ABAQUS/CAE USER'S GUIDE

DASSAULT SYSTEMES

Contents

Trademarks and Legal Notices....16
Abaqus/CAE User's Guide....17
What's New....18
Interacting with Abaqus/CAE....27
Introduction....28
Using this guide....28
Typographical conventions....28
Basic mouse actions....29
The basics of interacting with Abaqus/CAE....31
Starting and exiting Abaqus/CAE....32
The Abaqus/CAE main window....39
What is a module?....52
What is a toolset?....54
Using the mouse with Abaqus/CAE....56
Getting help....57
Understanding Abaqus/CAE windows, dialog boxes, and toolboxes....64
Using the prompt area during procedures....65
Interacting with dialog boxes....69
Understanding and using toolboxes and toolbars....95
Managing objects....98
Working with the Model Tree and the Results Tree....121
Understanding Abaqus/CAE GUI settings....134
Managing viewports on the canvas....135
Understanding viewports....136
Manipulating viewports and viewport annotations....141
Displaying the drawing area in full screen mode....146
Working with viewports....147
Working with viewport arrow and text annotations....156
Linking viewports for view manipulation....178
Working with background images and movies in viewports....182
Manipulating the view and controlling perspective....188
Understanding camera modes and view options....189
Understanding the view manipulation tools....194
The 3D compass....212
Customizing the view triad....219
Controlling perspective....221
Using the view manipulation tools....222
Using the 3Dconnexion motion controllers with Abaqus/CAE....238
Selecting objects within the viewport....241
Understanding selection within viewports....242
Selecting objects within the current viewport....247
Using the selection options....266
Configuring graphics display options....275

Using graphics display options....276
Using display lists....277
Using antialiasing....278
Choosing a highlight method....279
Choosing a translucency mode....280
Controlling drag mode....281
Choosing background colors....282
Printing viewports....283
Understanding printing....284
Controlling the destination and appearance of printed images....292
Working with Abaqus/CAE Model Databases, Models, and Files....308
Understanding and working with Abaqus/CAE models, model databases, and files....309
What is an Abaqus/CAE model database?....310
What is an Abaqus/CAE model?....311
Accessing an output database on a remote computer....315
Understanding the files generated by creating and analyzing a model....319
Abaqus/CAE command files....322
Using the File menu....329
Managing model and output databases....331
Managing models....346
Managing session objects and session options....353
Controlling the input file generated by Abaqus/CAE....357
Managing macros....364
Importing and exporting geometry data and models....366
Importing files into and exporting files from Abaqus/CAE....367
Valid parts, precise parts, and tolerance....382
Controlling the import process....387
Understanding the contents of an IGES file....391
What can you import from a model?....396
A logical approach to successful import of IGES files....404
Importing sketches and parts....405
Importing a model....435
Exporting geometry, model, and mesh data....438
Creating and analyzing a model using the Abaqus/CAE modules....446
The Part module....447
Understanding the role of the Part module....448
Entering and exiting the Part module....449
What is feature-based modeling?....450
How is a part defined in Abaqus/CAE?....459
Copying a part....463
What are orphan nodes and elements?....464
Modeling rigid bodies and display bodies....465
The reference point and point parts....473
What types of features can you create?....476
Using feature-based modeling effectively....492
Capturing your design and analysis intent....494
What is part and assembly locking?....496
What are extruding, revolving, and sweeping?....497

What is lofting?....510
Using the Sketcher in conjunction with the Part module....519
Understanding toolsets in the Part module....520
Using the Part module toolbox....533
Managing parts....534
Using the Create Part dialog box....539
Adding a feature to a part....546
Adding a solid feature....547
Adding a shell feature....561
Adding a wire feature....577
Adding a cut feature....586
Using the Edit Feature dialog box....602
Using the Edit Loft dialog box....604
Blending edges....608
Mirroring a part....612
The Property module....613
Entering and exiting the Property module....614
Understanding properties....615
Which properties can I assign to a part?....624
Understanding the Property module editors....626
Using material libraries....642
Using the Property module toolbox....649
Creating and editing materials....650
Defining general material data....664
Defining mechanical material models....671
Defining thermal material models....857
Defining electrical and magnetic material models....866
Defining other types of material models....873
Creating and editing sections....904
Creating and editing composite layups....956
Assigning sections, orientations, normals, and tangents to a part....982
Using discrete orientations for material orientations and composite layup orientations....1000
Creating material calibrations....1003
Using the Special menu in the Property module....1017
Using the Query toolset to obtain assignment information....1018
The Assembly module....1020
Understanding the role of the Assembly module....1021
Entering and exiting the Assembly module....1022
Working with part instances....1023
Working with model instances....1032
Creating the assembly....1035
Creating patterns of instances....1049
Performing Boolean operations on part instances....1051
Understanding toolsets in the Assembly module....1058
Using the Assembly module toolbox....1067
Creating and manipulating part and model instances....1068
Applying constraints to part and model instances....1088
Using the Query toolset to query the assembly....1102

The Step module....1103
Understanding the role of the Step module....1104
Entering and exiting the Step module....1105
Understanding steps....1106
Understanding output requests....1113
Understanding step control....1122
Understanding ALE adaptive meshing....1123
Understanding integrated, restart, diagnostic, and monitor output....1124
How can I customize the Abaqus analysis controls?....1129
Using the Step module toolbox....1132
Using the Step Manager....1133
Using the step editor....1140
Configuring analysis procedure settings....1144
Defining output requests....1244
Defining step control....1256
Requesting specialized output....1259
Customizing ALE adaptive meshing....1268
Customizing the Abaqus analysis controls....1277
The Interaction module....1285
Understanding the role of the Interaction module....1286
Entering and exiting the Interaction module....1288
Understanding interactions....1289
Understanding interaction properties....1293
Understanding constraints....1295
Understanding contact and constraint detection....1297
Understanding connectors....1320
Understanding connector sections and functions....1321
Understanding Interaction module managers and editors....1326
Understanding symbols that represent interactions, constraints, and connectors....1339
Using the Interaction module toolbox....1340
Using the Interaction module....1341
Using the interaction editors....1371
Using the interaction property editors....1457
Using the constraint editors....1498
Using contact and constraint detection....1519
Using the connector section editors....1540
Using the Query toolset to obtain connector assignment information....1571
The Load module....1572
Understanding the role of the Load module....1573
Entering and exiting the Load module....1574
Managing prescribed conditions....1575
Creating and modifying prescribed conditions....1577
Understanding symbols that represent prescribed conditions....1580
Transferring results between Abaqus analyses....1589
Using the Load module toolbox....1591
Using the Load module....1592
Using the load editors....1603
Using the boundary condition editors....1662

Using the predefined field editors....1707
The Mesh module....1734
Understanding the role of the Mesh module....1735
Entering and exiting the Mesh module....1736
Mesh module basics....1737
Understanding seeding....1751
Assigning Abaqus element types....1762
Verifying and improving meshes....1770
Understanding mesh generation....1782
Structured meshing and mapped meshing....1798
Swept meshing....1810
Free meshing....1825
Bottom-up meshing....1835
Mesh-geometry association....1870
Understanding adaptive remeshing....1872
Advanced meshing techniques....1878
Using the Mesh module toolbox....1888
Seeding a model....1889
Creating and deleting meshes....1903
Controlling mesh characteristics....1907
Obtaining mesh information and statistics....1933
Creating a mesh part....1940
Controlling adaptive remeshing....1941
The Optimization module....1951
Understanding the role of the Optimization module....1952
Entering and exiting the Optimization module....1953
Understanding optimization....1954
Using the Optimization module toolbox....1962
Viewing and troubleshooting an optimization....1963
Creating and configuring an optimization task....1965
Configuring design responses....2002
Creating objective functions....2014
Creating constraints....2015
Configuring geometric restrictions....2017
Creating local stop conditions....2075
The Job module....2077
Understanding the role of the Job module....2078
Understanding analysis jobs....2079
Understanding adaptivity processes....2093
Understanding co-executions....2100
Understanding optimization processes....2105
Restarting an analysis....2116
Creating, editing, and manipulating jobs....2127
Using the job editor....2135
Creating, editing, and manipulating adaptivity processes....2147
Using the adaptivity process editor....2153
Creating, editing, and manipulating co-executions....2160
Creating, editing, and manipulating optimization processes....2166

The Sketch module....2180
Understanding the role of the Sketch module....2181
Entering and exiting the Sketch module....2182
Using the Sketch module....2183
Basic Sketcher concepts....2186
Sketcher geometry....2198
Specifying precise geometry....2202
Controlling sketch geometry....2203
Modifying, copying, and offsetting objects....2210
Customizing the Sketcher....2225
Sketching simple objects....2240
Creating construction geometry....2256
Constraining, dimensioning, and parameterizing a sketch....2265
Editing dimensions....2274
Adding reference geometry....2276
Projecting edges onto a sketch....2277
Moving or copying sketch geometry....2278
Modifying objects....2283
Repairing short edges, gaps, and overlaps....2290
Creating patterns, offsetting, and deleting objects....2295
Undoing and redoing sketching actions....2302
Resetting the view....2303
Managing stand-alone sketches....2304
Modeling techniques....2309
Adhesive joints and bonded interfaces....2310
Modeling adhesive joints and bonded interfaces....2311
Embedding cohesive elements in an existing three-dimensional mesh....2312
Creating a model with cohesive elements using geometry and mesh tools....2313
Defining tie constraints between the cohesive layer and the surrounding bulk material....2315
Assigning cohesive modeling data....2316
Bolt loads....2317
Understanding bolt loads....2318
Creating and editing bolt loads....2321
Composite layups....2323
An overview of composite layups....2324
Creating a composite layup....2326
Understanding composite layups and orientations....2329
Understanding composite layups and distributions....2332
Requesting output from a composite layup....2333
Viewing a composite layup....2335
Connectors....2340
Modeling connectors....2341
What is a connector?....2342
What is a connector section?....2343
What is a CORM?....2344
What are connector behaviors?....2345
Creating the connector geometry, connector sections, and connector section assignments....2346
What is the relationship between reference points and connectors?....2348

Defining connector orientations in connector section assignments....2350
Requesting output from connectors....2351
Applying connector loads and connector boundary conditions....2352
Displaying connectors and connector output in the Visualization module....2353
Continuum shells....2355
Modeling continuum shells....2356
Meshing parts with continuum shell elements....2357
Co-simulation....2358
Overview of co-simulation....2359
What is a co-simulation?....2360
Linking and excluding part instances for a co-simulation....2361
Ensuring matching nodes at the interface regions....2362
Specifying the interface region and coupling schemes....2363
Identifying the models involved and specifying job parameters....2364
Viewing the results of the co-simulation....2365
Display bodies....2366
What is a display body?....2367
Should I mesh a display body?....2369
Displaying display bodies in the Visualization module....2370
Eulerian analyses....2371
Overview of Eulerian analyses....2372
Assembling coupled Eulerian-Lagrangian models in Abaqus/CAE....2374
Defining contact in Eulerian-Lagrangian models....2376
Assigning materials to Eulerian part instances....2377
Using the volume fraction tool....2381
Eulerian mesh motion....2384
Viewing output from Eulerian analyses....2385
Fasteners....2388
About fasteners....2389
Managing fasteners....2405
Creating point-based fasteners....2406
Creating discrete fasteners....2413
Creating assembled fasteners....2415
Fracture mechanics....2420
Seam cracks....2421
Using contour integrals to model fracture mechanics....2424
Using the extended finite element method to model fracture mechanics....2444
Using the virtual crack closure technique to model crack propagation....2456
Managing cracks....2460
Gaskets....2461
Modeling gaskets....2462
Defining materials for gaskets....2465
Assigning gasket elements to a region....2466
Imperfection....2467
Defining imperfections....2468
Managing imperfections....2469
Defining file imperfections....2470
Defining input imperfections....2471

Defining data imperfections....2472
Editing the region to which a file imperfection applied....2473
Inertia....2474
Defining inertia....2475
Managing inertia....2476
Defining point mass and rotary inertia....2477
Defining nonstructural mass....2480
Defining heat capacitance....2482
Editing the region to which inertia is applied....2483
Load cases....2484
What is a load case?....2485
Managing load cases....2486
Load case editors....2487
Viewing load case output....2489
Defining a load case....2491
Midsurface modeling....2493
Understanding midsurface modeling....2494
Understanding the reference representation....2495
Creating shell faces for the midsurface model....2496
Examples of creating a midsurface model....2500
Creating and editing midsurface models....2513
Skin and stringer reinforcements....2518
Defining skin reinforcements....2519
Defining stringer reinforcements....2521
Managing skin and stringer reinforcements....2523
Generating elements on a skin or stringer reinforcement....2524
Assigning element types to skin or stringer reinforcements....2525
Using offset meshes to create skin reinforcements....2526
Assigning surface properties to skins and stringers....2527
Creating and editing skin reinforcements....2528
Creating and editing stringer reinforcements....2530
Springs and dashpots....2532
Defining springs and dashpots....2533
Managing springs and dashpots....2534
Creating springs and dashpots connecting two points....2535
Editing springs and dashpots connecting two points....2538
Creating springs and dashpots connecting points to ground....2539
Editing the region to which springs and dashpots connecting points to ground are applied....2541
Submodeling....2542
Analyzing the global model....2543
Creating a submodel....2544
Removing regions....2545
Creating the submodel boundary condition....2546
Creating the submodel load....2548
Modifying the submodel....2549
Analyzing the submodel....2550
Checking the results from the submodel....2551
Substructures....2552

Using substructures in Abaqus/CAE....2553
Generating a substructure....2556
Specifying the retained nodal degrees of freedom and load cases for a substructure....2557
Importing a substructure into Abaqus/CAE....2558
Using substructure part instances in an assembly....2559
Activating load cases during substructure usage....2560
Recovering field output for substructures....2561
Visualizing substructure output....2562
Viewing results....2563
Visualization module basics....2564
Understanding the role of the Visualization module....2565
Entering and exiting the Visualization module....2568
Understanding plot states and plot customization....2569
Understanding toolsets in the Visualization module....2574
Understanding Visualization module performance....2575
Viewing diagnostic output....2576
Understanding job diagnostics....2577
Generating diagnostic information....2578
Interpreting diagnostic information....2579
Accessing diagnostic information....2588
Selecting model data and analysis results to plot....2589
Selecting results from an output database....2590
Selecting results from the current model database....2591
Selecting the results step and frame....2593
Customizing the display of steps and frames in the results....2596
Selecting the field output to display....2601
Selecting result options....2621
Creating and saving new field output....2639
Creating coordinate systems during postprocessing....2649
Creating node and element sets during postprocessing....2656
Plotting the undeformed and deformed shapes....2657
Understanding undeformed shape plotting....2658
Understanding deformed shape plotting....2659
Using common plot options....2660
Producing an undeformed shape plot....2661
Producing a deformed shape plot....2662
Superimposing deformed and undeformed model plots....2663
Contouring analysis results....2665
Understanding contour plotting....2666
Using contour plot options....2672
Producing a contour plot....2673
Producing a contour plot of linear beam section stresses....2674
Customizing a contour plot....2676
Plotting analysis results as symbols....2695
Understanding symbol plotting....2696
Using symbol plot options....2698
Producing a results symbol plot....2699
Producing a symbol plot of free body nodal forces....2700

Customizing symbol plot appearance....2701
Plotting material orientations....2706
Understanding material orientation plotting....2707
Using material orientation plot options....2708
Producing a material orientation plot....2709
Customizing material orientation plot triads....2710
X–Y plotting....2711
Understanding X–Y plotting....2712
Specifying and saving X–Y data objects....2719
Producing an X–Y plot....2738
Operating on saved X–Y data objects....2740
Customizing X–Y plot axes....2820
Customizing X–Y curve appearance....2835
Customizing X–Y plot appearance....2844
Customizing the X–Y plot title....2850
Customizing the appearance of the X–Y plot legend....2854
Customizing border and fill colors for an X–Y plot....2861
Viewing results along a path....2862
Understanding results along a path....2863
Creating a path through your model....2868
Obtaining X–Y data along a path....2879
Animating plots....2885
Understanding animation....2886
Object-based animation....2890
Saving an animation file....2897
Controlling animation playback....2903
Querying the model in the Visualization module....2912
Understanding the Query toolset in the Visualization module....2913
Using the Query toolset....2915
Probing the model....2920
Understanding probing....2921
Using the Query toolset to probe the model....2923
Calculating linearized stresses....2933
Understanding stress linearization....2934
Stress linearization example....2938
Obtaining linearized stress results....2942
Viewing a ply stack plot....2945
Understanding ply stack plots....2946
Customizing ply stack plots....2948
Generating tabular data reports....2955
Producing a tabular report....2956
Using tabular report options....2957
Selecting report data....2958
Specifying your report file name....2964
Controlling report layout, width, format, and coordinate system....2965
Sorting field output data....2967
Formatting report values....2968
Reporting data values, minimums, maximums, and totals....2970

