficients and associated sink pore pressures.	Unsupported	Abaqus/Standard
**FLUID BEHAVIOR*	Define fluid behavior for a fluid cavity.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**FLUID BULK MODULUS*	Define compressibility for a hydraulic fluid.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**FLUID CAVITY*	Define a fluid cavity.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**FLUID DENSITY*	Specify hydrostatic fluid density.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**FLUID EXCHANGE*	Define fluid exchange.	*Interaction module*	Abaqus/Standard Abaqus/Explicit

Keyword	Purpose	Module	Products
**FLUID EXCHANGE ACTIVATION*	Activate fluid exchange definitions.	*Interaction module*	Abaqus/Explicit
**FLUID EXCHANGE PROPERTY*	Define the fluid exchange property for flow in or out of a fluid cavity.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**FLUID EXPANSION*	Specify the thermal expansion coefficient for a hydraulic fluid.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**FLUID FLUX*	Change the amount of fluid in a fluid-filled cavity.	Unsupported	Abaqus/Standard Abaqus/Explicit
**FLUID ID FIELD*	Associate a fluid identifier with a predefined field variable in a multi-fluid definition.	Unsupported	Abaqus/Standard
**FLUID INFLATOR*	Define a fluid inflator.	*Interaction module*	Abaqus/Explicit
**FLUID INFLATOR ACTIVATION*	Activate fluid inflator definitions.	*Interaction module*	Abaqus/Explicit
**FLUID INFLATOR MIXTURE*	Define gas species used for a fluid inflator.	*Interaction module*	Abaqus/Explicit
**FLUID INFLATOR PROPERTY*	Define a fluid inflator property.	*Interaction module*	Abaqus/Explicit
**FLUID LEAKOFF*	Define fluid leak-off coefficients for pore pressure cohesive elements and enriched elements.	*Property module*	Abaqus/Standard
**FLUID PIPE CONNECTOR LOSS*	Specify fluid pipe connector element loss.	Unsupported	Abaqus/Standard
**FLUID PIPE CONNECTOR SECTION*	Specify fluid pipe connector element section properties.	Unsupported	Abaqus/Standard
**FLUID PIPE CONNECTOR THERMAL LOSS*	Define the method to solve for the convective heat transfer solution in thermal fluid pipe connector elements.	Unsupported	Abaqus/Standard
**FLUID PIPE CONNECTOR WALL*	Specify wall geometry for thermal fluid pipe connector elements.	Unsupported	Abaqus/Standard
**FLUID PIPE FLOW LOSS*	Specify fluid pipe element loss.	Unsupported	Abaqus/Standard
**FLUID PIPE SECTION*	Specify fluid pipe element section properties.	Unsupported	Abaqus/Standard
**FLUID PIPE THERMAL*	Define the method to solve for the convective heat transfer solution in the thermal fluid pipe elements.	Unsupported	Abaqus/Standard

Keyword	Purpose	Module	Products
**FLUID PIPE WALL*	Specify wall geometry for thermal fluid pipe elements.	Unsupported	Abaqus/Standard
**FOUNDATION*	Prescribe element foundations.	*Interaction module*	Abaqus/Standard
**FOURIER TRANSFORM CONTROLS*	Specification of control parameters for Fourier transform.	Unsupported	Abaqus/Standard
**FRACTURE CRITERION*	Specify crack propagation criteria.	*Property module* and *Interaction module*	Abaqus/Standard Abaqus/Explicit
**FRAME SECTION*	Specify a frame section.	Unsupported	Abaqus/Standard
**FREQUENCY*	Extract natural frequencies and modal vectors.	*Step module*	Abaqus/Standard Abaqus/AMS
**FRICTION*	Specify a friction model.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**GAP*	Specify clearance and local geometry for GAP-type elements.	Unsupported; similar functionality is available by modeling connectors.	Abaqus/Standard
**GAP CONDUCTANCE*	Introduce heat conductance between interface surfaces.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**GAP CONVECTION*	Define Nusselt number for gap convection.	Unsupported	Abaqus/Standard
**GAP DIFFUSIVITY*	Specify ion or species diffusion contact properties.	Unsupported	Abaqus/Standard
**GAP ELECTRICAL CONDUCTANCE*	Specify electrical conductance between surfaces.	Unsupported	Abaqus/Standard
**GAP FLOW*	Define constitutive parameters for tangential flow in pore pressure cohesive elements and enriched elements.	*Property module*	Abaqus/Standard
**GAP HEAT GENERATION*	Introduce heat generation due to energy dissipation at the interface.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**GAP RADIATION*	Introduce heat radiation between surfaces.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**GAS SPECIFIC HEAT*	Define reacted product's specific heat for an ignition and growth equation of state.	*Property module*	Abaqus/Explicit
**GASKET BEHAVIOR*	Begin the specification of a gasket behavior.	*Property module*	Abaqus/Standard

Keyword	Purpose	Module	Products
**GASKET CONTACT AREA*	Specify a gasket contact area or contact width for average pressure output.	*Property module*	Abaqus/Standard
**GASKET ELASTICITY*	Specify elastic properties for the membrane and transverse shear behaviors of a gasket.	*Property module*	Abaqus/Standard
**GASKET SECTION*	Specify element properties for gasket elements.	*Property module*	Abaqus/Standard
**GASKET THICKNESS BEHAVIOR*	Specify a gasket thickness-direction behavior.	*Property module*	Abaqus/Standard
**GEL*	Define a swelling gel.	*Property module*	Abaqus/Standard
**GEOSTATIC*	Obtain a geostatic stress field.	*Step module*	Abaqus/Standard
**GLOBAL DAMPING*	Specify global damping.	Supported in the *Step module* only for substructure generation.	Abaqus/Standard
**GLOBAL RESPONSE*	Specify global design response.	Unsupported	Abaqus/Standard
**HEADING*	Print a heading on the output.	*Job module*	Abaqus/Standard Abaqus/Explicit
**HEAT GENERATION*	Include volumetric heat generation in heat transfer analyses.	*Property module*	Abaqus/Standard Abaqus/Explicit
**HEAT TRANSFER*	Transient or steady-state uncoupled heat transfer analysis.	*Step module*	Abaqus/Standard
**HEATCAP*	Specify a point capacitance.	*Property module* and *Interaction module*.	Abaqus/Standard Abaqus/Explicit
**HOURGLASS STIFFNESS*	Specify nondefault hourglass stiffness.	*Mesh module*	Abaqus/Standard
**HYPERELASTIC*	Specify elastic properties for approximately incompressible elastomers.	*Property module*	Abaqus/Standard Abaqus/Explicit
**HYPERFOAM*	Specify elastic properties for a hyperelastic foam.	*Property module*	Abaqus/Standard Abaqus/Explicit
**HYPOELASTIC*	Specify hypoelastic material properties.	*Property module*	Abaqus/Standard
**HYSTERESIS*	Specify a rate-dependent elastomer model.	*Property module*	Abaqus/Standard
**IMPEDANCE*	Define impedances for acoustic analysis.	Unsupported	Abaqus/Standard Abaqus/Explicit

Keyword	Purpose	Module	Products
**IMPEDANCE PROPERTY*	Define the impedance parameters for an acoustic medium boundary.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**IMPERFECTION*	Introduce geometric imperfections for postbuckling analysis.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**IMPORT*	Import information from a previous Abaqus/Explicit or Abaqus/Standard analysis.	Supported for use in conjunction with part instances; importing selected part instances stored in an output database is supported using the **File** menu and importing the initial state of part instances is supported in the *Load module*.	Abaqus/Standard Abaqus/Explicit
**IMPORT CONTROLS*	Specify the full-model input format, the tie constraint formation configuration, and the tolerance for error checking on shell normals.	Unsupported	Abaqus/Standard Abaqus/Explicit
**IMPORT ELSET*	Import element set definitions from a previous Abaqus/Explicit or Abaqus/Standard analysis.	Unsupported	Abaqus/Standard Abaqus/Explicit
**IMPORT NSET*	Import node set definitions from a previous Abaqus/Explicit or Abaqus/Standard analysis.	Unsupported	Abaqus/Standard Abaqus/Explicit
**IMPORT SURFACE*	Import surface definitions from a previous Abaqus/Explicit or Abaqus/Standard analysis.	Unsupported	Abaqus/Standard Abaqus/Explicit
**INCIDENT WAVE*	Define incident wave loading for a blast or scattering load on a boundary.	Unsupported; this option has been superseded by incident wave interactions.	Abaqus/Standard Abaqus/Explicit
**INCIDENT WAVE FLUID PROPERTY*	Define the fluid properties associated with an incident wave.	Unsupported; this option has been superseded by incident wave interaction properties.	Abaqus/Standard Abaqus/Explicit
**INCIDENT WAVE INTERACTION*	Define incident wave loading for a blast or scattering load on a surface.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**INCIDENT WAVE INTERACTION PROPERTY*	Define the geometric data and fluid properties describing an incident wave.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**INCIDENT WAVE PROPERTY*	Define the geometric data describing an incident wave.	Unsupported; this option has been superseded by incident wave interaction properties.	Abaqus/Standard Abaqus/Explicit
**INCIDENT WAVE REFLECTION*	Define the reflection load on a surface caused by incident wave fields.	Unsupported	Abaqus/Standard Abaqus/Explicit