Customizing plot display....2971
Selecting plot display options....2972
Customizing render style, translucency, and fill color....2976
Customizing element and surface edges....2981
Customizing model shape....2988
Customizing model labels....2992
Displaying multiple plot states....3003
Displaying element and surface normals....3004
Customizing the appearance of display bodies....3005
Customizing camera movement....3006
Controlling the display of model entities....3008
Controlling the display of constraints in the Visualization module....3010
Customizing general model display....3011
Customizing viewport annotations....3030
Customizing the legend....3031
Customizing the title block....3034
Customizing the state block....3036
Using viewport annotation options....3038
Using toolsets....3039
The Amplitude toolset....3040
Understanding the role of the Amplitude toolset....3041
Understanding the amplitude editors....3042
Selecting an amplitude type to define....3043
Using tabular data to define an amplitude curve....3045
Using equally spaced data to define an amplitude curve....3046
Using periodic data to define an amplitude curve....3047
Using modulated data to define an amplitude curve....3048
Using exponential decay data to define an amplitude curve....3049
Defining a solution-dependent amplitude curve....3050
Using smooth step data to define an amplitude curve....3051
Defining a spectrum....3052
Defining a user-defined amplitude curve....3053
Defining a PSD definition....3054
The Analytical Field toolset....3055
Using the Analytical Field toolset....3056
Using analytical expression fields....3057
Using analytical mapped fields....3062
Displaying symbols for interactions and prescribed conditions that use analytical fields....3073
Displaying symbols to visualize mapping source data....3076
Creating expression fields....3077
Creating mapped fields....3079
The Attachment toolset....3089
Understanding attachment points and lines....3090
Understanding the projection methods....3092
Creating attachment points by picking or reading from a file....3093
Creating attachment points by choosing a direction and a spacing....3095
Creating patterns of attachment points based on edges....3097
Creating attachment lines by projecting points....3099

Editing attachment points and lines....3101
Removing attachment points and lines....3105
The CAD Connection toolset....3106
Creating a CAD connection....3107
Updating geometry parameters in an imported model....3110
The Customize toolset....3112
Configuring the visibility of toolbars....3113
Configuring keyboard shortcuts....3114
Custom toolbars....3115
Configuring icons in custom toolbars....3116
Using the Customize toolset....3117
The Datum toolset....3125
Understanding the role of datum geometry....3126
Using the Datum toolset....3128
Why are datum coordinate systems so important?....3129
Understanding a datum as a feature....3130
Datum creation techniques....3131
Creating datum points....3148
Creating datum axes....3159
Creating datum planes....3174
Creating datum coordinate systems....3184
The Discrete Field toolset....3192
Using the Discrete Field toolset....3193
Creating discrete fields....3194
Evaluating discrete fields....3196
Creating discrete fields for material volume fractions....3199
The Edit Mesh toolset....3201
What can I do with the Edit Mesh toolset?....3202
What is the difference between editing an orphan mesh, a meshed part, and a meshed part instance in the assembly?.3211
Meshing strategies and mesh editing techniques....3212
Using the mesh editing tools....3221
Editing nodes....3223
Editing elements....3243
Editing the entire mesh....3263
Editing and refining an orphan mesh....3287
Undoing or redoing a change in the Edit Mesh toolset....3291
The Feature Manipulation toolset....3295
Using the Feature Manipulation toolset....3296
Using the Model Tree to manage features....3298
Tuning feature regeneration....3300
Modifying and manipulating features....3306
The Filter toolset....3315
Filtering field and history data....3316
Applying bounding values to field and history data....3317
Creating a filter....3318
The Free Body toolset....3320
Resultant forces and moments on free body cuts in Abaqus/CAE....3321
Creating or editing a free body cut....3322

Selection methods for free body cross-sections....3325
Displaying, hiding, and highlighting free body cuts....3326
Customizing free body cut display....3327
The Options toolset....3334
Customizing memory limits and regeneration options....3335
Using view manipulation shortcuts....3336
Scaling the size of icons....3337
The Geometry Edit toolset....3338
Editing techniques....3339
Editing techniques....3340
What is stitching?....3348
A strategy for repairing geometry....3349
Creating a part from orphan elements....3351
Editing and repairing edges....3352
Editing and repairing faces....3360
Editing parts....3378
The Partition toolset....3381
Understanding the role of partitions....3382
Using the Partition toolset....3383
Understanding partitions....3384
Partitioning techniques....3388
Partitioning edges....3401
Partitioning faces....3406
Partitioning cells....3423
The Query toolset....3436
Understanding the role of the Query toolset....3437
Querying the model....3446
The Reference Point toolset....3459
What is a reference point?....3460
What is a reference point used for?....3461
Creating a reference point....3462
The Set and Surface toolsets....3463
Understanding the role of the Set and Surface toolsets....3464
Understanding sets and surfaces....3465
Using the Set and Surface toolsets....3474
The Stream toolset....3483
Understanding stream display....3484
Creating a stream....3485
Displaying and hiding streams....3486
Customizing stream display....3487
The Virtual Topology toolset....3490
What is virtual topology?....3491
What can I do with the Virtual Topology toolset?....3494
What can I do with a part or a part instance containing virtual topology?....3496
Why repair a part if I can use virtual topology?....3497
Creating virtual topology based on geometric parameters....3498
Using the Virtual Topology toolset....3503
Customizing model display....3510

Customizing geometry and mesh display....3511
Using geometry and mesh display options....3512
Choosing a render style....3513
Controlling edge visibility....3515
Controlling curve refinement....3518
Defining mesh feature edges....3519
Controlling translucency for substructure parts....3520
Controlling beam profile display....3521
Controlling shell thickness display....3523
Controlling datum display....3525
Controlling the display of individual coordinate systems....3526
Controlling reference point display....3527
Customizing mesh display....3528
Controlling model lighting....3529
Controlling instance visibility....3531
Controlling the display of attributes....3532
Saving your display options settings....3534
Color coding geometry and mesh elements....3535
Understanding color coding....3536
Changing the initial color....3540
Changing the translucency....3541
Coloring geometry and mesh elements....3542
Coloring all geometry in the Visualization module....3543
Coloring nodes or elements in the Visualization module....3544
Coloring constraints in the Visualization module....3546
Customizing the display color of individual objects....3547
Displaying multiple color mappings....3549
Editing the colors in the Auto-Color List....3550
Saving and restoring custom color mappings....3551
Using display groups to display subsets of your model....3552
Understanding display groups....3553
Managing display groups....3558
Overlaying multiple plots....3569
Understanding how to overlay plots....3570
Producing and modifying overlay plots....3572
Cutting through a model....3579
Understanding view cuts....3580
Managing view cuts....3585
Using plug-ins....3600
The Plug-in toolset....3601
What is a plug-in?....3602
Where can I get plug-ins?....3603

For a full list of the third-party software contained in this release, please go to the Legal Notices in the Abaqus 2026 HTML documentation, which can be obtained from a documentation installation, or in the SIMULIA Established Products 2026 Program Directory, which is available on *www.3ds.com*.

Abaqus/CAE User's Guide

The Abaqus/CAE User's Guide is a complete reference to using Abaqus/CAE.

This guide is a part of the Abaqus® documentation collection, which describes all the capabilities of the Abaqus finite element analysis technology used in SIMULIA® applications.

Detailed descriptions of how to use Abaqus/CAE for model generation, analysis, and results evaluation and visualization are provided. Abaqus/Viewer users should refer to the information on the Visualization module in this guide.

What's New

This page describes recent changes in Abaqus/CAE.

2026 FD02

Creo Parametric

The Pro/ENGINEER Associative Interface is renamed to Abaqus Associative Interface for Creo Parametric. In addition, a new option, `PART_PARAMS`, supported in the `proe_abaqus.properties` file allows the **PartScope** parameters defined in Creo Parametric to be written to the parameter file (`*.par_abq`).

Benefits: This feature expands the capabilities of Abaqus/CAE.

For more information, see *Creating a CAD connection* and *Updating geometry parameters in an imported model*.

2026 FD01

Datum Creation Methods

The datum toolkit in Abaqus/CAE offers new methods for creating datum points, datum axes, and datum coordinate systems.

Benefits: You have more options for creating datums, simplifying model creation by requiring fewer intermediate datums.
You can now create a datum point by:

- Entering coordinates in a local coordinate system
- Intersecting an axis and a plane
- Offsetting from a point in a given direction

You can now create a datum axis by:

- Using the cross product of two lines
- Projecting a line onto a plane

You can now create a datum coordinate system by rotating another coordinate system by a given angle around an axis.

Background Grid SPH Particle Element Conversion

In Abaqus/CAE you can now specify section controls for smoothed particle hydrodynamics (SPH) parameters in Abaqus/Explicit analyses involving the conversion of continuum elements to SPH particles based on a uniform background grid. In earlier releases, you could specify parameters only for per-element particle conversion.

Benefits: This support allows greater flexibility when running SPH analyses in Abaqus/CAE without having to use the keywords editor.

For more information, see *Section Controls*.

2026 GA

Fluid Electric Potential Predefined Field

Abaqus/CAE now supports the definition of the fluid electric potential predefined field.

Benefits: This support allows greater flexibility to define fluid electric potential as a predefined field in Abaqus/CAE without having to use the keywords editor.

For more information, see *Defining a fluid electric potential field*.

Solid Electric Potential Predefined Field

Abaqus/CAE now supports the definition of the solid electric potential predefined field.

Benefits: This support allows greater flexibility to define solid electric potential as a predefined field in Abaqus/CAE without having to use the keywords editor.

For more information, see *Defining a solid electric potential field*.

Ion Concentration Predefined Field

Abaqus/CAE now supports the definition of the ion concentration predefined field.

Benefits: This support allows greater flexibility to define ion concentration as a predefined field in Abaqus/CAE without having to use the keywords editor.

For more information, see *Defining an ion concentration field*.

Electric Potential Electrolyte Boundary Condition

Abaqus/CAE now supports the definition of the electric potential electrolyte boundary condition.

Benefits: This support allows greater flexibility to define the electric potential electrolyte as a boundary condition in Abaqus/CAE without having to use the keywords editor.

For more information, see *Defining an electric potential electrolyte boundary condition*.

Ion Concentration Boundary Condition

Abaqus/CAE now supports the definition of the ion concentration boundary condition.

Benefits: This support allows greater flexibility to define ion concentration as a boundary condition in Abaqus/CAE without having to use the keywords editor.

For more information, see *Defining an ion concentration boundary condition*.

Distributed Ion Concentration Body Flux

Abaqus/CAE now supports the definition of distributed ion concentration body flux load.

Benefits: This support allows greater flexibility to define ion concentration as a boundary condition in Abaqus/CAE without having to use the keywords editor.

For more information, see *Defining a distributed ion concentration body flux*.

Ion Concentration Flux

Abaqus/CAE now supports the definition of ion concentration flux load.

Benefits: This support allows greater flexibility to define ion concentration as a boundary condition in Abaqus/CAE without having to use the keywords editor.

For more information, see *Defining an ion concentration flux*.

Fluid Surface Current

Abaqus/CAE now supports the definition of fluid current densities over a surface in a coupled thermal-electrochemical analysis.

Benefits: This support allows greater flexibility for modelling fluid surface current as a load in Abaqus/CAE without having to use the keywords editor.

For more information, see *Defining a fluid surface current*.

Support for Additional Degrees of Freedom in Tie Constraints

You can specify tie constraints on additional degrees of freedom, including temperature, pore pressure, electric potential in solid, electric potential in fluid, and ion concentration in fluid.

Benefits: This support allows you to specify more degrees of freedom for constraining the surfaces.

For more information, see *Defining tie constraints*.

Support for Uniform Coupling

You can use Uniform as the coupling type while defining the coupling constraints.

Benefits: This support allows you to specify a Uniform coupling type to couple nondisplacement degrees of freedom.

For more information, see *Defining coupling constraints*.

Support for Defining a Coupled Thermal-Electrochemical Procedure in Abaqus/CAE

Abaqus/CAE now supports the coupled thermal-electrochemical procedure in the GUI.

Benefits: This support allows you to define and modify a coupled thermal-electrochemical procedure interactively in Abaqus/CAE.

For more information, see *Configuring a coupled, thermal electrochemical procedure*.

Support for Defining a Fully Coupled Thermal-Electrochemical Structural Procedure in Abaqus/CAE

Abaqus/CAE now supports the coupled thermal-electrochemical structural procedure in the GUI.

Benefits: This support allows you to define and modify a coupled thermal-electrochemical structural procedure interactively in Abaqus/CAE.

For more information, see *Configuring a fully coupled, thermal electrochemical structural procedure*.

Support for Defining a Fully Coupled Thermal-Electrochemical Structural Pore Pressure Procedure in Abaqus/CAE

Abaqus/CAE now supports the coupled thermal-electrochemical procedure in the GUI.

Benefits: This support allows you to define and modify a coupled thermal-electrochemical structural pore pressure procedure interactively in Abaqus/CAE.

For more information, see *Configuring a fully coupled, thermal electrochemical structural pore pressure procedure*.

Support for Defining a Surface Film Condition on the Evolving Face of the Element

Abaqus/CAE now supports the surface film condition on the evolving faces of an element.

Benefits: This support provides more flexibility to define the surface film condition on the evolving faces of elements.

For more information, see *Defining a surface film condition interaction*.

Support for Defining a Surface Radiative Interaction on the Evolving Face of the Element

Abaqus/CAE now supports the surface radiative interaction on the evolving faces of an element.

Benefits: This support provides more flexibility to define the surface radiative interaction on the evolving face of elements.

For more information, see *Defining a surface radiative interaction*.

Support for Gap Diffusivity Contact Interaction Property in Abaqus/CAE

Abaqus/CAE now supports the gap diffusivity contact interaction property in the GUI.

Benefits: This support allows you to define and modify a gap diffusivity contact interaction property interactively in Abaqus/CAE.

For more information, see *Specifying gap diffusivity for electrical contact property options*.

Extended Support for Gap Electrical Conductance Contact Interaction Property in Abaqus/CAE

Abaqus/CAE now supports additional options for the gap electrical conductance contact interaction property in the GUI.

Benefits: You can now specify the additional options of `Type= solid/liquid` and other properties for these types. For liquid electrolyte, additional ion concentration dependent data is also supported.

For more information, see *Specifying gap conductance for electrical contact property options*.

Extended Support for Gap Heat Generation Contact Interaction Property in Abaqus/CAE

Abaqus/CAE now supports additional options for the gap heat generation contact interaction property in the GUI.

Benefits: You can now can specify the following options:

- `mechanical Interaction Fraction`
- `mechanical Interaction Weighting Factor`
- `electrical Conduction Solids Fraction`
- `electrical Conduction Solids Weighting Factor`
- `electrical Conduction Liquids Fraction`
- `electrical Conduction Liquids Weighting Factor`

For more information, see *Specifying heat generation for thermal contact property options*.

Support for Defining Step Control in Abaqus/CAE

Abaqus/CAE now supports step controls in the GUI.

Benefits: You can now define and modify step controls interactively in Abaqus/CAE.

For more information, see *Understanding step control*.

Support for Follower Parameter of Pre-tension Sections

Abaqus/CAE now extends support for the follower parameter in pre-tension sections.

Benefits: You can now define a varying normal for a pre-tension section in Abaqus/CAE, indicating that the normal is updated when performing a large-displacement analysis.

For more information, see *Creating and editing bolt loads*.

View Cut along a Path Plug-in

Abaqus/CAE now supports moving a cut plane through the model along a user-defined point-list or node-list path in the Visualization module, via an included plug-in.

Benefits: You can now move a cut plane along a user-defined path, dynamically modifying the view cut to different positions along the path. In addition, you can further rotate the view cut at the given position with orthogonal axes to arrive at a desired view cut.

For more information, see *View cut along a path*.

2025 FD01

Animation File Formats

You can now save and load animations in MP4 and animated GIF formats in Abaqus/CAE.

Benefits: New file formats offer improved compatibility with modern media players and editing software, as well as HTML5 and common applications for producing presentations. The file size can be significantly smaller, with no appreciable loss of quality.

You can save MP4 animations with the MPEG-4 codec. If you have an installation of the FFmpeg program that supports H.264 encoding on your system, you can save MP4 animations using the H.264 codec.

For more information, see *Choosing the animation file format* and *Using background images and movies*.