Keyword	Purpose	Module	Products
**INCLUDE*	Reference an external file containing Abaqus input data.	Several input data options in Abaqus/CAE provide the capability to reference external files; for example, the material editor can read material properties from an ASCII file.	Abaqus/Standard Abaqus/Explicit
**INCREMENTATION OUTPUT*	Define output database requests for time incrementation data.	*Step module*	Abaqus/Standard Abaqus/Explicit
**INELASTIC HEAT FRACTION*	Define the fraction of the rate of inelastic dissipation that appears as a heat source.	*Property module*	Abaqus/Standard Abaqus/Explicit
**INERTIA RELIEF*	Apply inertia-based load balancing.	*Load module*	Abaqus/Standard
**INITIAL CONDITIONS*	Specify initial conditions for the model.	*Load module*	Abaqus/Standard Abaqus/Explicit Abaqus/Aqua
**INSTANCE*	Begin an instance definition.	*Assembly module* for part instances not imported from a previous analysis; *Load module* for part instances imported from a previous analysis	Abaqus/Standard Abaqus/Explicit
**INTEGRATED OUTPUT*	Specify variables integrated over a surface to be written to the output database.	*Step module*	Abaqus/Standard Abaqus/Explicit
**INTEGRATED OUTPUT SECTION*	Define an integrated output section over a surface with a local coordinate system and a reference point.	*Step module*	Abaqus/Standard Abaqus/Explicit
**INTERFACE*	Define properties for contact elements.	*Property module*; supported for two-dimensional, three-dimensional, and axisymmetric acoustic interface elements. Contact elements are not supported.	Abaqus/Standard
**INTERFACE REACTION*	Introduce an interface reaction between surfaces.	Unsupported	Abaqus/Standard
**INTERNAL FLUX GENERATION*	This option is used to define user-defined internal source terms at the material integration point across multiple physics fields.	Unsupported	Abaqus/Standard
**ISOTROPIZATION PARAMETERS*	Define isotropization parameters for a multiscale material.	Unsupported	Abaqus/Standard
**ITS*	Define properties for ITS elements.	Unsupported; similar functionality (with the exception of friction) is available by modeling connectors.	Abaqus/Standard

Keyword	Purpose	Module	Products
**JOINT*	Define properties for JOINTC elements.	Unsupported; similar functionality is available by modeling connectors.	Abaqus/Standard
**JOINT ELASTICITY*	Specify elastic properties for elastic-plastic joint elements.	Unsupported	Abaqus/Standard
**JOINT PLASTICITY*	Specify plastic properties for elastic-plastic joint elements.	Unsupported	Abaqus/Standard
**JOINTED MATERIAL*	Specify the jointed material model.	Unsupported	Abaqus/Standard
**JOULE HEAT FRACTION*	Define the fraction of electric energy released as heat.	*Property module*	Abaqus/Standard
**KAPPA*	Specify the material parameters for mass diffusion driven by gradients of temperature and equivalent pressure stress.	*Property module*	Abaqus/Standard
**KINEMATIC*	Define a kinematic coupling constraint.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**KINEMATIC COUPLING*	Constrain all or specific degrees of freedom of a set of nodes to the rigid body motion of a reference node.	Unsupported; this option has been superseded by coupling constraints used in conjunction with the kinematic option.	Abaqus/Standard
**LATENT HEAT*	Specify latent heats.	*Property module*	Abaqus/Standard Abaqus/Explicit
**LOAD CASE*	Begin a load case definition for multiple load case analysis.	*Load module*	Abaqus/Standard
**LOADING DATA*	Provide loading data for uniaxial behavior models in connectors or provide data from a uniaxial or a shear loading test for fabric materials.	Unsupported	Abaqus/Explicit
**LOW DENSITY FOAM*	Specify properties for a low-density foam.	*Property module*	Abaqus/Standard Abaqus/Explicit
**M1*	Define the first bending moment behavior of beams.	Unsupported	Abaqus/Standard Abaqus/Explicit
**M2*	Define the second bending moment behavior of beams.	Unsupported	Abaqus/Standard Abaqus/Explicit
**MAGNETIC PERMEABILITY*	Specify magnetic permeability.	*Property module*	Abaqus/Standard
**MAGNETOSTATIC*	Magnetostatic analysis.	Unsupported	Abaqus/Standard

Keyword	Purpose	Module	Products
**MANIFEST*	Specify the input files to execute in an evolution analysis.	Unsupported	Abaqus/Standard
**MAP SOLUTION*	Map a solution from an old mesh to a new mesh.	Unsupported	Abaqus/Standard
**MASS*	Specify a point mass.	*Property module* and *Interaction module*.	Abaqus/Standard Abaqus/Explicit
**MASS ADJUST*	Adjust and/or redistribute the mass of an element set.	Unsupported	Abaqus/Explicit
**MASS DIFFUSION*	Transient or steady-state uncoupled mass diffusion analysis.	*Step module*	Abaqus/Standard
**MASS FLOW RATE*	Specify fluid mass flow rate in a heat transfer analysis.	Unsupported	Abaqus/Standard
**MATERIAL*	Begin the definition of a material.	*Property module*	Abaqus/Standard Abaqus/Explicit
**MATRIX*	Read in the stiffness or mass matrix for a linear user element.	Unsupported	Abaqus/Standard
**MATRIX ASSEMBLE*	Define stiffness, mass, or damping matrices for a part of the model.	Unsupported	Abaqus/Standard
**MATRIX CHECK*	Check the quality of the generated stiffness and mass matrices.	Unsupported	Abaqus/Standard
**MATRIX EXPORT*	Write generated matrices to files in specific formats for selected workflows.	Unsupported	Abaqus/Standard
**MATRIX GENERATE*	Generate global or element matrices.	Unsupported	Abaqus/Standard
**MATRIX INPUT*	Read in a matrix for a part of the model.	Unsupported	Abaqus/Standard
**MATRIX OUTPUT*	Output generated matrices in various forms.	Unsupported	Abaqus/Standard
**MEAN FIELD DAMAGE*	Define the impact of microlevel damage on the behavior of the composite material at the macro level.	Unsupported	Abaqus/Standard Abaqus/Explicit
**MEAN FIELD HOMOGENIZATION*	Begin the definition of a multiscale material modeled with mean-field homogenization.	Unsupported	Abaqus/Standard Abaqus/Explicit

Keyword	Purpose	Module	Products
**MEDIA TRANSPORT*	Activate or deactivate a periodic media.	Unsupported	Abaqus/Explicit
**MEMBRANE SECTION*	Specify section properties for membrane elements.	*Property module*	Abaqus/Standard Abaqus/Explicit
**MODAL DAMPING*	Specify damping for modal dynamic analysis.	*Step module*	Abaqus/Standard
**MODAL DYNAMIC*	Dynamic time history analysis using modal superposition.	*Step module*	Abaqus/Standard
**MODAL FILE*	Write generalized coordinate (modal amplitude) data or eigendata to the results file during a mode-based dynamic or eigenvalue extraction procedure.	Unsupported; Abaqus/CAE reads output from the output database file only.	Abaqus/Standard
**MODAL OUTPUT*	Write generalized coordinate (modal amplitude) data to the output database during a mode-based dynamic or complex eigenvalue extraction procedure.	*Step module*	Abaqus/Standard
**MODAL PRINT*	Print generalized coordinate (modal amplitude) data during a mode-based dynamic procedure.	Unsupported	Abaqus/Standard
**MODEL CHANGE*	Remove or reactivate elements and contact pairs.	*Interaction module*	Abaqus/Standard
**MOHR COULOMB*	Specify the Mohr-Coulomb plasticity model.	*Property module*	Abaqus/Standard Abaqus/Explicit
**MOHR COULOMB HARDENING*	Specify hardening for the Mohr-Coulomb plasticity model.	*Property module*	Abaqus/Standard Abaqus/Explicit
**MOISTURE SWELLING*	Define moisture-driven swelling.	*Property module*	Abaqus/Standard
**MOLECULAR WEIGHT*	Define the molecular weight of an ideal gas species.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**MONITOR*	Define a degree of freedom to monitor.	*Step module*	Abaqus/Standard Abaqus/Explicit
**MOTION*	Specify motions as a predefined field.	Unsupported	Abaqus/Standard
**MPC*	Define multi-point constraints.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**MULLINS EFFECT*	Specify Mullins effect material parameters for elastomers.	*Property module*	Abaqus/Standard Abaqus/Explicit