PDF Guides Available

You can download PDF versions of the Abaqus guides from each guide overview.

Benefits: You can easily access the PDF versions of the guides.
In earlier releases, PDF versions of the guides were updated only for the GA (General Availability) release and could be downloaded from the Dassault Systèmes Knowledge Base. As of 2025 FD01, the PDF guides will be updated with each release of the HTML versions of the guides.

For more information, see *Abaqus/CAE User's Guide*.

2025 GA

AutoCAD DXF Sketch Import

Users can now import polylines, splines, ellipses, and other complex entities from AutoCAD files.

Benefits: The import of `.dxf` files as sketches in Abaqus/CAE is greatly improved.

For more information, see *Importing sketches*.

Wear Modeling in Abaqus/CAE

Abaqus/CAE now supports the wear surface property and its assignment in general contact interactions.

Benefits: The support allows greater flexibility for modeling wear phenomena in Abaqus/CAE without having to use the keyword editor.

For more information, see *Specify wear surface property assignments* and *Defining a wear interaction property*.

Rotordynamic Loads in Abaqus/CAE

Abaqus/CAE now supports rotordynamic loads as a rotational body force type in Abaqus/CAE.

Benefits: This support allows greater flexibility to define a rotordynamic load as a rotational body force in Abaqus/CAE without having to use the keyword editor.

For more information, see *Defining a rotational body force*.

Step Dependence for Fluid Inflator and Fluid Exchange

Abaqus/CAE now supports the activation of fluid inflators and fluid exchange in steps.

Benefits: This support allows greater flexibility for modeling the inflator and cavity exchange in Abaqus/CAE without having to use the keyword editor.
Earlier releases of Abaqus/CAE supported automatic activation in Abaqus/Explicit steps, offering no flexibility to the user.

For more information, see *Defining a fluid inflator activation interaction* and *Defining a fluid exchange activation interaction*.

Modeling Cracks and Seams

Abaqus/CAE now supports the creation of a seam on a dependent part instance.

Benefits: Seam creation on a dependent part instance allows greater flexibility when modeling seams for fracture simulation in Abaqus/CAE.
Earlier releases of Abaqus/CAE supported seam creation only for independent instances.

For more information, see *The Special menu in the Interaction module*.

2024 FD03

State Space Solver for Transient Modal Dynamic Analysis

The new state space solver for transient modal dynamic analysis of systems with nondiagonal modal damping operators is now the default solver in Abaqus/CAE.

Benefits: The state space solver is unconditionally stable and offers improved performance for models with many time increments and a moderate number of modes.
In earlier releases, the conventional solver was the default for transient modal dynamic analysis in Abaqus/CAE. Now, you must use the keywords editor to access the conventional solver in Abaqus/CAE.

For more information, see *Transient Modal Dynamic Analysis*.

Job Execution Using **3D**EXPERIENCE On-Cloud Licensing

When you launch Abaqus/CAE from the **3D**EXPERIENCE Platform Connector for Abaqus/CAE, you can now specify that jobs should execute using the **3D**EXPERIENCE Platform license server instead of a locally installed license server.

Benefits: You can take advantage of available cloud SIM Unit licenses to execute an Abaqus analysis locally.

For more information, see *Setting the license type for the SimUnit license model*.

2024 GA

Python 3

Abaqus Python and Abaqus/CAE are now based on Python 3.10 instead of Python 2.7.

Benefits: This update brings Abaqus Python into conformance with a version of Python that is supported in the open-source community.

For more information, see *https://go.3ds.com/AbaqusPython*.

Render Styles in Plots for Continuum Particle Elements

Abaqus/CAE now supports visualization of element particle edges with wireframe, hidden, filled, and shaded render styles (**View > ODB Display Options**).

Benefits: The ability to assign different render styles makes it easier to distinguish between continuum particle elements.

For more information, see *Output*, *Output*, and *Controlling the display of model entities*.

Step-Dependent General Contact

Abaqus/CAE now supports the definition of general contact in Abaqus/Standard in any analysis step or in the initial step.

Benefits: Defining general contact in analysis steps enables definition of more complex contact behaviors in Abaqus/Standard simulations.

For more information, see *Defining general contact* and *About General Contact in Abaqus/Standard*.

Contact Mass Scaling

Abaqus/CAE now supports the definition of contact mass scaling in Abaqus/Explicit.

Benefits: Contact mass scaling can reduce the number of increments required for Abaqus/Explicit simulations that use nondefault penalty stiffness.
You can apply mass scaling to the contact surfaces or elements involved in the contact definition. Contact mass scaling reduces the impact of higher-than-default contact penalty stiffness on the global stable time increment in an Abaqus/Explicit analysis by increasing the mass associated with the contact surfaces.

For more information, see *Defining contact mass scaling* and **CONTACT MASS SCALING*.

Channel and Hat Section Profiles

You can now define channel and hat section profiles in the Property module.

Benefits: The addition of channel and hat profiles simplifies the specification of these common beam cross-sections in Abaqus/CAE.

For more information, see *Defining a channel profile*, *Defining a hat profile*, *ChannelProfile object*, *HatProfile object*, and *Beam cross-section analysis*.

Beam Section Offset for *BEAM SECTION

Abaqus/CAE now supports the definition of a beam section offset for beam sections integrated during the analysis (*BEAM SECTION).

Benefits: Beam offsets allow greater flexibility when modeling with beam elements in Abaqus/CAE.
Earlier releases of Abaqus/CAE supported beam section offsets only for **BEAM GENERAL SECTION*.

For more information, see **BEAM SECTION*, *Using a Beam Section Integrated during the Analysis to Define the Section Behavior*, and *BeamSection object*.

Rotational Couplings

You can now define a rotational coupling type in discrete fasteners and coupling constraints in Abaqus/CAE.

Benefits: Defining the rotational coupling type gives you greater control over the behavior of distributing couplings involving cloud nodes with rotational degrees of freedom.

For more information, see **DISTRIBUTING*, *Creating discrete fasteners*, and *Defining coupling constraints*.

Using the Linearized Contact Capability to Solve for Contact Status and Contact Stresses

Abaqus/CAE now supports the activation of the linearized contact capability to solve for contact status and contact stresses within a static perturbation step with small-sliding, frictionless contact.

Benefits: The Linear Complementarity Problem (LCP) solution technique provides a faster solution for certain classes of contact problem.

For more information, see *Configuring a static, linear perturbation procedure* and **SOLUTION TECHNIQUE*.

Interacting with Abaqus/CAE

This guide is the main reference document for Abaqus/CAE, including Abaqus/Viewer.

Abaqus/CAE

Abaqus/CAE is a complete Abaqus environment that provides a simple, consistent interface for creating, submitting, monitoring, and evaluating results from Abaqus/Standard and Abaqus/Explicit simulations. Abaqus/CAE is divided into modules, where each module defines a logical aspect of the modeling process; for example, defining the geometry, defining material properties, and generating a mesh. As you move from module to module, you build the model from which Abaqus/CAE generates an input file that you submit to the Abaqus/Standard or Abaqus/Explicit analysis product. The analysis product performs the analysis, sends information to Abaqus/CAE to allow you to monitor the progress of the job, and generates an output database. Finally, you use the Visualization module of Abaqus/CAE (also licensed separately as Abaqus/Viewer) to read the output database and view the results of your analysis.

Abaqus/Viewer

Abaqus/Viewer provides graphical display of Abaqus finite element models and results. Abaqus/Viewer is incorporated into Abaqus/CAE as the Visualization module.

This part of the guide introduces you to the Abaqus/CAE working environment.

In this section:

- *Introduction*
- *The basics of interacting with Abaqus/CAE*
- *Understanding Abaqus/CAE windows, dialog boxes, and toolboxes*
- *Managing viewports on the canvas*
- *Manipulating the view and controlling perspective*
- *Selecting objects within the viewport*
- *Configuring graphics display options*
- *Printing viewports*

Introduction

This guide is a complete reference to using Abaqus/CAE.

This section provides information about the contents of this guide and the typographical conventions used.

Using this guide

This guide is a complete reference to using Abaqus/CAE (including Abaqus/Viewer, a subset of Abaqus/CAE that contains only the Visualization module).
In general, any references to the Visualization module throughout this guide apply equally to Abaqus/Viewer.

The Abaqus/CAE user interface is very intuitive and allows you to begin working without a great deal of preparation. However, you may find it useful to read through the tutorials at the end of the *Getting Started with Abaqus/CAE* guide before using the product for the first time. Only *Viewing the Output from Your Analysis* applies if you are running Abaqus/Viewer.

This guide is divided into the following parts:

- *Interacting with Abaqus/CAE* contains general information on the user interface
- *Working with Abaqus/CAE Model Databases, Models, and Files* contains information on the various files created by and used with Abaqus/CAE
- *Creating and analyzing a model using the Abaqus/CAE modules* discusses each of the Abaqus/CAE modules in detail, except the Visualization module
- *Modeling techniques* discusses how to define special engineering features in an Abaqus/CAE model and discusses modeling techniques that span multiple Abaqus/CAE modules.
- *Viewing results* discusses the Visualization module (Abaqus/Viewer) in detail
- *Using toolsets* contains information on the toolsets in all Abaqus/CAE modules except the Visualization module (discussed in *Viewing results*)
- *Customizing model display* contains customization information
- *Using plug-ins* discusses how you can use plug-ins and the Plug-in toolset to extend the capabilities of Abaqus/CAE.

Abaqus keyword browser table and *Keyword support from the input file reader* provide tables that you can use to determine which Abaqus/CAE module embodies the functionality of a particular Abaqus keyword, as well as whether a particular keyword is supported. *Special element types* lists element types used in Abaqus for model features that are not part of the mesh. *Special graphical symbols* explains how to interpret the special graphical symbols used by Abaqus/CAE. *Element and output variable support* lists the Abaqus output variables that are not supported by the Visualization module.

Typographical conventions

This guide adheres to a set of typographical conventions so that you can recognize actions and items.

The following list illustrates each of the conventions:

- Text you enter from the keyboard or that Abaqus/CAE outputs: `crankshaft_steel`, `1.35E10`
- Labels of items on the screen: **Job Manager**
- Hyperlinks: *click here*
- Keyboard actions: **[Shift]**
- Keystroke combinations (two keys that must be pressed simultaneously): **[Alt] + F**
- Compound keyboard/mouse actions: **[Shift] + Click**

- Text indicating that the user has a choice: *odb_file*, **Options->*plot state***
- Menu selections and tabs within dialog boxes:

  View->Graphics Options->Hardware

Basic mouse actions

Figure 1 shows the mouse button orientation for a left-handed and a right-handed 3-button mouse.

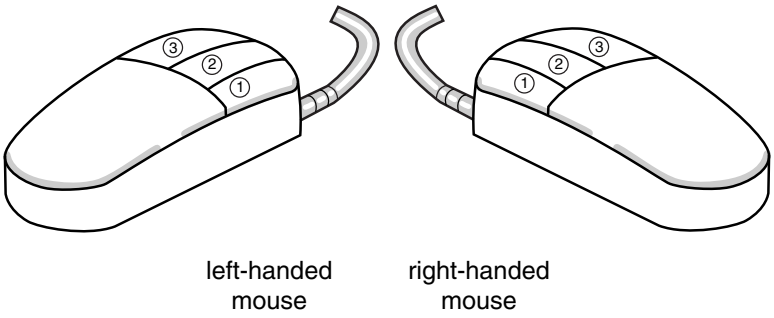

Figure 1: Mouse buttons.

The following terms describe actions you perform using the mouse:

Click

Press and quickly release the mouse button. Unless otherwise specified, the instruction “click” means that you should click mouse button 1.

Drag

Press and hold down mouse button 1 while moving the mouse.

Point

Move the mouse until the cursor is over the desired item.

Select

Point to an item and then click mouse button 1.

[Shift] + Click

Press and hold the **[Shift]** key, click mouse button 1, and then release the **[Shift]** key.

[Ctrl] + Click

Press and hold the **[Ctrl]** key, click mouse button 1, and then release the **[Ctrl]** key.

Abaqus/CAE is designed for use with a 3-button mouse. Accordingly, this guide refers to mouse buttons 1, 2, and 3 as shown in *Figure 1*. However, you can use Abaqus/CAE with a 2-button mouse as follows:

- The two mouse buttons are equivalent to mouse buttons 1 and 3 on a 3-button mouse.
- Pressing both mouse buttons simultaneously is equivalent to pressing mouse button 2 on a 3-button mouse.

Tip: You are instructed to click mouse button 2 in procedures throughout this guide. Make sure that you configure mouse button 2 (or the wheel button) to act as a middle button click.

The basics of interacting with Abaqus/CAE

Before you can begin creating and analyzing a model or interpreting analysis results, it is helpful to become familiar with the basics of interacting with Abaqus/CAE. This chapter introduces you to the user interface.

In this section:

- *Starting and exiting Abaqus/CAE*
- *The Abaqus/CAE main window*
- *What is a module?*
- *What is a toolset?*
- *Using the mouse with Abaqus/CAE*
- *Getting help*

Starting and exiting Abaqus/CAE

This section explains how to start and how to exit Abaqus/CAE.

In this section:

- *Starting Abaqus/CAE (or Abaqus/Viewer)*
- *Exiting an Abaqus/CAE session*
- *Working with abaqus_2026.gpr files*
- *Saving model data from an inactive session*

Starting Abaqus/CAE (or Abaqus/Viewer)

When you create a model and analyze it, Abaqus/CAE generates a set of files containing the definition of your model, the analysis input, and the results of the analysis. In addition, Abaqus/CAE and Abaqus/Viewer generate replay files that reflect all your interactions with the application.
Consequently, before you run either product, you should move to a directory where you have permission to create files.

You execute Abaqus/CAE (or Abaqus/Viewer) by running the **abaqus** execution procedure and specifying the **cae** (or **viewer**) parameter:

abaqus cae or **viewer[database =** *database-file*]**[replay =** *replay-file*]**[recover =** *journal-file*]**[startup =** *startup-file*]**[script =** *script-file*]**[noGUI =** *noGUI-file*]**[noenvstartup][noSavedOptions][noSavedGuiPrefs][noStartupDialog][custom =** *script-file*]**[[guiTester][**GUI-script]]**[guiRecord][guiNoRecord]**

You can include the following options on the command line:

database

This option specifies the name of the model database file or output database file to open. You can open either type of file in Abaqus/CAE; you can open only output database files in Abaqus/Viewer. To specify a model database file, include either the `.cae` file extension or no file extension in your file name. To specify an output database file when running Abaqus/CAE, include the `.odb` file extension in your file name. If you are running Abaqus/Viewer, you can omit the `.odb` file extension.

replay

This option specifies the name of the file from which Abaqus/CAE commands are to be replayed. The commands in *replay-file* will execute immediately upon startup of Abaqus/CAE. You cannot use the `replay` option to execute a script with control flow statements. For more information, see *Replaying an Abaqus/CAE session*.

recover

This option specifies the name of the file from which a model database is to be rebuilt; it is not available if you are running Abaqus/Viewer. The commands in *journal-file* (*model_database_name* `.jnl`) will execute immediately upon startup of Abaqus/CAE. For more information, see *Recreating a saved model database*, and *Recreating an unsaved model database*.

startup

This option specifies the name of the file containing Python configuration commands to be run at application startup. Commands in this file are run after any configuration commands that have been set in the environment file. Abaqus/CAE does not echo the commands to the replay file when they are executed.

Arguments can be passed into the file by entering `--` on the command line, followed by the arguments separated by one or more spaces. These arguments will be ignored by the Abaqus/CAE execution procedure, but they will be accessible within the script.

script

Same as **startup**.

noGUI

This option specifies the name of a file containing Python scripts to be run without the graphical user interface (GUI). This option is useful for automating pre- or post-analysis processing tasks without the added expense of running a display. Since no interface is provided, the scripts cannot include any user interaction. Abaqus/CAE runs the commands in the file and exits upon their completion. If no file extension is given, the default extension is `.py`. If you use the `noGUI` option, Abaqus/CAE ignores any other command line options that you provide.

Arguments can be passed into the file by entering `--` on the command line, followed by the arguments separated by one or more spaces. These arguments will be ignored by the Abaqus/CAE execution procedure, but they will be accessible within the Python script. If you are using the `noGUI` option, you can use an argument to pass in a variable that would otherwise be provided by a command line option. For example, you can pass in the name of a file that would otherwise be specified by the `script` option.