Keyword	Purpose	Module	Products
**MULTIPHYSICS LOAD*	Specify a Butler-Volmer surface load to model solid electrodes.	Unsupported	Abaqus/Standard
**NCOPY*	Create nodes by copying.	Not applicable; copying portions of sketches and instancing of parts serve similar purposes.	Abaqus/Standard Abaqus/Explicit
**NETWORK STIFFNESS RATIO*	Specify stiffness ratios for viscoelastic networks.	Unsupported	Abaqus/Standard Abaqus/Explicit
**NEURAL NETWORK*	Define the configuration of a neural network.	Unsupported	Abaqus/Standard
**NEURAL NETWORK DATA*	Define the bulk data for a neural network.	Unsupported	Abaqus/Standard
**NFILL*	Fill in nodes in a region.	Not applicable; nodes are generated when you *mesh* the model.	Abaqus/Standard Abaqus/Explicit
**NGEN*	Generate incremental nodes.	Not applicable; nodes are generated when you *mesh*the model.	Abaqus/Standard Abaqus/Explicit
**NMAP*	Map nodes from one coordinate system to another and rotate, translate, or scale the nodal coordinates.	Unsupported; meshing techniques in the *Mesh module* are usually preferable.	Abaqus/Standard Abaqus/Explicit
**NO COMPRESSION*	Introduce a compressive failure theory (tension only materials).	*Property module*	Abaqus/Standard Abaqus/Explicit
**NO TENSION*	Introduce a tension failure theory (compression only material).	*Property module*	Abaqus/Standard Abaqus/Explicit
**NODAL ENERGY RATE*	Define critical energy release rates at nodes.	Unsupported	Abaqus/Standard Abaqus/Explicit
**NODAL THICKNESS*	Define shell or membrane thickness at nodes.	*Property module*	Abaqus/Standard Abaqus/Explicit
**NODE*	Specify nodal coordinates.	*Mesh module*	Abaqus/Standard Abaqus/Explicit
**NODE FILE*	Define results file requests for nodal data.	Unsupported; Abaqus/CAE reads output from the output database file only.	Abaqus/Standard Abaqus/Explicit
**NODE OUTPUT*	Define output database requests for nodal data.	*Step module*	Abaqus/Standard Abaqus/Explicit
**NODE PRINT*	Define print requests for nodal variables.	Unsupported	Abaqus/Standard

Keyword	Purpose	Module	Products
**NODE RESPONSE*	Define nodal responses for design sensitivity analysis.	Unsupported	Abaqus/Design
**NONLINEAR BH*	Specify nonlinear magnetic behavior of a soft magnetic material.	*Property module*	Abaqus/Standard
**NONSTRUCTURAL MASS*	Specify mass contribution to the model from nonstructural features.	*Property module* and *Interaction module*.	Abaqus/Standard Abaqus/Explicit
**NORMAL*	Specify a particular normal direction.	Unsupported	Abaqus/Standard Abaqus/Explicit
**NSET*	Assign nodes to a node set.	*Set toolset*	Abaqus/Standard Abaqus/Explicit
**ONE-STEP INVERSE*	Perform a one-step inverse analysis of a sheet metal part.	Unsupported	Abaqus/Standard
**OPERATOR OUTPUT*	Write operator output to a SIM document.	Unsupported	Abaqus/Standard
**ORIENTATION*	Define a local axis system for material or element property definition, for kinematic coupling constraints, for free directions for inertia relief loads, or for connectors.	*Property module*, *Interaction module*, and *Load module*	Abaqus/Standard Abaqus/Explicit
**ORNL*	Specify constitutive model developed by Oak Ridge National Laboratory.	*Property module*	Abaqus/Standard
**OUTPUT*	Define output requests to the output database.	*Step module*	Abaqus/Standard Abaqus/Explicit
**PAPERBOARD HARDENING*	Specify the hardening data of the in-plane paperboard plasticity model.	Unsupported	Abaqus/Standard Abaqus/Explicit
**PAPERBOARD PLASTICITY*	Specify the in-plane paperboard plasticity model.	Unsupported	Abaqus/Standard Abaqus/Explicit
**PAPERBOARD THICKNESS COMPRESSION ELASTIC*	Define the out-of-plane compression elasticity for the paperboard model.	Unsupported	Abaqus/Standard Abaqus/Explicit
**PAPERBOARD THICKNESS COMPRESSION PLASTICITY*	Define the out-of-plane compression yield surface for the paperboard model.	Unsupported	Abaqus/Standard Abaqus/Explicit
**PAPERBOARD TRANSVERSE SHEAR PLASTICITY*	Define the transverse shear yield surface for the paperboard model.	Unsupported	Abaqus/Standard Abaqus/Explicit

Keyword	Purpose	Module	Products
**PARAMETER*	Define parameters for input parametrization.	Unsupported	Abaqus/Standard Abaqus/Explicit
**PARAMETER DEPENDENCE*	Define dependence table for tabularly dependent parameters.	Unsupported	Abaqus/Standard Abaqus/Explicit
**PARAMETER SHAPE VARIATION*	Define parametric shape variations.	Unsupported	Abaqus/Standard Abaqus/Explicit
**PARAMETER TABLE*	Define a parameter table.	Unsupported	Abaqus/Standard Abaqus/Explicit
**PARAMETER TABLE TYPE*	Define the type of parameter table.	Unsupported	Abaqus/Standard
**PART*	Begin a part definition.	*Part module*	Abaqus/Standard Abaqus/Explicit
**PARTICLE BEHAVIOR*	Specify the behavior of a particle.	Unsupported	Abaqus/Explicit
**PARTICLE GENERATOR*	Specify a particle generator.	Unsupported	Abaqus/Explicit
**PARTICLE GENERATOR FLOW*	Specify flow speed and mass flow rate per unit inlet area for a particle species.	Unsupported	Abaqus/Explicit
**PARTICLE GENERATOR INLET*	Specify a particle generator inlet surface.	Unsupported	Abaqus/Explicit
**PARTICLE GENERATOR MIXTURE*	Specify particle generator species mixture.	Unsupported	Abaqus/Explicit
**PARTICLE OUTLET*	Specify a particle outlet.	Unsupported	Abaqus/Explicit
**PARTICLE OUTLET FLOW*	Specify nonreflecting or pressure boundary conditions.	Unsupported	Abaqus/Explicit
**PARTICLE SURFACE DEPOSITION*	Specify surface deposition properties for discrete particles.	Unsupported	Abaqus/Explicit
**PARTICLE SWELLING*	Specify swelling for discrete particles.	Unsupported	Abaqus/Explicit
**PERFECTLY MATCHED LAYER*	Specify perfectly matched layer properties.	Unsupported	Abaqus/Standard
**PERIODIC*	Define periodic symmetry for a cavity radiation heat transfer analysis.	*Interaction module*	Abaqus/Standard
**PERIODIC MEDIA*	Specify a periodic media.	Unsupported	Abaqus/Explicit

Keyword	Purpose	Module	Products
**PERMANENT MAGNETIZATION*	Specify permanent magnetization.	Unsupported	Abaqus/Standard
**PERMEABILITY*	Define permeability for pore fluid flow.	*Property module*	Abaqus/Standard
**PHYSICAL CONSTANTS*	Specify physical constants.	*Model attribute*	Abaqus/Standard Abaqus/Explicit
**PIEZOELECTRIC*	Specify piezoelectric material properties.	*Property module*	Abaqus/Standard
**PIEZOELECTRIC DAMPING*	Specify piezoelectric material damping for a piezoelectric material.	Unsupported	Abaqus/Standard
**PIEZORESISTIVITY*	Specify piezoresistivity coefficients.	Unsupported	Abaqus/Standard
**PIPE-SOIL INTERACTION*	Specify element properties for pipe-soil interaction elements.	Unsupported	Abaqus/Standard
**PIPE-SOIL STIFFNESS*	Define constitutive behavior for pipe-soil interaction elements.	Unsupported	Abaqus/Standard
**PLANAR TEST DATA*	Used to provide planar test (or pure shear) data (compression and/or tension).	*Property module*	Abaqus/Standard Abaqus/Explicit
**PLASTIC*	Specify a metal plasticity model.	*Property module*	Abaqus/Standard Abaqus/Explicit
**PLASTIC AXIAL*	Define plastic axial force for frame elements.	Unsupported	Abaqus/Standard
**PLASTIC M1*	Define the first plastic bending moment behavior for frame elements.	Unsupported	Abaqus/Standard
**PLASTIC M2*	Define the second plastic bending moment behavior for frame elements.	Unsupported	Abaqus/Standard
**PLASTIC TORQUE*	Define the plastic torsional moment behavior for frame elements.	Unsupported	Abaqus/Standard
**PLASTICITY CORRECTION*	Specify the plastic response used to compute Neuber and Glinka plasticity corrections.	*Property module*	Abaqus/Standard
**PLY FABRIC FAILURE*	Defines the conditions that trigger material failure for the ply fabric damage model for bidirectional fabric-reinforced composites.	Unsupported	Abaqus/Standard Abaqus/Explicit

Keyword	Purpose	Module	Products
**PLY FABRIC HARDENING*	Specify hardening for the in-plane shear plasticity response of bidirectional fabric-reinforced composite materials.	Unsupported	Abaqus/Standard Abaqus/Explicit
**PML COEFFICIENT*	Specify perfectly matched layer coefficients.	Unsupported	Abaqus/Standard
**PORE FLUID PRESSURE*	Specify a known pore fluid pressure field in a static or in an explicit dynamic stress analysis.	Unsupported	Abaqus/Standard Abaqus/Explicit
**POROUS BULK MODULI*	Define bulk moduli for soils and rocks.	*Property module*	Abaqus/Standard Abaqus/Explicit
**POROUS ELASTIC*	Specify elastic material properties for porous materials.	*Property module*	Abaqus/Standard
**POROUS ELECTRODE THEORY*	Activate use of the electrochemistry framework to model a porous electrode.	Unsupported	Abaqus/Standard
**POROUS FAILURE CRITERIA*	Define porous material failure criteria for a *POROUS METAL PLASTICITY model.	*Property module*	Abaqus/Explicit
**POROUS METAL PLASTICITY*	Specify a porous metal plasticity model.	*Property module*	Abaqus/Standard Abaqus/Explicit
**POST OUTPUT*	Postprocess for output from the restart file.	Unsupported	Abaqus/Standard
**POTENTIAL*	Define the stress potential of a yield/creep model.	*Property module*	Abaqus/Standard Abaqus/Explicit
**PREPRINT*	Select printout for the analysis input file processor.	*Job module*	Abaqus/Standard Abaqus/Explicit
**PRESSURE PENETRATION*	Specify pressure penetration loads with surface-based contact.	*Interaction module*	Abaqus/Standard
**PRESSURE STRESS*	Specify equivalent pressure stress as a predefined field for a mass diffusion analysis.	Unsupported	Abaqus/Standard
**PRESTRESS HOLD*	Keep rebar prestress constant during initial equilibrium solution.	Unsupported	Abaqus/Standard
**PRE-TENSION SECTION*	Associate a pre-tension node with a pre-tension section.	*Load module*	Abaqus/Standard
**PRINT*	Request or suppress output to the message file in an Abaqus/Standard analysis or to	*Step module*	Abaqus/Standard Abaqus/Explicit

Keyword	Purpose	Module	Products
	the status file in an Abaqus/Explicit analysis.		
**PROBABILITY DENSITY FUNCTION*	Specify a probability density function.	Unsupported	Abaqus/Explicit
**PROPERTY TABLE*	Define a property table.	Unsupported	Abaqus/Standard Abaqus/Explicit
**PROPERTY TABLE TYPE*	Define the type of property table.	Unsupported	Abaqus/Standard
**PSD-DEFINITION*	Define a cross-spectral density frequency function for random response loading.	Unsupported	Abaqus/Standard
**RADIATE*	Specify radiation conditions in heat transfer analyses.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**RADIATION FILE*	Define results file requests for cavity radiation heat transfer.	Unsupported; Abaqus/CAE reads output from the output database file only.	Abaqus/Standard
**RADIATION OUTPUT*	Define output database requests for cavity radiation variables.	*Step module*	Abaqus/Standard
**RADIATION PRINT*	Define print requests for cavity radiation heat transfer.	Unsupported	Abaqus/Standard
**RADIATION SYMMETRY*	Define cavity symmetries for radiation heat transfer analysis.	*Interaction module*	Abaqus/Standard
**RADIATION VIEW FACTOR*	Control cavity radiation and view factor calculations.	*Interaction module*	Abaqus/Standard
**RANDOM RESPONSE*	Calculate response to random loading.	*Step module*	Abaqus/Standard
**RATE DEPENDENT*	Define a rate-dependent viscoplastic model.	*Property module*	Abaqus/Standard Abaqus/Explicit
**RATIOS*	Define anisotropic swelling.	*Property module*	Abaqus/Standard
**REACTION RATE*	Define the reaction rate for an ignition and growth equation of state.	*Property module*	Abaqus/Explicit
**REBAR*	Define rebar as an element property.	Unsupported	Abaqus/Standard Abaqus/Explicit
**REBAR LAYER*	Define layers of reinforcement in membrane, shell, surface, and continuum elements.	*Property module*; supported only for membrane and shell elements.	Abaqus/Standard Abaqus/Explicit
**REBAR LINE*	Define rebar reinforcement in beam elements.	Unsupported	Abaqus/Standard

Keyword	Purpose	Module	Products
			Abaqus/Explicit
**REDUCED BASIS GENERATE*	Reduced basis generation analysis.	Unsupported	Abaqus/Standard
**REFLECTION*	Define reflection symmetries for a cavity radiation heat transfer analysis.	*Interaction module*	Abaqus/Standard
**RELEASE*	Release rotational degrees of freedom at one or both ends of a beam element.	Unsupported	Abaqus/Standard
**RESPONSE SPECTRUM*	Calculate the response based on user-supplied response spectra.	*Step module*	Abaqus/Standard
**RESTART*	Save and reuse data and analysis results.	*Step module* for saving restart data; *Job module* for performing a restart analysis	Abaqus/Standard Abaqus/Explicit
**RETAINED NODAL DOFS*	Specify the degrees of freedom to retain as external to a substructure.	*Load module*	Abaqus/Standard
**RIGID BODY*	Define a set of elements as a rigid body and define rigid element properties.	*Part module* and *Interaction module*	Abaqus/Standard Abaqus/Explicit
**RIGID SURFACE*	Define an analytical rigid surface.	*Part module*	Abaqus/Standard
**ROTARY INERTIA*	Define rigid body rotary inertia.	*Property module* and *Interaction module*.	Abaqus/Standard Abaqus/Explicit
**SCALE MASS*	Specify scale factors and, for adjoint design sensitivity analysis, quantities that represent the derivatives of the scale factors divided by the scale factors for material mass.	Unsupported	Abaqus/Standard
**SCALE STIFFNESS*	Specify scale factors and, for adjoint design sensitivity analysis, quantities that represent the derivatives of the scale factors divided by the scale factors for material stiffness.	Unsupported	Abaqus/Standard
**SCALE STRESS DESIGN*	Specify scale factors and quantities that represent the derivatives of the scale factors divided by the scale factors for material stress design response.	Unsupported	Abaqus/Standard
**SCALE THERMAL CONDUCTIVITY*	Specify scale factors for thermal conductivity.	Unsupported	Abaqus/Standard
**SECTION CONTROLS*	Specify section controls.	*Mesh module*	Abaqus/Standard