A sample usage of the **noGUI** option is available in *Abaqus/CAE Execution*.

noenvstartup

This option specifies that all configuration commands in the environment files should not be run at application startup. This option can be used in conjunction with the **startup** command to suppress all configuration commands except for those in the **startup** file.

noSavedOptions

This option specifies that Abaqus/CAE should not apply the display options settings (for example, the render style and the display of datum planes) stored in the `abaqus_2026.gpr` file. For more information, see *Working with abaqus_2026.gpr files*, and *Saving your display options settings*.

noSavedGuiPrefs

This option specifies that Abaqus/CAE should not apply the GUI options settings (for example, the size and location of the Abaqus/CAE main window or its dialog boxes) stored in the `abaqus_2026.gpr` file.

noStartupDialog

This option specifies that the **Start Session** dialog box for Abaqus/CAE or Abaqus/Viewer should not be displayed.

custom

This option specifies the name of the file containing Abaqus GUI Toolkit commands. This option executes an application that is a customized version of Abaqus/CAE or Abaqus/Viewer. For more information, see *Introduction*.

guiTester

This option starts a separate user interface containing the Abaqus Python development environment along with Abaqus/CAE or Abaqus/Viewer. The Abaqus Python development environment allows you to create, edit, step through, and debug Python scripts. For more information, see *The Abaqus Python Development Environment*.

You can specify a script as the argument for this option, which prompts Abaqus/CAE or Abaqus/Viewer to run a GUI script. Abaqus/CAE or Abaqus/Viewer closes when the end of the script is reached.

guiRecord

This option enables you to record your actions in the Abaqus/CAE or Abaqus/Viewer user interface in a file named `abaqus.guiLog`. Creating a record of your actions in the GUI can help you capture and replay common activities in Abaqus/CAE or Abaqus/Viewer for demonstration or training purposes. You can replicate all of the actions from a `.guiLog` file in Abaqus/CAE or Abaqus/Viewer by running the file in the Abaqus Python Development Environment (PDE); for more information, see *Running a script*.

If desired, you can set **guiRecord** at startup by using the environment variable `ABQ_CAE_GUIRECORD`. The **guiRecord** option cannot be used with the **guiTester** option.

guiNoRecord

This option enables you to disable user interface recording when the environment variable `ABQ_CAE_GUIRECORD` is set.

Abaqus/CAE begins. If you do not include the **database**, **replay**, **recover**, or **noStartupDialog** options, the **Start Session** dialog box appears. Choose one of the following session startup options:

Create Model Database: With Standard/Explicit Model

Use this option (not available if you are running Abaqus/Viewer) to begin a new Abaqus/Standard or Abaqus/Explicit analysis (equivalent to choosing **File->New Model Database->With Standard/Explicit Model** from the main menu bar).

Create Model Database: With Electromagnetic Model

Use this option (not available if you are running Abaqus/Viewer) to begin an electromagnetic analysis (equivalent to choosing **File->New Model Database->With Electromagnetic Model** from the main menu bar).

Open Database

Use this option to open a previously saved model database or output database file (equivalent to choosing **File->Open** from the main menu bar).

Run Script

Use this option to run a file containing Abaqus/CAE commands (equivalent to choosing **File->Run Script** from the main menu bar). For more information, see *Creating and running your own scripts*.

Start Tutorial

Use this option to begin an introductory tutorial from the online documentation (equivalent to choosing **Help->Getting Started** from the main menu bar).

Recent Files

Use this option to open one of the five model database files or output database files that were most recently opened in Abaqus/CAE (equivalent to choosing one of the recent files listed under the **File** menu).

Exiting an Abaqus/CAE session

You can exit the Abaqus/CAE session at any time by selecting **File->Exit** from the main menu bar. If you made any changes to the current model database, Abaqus/CAE asks if you want to save the changes before exiting the session. Abaqus/CAE then closes the current model or output database and all windows and exits the session.

Abaqus/CAE saves your GUI settings; for example, the size of the main window and the size and location of dialog boxes. For more information, see *Working with abaqus_2026.gpr files*, and *Understanding Abaqus/CAE GUI settings*. In addition, Abaqus/CAE automatically creates a file called `abaqus.rpy` that records your operations during the session; you can use this file to reproduce your operations. For more information on reproducing operations and on recovering interrupted sessions, see *Recreating an unsaved model database*.

Additional information

- *Understanding the files generated by creating and analyzing a model*
- *Using the File menu*

Working with abaqus_2026.gpr files

The abaqus_2026.gpr file in your home directory stores GUI settings (such as the size of the main window) as well as display options settings (such as the render style). You can also store display options settings in an abaqus_2026.gpr file in a directory other than your home directory. If you start Abaqus/CAE with **noSavedOptions** specified, Abaqus/CAE does not apply the display options settings (for example, the render style and the display of datum planes) stored in the abaqus_2026.gpr file. For more information, see *Starting Abaqus/CAE (or Abaqus/Viewer)*.

When you start Abaqus/CAE

- GUI settings are read from the abaqus_2026.gpr file in your home directory.
- Display options settings are read from the abaqus_2026.gpr file in the directory from which you start Abaqus/CAE.
  - If no abaqus_2026.gpr file is present but a .gpr file from an earlier release exists in that directory, Abaqus/CAE attempts to apply the settings specified in that file and creates an abaqus_2026.gpr file to store the settings.
  - If no .gpr file is present in that directory, the display options settings are read from the abaqus_2026.gpr file in your home directory.

During an Abaqus/CAE session

You can use **File->Save Display Options** to save display options settings to the abaqus_2026.gpr file in your home directory or in the current directory. For more information, see *Saving your display options settings*. This save option does not apply to GUI settings.

When you exit Abaqus/CAE

Your GUI settings are saved automatically to the abaqus_2026.gpr file in your home directory. For more information, see *Understanding Abaqus/CAE GUI settings*.

You can edit the abaqus_2026.gpr file using API commands in the Abaqus Scripting Interface; for more information, see *Editing display preferences and GUI settings*. You can also delete the file to restore the default GUI and display options settings.

Saving model data from an inactive session

Abaqus/CAE and Abaqus/Viewer include an inactivity timer. If the applications are left inactive for an extended period of time, the license tokens are returned to the server to make them available to other users. Your session does not end if the server connection is lost or if new license tokens cannot be acquired. Instead, when no licenses are available, a dialog box appears listing your options. For both Abaqus/CAE and Abaqus/Viewer you can attempt to reacquire a license or you can exit the application. For Abaqus/CAE you also have the option to save the current model database. Saving the model allows you to preserve any completed model information that you did not already save; any partially completed information, such as for a procedure that was active at the time the license was lost, is not saved. Once you have saved the model database, only the reacquire and exit options remain in the dialog box. The save option is not provided in Abaqus/Viewer since all changes that affect the output database are saved immediately when you make them.

The default time limit is 60 minutes. You can change the time limit by using the **cae_timeout** environment variable in the Abaqus environment file (`abaqus_v6.env`). For more information on the environment file, see *Using the Abaqus environment files*.

Additional information

- *Saving the current model database without a license*
- *License management parameters*

The Abaqus/CAE main window

This section provides an overview of the main window and explains how to operate and manipulate the elements of the window during a session.

In this section:

- *Components of the main window*
- *Components of the main menu bar*
- *Components of the toolbars*
- *The context bar*
- *Components of the viewport*

Components of the main window

You interact with Abaqus/CAE through the main window, and the appearance of the window changes as you work through the modeling process. *Figure 1* shows the components that appear in the main window.

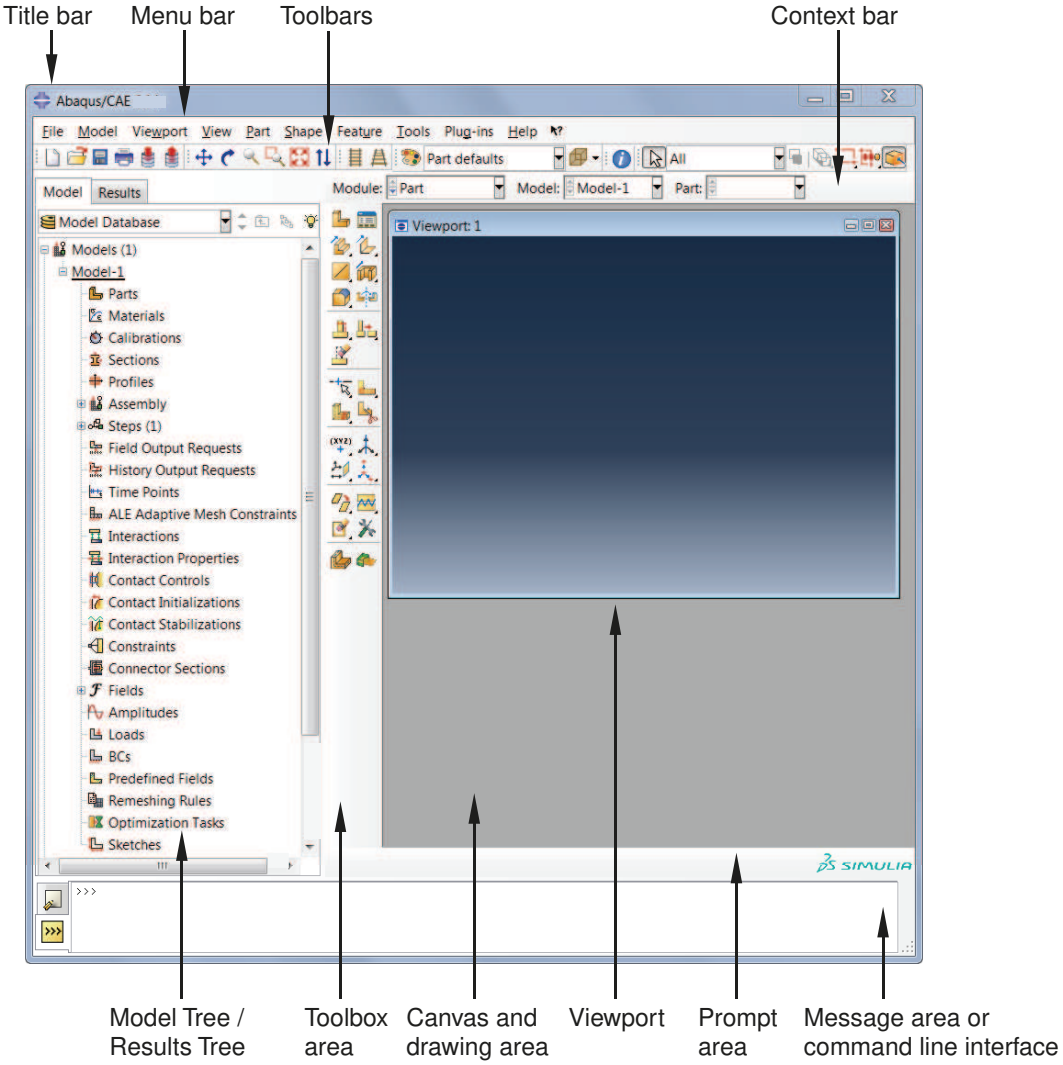

Figure 1: Components of the main window.

The components are:

Title bar

The title bar indicates the release of Abaqus/CAE you are running and the name of the current model database.

Menu bar

The menu bar contains all the available menus; the menus give access to all the functionality in the product. Different menus appear in the menu bar depending on which module you selected from the context bar. For more information, see *Components of the main menu bar*.

Toolbars

The toolbars provide quick access to items that are also available in the menus. For more information, see *Components of the toolbars*.

Context bar

Abaqus/CAE is divided into a set of modules, where each module allows you to work on one aspect of your model; the **Module** list in the context bar allows you to move between these modules. Other items in the context bar are a function of the module you are working in. For example, the context bar allows you to retrieve an existing part while creating the geometry of the model or to change the output database associated with the current viewport. Similarly, in the Mesh module you can choose whether to display the assembly or a particular part. For more information, see *The context bar*.

Model Tree

The Model Tree provides you with a graphical overview of your model and the objects that it contains, such as parts, materials, steps, loads, and output requests. In addition, the Model Tree provides a convenient, centralized tool for moving between modules and for managing objects. If your model database contains more than one model, you can use the Model Tree to move between models. When you become familiar with the Model Tree, you will find that you can quickly perform most of the actions that are found in the main menu bar, the module toolboxes, and the various managers. For more information, see *The Model Tree*.

Results Tree

The Results Tree provides you with a graphical overview of your output databases and other session-specific data such as *X*–*Y* plots. If you have more than one output database open in your session, you can use the Results Tree to move between output databases. When you become familiar with the Results Tree, you will find that you can quickly perform most of the actions in the Visualization module that are found in the main menu bar and the toolbox. For more information, see *The Results Tree*.

Toolbox area

When you enter a module, the toolbox area displays tools in the toolbox that are appropriate for that module. The toolbox allows quick access to many of the module functions that are also available from the menu bar. For more information, see *Understanding and using toolboxes and toolbars*.

Canvas and drawing area

The canvas can be thought of as an infinite screen or bulletin board on which you post viewports; for more information, see *Managing viewports on the canvas*. The drawing area is the visible portion of the canvas. You can display the drawing area full screen using the **View** menu; you can also press **[F11]** to toggle between full screen mode and normal mode.

Viewport

Viewports are windows on the canvas in which Abaqus/CAE displays your model. For more information, see *Managing viewports on the canvas*.

Prompt area

The prompt area displays instructions for you to follow during a procedure; for example, it asks you to select the geometry as you create a set. In the Visualization module a set of buttons is displayed in the prompt area that allow you to move between the steps and the frames of your analysis. For more information, see *Using the prompt area during procedures*.

Message area

Abaqus/CAE prints status information and warnings in the message area. To resize the message area, drag the top edge; to see information that has scrolled out of the message area, use the scroll bar on the right side. The message area is displayed by default, but it uses the same space occupied by the command line interface. If you have recently used the command line interface, you must click  in the bottom left corner of the main window to activate the message area.

Note:

If new messages are added while the command line interface is active, Abaqus/CAE changes the background color surrounding the message area icon to red. When you display the message area, the background reverts to its normal color.

Command line interface

You can use the command line interface to type Python commands and evaluate mathematical expressions using the Python interpreter that is built into Abaqus/CAE. The interface includes primary (>>>) and secondary (`...`) prompts to indicate when you must indent commands to comply with Python syntax. For more information on Python commands, see *The basics of Python*.

The command line interface is hidden by default, but it uses the same space occupied by the message area. Click  in the bottom left corner of the main window to switch from the message area to the command line interface.

Additional information

- *The basics of interacting with Abaqus/CAE*

Components of the main menu bar

When you start a session, the menus listed below appear on the main menu bar. Abaqus/CAE displays additional menu options and provides access to toolsets depending on the current module in use.

File

The items in the **File** menu allow you to create, open, and save model databases; open and close output databases; import and export files; save and load session objects and options; run scripts; manage macros; print viewports; and exit Abaqus/CAE. For more information, see *Using the File menu*.

Model

The items in the **Model** menu allow you to open, copy, rename, and delete the models in the current model database. For more information, see *Managing models*.

Viewport

The items in the **Viewport** menu allow you to create or manipulate viewports and viewport annotations. For more information, see *Managing viewports on the canvas*.

View

The items in the **View** menu allow you to manipulate views, customize certain aspects of the appearance of your model or plots, control display performance, switch to full screen mode, and turn off the display of the Model Tree, the Results Tree, and individual toolbars. Some of the operations available in the view manipulation menu are also available in the View Manipulation toolbar. For more information, see:

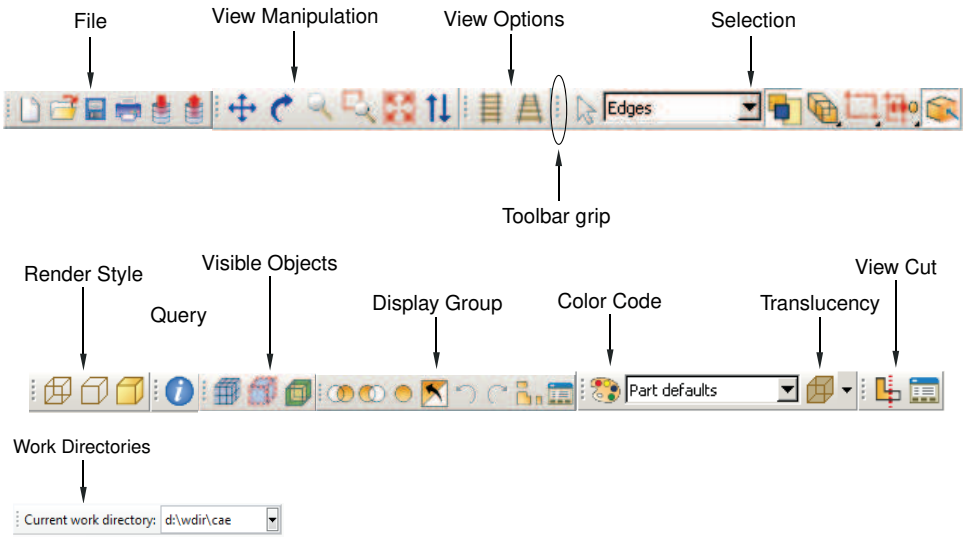
- *Working with the Model Tree and the Results Tree*
- *Managing viewports on the canvas*
- *Manipulating the view and controlling perspective*
- *Configuring graphics display options*
- *Customizing plot display*
- *The Customize toolset*
- *Customizing geometry and mesh display*

Plug-ins

The items in the **Plug-ins** menu allow you to access the plug-ins distributed with Abaqus/CAE or plug-ins that you have downloaded or created. For more information, see *The Plug-in toolset*.