Keyword	Purpose	Module	Products
			Abaqus/Explicit
**SECTION CURVATURE*	Define the precurvatures and the pretorsion of the beam centerline for 3-DOF warping elements.	Unsupported	Abaqus/Standard
**SECTION FILE*	Define results file requests of accumulated quantities on user-defined surface sections.	Unsupported	Abaqus/Standard
**SECTION INERTIA*	Define inertia properties for meshed general beam sections.	Unsupported	Abaqus/Standard Abaqus/Explicit
**SECTION ORIGIN*	Define a meshed cross-section origin.	Unsupported	Abaqus/Standard
**SECTION POINTS*	Locate points in the beam section for which stress and strain output are required.	*Property module*	Abaqus/Standard Abaqus/Explicit
**SECTION PRINT*	Define print requests of accumulated quantities on user-defined surface sections.	Unsupported	Abaqus/Standard
**SECTION STIFFNESS*	Define stiffness properties for meshed general beam sections.	Unsupported	Abaqus/Standard Abaqus/Explicit
**SECTION TANGENT*	Define the inclination of the tangent of the beam centerline with respect to the cross-section normal direction for 3-DOF warping elements.	Unsupported	Abaqus/Standard
**SELECT CYCLIC SYMMETRY MODES*	Specify the cyclic symmetry modes in an eigenvalue analysis of a cyclic symmetric structure.	*Interaction module*	Abaqus/Standard
**SELECT EIGENMODES*	Select the modes to be used in a modal dynamic, complex eigenvalue extraction, or substructure generation analysis.	Supported in the *Step module* only for substructure generation.	Abaqus/Standard
**SFILM*	Define film coefficients and associated sink temperatures over a surface.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**SFLOW*	Define seepage coefficients and associated sink pore pressures normal to a surface.	Unsupported	Abaqus/Standard
**SHEAR CENTER*	Define the position of the shear center of a beam section.	*Property module*	Abaqus/Standard Abaqus/Explicit
**SHEAR FAILURE*	Specify a shear failure model and criterion.	Unsupported	Abaqus/Explicit

Keyword	Purpose	Module	Products
**SHEAR RETENTION*	Define the reduction of the shear modulus associated with crack surfaces in a *CONCRETE model as a function of the tensile strain across the crack.	*Property module*	Abaqus/Standard
**SHEAR TEST DATA*	Used to provide shear test data.	*Property module*	Abaqus/Standard Abaqus/Explicit
**SHELL GENERAL SECTION*	Define a general, arbitrary, elastic shell section.	*Property module*	Abaqus/Standard Abaqus/Explicit
**SHELL SECTION*	Specify a shell cross-section.	*Property module*	Abaqus/Standard Abaqus/Explicit
**SHELL TO SOLID COUPLING*	Define a surface-based coupling between a shell edge and a solid face.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**SIMPEDANCE*	Define impedances of acoustic surfaces.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**SIMPLE SHEAR TEST DATA*	Used to provide simple shear test data.	*Property module*	Abaqus/Standard Abaqus/Explicit
**SLIDE LINE*	Specify slide line surfaces on which deformable structures may interact.	Unsupported; the *Interaction module* uses surface-based contact.	Abaqus/Standard
**SLOAD*	Apply loads to a substructure.	Unsupported	Abaqus/Standard
**SOFT ROCK HARDENING*	Specify hardening for the soft rock plasticity model.	*Property module*	Abaqus/Standard Abaqus/Explicit
**SOFT ROCK PLASTICITY*	Specify the soft rock plasticity model.	*Property module*	Abaqus/Standard Abaqus/Explicit
**SOFTENING REGULARIZATION*	Specify softening regularization for the clay plasticity model and the soft rock plasticity model.	*Property module*	Abaqus/Standard Abaqus/Explicit
**SOILS*	Effective stress analysis for fluid-filled porous media.	*Step module*	Abaqus/Standard
**SOLID ELECTROLYTE THEORY*	Activate use of the electrochemistry framework to model a solid electrolyte.	Unsupported	Abaqus/Standard
**SOLID SECTION*	Specify element properties for solid, infinite, acoustic, particle, and truss elements.	*Property module*	Abaqus/Standard Abaqus/Explicit
**SOLUBILITY*	Specify solubility.	*Property module*	Abaqus/Standard

Keyword	Purpose	Module	Products
**SOLUTION TECHNIQUE*	Specify alternative solution methods.	*Step module*	Abaqus/Standard
**SOLVER CONTROLS*	Specify controls for the iterative and direct linear solvers.	*Step module*	Abaqus/Standard
**SORPTION*	Define absorption and exsorption behavior.	*Property module*	Abaqus/Standard
**SPECIFIC HEAT*	Define specific heat.	*Property module*	Abaqus/Standard Abaqus/Explicit
**SPECTRUM*	Define or create a response spectrum.	*Amplitude toolset*; supported only for defining a spectrum.	Abaqus/Standard
**SPH SURFACE BEHAVIOR*	Define boundary surface interaction properties between SPH particles and Lagrangian surfaces.	Unsupported	Abaqus/Explicit
**SPRING*	Define spring behavior.	*Property module* and *Interaction module*; supported only for linear behavior independent of field variables. For nonlinear behavior or to include field variables, model connectors in the *Interaction module.*	Abaqus/Standard Abaqus/Explicit
**SRADIATE*	Specify surface radiation conditions in heat transfer analysis.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**STATIC*	Static stress/displacement analysis.	*Step module*	Abaqus/Standard
**STEADY STATE CRITERIA*	Specify steady-state criteria for terminating a quasi-static unidirectional simulation.	Unsupported	Abaqus/Explicit
**STEADY STATE DETECTION*	Specify steady-state requirements for terminating a quasi-static unidirectional simulation.	Unsupported	Abaqus/Explicit
**STEADY STATE DYNAMICS*	Steady-state dynamic response based on harmonic excitation.	*Step module*	Abaqus/Standard
**STEADY STATE TRANSPORT*	Steady-state transport analysis.	Unsupported	Abaqus/Standard
**STEP*	Begin a step.	*Step module*	Abaqus/Standard Abaqus/Explicit
**STEP CONTROL*	Control progress of the simulation based on the solution state.	*Step module*	Abaqus/Standard

Keyword	Purpose	Module	Products
**STEP CYCLING*	Define a step or series of steps to be repeated.	Unsupported	Abaqus/Standard
**STEP CYCLING CONTROL*	Specify sensor-based or contact wear-based criteria to control early termination of step cycling.	Unsupported	Abaqus/Standard
**SUBCYCLING*	Define a subcycling zone.	Unsupported	Abaqus/Explicit
**SUBMODEL*	Specify driven boundary nodes in submodeling analysis.	*Load module* and *model attribute*	Abaqus/Standard Abaqus/Explicit
**SUBMODEL CONDITIONS*	Specify that submodel conditions are to be imposed on cut surfaces during this step.	Unsupported	Abaqus/Standard
**SUBMODEL CUT*	Define a submodel cut surface.	Unsupported	Abaqus/Standard
**SUBMODEL LINEAR LOAD CASE REFERENCE*	Specify the name of the global model load case that refers to this submodel load case.	Unsupported	Abaqus/Standard
**SUBMODEL TIME SYNCHRONIZATION*	Specify the step and increment number (if needed) in the global model to provide how the time in the submodel synchronizes with the time in the global model.	Unsupported	Abaqus/Standard
**SUBSTRUCTURE CHANGE*	Change substructure properties for the current analysis step.	Unsupported	Abaqus/Standard
**SUBSTRUCTURE DAMPING*	Specify mass proportional and stiffness proportional damping for a substructure.	Unsupported	Abaqus/Standard Abaqus/AMS
**SUBSTRUCTURE DAMPING CONTROLS*	Specify damping controls for a substructure property.	Unsupported	Abaqus/Standard
**SUBSTRUCTURE GENERATE*	Substructure generation analysis.	*Step module*	Abaqus/Standard
**SUBSTRUCTURE LOAD CASE*	Begin the definition of a substructure load case.	Unsupported	Abaqus/Standard
**SUBSTRUCTURE MATRIX OUTPUT*	Write a substructure's recovery matrix, reduced stiffness matrix, mass matrix, load case vectors, and gravity load vectors to a file.	Unsupported	Abaqus/Standard
**SUBSTRUCTURE MODAL DAMPING*	Specify damping for a substructure property.	Unsupported	Abaqus/Standard
**SUBSTRUCTURE OUTPUT*	Output the solution in the substructure usage analysis.	Unsupported	Abaqus/Standard