Help

The items in the **Help** menu allow you to request context-sensitive help, search or browse the documentation, access the Learning Community, and obtain information about the release and licensing. For more information, see *Getting help*.



Additional information

- *Components of the main window*

Components of the toolbars

The toolbars contain convenient sets of tools for managing your files, filtering object selection, and viewing your model.
Items in a toolbar are shortcuts to functions that are also available from the main menu bar. By default, Abaqus/CAE displays all of the toolbars in a row underneath the main menu bar. Abaqus/CAE may place some toolbars in a second row depending on your display resolution and the size of the main window.

The toolbars are shown in the following figure:

You can change the location of a toolbar using the toolbar's grip, as indicated in the above figure. Clicking and dragging the grip moves the toolbar around the main window. If you release the toolbar grip while the toolbar is over one of the four available docking regions of the main window (see *Figure 1*), Abaqus/CAE “docks” the toolbar; a docked toolbar has no title bar and does not obstruct any other portion of the main window.

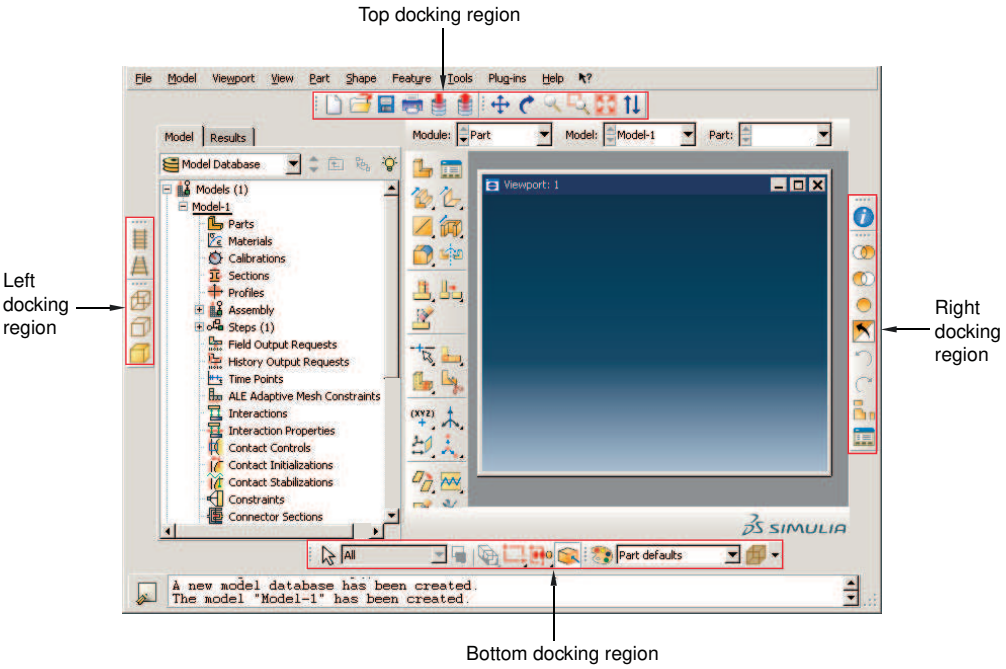


Figure 1: Available docking regions for toolbars.

If you release the toolbar grip while the toolbar is not near a docking region, Abaqus/CAE creates a floating toolbar with a title bar. A floating toolbar obstructs other items in the main window (see *Figure 2*); however, a floating toolbar can be positioned outside of the Abaqus/CAE main window.

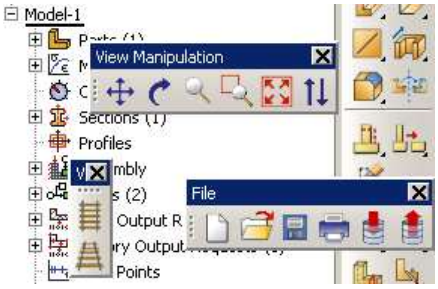

Figure 2: Floating toolbars.

Clicking mouse button 3 on a toolbar grip displays a menu that lets you specify the location and format of the toolbar:

- Select **Top** to dock the toolbar in the top docking region.
- Select **Bottom** to dock the toolbar in the bottom docking region.
- Select **Left** to dock the toolbar in the left docking region.
- Select **Right** to dock the toolbar in the right docking region.
- Select **Float** to change a docked toolbar into a floating toolbar; this option is available only for docked toolbars.
- Select **Flip** to change the orientation of a floating toolbar from horizontal to vertical, or vice versa; this option is available only for floating toolbars.

You can also hide toolbars and create custom toolbars that include shortcuts to additional functions. For more information, see *The Customize toolset*.

To obtain a short description of a tool in a toolbar, place the cursor over that tool for a moment; a small box containing a description, or “tooltip,” will appear. To obtain the name of a toolbar, place the cursor over the toolbar grip for a moment.

The Abaqus/CAE toolbars contain the following functionality:

File

The File toolbar allows you to create, open, and save model databases; to open output databases; to print viewports; and to save and load session objects and options. For more information, see *Working with Abaqus/CAE Model Databases, Models, and Files*; *Printing viewports*; and *Managing session objects and session options*.

Work Directories

The Work Directories toolbar allows you to change the current working directory. The list provided in the toolbar contains the five most recently used work directories. For more information, see *Setting the work directory*.

Viewport

The Viewport toolbar allows you to create and align viewports, link viewports, and create viewport annotations. For more information, see *Managing viewports and viewport annotations from the Viewport toolbar*. The Viewport toolbar is not displayed by default.

View Manipulation

The View Manipulation toolbar allows you to specify different views of the model or plot. For example, you can pan, rotate, or zoom the model or plot using these tools. For more information, see *Manipulating the view and controlling perspective*.

View Options

The View Options toolbar allows you to specify whether or not perspective is applied to your model. For more information, see *Controlling perspective*.

Views

The Views toolbar allows you to apply a custom view to the model in the viewport. For more information, see *Custom views*. The Views toolbar is not displayed by default.

Render Style

The Render Style toolbar allows you to specify whether the wireframe, hidden line, or shaded render style will be used to display your model. In the Visualization module the Render Style toolbar also includes the filled render style  tool. For more information, see *Choosing a render style*.

Visible Objects

The Visible Objects toolbar allows you to switch between displaying the geometry of an Abaqus/CAE native part and the meshed representation of the same part, to toggle the display of seeds on and off, and to toggle the display of the reference representation on or off if the meshed representation and reference representation exist. For more information, see *Displaying a native mesh*, *What are mesh seeds?*, and *Understanding the reference representation*.

Selection

The Selection toolbar allows you to enable or disable object selection by toggling on the arrow icon. You can use the list to the right of the arrow to limit the types of objects that you can select. The **Selection** toolbar is available only when there are no active procedures running in a viewport. For more information, see *Selecting objects before choosing a procedure*.

Query

The Query toolset allows you to obtain information about the geometry and features of your model, to probe model and *X*–*Y* plots for output data, and to perform stress linearization on your results. For more information, see *The Query toolset*; *Probing the model*; and *Calculating linearized stresses*.

Display Group

The Display Group toolbar allows you to selectively plot one or more model or output database items. For example, you can create a display group that contains only the elements belonging to specified sets in your model. For more information, see *Using display groups to display subsets of your model*.

Color Code

The Color Code toolbar allows you to customize the colors of items in the viewport and change the degree of their translucency.

For color coding, you can create color mappings that assign unique colors to different elements of a display. For example, when using a part instance color mapping, each part instance in a model will appear as a different color. For more information, see *Color coding geometry and mesh elements*.

For translucency, you can click the arrow to the right of the  tool to reveal a slider, which you can drag to make the display colors more transparent or more opaque. For more information, see *Changing the translucency*.

View Cut

The View Cut toolbar allows you to toggle the display of view cuts in modules other than the Visualization module and to customize their definition and display. For more information, see *Cutting through a model*. The View Cut toolbar is displayed by default; in the Visualization module, view cut options are available in the toolbox.

Field Output

The Field Output toolbar allows you to control two aspects of field output variable display:

- You can select the field output variable that you want to display in the current viewport. Selections include the type of field output variable (**Primary**, **Deformed**, or **Symbol**), the variable name, and if available, the invariants and components for the selected primary variable.
- For changes in variable type, you can control whether Abaqus/CAE automatically synchronizes the plot state in the current viewport with the new selection of variable type. If the tool is toggled on, Abaqus/CAE synchronizes the plot state if the newly selected field output variable requires a change in plot state; if this option is toggled off, Abaqus/CAE still updates the output variable displayed in the viewport but does not change the plot state in the current viewport.

The selections in the toolbar are limited, but the tool provides access to the **Field Output** dialog box, if needed. For more information about the options in the toolbar, see *Using the field output toolbar*.

Additional information

• *Components of the main window*

The context bar

The context bar is located above the canvas and drawing area; you can use it to do the following:

Select the current module

The **Module** list on the context bar allows you to move between modules. (For more information, see *What is a module?*.) *Figure 1* shows the context bar. To move to a different module, you can choose from the list (the arrow on the right) or click the up and down arrows (on the left) to move to the previous or next module.

Figure 1: The context bar in the Part module.

Note:

Abaqus/Viewer contains only the Visualization module.

Select module-specific items

As you move between modules, Abaqus/CAE displays additional items on the context bar that help you select the context of your current operations. For example, when you are in the Part module or Mesh module, Abaqus/CAE displays the **Part** list in the context bar. The **Part** list contains every part in your model; you can use it to retrieve a particular part. These lists also include the up and down navigation arrows that allow you to move to the previous or next item in the list.

The context bar also allows you to move between models in the model database or to change the output database associated with the current viewport. The additional items in the context bar are a function of the module in which you are working.

The items displayed in the context bar always refer to the current viewport, which is indicated by a dark gray title bar. For example, if you have different parts displayed in different viewports, the context bar indicates the name of the part displayed in the current viewport.

Additional information

- *What is a module?*
- *What is an Abaqus/CAE model?*

Components of the viewport

Figure 1 shows the components of the viewport in the Visualization module.

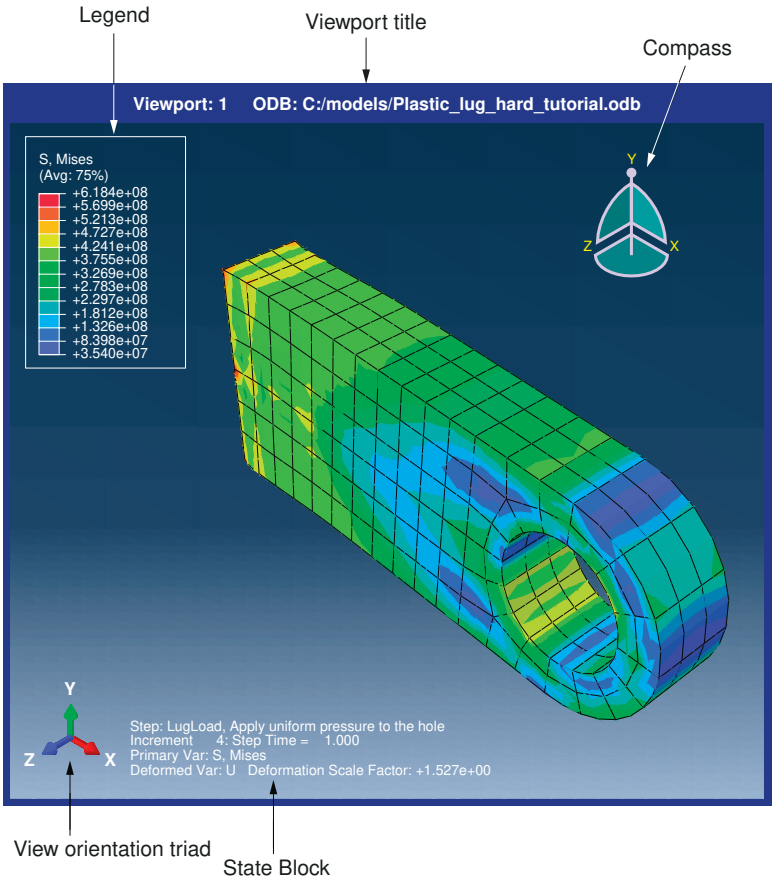

Figure 1: Components of the viewport.

The viewport title and the border around the viewport are called the viewport decorations. The legend, state block, title block, view orientation triad, and 3D compass are called the viewport annotations. The view orientation triad and 3D compass indicate the orientation of the model currently being displayed. You can change the view of the model by clicking and dragging on the 3D compass; the three perpendicular axes on the view orientation triad rotate with the compass to indicate the current view orientation. For more information, see *The 3D compass*, and *Customizing the view triad*. The legend, state block, and title block identify results you display using the Visualization module. For more information, see *Customizing viewport annotations*.

Additional information

- *Managing viewports on the canvas*
- *Customizing viewport annotations*

What is a module?

Abaqus/CAE is divided into functional units called modules. Each module contains only those tools that are relevant to a specific portion of the modeling task. For example, the Mesh module contains only the tools needed to create finite element meshes, while the Job module contains only the tools used to create, edit, submit, and monitor analysis jobs. Abaqus/Viewer is a subset of Abaqus/CAE that contains only the Visualization module.

You can select a module from the **Module** list in the context bar. Alternatively, you can select a module by switching to the context of a selected object in the Model Tree; for more information, see *The Model Tree*. The order of the modules in the menu and in the Model Tree corresponds to the logical sequence you follow to create a model. In many circumstances you must follow this natural progression to complete a modeling task; for example, you must create parts before you create an assembly. Although the order of the modules follows a logical sequence, Abaqus/CAE allows you to select any module at any time, regardless of the state of your model.

The following list of the modules available within Abaqus/CAE briefly describes the modeling tasks you can perform in each module. The order of the modules in the list corresponds to the order of the modules in the context bar's **Module** list and in the Model Tree:

Part

Create individual parts by sketching or importing their geometry. For more information, see *The Part module*.

Property

Create section and material definitions and assign them to regions of parts. For more information, see *The Property module*.

Assembly

Create and assemble part instances. For more information, see *The Assembly module*.

Step

Create and define the analysis steps and associated output requests. For more information, see *The Step module*.

Interaction

Specify the interactions, such as contact, between regions of a model. For more information, see *The Interaction module*.

Load

Specify loads, boundary conditions, and fields. For more information, see *The Load module*.

Mesh

Create a finite element mesh. For more information, see *The Mesh module*.

Optimization

Create and configure an optimization task. For more information, see *The Optimization module*.

Job

Submit a job for analysis and monitor its progress. For more information, see *The Job module*.

Visualization

View analysis results and selected model data. For more information, see *Viewing results*.

Sketch

Create two-dimensional sketches. For more information, see *The Sketch module*.

Modules can be classified by the objects that are displayed in the viewport. Parts are displayed when you are in the Part and Property modules; the assembly is displayed when you are in the Assembly, Step, Interaction, Load, Mesh, and Job modules; and output database results are displayed when you are in the Visualization module.

The contents of the main window change as you move between modules. Selecting a module from the **Module** list on the context bar or by switching to the context of a selected object in the Model Tree causes the context bar, module toolbox, and menu bar to change to reflect the functionality of the current module.

When you move between modules, Abaqus/CAE associates the current viewport with the module you select. You can have multiple viewports, and different viewports can be associated with different modules. As you select a viewport and make it current, the module associated with the viewport becomes the current module. For more information on moving between viewports, see *Selecting viewports*.

Additional information

- *The context bar*
- *What is a viewport?*

What is a toolset?

A toolset is a functional unit that allows you to perform a specific modeling task.
When you enter most modules, a **Tools** menu appears in the main menu bar containing all of the toolsets relevant to that module.

In most cases the objects that you create with a toolset in one module are useful in other modules. For example, you can use the Set toolset to create sets in the Assembly module and then apply boundary conditions to those sets in the Load module. Most of the toolsets include manager menus and manager dialog boxes that allow you to edit, copy, rename, and delete the objects you create with the toolset.

The following toolsets are available in Abaqus/CAE:

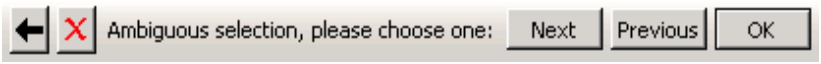
- The Amplitude toolset allows you to define arbitrary time or frequency variations of load, displacement, and other prescribed variables. For more information, see *The Amplitude toolset*.
- The Analytical Field toolset allows you to create analytical fields that you can use to define spatially varying parameters for selected interactions and prescribed conditions. For more information, see *The Analytical Field toolset*.
- The Attachment toolset allows you to create attachment points and lines that you can use to define point-based and discrete fasteners, connector points for a connector, and regions for a coupling definition, point mass, load, or boundary condition. For more information, see *The Attachment toolset*.
- The CAD Connection toolset allows you to create a connection that you can use for associative import of parts into Abaqus/CAE from CATIA and third-party CAD systems. For more information, see *The CAD Connection toolset*.
- The Color Code toolset allows you to customize the edge and fill color of individual elements. For more information, see *Color coding geometry and mesh elements*.
- The Coordinate System toolset allows you to create local coordinate systems for use in postprocessing. For more information, see *Creating coordinate systems during postprocessing*.
- The Customize toolset allows you to control the appearance of Abaqus/CAE toolbars, to create customized toolbars, and to specify keyboard shortcuts for many Abaqus/CAE features. For more information, see *The Customize toolset*.
- The Datum toolset allows you to create datum points, axes, planes, and coordinate systems for a variety of modeling tasks. For more information, see *The Datum toolset*.
- The Discrete Field toolset allows you to create a spatially varying field where values are associated with nodes or elements. For more information, see *The Discrete Field toolset*.
- The Display Group toolset allows you to selectively plot one or more model or output database items. For more information, see *Using display groups to display subsets of your model*.
- The Edit Mesh toolset allows you to modify a mesh to improve mesh quality. For more information, see *The Edit Mesh toolset*.
- The Feature Manipulation toolset allows you to modify and manage the existing features in your model. For more information, see *The Feature Manipulation toolset*.
- The Field Output toolset allows you to perform operations on the field output available in an output database. For more information, see *Creating and saving new field output*.
- The Filter toolset allows you to remove extraneous output data—noise—during the analysis of a model without a loss of resolution in the desired data range. For more information, see *The Filter toolset*.
- The Free Body toolset allows you to create and customize free body cuts in the Visualization module of Abaqus/CAE. For more information, see *The Free Body toolset*.
- The Geometry Edit toolset allows you to repair invalid and imprecise imported parts. For more information, see *The Geometry Edit toolset*.
- The Partition toolset allows you to divide a part or assembly into regions. For more information, see *The Partition toolset*.

- The Path toolset allows you to specify a path through your model along which you can obtain and view *X*–*Y* data. For more information, see *Viewing results along a path*.
- The Query toolset allows you to obtain general information about your model and to probe model and *X*–*Y* plots for output data. For more information, see *The Query toolset*.
- The Reference Point toolset allows you to create reference points associated with a part or assembly. For more information, see *The Reference Point toolset*.
- The Set toolset and the Surface toolset allow you to define sets and surfaces from regions of a model. For more information, see *The Set and Surface toolsets*.
- The Stream toolset allows you to display streamlines to investigate velocity or vorticity in a fluid flow analysis. For more information, see *The Stream toolset*.
- The Virtual Topology toolset allows you to ignore details, such as very small faces and edges, when you are meshing a part or a part instance. For more information, see *The Virtual Topology toolset*.
- The XY Data toolset allows you to create and operate on *X*–*Y* data objects. For more information, see *X–Y plotting*.

Using the mouse with Abaqus/CAE

Many of the procedures in the Abaqus/CAE documentation involve using one or more of the three mouse buttons. The following list explains the importance of each mouse button when interacting with Abaqus/CAE:

Mouse button 1

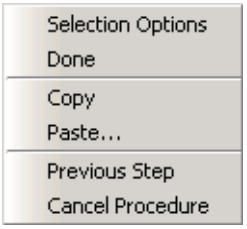


You use mouse button 1 to select objects in the viewport, to expand pull-down menus, and to select items from menus. The instructions “click,”“select,” and “drag” in the documentation refer to mouse button 1.

Mouse button 2

Clicking mouse button 2 in the viewport signifies that you have finished the current task. For example:

- Selecting entities from the model: when you create a node set, you select the nodes to include in the set. Clicking mouse button 2 indicates that your selection is complete and you are ready to create the set.
- Using a tool: click mouse button 2 to indicate that you have finished with a view manipulation tool.



In addition, clicking mouse button 2 in the viewport is equivalent to clicking the highlighted button in the prompt area. For example, if you tried to select nodes from your model and Abaqus/CAE displayed the following prompt, clicking mouse button 2 would have the same effect as clicking **OK**:

If your mouse has a wheel as mouse button 2, you can scroll the wheel vertically to manipulate your view of the model or plot in the viewport. Scroll downward to magnify your view of the contents of the viewport, or scroll upward to reduce your view of the contents of the viewport.

Mouse button 3

You press and hold mouse button 3 to access a popup menu that contains shortcuts to functions related to the current procedure. For example, when you press mouse button 3 in a viewport while creating a geometry set, Abaqus/CAE displays the following menu:

If you use mouse button 3 in a viewport, most of the items in the popup menu duplicate the buttons in the prompt area. The mouse button 3 shortcut is also available for selections from the Model Tree and Results Tree, as described in *Using popup menus in the Model Tree and the Results Tree*.

Getting help

The Abaqus/CAE HTML documentation is available through the **Help** menu on the main menu bar. This section provides a brief description of the HTML online documentation and explains how to use the **Help** menu to find information.

The features described in this section apply only to the HTML documentation, not the PDF-format guides.

Note:

- On Windows platforms, the help system uses your default web browser to display the online documentation.
- On Linux platforms, the help system searches the system path for Firefox. If the help system cannot find Firefox, an error is displayed.

  The **browser_type** and **browser_path** variables can be set in the environment file to modify this behavior. For more information, see *System customization parameters*.

In this section:

- *Displaying context-sensitive help*
- *Browsing and searching the HTML guides*
- *Finding special sections of the online documentation*
- *Finding information about keywords*
- *Accessing the Learning Community*
- *Obtaining information about the release and licensing*

Displaying context-sensitive help

You can display detailed HTML help on any icon, menu, or dialog box that you use in Abaqus/CAE.

You can use the help tool  on the main menu bar to display detailed HTML help on any icon, menu, or dialog box that you use in Abaqus/CAE. When you click the help tool and then click an item in the Abaqus/CAE window, a help window appears containing the section from the online documentation that is relevant to that item.

Display help on an item in the main window or in a dialog box

1. Click the help tool  on the main menu bar.

    **Tip:** You can also select **Help->On Context** from the main menu bar.

   The cursor changes to a question mark.

2. Position the cursor over the item about which you need help, and click mouse button 1.

   A help window appears. The window contains the appropriate online documentation and links to associated topics.

Display help using the [F1] key

Alternatively, you can use the **[F1]** key to display help on a particular item. In most cases you can gain access to context-sensitive help by using the **Help** menu, the help tool icon, or the **[F1]** key. However, you must use **[F1]** if you are seeking information about menu items or dialog boxes that do not allow access to the help tool.

1. Click the feature in the Abaqus/CAE window that you want help with. If the feature is part of a menu, do not release the mouse button.
2. Press **[F1]**.

   A help window appears. The window contains the appropriate online documentation and links to associated topics. If you selected a menu item without releasing the mouse button, that menu disappears.

 **Note:**

Abaqus/CAE also provides brief “tooltips” that describe the function of tools in toolboxes and in the toolbars. To see a “tooltip,” position the cursor over a tool and leave it stationary for a short time.

Browsing and searching the HTML guides

You can open and browse and search the entire HTML collection using the **Help** menu.

1. From the main menu bar, select **Help->Search & Browse Guides**.

   The documentation displays in your web browser open to a topic that contains an overview of the guides in the documentation.

2. To view a particular guide, click **Abaqus** in the table of contents and click the title of interest.

   The guide that you selected opens in your browser window.

3. Navigate through the guide's contents using any of the following techniques:

Browsing

Expand and collapse the table of contents to vary the level of detail displayed. Click the topic of interest. You can also use the web browser functions to return to recently viewed pages.

Searching

Use the search panel located in the navigation frame to search for specific words or phrases.

Using hyperlinks

Use hyperlinks to move from one part of a guide to another or from one guide to another guide.

Finding special sections of the online documentation

The following **Help** menu items allow you to display sections of the HTML documentation that you may find useful:

On Module

Select **Help->On Module** to display the *Abaqus/CAE User's Guide* opened to the beginning of the chapter that describes the current module. If you have not yet entered a module, the guide will be opened to a description of the module concept. In either case, you are then free to read additional information as needed and to conduct text searches through the entire guide.

On Help

Select **Help->On Help** to display the *Abaqus/CAE User's Guide* opened to the section that describes how to use the help system. You are also free to read additional information as needed and to conduct text searches through the entire guide.

Getting Started

Select **Help->Getting Started** to display a section that provides basic information on how to work in the Abaqus/CAE window. This section also contains links to helpful tutorials in the *Getting Started with Abaqus/CAE* guide.

Release Notes

Select **Help->Release Notes** to display the *Abaqus Release Notes*. Release notes detail new features of the software and provide a list of updates and enhancements.

Finding information about keywords

The keyword browser is a scrollable table that contains the following information:

- The purpose of each keyword.
- The Abaqus/CAE module or toolset that contains the functionality associated with each keyword.

To view the keyword browser, select **Help->Keyword Browser** from the main menu bar. For example, you could use the keyword browser to verify that the **ELASTIC* option allows you to specify elastic material properties and that the Property module is the Abaqus/CAE module associated with this keyword.

The keyword browser also contains hyperlinks to relevant sections in the online documentation. You can click a particular keyword in the table to display detailed information concerning the function of that keyword. You can also click the name of a module or toolset in the table to view related documentation in the *Abaqus/CAE User's Guide*.

1. From the main menu bar, select **Help->Keyword Browser**.

   The *Abaqus/CAE User's Guide* is opened to a table of Abaqus keywords and their associated modules.
2. In the **Keyword** column, click the keyword of interest to view online documentation describing that keyword.
3. In the **Module** column, click the module or toolset name of interest to view online documentation concerning that module or toolset.

Accessing the Learning Community

You can access the Learning Community at *https://www.3ds.com/products-services/simulia/simulia-academic-program/learning-community/*. The Learning Community contains online tutorials and technical content. The community also hosts a question-and-answer area that enables the global community of users to share their expertise and learn how to leverage the latest features and enhancements available in the SIMULIA portfolio.

Obtaining information about the release and licensing

The following **Help** menu items allow you to obtain additional information:

About Abaqus

Select **Help->About Abaqus** to determine which release of Abaqus/CAE you are currently using. Abaqus also provides the location of release information for open source software used by Abaqus/CAE; for example, Python.

About Licensing

Select **Help->About Licensing** to determine product license information. Abaqus displays your site identification and the name of your license server along with your license number and the total number of licenses available from your site.

Understanding Abaqus/CAE windows, dialog boxes, and toolboxes

This chapter explains how to interact with the various windows, dialog boxes, and toolboxes that appear throughout the Abaqus/CAE application.

In this section:

- *Using the prompt area during procedures*
- *Interacting with dialog boxes*
- *Understanding and using toolboxes and toolbars*
- *Managing objects*
- *Working with the Model Tree and the Results Tree*
- *Understanding Abaqus/CAE GUI settings*

Using the prompt area during procedures

This section explains how to make use of the procedural steps that Abaqus/CAE displays in the prompt area.

In this section:

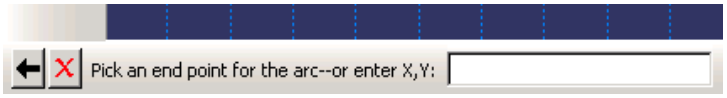
- *What is a procedure?*
- *Following instructions and entering data in the prompt area*
- *Using mouse shortcuts with procedures*

What is a procedure?

Many tasks within Abaqus/CAE are broken into step-by-step procedures. For example, creating an arc in the Sketcher is a three-step procedure:

1. Pick the center point for the arc.
2. Pick the start point.
3. Pick the end point.

Abaqus/CAE displays each step of a procedure in the prompt area near the bottom of the main window so that you do not need to remember all the steps and their order.

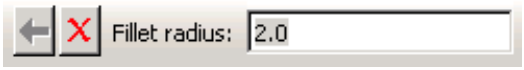


Additional information

• *Using the prompt area during procedures*

Following instructions and entering data in the prompt area

To use a procedure, simply follow the directions that appear in the prompt area near the bottom of the main window.



For example, follow the directions as shown here:

The button marked X in the above figure is the Cancel button; click this button to cancel the entire procedure at any time. The arrow to the left of the Cancel button is the Previous button; click it to end the current step of the procedure and return to the previous one. (The Previous button appears dimmed during the first step of any procedure.) If you prefer, you can place the cursor over the canvas and press mouse button 3; then select **Previous Step** or **Cancel Procedure** from the menu that appears.

A **Stop** button appears in the prompt area during certain time-consuming operations, such as part healing or meshing or the extraction of *X–Y* data from history for large models. You can click **Stop** to interrupt and cancel the operation.

Many procedures require textual or numeric data; for example, when creating a fillet using the Sketch module, you must first specify the fillet radius. When textual or numeric data are required, Abaqus/CAE displays a text field in the prompt area for you to fill in; usually the text box will already contain a default value, as shown here:

Position your cursor over the viewport, and enter data into the text field as follows:

- To accept the default value, press either **[Enter]** or mouse button 2.
- To replace the default value, simply begin typing; you need not click the text field before typing. The default value disappears as soon as you begin to type.
- To change a portion of the default value, first click the text field; then use the **[Delete]** key and the other keys on your keyboard to change the value.
- To commit any changes, press **[Enter]** or mouse button 2.
- You can also enter an expression in a text field in the prompt area. For more information, see *Entering expressions*.

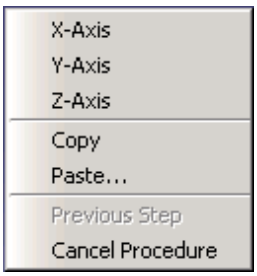
Some procedures require you to choose from a number of options. For example, the Datum toolset may ask you to choose a principal axis. Such options are represented by buttons in the prompt area, as shown here:

Click the appropriate button to select the desired option.

In some procedures a default option is indicated by a border around the corresponding button; in the above example the border is drawn around the **X-Axis** button. To select the default option, click mouse button 2.

Additional information

• *Using the prompt area during procedures*



Using mouse shortcuts with procedures

Mouse shortcuts are available for many of the actions that take place in the prompt area. To use the shortcuts, first make sure that the cursor is in the current viewport.

- To commit the contents of any text field that appears in the prompt area, click mouse button 2.
- To accept any default option depicted by a highlighted button in the prompt area, click mouse button 2.
- To reveal a menu containing options identical to those in the prompt area, click mouse button 3. For example, given the following prompt:

Clicking mouse button 3 will reveal the following menu:

Items above the horizontal line correspond to the option buttons on the right side of the prompt area, while items below the line correspond to the Previous and Cancel buttons.

Additional information

• *Using the prompt area during procedures*

Interacting with dialog boxes

This section explains how to use the various dialog box components that appear within Abaqus/CAE.

In this section:

- *Using basic dialog box components*
- *Entering expressions*
- *Using dimmed dialog box and toolbox components*
- *Disabling warning dialog boxes*
- *Understanding the OK, Apply, Defaults, Continue, Cancel, and Dismiss buttons*
- *Using dialog boxes separated by tabs*
- *Entering tabular data*
- *Customizing fonts*
- *Customizing colors*
- *Using file selection dialog boxes*
- *Selecting multiple items from lists and tables*
- *Using keyboard shortcuts*

Using basic dialog box components

Dialog box components include text fields, numeric fields, combo boxes, radio buttons, check boxes, scroll bars, and sliders.

The following types of components are present in dialog boxes throughout Abaqus/CAE:

Text fields

Text fields are areas in dialog boxes in which you can enter information. For example, when you save a display group, you must enter its name in the text field shown below:

If you are entering a floating point number, most text fields allow you to enter an expression; for example, `cos(2.5/(4.9*pi))`. The expression can be any valid Python expression. For more information, see *Entering expressions*.