Keyword	Purpose	Module	Products
**SUBSTRUCTURE PATH*	Enter into a substructure to obtain output or return back from a previously entered substructure.	Unsupported	Abaqus/Standard
**SUBSTRUCTURE PROPERTY*	Translate, rotate, and/or reflect substructures.	Unsupported	Abaqus/Standard
**SUPERELASTIC*	Define the data for the superelastic model.	*Property module*	Abaqus/Standard Abaqus/Explicit
**SUPERELASTIC HARDENING*	Specify hardening data for martensite.	*Property module*	Abaqus/Standard Abaqus/Explicit
**SUPERELASTIC HARDENING MODIFICATIONS*	Specify the stress-strain response of superelastic materials as a function of plastic strain.	*Property module*	Abaqus/Standard Abaqus/Explicit
**SURFACE*	Define a surface or region in a model.	Element-based surfaces are supported by the *Surface toolset*. Node-based surfaces are not supported; if node-based surfaces are imported into Abaqus/CAE, they are treated as sets.	Abaqus/Standard Abaqus/Explicit
**SURFACE BEHAVIOR*	Define alternative pressure-overclosure relationships for contact.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**SURFACE FLAW*	Define geometry of surface flaws.	Unsupported	Abaqus/Standard
**SURFACE INTERACTION*	Define surface interaction properties.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**SURFACE PROPERTY*	Define named surface properties for cavity radiation or contact-based wear.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**SURFACE PROPERTY ASSIGNMENT*	Assign surface properties to a surface for the general contact algorithm.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**SURFACE SECTION*	Specify section properties for surface elements.	*Property module*	Abaqus/Standard Abaqus/Explicit Abaqus/Aqua
**SURFACE SMOOTHING*	Define surface smoothing methods.	*Interaction module*	Abaqus/Standard
**SURFACE TENSION*	Define the surface tension of an element-based surface.	Unsupported	Abaqus/Standard Abaqus/Explicit
**SURFACE TENSION CONTACT ANGLE*	Specify the surface tension contact angle property for a given contact interaction.	Unsupported	Abaqus/Standard Abaqus/Explicit

Keyword	Purpose	Module	Products
**SWELLING*	Specify time-dependent volumetric swelling.	*Property module*	Abaqus/Standard
**SYMMETRIC MODEL GENERATION*	Create a three-dimensional model from an axisymmetric or partial three-dimensional model.	Unsupported	Abaqus/Standard
**SYMMETRIC RESULTS TRANSFER*	Import results from an axisymmetric or partial three-dimensional analysis.	Unsupported	Abaqus/Standard
**SYSTEM*	Specify a local coordinate system in which to define nodes.	Not applicable; instancing a part in the *Assembly module* creates a local coordinate system.	Abaqus/Standard Abaqus/Explicit
**TABLE COLLECTION*	Define a table collection.	Unsupported	Abaqus/Standard Abaqus/Explicit
**TEMPERATURE*	Specify temperature as a predefined field.	*Load module*	Abaqus/Standard Abaqus/Explicit
**TENSILE FAILURE*	Specify a tensile failure model and criterion.	*Property module*	Abaqus/Explicit
**TENSION CUTOFF*	Specify tension cutoff data for the Mohr-Coulomb plasticity model.	*Property module*	Abaqus/Standard Abaqus/Explicit
**TENSION STIFFENING*	Define the retained tensile stress normal to a crack in a *CONCRETE model.	*Property module*	Abaqus/Standard
**THERMAL EXPANSION*	Define the thermal expansion behavior of beams.	Unsupported	Abaqus/Standard Abaqus/Explicit
**THERMAL RUNAWAY*	Define the temperature at which thermal runaway can be activated in a material that uses porous electrode theory.	Unsupported	Abaqus/Standard
**THREADED INTERFACE*	Specify the settings to be referenced in the surface element representation of the external and internal threads for general contact in Abaqus/Standard.	Unsupported	Abaqus/Standard
**TIE*	Define surface-based tie and cyclic symmetry constraints or coupled acoustic-structural interactions.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**TIME POINTS*	Specify time points at which data are written to the output database file, or specify time points in the loading history at which the response of a structure will be	*Step module*	Abaqus/Standard Abaqus/Explicit

Keyword	Purpose	Module	Products
	evaluated in a direct cyclic analysis.		
**TORQUE*	Define the torsional behavior of beams.	Unsupported	Abaqus/Standard Abaqus/Explicit
**TORQUE PRINT*	Print a summary of the total torque that can be transmitted across axisymmetric slide lines.	Unsupported	Abaqus/Standard
**TRACER PARTICLE*	Define tracer particles for tracking the location of and results at material points during a step.	Unsupported	Abaqus/Explicit
**TRANSFORM*	Specify a local coordinate system at nodes.	Define nodal coordinate systems for prescribed conditions in the *Load module*.	Abaqus/Standard Abaqus/Explicit
**TRANSPORT VELOCITY*	Specify angular transport velocity.	Unsupported	Abaqus/Standard
**TRANSVERSE SHEAR*	Specify the transverse shear moduli for computing the transverse shear stiffness of shells and beams.	Unsupported	Abaqus/Standard Abaqus/Explicit
**TRANSVERSE SHEAR STIFFNESS*	Define transverse shear stiffness for beams and shells.	*Property module*	Abaqus/Standard Abaqus/Explicit
**TRIAXIAL TEST DATA*	Provide triaxial test data.	*Property module*	Abaqus/Standard Abaqus/Explicit
**TRS*	Used to define temperature-time shift for time history viscoelastic analysis.	*Property module*	Abaqus/Standard Abaqus/Explicit
**UEL PROPERTY*	Define property values to be used with a user element type.	Actuator/sensor interaction properties can be defined in the *Interaction module.*	Abaqus/Standard Abaqus/Explicit
**UNDEX CHARGE PROPERTY*	Define an UNDEX charge for incident waves.	*Interaction module*	Abaqus/Standard Abaqus/Explicit
**UNIAXIAL*	Characterize fabric materials through loading and unloading test data.	Unsupported	Abaqus/Explicit
**UNIAXIAL TEST DATA*	Used to provide uniaxial test data (compression and/or tension).	*Property module*	Abaqus/Standard Abaqus/Explicit
**UNIFORM*	Define a uniform coupling constraint.	Unsupported	Abaqus/Standard Abaqus/Explicit

Keyword	Purpose	Module	Products
**UNIT SYSTEM*	Define a unit system for an Abaqus model for translation to other solvers.	Unsupported	Abaqus/Standard Abaqus/Explicit
**UNLOADING DATA*	Provide unloading data for uniaxial behavior models in connectors or unloading data from uniaxial and shear tests for fabrics.	Unsupported	Abaqus/Explicit
**USER DEFINED FIELD*	Redefine field variables at a material point.	*Property module*	Abaqus/Standard Abaqus/Explicit
**USER ELEMENT*	Introduce a user-defined element type.	Actuator/sensor interactions can be defined in the *Interaction module.*	Abaqus/Standard Abaqus/Explicit
**USER MATERIAL*	Define material constants for use in subroutine UMAT, UMATHT, VUMAT, or VUMATHT.	*Property module*	Abaqus/Standard Abaqus/Explicit
**USER OUTPUT VARIABLES*	Specify number of user variables.	*Property module*	Abaqus/Standard
**VARIABLE MASS SCALING*	Specify mass scaling during the step.	*Step module*	Abaqus/Explicit
**VIEW FACTOR OUTPUT*	Write radiation view factors to the results file in cavity radiation heat transfer analysis.	Unsupported	Abaqus/Standard
**VISCO*	Transient, static, stress/displacement analysis with time-dependent material response (creep, swelling, and viscoelasticity).	*Step module*	Abaqus/Standard
**VISCOELASTIC*	Specify dissipative behavior for use with elasticity.	*Property module*	Abaqus/Standard Abaqus/Explicit
**VISCOSITY*	Specify material shear viscosity.	*Property module*	Abaqus/Standard Abaqus/Explicit
**VISCOUS*	Specify viscous material properties for the two-layer viscoplastic model.	*Property module*	Abaqus/Standard
**VISCOUS SOFTENING*	Specify viscous softening in nonlinear viscous networks.	Unsupported	Abaqus/Standard Abaqus/Explicit
**VOID NUCLEATION*	Define the nucleation of voids in a porous material.	*Property module*	Abaqus/Standard Abaqus/Explicit
**VOLUMETRIC TEST DATA*	Provide volumetric test data.	*Property module*	Abaqus/Standard Abaqus/Explicit

Keyword	Purpose	Module	Products
**WAVE*	Define gravity waves for use in immersed structure calculations.	Unsupported	Abaqus/Aqua
**WEAR SURFACE PROPERTIES*	Specify wear properties to activate wear distance accumulation at contact surface nodes.	Unsupported	Abaqus/Standard Abaqus/Explicit
**WIND*	Define wind velocity profile for wind loading.	Unsupported	Abaqus/Aqua

Special element types

Abaqus uses special element types to designate model features such as analytical rigid surfaces that are not part of the mesh. These element types appear in the output database. You may see them in the Visualization module while querying the model or creating display groups based on element type. *Table 1* lists the element types generated by Abaqus.