Text fields are available whenever you need to name an object (such as a part, material, set, path, or *X*–*Y* data) or provide a description for an object (such as a material or step). In general, you should avoid using an asterisk (*) in an object name or description.

Object names must adhere to the following rules:

- Part, model, instance, set, surface, feature, and job names can have up to 80 characters; other object names can have up to 38 characters. Instance names of models that have been instantiated as model instances in another model still have a 38-character limit. For imported sets/surfaces, parts, and model instances, the names are generated internally in Abaqus/CAE by combining part/instance/set names. You must ensure that the combined length will not exceed 80 characters; otherwise, the data check analysis will fail.
- The name can include spaces and most punctuation marks and special characters.
- The name must not begin with a number.
- The name must not begin or end with an underscore or a space.
- The name must not contain a period or double quotes.
- The name must not contain a backslash.
- The name cannot be `Assembly`, which is reserved for internal use by Abaqus/CAE.

Additional restrictions apply to model names, part names, and job names.

- When you name a model or a job, the name can begin with a number.
- When you name a model, you cannot use the following characters:

  ```
  $&*~!()[]{}|;'`",.?/\><
  ```

- When you name a part, the name should not be the same as the model name.
- When you name a job, you cannot use the following characters:

  ```
  <space>$&*~!()[]{}|:;'`",.?/\><
  ```

  In addition, a job name cannot begin with a dash −.

The material evaluation procedure (*Evaluating hyperelastic, hyperfoam and viscoelastic material behavior*) generates jobs with the same names as the materials; therefore, these material names must adhere to the same

rules as job names. In general, when you are specifying a name that will be used external to Abaqus/CAE, such as a file name, you should avoid any character that may have a reserved meaning on your platform.

Note:

Abaqus/CAE retains the case of any text you enter in a text field. For example, if you create a material called `Steel Alloy` in the **Edit Material** dialog box in the Property module, the material will appear as `Steel Alloy` in the graphical user interface (material manager, section editor, Model Tree, etc.). In the graphical user interface, object names are case insensitive. For example, you cannot create a second material called `steel alloy`. Conversely, Python (which is used in the command line interface) is case sensitive, but you should not rely on this behavior to distinguish between objects.

Numeric fields

Numeric fields are specialized text fields for integer input values. They have two opposing arrows directly to the right of the text area. You can enter a numeric value into the text field, or you can use the arrows to cycle up and down through a list of fixed values.

Unlike other text fields, numeric fields do not accept text or special characters.

Numeric fields often have upper and lower limits. If the value you enter exceeds the limits, Abaqus/CAE changes the entry to the closest acceptable value when you move to another field or try to apply the value.

Combo boxes

Combo boxes are fields having an arrow directly to the right of the field. If you click this arrow, a list of the possible choices that you can enter in the field appears. For example, if you click the arrow to the right of the **Module** field in the context bar, a list of all the Abaqus/CAE modules appears, and you can select the module of your choice from the list.

Radio buttons

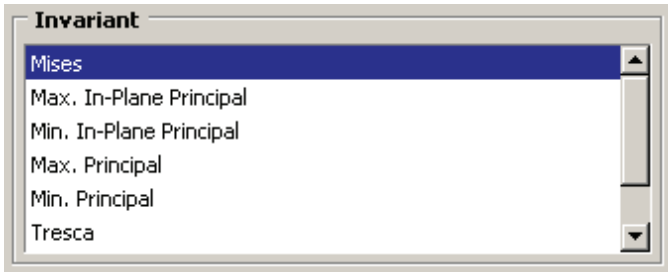
Radio buttons present a mutually exclusive choice. When an option is controlled by radio buttons, you can choose only one of the buttons at a time.

Check boxes

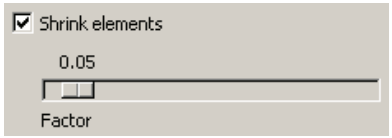
You can toggle a check box to turn a particular option off or on.

For example, the visibility of the triad in the current viewport depends on the status of the **Show triad** check box. If the box is toggled on, as shown below, the triad appears in the viewport.

If the box is toggled off, as shown below, the triad does not appear in the viewport.



In some cases the option controlled by a check box can apply to more than one object. For example, a single **Show line** check box in the **XY Curve Options** dialog box individually controls the display of all *X–Y* curve lines in an *X–Y* plot. If you have toggled **Show line** on for some curves and off for others, that check box appears gray with a darker gray check mark, as shown below.



Scroll bars

Scroll bars appear in lists whose contents are too big to display; they allow you to scroll through the visible contents of the list as well as any contents that are hidden. Scrolling is often necessary when numerous items must be listed, as shown below.

Sliders

Sliders allow you to set the value of an option that has a continuous range of possible values. An example of a slider is shown in the following figure:

Additional information

• *Interacting with dialog boxes*

Entering expressions

If a field in a dialog box or in the prompt area is expecting a floating point number or a complex number, you can enter an arithmetic expression, as shown in *Figure 1*.

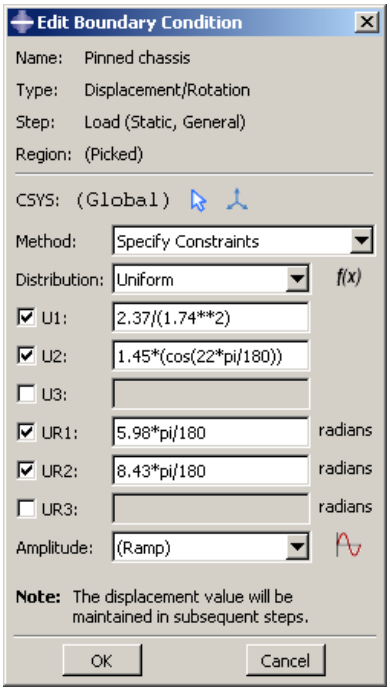


Figure 1: An expression in a text field.

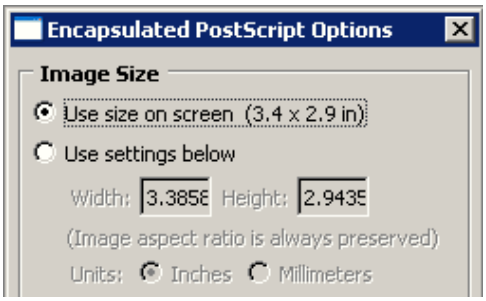
The expression is evaluated by the Python interpreter that is built into Abaqus/CAE. The arithmetic expression is replaced by its value; if you reopen a dialog that contained expressions, only the values are available. Variables like `pi` and functions like `sin()` are available because Abaqus/CAE imports the Python math module when you start a session. As a result, you can enter any expression that can be evaluated by Python's built-in functions or by the Python math module. For more information, see the documentation for built-in functions and the math module accessible from the official Python home page (*http://www.python.org*).

To make sure that your expression is evaluated as expected, you should be aware of the following:

- If you enter numbers as integers, Python will perform integer division and round down any remainder. For example, Python will interpret `3/2` as `1` and `1/2` as `0`. In contrast, Python interprets `3./2` as `1.5` and `1/2.` as `0.5`.
- Python interprets numbers with leading zeros as octal numbers (for example, `0123` is interpreted as `83.0`). However, Abaqus/CAE will ignore leading zeros in numbers in text fields before Python interprets them; such numbers are evaluated as decimals.
- Python interprets `e` as the base of the natural logarithm; that is, `e` equates to `2.71828182846` and `e+2` equates to `4.71828182846`.
- If the "e" character is preceded by a number, Python interprets it as an exponent, not a natural logarithm. For example, Python interprets `2e+2` as 2×10^2 and equates it to `200`.
- Python interprets `2e+` as 2×10^0 and equates it to `2`. Similarly, Python interprets `2e++11` as 2×10^0 `+ 11` and equates it to `13`.

If you are unsure how Python will interpret your expression, you can enter the expression on the command line; Abaqus/CAE will print the resulting interpreted value in the message area. To access the command line interface, click 



in the bottom left corner of the main window. For more information, see *Components of the main window*.

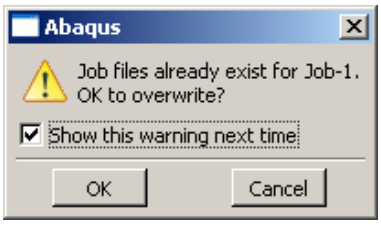
You can also test how Abaqus/CAE interprets an expression by entering `abaqus python` at an operating system prompt and entering the expression at the Python prompt that appears. The prompt line and some dialog boxes do not allow you to enter an expression. As an alternative, you can enter the expression on the command line or at the Python prompt and paste the resulting value in the prompt line or dialog box.

Using dimmed dialog box and toolbox components

Some objects in dialog boxes and toolboxes are available only under certain circumstances. When an object is unavailable, it appears dimmed in the dialog box.

Items are usually dimmed as a result of some other setting in the dialog box. For example, if **Use settings below** is not selected, the image size options below it are not available and appear dimmed, as shown below.

Context-sensitive help is available even for dimmed options, although tooltips are not.



Additional information

• *Interacting with dialog boxes*

Disabling warning dialog boxes

Some dialog boxes can be disabled so that they will not appear again during the current Abaqus/CAE session.

For example, if you submit a job for analysis and job files with the same name already exist, Abaqus/CAE displays a dialog box asking if it is OK to overwrite the job files, as shown below.

If you toggle off **Show this warning next time**, the dialog box will be disabled for the remainder of the current Abaqus/CAE session.

Additional information

• *Interacting with dialog boxes*

Understanding the OK, Apply, Defaults, Continue, Cancel, and Dismiss buttons

When you are finished working with a dialog box, you can specify how to proceed by using different action buttons. For example, if you enter data in a dialog box, you can save the data and apply them by clicking **OK**. If the dialog box is part of an intermediate step of a procedure, you can click **Continue** to move on to the next step.

The following action buttons can appear in a dialog box:

OK

Click **OK** to commit the current contents of a dialog box and to close the dialog box.

Apply

When you click **Apply**, any changes you have made in the dialog box take effect, but the dialog box remains displayed. This button is useful if you make changes in a dialog box and would like to see the effects of these changes before closing the dialog box.

Defaults

If you want to revert back to the predefined default values after entering data or specifying preferences in a dialog box, you can click **Defaults**. This button affects only the information entered in the dialog box. It does not apply your changes or close the dialog box; therefore, to see the effect of reverting to the default values, you must click **Apply** or **OK**.

Cancel

Click **Cancel** to close a dialog box without applying any of the changes that you made. If the dialog box appears in the middle of a procedure, clicking **Cancel** usually also cancels the procedure. In some cases clicking **Cancel** returns you to the previous step in the procedure.

Continue

Dialog boxes that appear in the middle of a procedure contain **Continue** buttons. When you click **Continue**, you indicate that you have finished entering data in the current dialog box and would like to move on to the next step of the procedure. **Continue** causes the dialog box to be closed and all data in it to be saved unless you click **Cancel** at some point later in the procedure.

Dismiss

Dismiss buttons appear in dialog boxes that contain data that you cannot modify. For example, some managers contain lists of objects that exist but no fields in which you can enter data or specify preferences. **Dismiss** buttons also appear in message dialog boxes. When you click **Dismiss**, the dialog box closes.

To close a toolbox or a dialog box that does not have a **Cancel** or **Dismiss** button, click the close button in the upper right corner of the toolbox or dialog box. Alternatively, you can close an active toolbox or dialog box by pressing **[Esc]**.

Note:

On Linux platforms, depending on your settings, **[Esc]** may be the only way to close a toolbox or dialog box. For more information, see *Linux settings that affect Abaqus/CAE and Abaqus/Viewer*.

Additional information

• *Interacting with dialog boxes*

Using dialog boxes separated by tabs

For the sake of organization and convenience, some dialog boxes are separated by tabs. Only one dialog box is visible at a time. To view a particular dialog box, click its labeled tab.

For example, *Figure 1* displays the **Common Plot Options** dialog boxes.

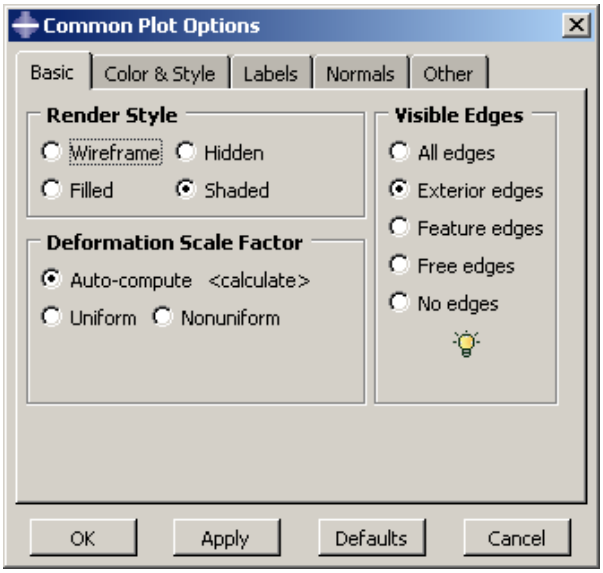


Figure 1: Dialog boxes separated by tabs.

If you click the **Color & Style** tab, the dialog box containing the color and edge attributes options comes forward, obscuring the other four dialog boxes, as shown in *Figure 2*.

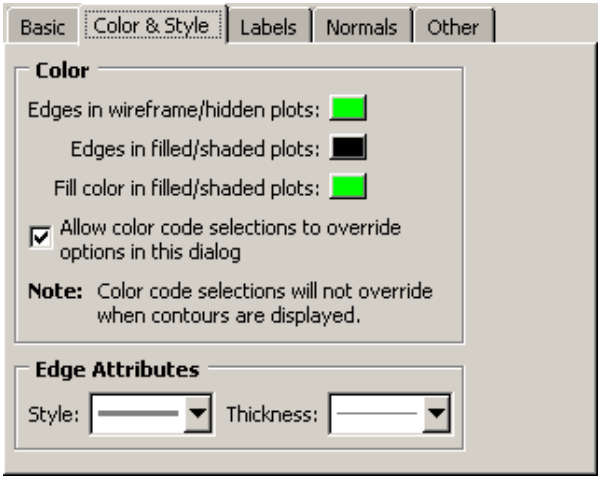

Figure 2: Using tabs to display particular dialog boxes.

In addition, separated dialog boxes can exist within a single dialog box. In this case the tabs of the separated dialog boxes are aligned vertically but work the same way as tabs aligned horizontally. In *Figure 3* the **Other** dialog box contains two dialog boxes separated by tabs: **Scaling** and **Translucency**.

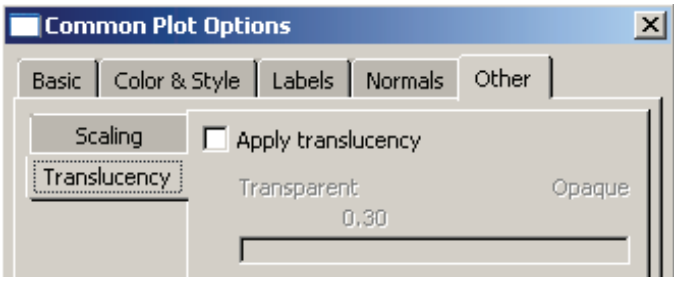

Figure 3: Dialog box containing additional dialog boxes.

The action buttons in a dialog box apply to the whole set of dialog boxes, not just the one you are currently viewing. If you click **Cancel**, all of the unapplied changes you have made in the set of dialog boxes are canceled, not just those in the current dialog box. Likewise, clicking **OK** saves all changes that you have made in any of the dialog boxes.

Additional information

• *Interacting with dialog boxes*

Entering tabular data

Some operations require the entry of tabular data. For example, the XY Data toolset can produce plots of data that you enter in the dialog box shown in *Figure 1*.

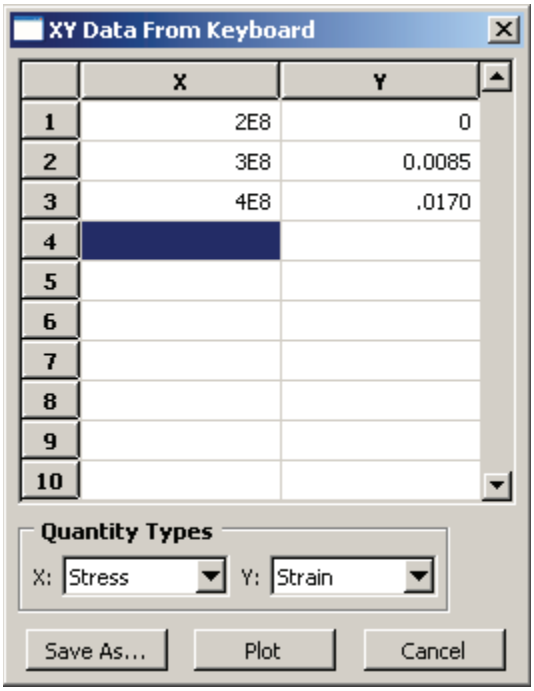

Figure 1: *X–Y* data table.

Data tables are composed of input boxes, or cells, organized into rows and columns. You can type data into a table using the keyboard, or you can read data in from a file.

The following list describes techniques for entering and modifying tabular data:

Entering data

Click any cell, and type the required data. You can press **[Enter]** to commit the data in a particular cell.

Abaqus/CAE does not allow you to enter character data in tables requiring numeric data; the program beeps if you attempt to enter character data in a numeric field. (The letter E that denotes scientific notation, as in 12.E6, is an exception to this rule.)

Adding new rows

Use the menu that appears when you click mouse button 3 to add a new row before or after an existing row. Click mouse button 3 while holding the cursor over the row of interest; then select the item of your choice from the menu that appears:

- Select **Insert Row Before** to add a blank row above the current row.
- Select **Insert Row After** to add a blank row below the current row.

Alternatively, you can add a blank row to the end of the table by clicking the cell in the last row and in the last column of the table and then pressing **[Enter]**.

Reading data from a file

You can enter data by reading it in from an ASCII file. Data fields within the file can be delimited by any combination of spaces, tabs, or commas; each space, tab, or comma is considered a single field delimiter. To enter data from a file, click mouse button 3 while holding the cursor over the target cell; then select **Read From File** from the menu that appears. The **Read Data from ASCII File** dialog box appears. In this dialog box, specify the following:

- In the **File** text field, enter the name of the file to read.
- Specify the row number and column number of the target cell in the **Start reading values into table row** and **Start reading values into table column** fields, respectively. (By default, Abaqus sets these fields to the cell your cursor was over when you clicked mouse button 3.)

Click **OK**. Abaqus reads data values from the file into the table according to your specifications.

Moving from cell to cell

Use the **[Enter]** key to move from left to right between the cells in a row. When you have reached the end of the row, press **[Enter]** to move the cursor to the first cell in the following row.

In addition, you can use a combination of the **[Tab]** key and the up and down arrow keys to move from cell to cell. Use **[Tab]** to move to the right and **[Shift][Tab]** to move to the left; use the up and down arrows to move up and down. You can also simply click the cell of interest.

Changing data

If a cell already contains data, clicking the cell highlights the data; as soon as you begin typing, the highlighted contents of the cell disappear and are replaced by whatever you type. You can also use the **[Backspace]** or **[Delete]** keys to delete highlighted data in a cell.

After clicking the cell once, you can click a second time to remove the highlighting and position the cursor within the cell. Use the **[Backspace]** key and the other keys on your keyboard to modify the data.

Cutting, copying, and pasting data

Use the menu that appears when you click mouse button 3 to cut, copy, and paste data from one location in a table to another. You can cut or copy data in single cells, in rows or parts of rows, in columns or parts of columns, and in series of consecutive rows or columns.

First, drag the mouse over the cells containing the data that you want to cut or copy. All of the selected cells will become highlighted except the cell that you selected first. This cell becomes highlighted when you move the cursor outside the data table window or if you click mouse button 3.

Once you have selected the cells of interest, click mouse button 3 while holding the cursor over the selection; then select either **Cut** or **Copy** from the menu that appears. To paste the data, select the target cell, click mouse button 3, and select **Paste** from the menu that appears.

Sorting data

Some data tables offer a sorting feature. (To determine if sorting is available for a particular table, hold the cursor over the table; then click mouse button 3. If it is available, **Sort** is listed in the menu that appears.)

To sort table data, click mouse button 3 while holding the cursor over the table; then click **Sort**. The **Sort Table** dialog box appears. In this dialog box, choose the following:

- In the **Sort by** text field, choose the column by which to sort.
- Choose **Ascending** or **Descending** sort order.

Click **OK** or **Apply**. Abaqus sorts all rows according to data values in the specified column.

Expanding and contracting columns

You can change the size of the columns in some tables. To expand or contract a column, move the cursor to the line that divides the headings of the columns you want to resize; a resize cursor will appear. Drag this cursor to the left or right to resize the two columns on either side of the dividing line.

You can also resize the last column in some tables by horizontally enlarging the dialog box that contains the table.

Viewing data that extend beyond the edge of the dialog box

Use the horizontal and vertical scroll bars to view portions of a table that are outside the boundaries of the dialog box. In some cases scroll bars may not be available; instead, increase the size of the dialog box to display more data.

Deleting rows of data

Click any cell within the row you want to delete, or select multiple cells in consecutive rows. Then, while holding the cursor over the dialog box containing the table, click mouse button 3 and select **Delete Rows** from the menu that appears. The row or rows disappear; if the rows are numbered, Abaqus/CAE automatically renumbers the remaining rows.

You cannot delete rows from tables that display matrices or tensors of fixed size, such as those used in the orthotropic or anisotropic elasticity data input forms in the Property module.

Creating X–Y data from table data

While you are creating a material in the Property module, you can use the data in a table to create *X*–*Y* data. You can then use the Visualization module to plot the *X*–*Y* data and to visually check its validity. To create an *X*–*Y* data object, click mouse button 3 while holding the cursor over the table; then select **Create XY Data** from the menu that appears. The **Create XY Data** dialog box appears. In this dialog box, do the following:

- Enter the name of the *X*–*Y* data to create.
- Specify the column number containing the *X*-values and the column number containing the *Y*-values.
- Click **OK**. Abaqus reads the data values from the table into the *X*–*Y* data. Abaqus/CAE retains saved *X*–*Y* data only for the duration of the session.

To view the *X*–*Y* data, do the following:

- From the module list on the context bar, select **Visualization**.
- From the main menu bar, select **Tools->XY Data->Plot**, and select the *X*–*Y* data from the pull-right menu.

For more information, see *X–Y plotting*.

Clearing the table

You can delete all data from a table. While holding the cursor over the table, click mouse button 3 and select **Clear Table** from the menu that appears. The table data disappear.

Additional information

• *Interacting with dialog boxes*

Customizing fonts

The **Select Font** dialog box allows you to customize the font of certain kinds of text; for example, you can use this dialog box to customize the font that appears in viewport annotations. A similar dialog box is used to customize the font of the Visualization module labels and titles.

The **Select Font** dialog box allows you to specify and preview the following:

- Proportional or fixed fonts.
- The font family.
- The font size, in points.
- Regular, bold, or italic font.

The available options vary depending on which fonts are installed on your system.

1. Display the **Select Font** dialog box for the text that you want to customize. For more information, see the following sections:
   - *Customizing X–Y plot axes*
   - *Customizing the X–Y plot legend*
   - *Customizing viewport annotations*”
   - *Setting the label font*
2. Select the desired font and properties.

   A preview of the selected font appears in the **Sample** area of the **Select Font** dialog box.
3. In the **Apply To** field of the **Select Font** dialog box, toggle on the items to which the selected font will apply. The **Apply To** field does not appear unless there are multiple items to which the font can apply.
4. Click **OK** to accept your changes and to close the **Select Font** dialog box.

Additional information

• *Customizing viewport annotations*
• *Setting the label font*

Customizing colors

The **Select Color** dialog box allows you to customize the color of many objects in Abaqus/CAE. For more information about the objects that you can change, see the following sections:

- *Customizing the view triad*
- *Choosing background colors*
- *Selecting overall element and surface edge color*
- *Coloring elements with no results*
- *Customizing the legend*
- *Customizing the title block*
- *Customizing the state block*

The current color is displayed on the left side of the **Select Color** dialog box, below the eyedropper tool. You can use the methods in the **Select Color** dialog box to update the displayed color. The color is not updated elsewhere until you click **OK** to accept your changes and to close the **Select Color** dialog box. You can choose from the following methods of color selection:

Color palette

Twenty-four common colors are displayed in boxes along the bottom of the dialog box. Click a color to select it; you cannot modify the palette to show different colors.

Eyedropper tool

The eyedropper tool is located on the left side of the dialog box. When you click the eyedropper tool, the cursor changes to crosshairs. The next time you click mouse button 1 anywhere on the computer screen, Abaqus/CAE selects the color at the cursor position.

Note:

The cursor returns to its normal form if you move it outside the Abaqus/CAE application window, but you can still select a color by clicking mouse button 1.

Color wheel

The color wheel and brightness control are located in the **Wheel** tab. A black dot indicates the position of the currently selected color, regardless of the method that was used to select it. Click anywhere on the wheel to select a new color. Move the vertical slider to change the brightness; as you move the slider downward, Abaqus/CAE adds black to the selected color.

RGB controls

RGB (Red, Green, and Blue) controls are located in the **RGB** tab. The RGB settings match the color displayed on the left side of the **Select Color** dialog box, regardless of the method that was used to select it. You can move the sliders or enter values from 0 to 255 to mix the three colors of light and produce the full color spectrum. 0, 0, 0 is black (no light); and 255, 255, 255 is white (full intensity, full spectrum light).

HSV controls

HSV (Hue, Saturation, and Value) controls are located in the **HSV** tab. The HSV settings match the color displayed on the left side of the **Select Color** dialog box, regardless of the method that was used to select it. The Hue control ranges from 0 to 360, and changing the setting corresponds to moving the black dot around the perimeter of the color wheel (0 and 360 are both red). The Saturation control ranges from 0 to 100 and varies the amount of the selected color added to the background color. The Value control indicates the background color; 0 is black, 100 is white.

CMY controls

CMY (Cyan, Magenta, and Yellow) controls are located in the **CMY** tab. The CMY settings match the color displayed on the left side of the **Select Color** dialog box, regardless of the method that was used to select it. You can move the sliders or enter values from 0 to 255 to mix the three colors of tint and produce the full color spectrum. The CMY controls work like adding tint to paint; 0, 0, 0 is white (no tint), and 255, 255, 255 is black (all tint).

Color list

The color list is located in the **List** tab. You can choose from several hundred colors, including shades of gray. The color list provides you with a more extensive range of colors than the color palette, but it does not provide you with the full color spectrum.

1. Open the dialog box that contains the settings for the object that you want to change.
2. Click the color sample  for the object that you want to customize.

   Abaqus/CAE displays the **Select Color** dialog box.
3. Use one of the methods in the dialog box to select a new color.

   A preview of the selected color appears on the left side of the **Select Color** dialog box, below the eyedropper tool.
4. Click **OK** to accept your changes and to close the **Select Color** dialog box.

   Abaqus/CAE returns you to the originating dialog box and updates the color sample to display the color that you selected.

When you click **OK** or **Apply** in the originating dialog box, Abaqus/CAE updates the color in the viewport.

Additional information

- *Customizing model labels*
- *Customizing viewport annotations*

Using file selection dialog boxes

File selection dialog boxes allow you to select files from lists that are filtered based on file type or location. To use a file selection dialog box, you first choose the type of file to open and then specify the directory to list. Abaqus/CAE refreshes the dialog box to list only files that meet your criteria. From this list, you select the file to open.

The dialog box for selecting model databases or output databases is shown in *Figure 1*.

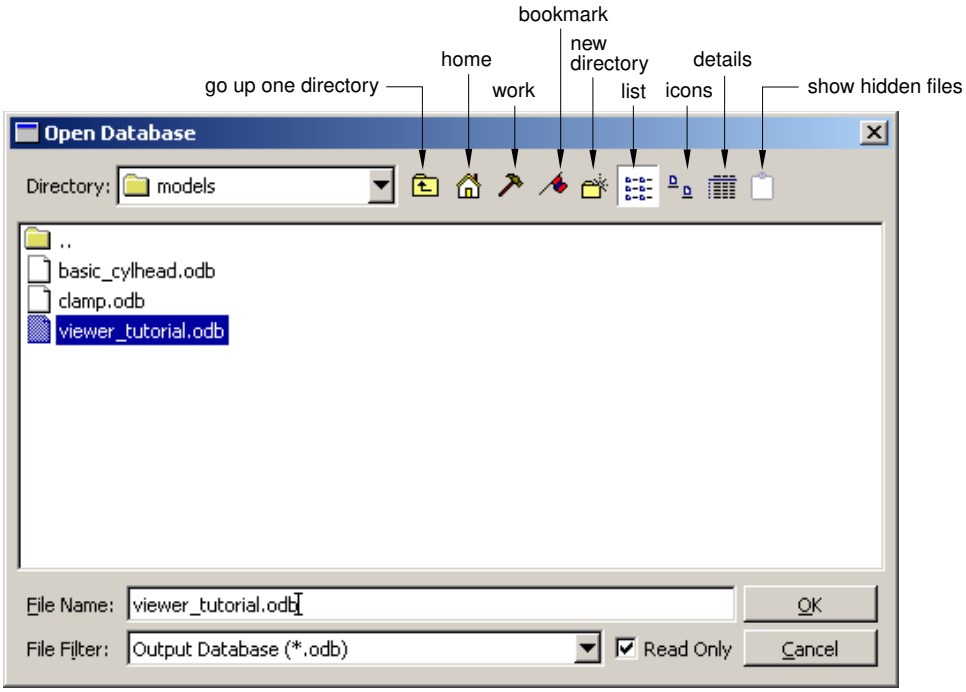

Figure 1: Selecting a model database or an output database.

Note:

In Abaqus/Viewer you can open only output database files; therefore, **Output Database (*.odb)** is the only type available in the **File Filter** field.

Similar file selection dialog boxes appear when you perform other **File** menu functions, such as importing a part or printing to a file.

Use the following techniques to select the file of your choice:

Filtering the file list according to file type

File selection dialog boxes contain **File Filter** fields, which allow you to select the file extension of interest. For example, the **File Filter** selection in *Figure 1* is **Output Database (*.odb)**. Therefore, only files with the extension `.odb` appear in the list in the center of the dialog box.

Using wildcards to search for a file name

You can use a wildcard filter to search for partial names of files. A wildcard search is helpful when you have a large number of files stored in the same directory. Wildcard searches also override the file extensions (**File Filter** field, as described above), allowing you to open files saved with nonstandard file extensions.

To use a wildcard search, enter a partial file name into the **File Name** field using one of the following forms:

?

matches a single character

*****

matches zero or more characters

abc

matches a single character, but it must be one of the characters listed

^abc or !abc

matches a single character, but it must *not* be one of the characters listed

a-zA-Z

matches a single character, but it must be within the ranges provided

^a-zA-Z or !a-zA-Z

matches a single character, but it must *not* be within the ranges provided

pat1|pat2 or pat1,pat2

matches either pat1 or pat2

(pat1|pat2) or (pat1,pat2)

matches either pat1 or pat2, and the patterns may be nested

You can combine several wildcard filters to further narrow your search. For example, entering `[abc]*.(cae,odb)` will list all files beginning with `a`, `b`, or `c` and having a `.cae` or `.odb` file extension.

Specifying the directory from which to select a file

By default, the **Directory** field shows the directory in which you started Abaqus/CAE. If you want to view a list of files from a different directory, you can click the directory name in the list to view directories within the current path or you can click the arrow next to the **Directory** field to access other paths that are available on your system. In addition, icons at the top of the dialog box allow you to do the following (keyboard shortcuts are shown in parentheses when available):

- Go up one directory level (**[Backspace]**).
- Access your system default, or **Home**, directory (**[Ctrl] + H**).
- Access the **Work** directory (**[Ctrl] + W**). The work directory is the directory from which you started Abaqus/CAE unless you specified the directory using **File->Set Work Directory**.
- Set or use **Bookmarks** to any directory on your system.
- Create a new directory (**[Ctrl] + N**).

The **Directory** field includes a **Network connectors** item. If you have created and started a network ODB connector, you can use this item to access a remote directory and to open a remote output database. For more information, see *Creating a network ODB connector*.

Selecting a file

To select and open a file, double-click the file name of interest from the list. You can also begin typing the file name; the cursor will reposition to the matching location in the file list, and the first file starting with the letters you typed will be selected. Alternatively, you can enter the entire directory path and file name of interest directly in the **File Name** field and then click **OK**. Icons at the top of the dialog box allow you to change the displayed file format to one of the following (keyboard shortcuts are shown in parentheses):

- A list (**[Ctrl] + `S`**).
- Icons (**[Ctrl] + `B`**).
- A detailed list (**[Ctrl] + `L`**).

The icon farthest to the right allows you to display or suppress “hidden” files.

Selecting multiple items from lists and tables

In some Abaqus/CAE dialog boxes it is necessary to select an item from a list or a table before you can perform certain functions. For example, if you want to plot *X–Y* data, you must first select the data object of your choice from the list in the **XY Data