Table 1: Special element types in the output database.

ARSC	Analytic rigid surface (cylindrical)
ARSR	Analytic rigid surface (rotational)
ARSSE	Analytic rigid surface (extruded)
ARSSS	Analytic rigid surface (segmented)
LSURF1	2-node line on two-dimensional surface
LSURF2	2-node line on axisymmetric surface
LSURF3	3-node line on three-dimensional surface
LSURF4	3-node line on two-dimensional surface
LSURF5	3-node line on axisymmetric surface
LSURF6	Quadratic triangular surface
PSURF1	Node (point) on two-dimensional surface
PSURF2	Node on axisymmetric surface
PSURF3	Node on three-dimensional surface
QSURF1	4-node facet on three-dimensional surface
QSURF2	8-node facet on three-dimensional surface
QSURF3	9-node facet on three-dimensional surface
RNODE2D	Reference node (two-dimensional)
RNODE3D	Reference node (three-dimensional)
TSURF1	3-node facet on three-dimensional surface
TSURF1	6-node facet on three-dimensional surface

Special graphical symbols

Abaqus/CAE uses special graphical symbols to represent prescribed conditions; interactions; constraints; connectors; special engineering features; and spring and dashpot elements, reference nodes, and tracer particles in the Visualization module.

In this section:

- *Symbols used to represent prescribed conditions*
- *Symbols used to represent interactions, constraints, and connectors*
- *Symbols used to represent special engineering features*
- *Symbols used in the Visualization module*

Symbols used to represent prescribed conditions

Table 1, *Table 2*, and *Table 3* present the special graphical symbols used by Abaqus/CAE to represent loads, boundary conditions, and predefined fields, respectively. For information about symbol size and location, see *Understanding symbols that represent prescribed conditions*. For information on controlling the display of these symbols, see *Controlling the display of attributes*.

Table 1: Load symbol types and color.

Load category	Load type	Symbol	Color
Mechanical	Concentrated force	Arrow	Yellow
	Moment	Arrow	Violet
	Pressure	Arrow	Pink
	Shell edge traction	Arrow	Pink
	Shell edge moment	Arrow	Violet
	Surface traction	Arrow	Pink
	Pipe pressure	Arrow	Pink
	Body force	Arrow	Yellow
	Line	Arrow	Yellow
	Gravity	Arrow	Yellow
	Bolt load	Arrow	Yellow
	Generalized plane strain	Arrow	Yellow
	Rotational body force	Arrow	Green
	Connector force	Arrow	Yellow
	Connector moment	Arrow	Violet
	Inertia relief	Sphere with arrow	Green
Thermal	Surface heat flux	Arrow	Green
	Body heat flux	Square	Yellow
	Concentrated heat flux	Square	Yellow
Acoustic	Inward volume acceleration	Square	Yellow
Fluid	Concentrated pore fluid flow	Square	Yellow
	Surface pore fluid flow	Arrows	Blue
Electrical/Magnetic	Concentrated current	Square	Yellow
	Surface current	Square	Green
	Body current	Circle	Green
	Surface current density	Arrow	Yellow
	Body current density	Arrow	Green
	Concentrated charge	Square	Yellow
	Surface charge	Square	Green
	Body charge	Circle	Green
Mass diffusion	Concentrated concentration flux	Square	White

Load category	Load type	Symbol	Color
	Surface concentration flux	Arrow	Yellow
	Body concentration flux	Circle	Yellow

Table 2: Boundary condition symbol types and color.

Boundary condition category	Boundary condition type	Symbol	Color
Mechanical	Symmetry/Antisymmetry/ Encastre	Arrow	Orange for components applied to degrees of freedom 1–3.
			Blue for components applied to degrees of freedom 4–6.
	Displacement/Rotation	Arrow	Orange for components applied to degrees of freedom 1–3.
			Blue for components applied to degrees of freedom 4–6.
	Velocity/Angular velocity	Arrow	Sandy brown for components applied to degrees of freedom 1–3.
			Magenta for components applied to degrees of freedom 4–6.
	Acceleration/Angular acceleration	Arrow	Yellow for components applied to degrees of freedom 1–3.
			Blue for components applied to degrees of freedom 4–6.
	Connector displacement	Arrow	Orange for components applied to degrees of freedom 1–3.
			Blue for components applied to degrees of freedom 4–6.
	Connector velocity	Arrow	Sandy brown for components applied to degrees of freedom 1–3.
			Magenta for components applied to degrees of freedom 4–6.
	Retained nodal DOFs (while being defined in **Substructure generation** step)	Arrow	Blue
	Retained nodal DOFs (during substructure usage)	Cross	Blue
Electrical/Magnetic	Electrical potential	Square	Yellow
	Magnetic vector potential	Arrow	Green
Other	Temperature	Square	Yellow
	Pore pressure	Square	Yellow
	Fluid cavity pressure	Circle	Yellow
	Normalized concentration	Square	Yellow
	Acoustic pressure	Square	Yellow
	Connector material flow	Square	Yellow
	Eulerian boundary	Arrow	Green

Boundary condition category	Boundary condition type	Symbol	Color
	Eulerian mesh motion	Square	Yellow
	Submodel boundary condition	Square	Yellow
	Submodel load	Circle	Yellow

Table 3: Predefined field symbol types and color.

Predefined field category	Predefined field type	Symbol	Color
Mechanical	Translational/rotational velocity	Arrow	Sandy brown
	Stress/Geostatic stress	Circle	Blue
	Hardening	Circle	Magenta
Other	Temperature	Square	Yellow
	Field	Square	Yellow
	Material assignment	Circle	Sandy brown
	Initial state	Circle	Yellow
	Saturation	Square	Green
	Void ratio	Square	Sandy brown
	Pore pressure	Square	Magenta
	Fluid cavity pressure	Diamond	Green

Symbols used to represent interactions, constraints, and connectors

Table 1, *Table 2*, and *Table 3* present the special graphical symbols used by Abaqus/CAE to represent interactions, constraints, and connectors, respectively. For information about symbol size and location, see *Understanding symbols that represent interactions, constraints, and connectors*. For information on controlling the display of these symbols, see *Controlling the display of attributes*.

Table 1: Interaction symbol types and color.

Interactions	Symbol	Color
Surface-to-surface contact	Square	Yellow
Self-contact	Square	Yellow
Fluid cavity	Filled circle (cavity point)	Green
	Square (cavity surface)	Green
Fluid exchange	Circle (large)	Yellow
Fluid inflator	Circle (large) (cavity point)	Yellow
Model change	Square	Yellow
Cyclic symmetry	Square	Yellow
Elastic foundation	Square	Yellow
Cavity radiation	Square	Yellow
Actuation/sensor	Square	Yellow
Standard-Explicit co-simulation	Filled circle	Magenta
Incident wave	Square	Yellow
	Sphere (source point)	Yellow
	Filled circle (standoff point)	Yellow
Acoustic impedance	Square	Yellow
Surface film condition	Square	Yellow
Concentrated film condition	Square	Yellow
Surface radiation	Square	Yellow
Concentrated radiation to ambient	Square	Yellow
Pressure penetration (2D)	Arrow	Green
	Square (penetration region)	Green
Pressure penetration (3D)	Filled triangle	Green
	Square (penetration region)	Green

Table 2: Constraint symbol types and color.

Constraints	Symbol	Color
Tie	Circle	Yellow
Rigid body	Circle	Yellow
Coupling	Circle	Pink
	Lines	Gray
MPC constraint	Circle	Green

Constraints	Symbol	Color
	Lines	Green
Shell-to-solid coupling	Circle	Yellow
Embedded region	Circle	Yellow
Equation	Circle	Yellow

Table 3: Connector symbols and color.

Connector symbols	Color
Square (first points of wires)	Orange
Triangle (second points of wires)	Yellow
Orientation triad, if not the global coordinate system	Orange
Connection type label	Orange
Connector section assignment tag	Orange

Symbols used to represent special engineering features

Special graphical symbols are used by Abaqus/CAE to represent special engineering features.

Table 1: Engineering feature symbol types and color.

Engineering feature	Type	Symbol	Color
Crack	Crack front	Cross	Green
Fastener	Assembled (attachment points only)	Square	Light green
	Point based (positioning point only)	Square	Green
	Discrete	Circle	Green
		Lines	
Inertia	Point mass/inertia	Filled square	Green
	Heat capacitance	Filled square	Green
	Nonstructural mass	Filled square	Green
Springs/Dashpots	Connect two points	Spheres with connecting line	Magenta
		Label (K, C, or K+C)	
		Orientation triad, if not the global coordinate system	
	Connect points to ground	Sphere	Magenta
		Label (K, C, or K+C)	
		Orientation triad, if not the global coordinate system	
Topology and shape optimization	Design area	Diamond	Green
	Geometric restriction	Circle	Magenta
	Stop condition	Square	Yellow

Symbols used in the Visualization module

Special graphical symbols are used by Abaqus/CAE in the Visualization module.

Table 1 presents the special graphical symbols used by the Visualization module. These special symbols appear when you produce an undeformed, deformed, contour, or symbol plot of a model containing any of these components. For information on customizing the color and size of these symbols, see *Coloring all geometry in the Visualization module* and *Controlling the display of model entities*, respectively.

Table 1: Special graphical symbols used by the Visualization module.

Two-node dashpot elements

The Visualization module displays two-node dashpot elements using the symbol shown. You can choose to display a straight line in place of this symbol by selecting **Extra coarse** refinement for all curved edges and faces in your model. For more information, see *Refining curved edges and faces*.

Two-node spring elements

The Visualization module displays two-node spring elements using the symbol shown. You can customize the appearance of the curves in this symbol using the options for refining curved edges and faces. The Visualization module displays a two-node spring element as a straight line when you select **Extra coarse** refinement for all curved edges and faces in your model. For more information, see *Refining curved edges and faces*.

Reference nodes

The Visualization module displays the reference node for a rigid surface as a cross. You cannot customize the shape of this symbol.

Tracer particles

The Visualization module displays a tracer particle as a cross within a square. You cannot customize the shape of this symbol.

In addition to the special symbols the Visualization module uses to display the model components listed above, you can choose to display symbols representing results, model entities (boundary conditions, connectors, coordinate systems, and point elements), and nodal locations. For more information, see the following sections:

- *Plotting analysis results as symbols*
- *Controlling the display of model entities*
- *Controlling the display of constraints in the Visualization module*
- *Customizing node symbols*

Element and output variable support

Most Abaqus elements are supported in the Visualization module, with the following limitations:

- User-defined normals are not supported for gasket elements.
- Slide line elements applied to asymmetric-axisymmetric models are always displayed in the θ=0° plane, regardless of the specified θ for the element.
- Swept contour plots of CAXA elements may include colors that do not represent the current state at the nodes. Use of two Fourier modes improves the appearance, but for best results print the integration point values using **Report->Field Output**.

See *What kinds of elements must be generated outside the Mesh module?*, for a description of element support in the Mesh module of Abaqus/CAE.

Table 1 and *Table 2* list the output variables that are not supported by the Visualization module or the output database.

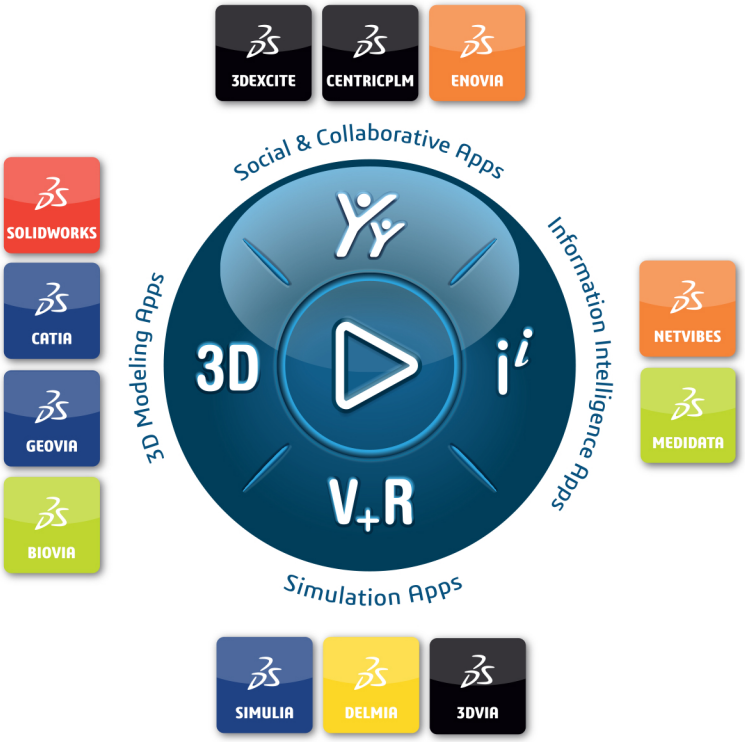

Table 1: Unsupported Abaqus/Standard variables.

CHRGS	Current values of distributed electrical charges.
CONF	Number of cracks at a concrete material point.
CRACK	Unit normal to cracks in concrete.
CS11	Average contact pressure for link and three-dimensional line gasket elements.
DG, DG*ij*	Deformation gradient.
DGP, DGP*n*	Principal stretches.
ECURS	Current values of distributed electrical currents.
FILM	Current values of **FILM* conditions.
FLUXS	Current values of distributed (heat or concentration) fluxes.
FOUND	Current values of foundation pressures.
GPU, GPU*n*	Phase angle of generalized displacements for modal analysis.
GPV, GPV*n*	Phase angle of generalized velocities for modal analysis.
GPA, GPA*n*	Phase angle of generalized accelerations for modal analysis.
LOADS	Current values of distributed loads.
MAXSS	Maximum axial stress on a section.
PHCHG	Reactive charge magnitude and phase angle for steady-state dynamic analysis.
PHE, PHE*ij*	Strain magnitude and phase angle for steady-state dynamic analysis.
PHEPG, PHEPG*n*	Electrical potential gradient vector magnitude and phase angle for steady-state dynamic analysis.
PHEFL, PHEFL*n*	Electrical flux vector magnitude and phase angle for steady-state dynamic analysis.
PHMFL	Mass flow rate magnitude and phase angle for steady-state dynamic analysis.
PHMFT	Total mass flow magnitude and phase angle for steady-state dynamic analysis.
PHPOT	Electrical potential magnitude and phase angle for steady-state dynamic analysis.
PHS, PHS*ij*	Stress magnitude and phase angle for steady-state dynamic analysis.
PPOR	Fluid, pore, or acoustic pressure magnitude and phase angle for steady-state dynamic analysis.
PRF, PRF*n*, PRM*n*	Reaction force and moment magnitudes and phase angles for steady-state dynamic analysis.

PTU, PTU*n*, PTUR*n*	Total displacement and rotation magnitudes and phase angles for mode-based steady-state dynamic analysis.
PU, PU*n*, PUR*n*	Displacement and rotation magnitudes and phase angles for steady-state dynamic analysis.
RAD	Current values of **RADIATE*.
SJP	Strain jumps at nodes. (Use the contour averaging options to obtain this variable.)
SOAREA	Area of the defined section.
SOCF	Center of the total force in the section.
SOD	Total mass flow across the section.
SOE	Total current across the section.
SOF	Total force in the section.
SOH	Total heat flux across the section.
SOM	Total moment in the section.
SOP	Total pore fluid volume flux across the section.
SS, SS*n*	Substresses for ITS elements.
SSAVG*n*	Average shell section stress component *n*.
TPFL	Total pore fluid volume flux leaving the secondary surface.
TPTL	Time integrated TPFL.
Connector output for steady-state dynamic analysis.	
Element output for user elements.	

Table 2: Unsupported Abaqus/Explicit variables.

BONDSTAT	Spot weld bond status for nodes.
BONDLOAD	Spot weld bond load for nodes.
CRACK	Crack orientations.
EIHEDEN	Internal heat energy density.
ESEDEN	Total elastic strain energy density.
SSAVG*n*	Average membrane or transverse shear stress component *n*.

Our **3D**EXPERIENCE® platform powers our brand applications, serving 12 industries, and provides a rich portfolio of industry solution experiences.

Dassault Systèmes is a catalyst for human progress. We provide business and people with collaborative virtual environments to imagine sustainable innovations. By creating virtual twin experiences of the real world with our **3D**EXPERIENCE platform and applications, our customers can redefine the creation, production and life-cycle-management processes of their offer and thus have a meaningful impact to make the world more sustainable. The beauty of the Experience Economy is that it is a human-centered economy for the benefit of all – consumers, patients and citizens.

Dassault Systèmes brings value to more than 300,000 customers of all sizes, in all industries, in more than 150 countries. For more information, visit **www.3ds.com**.
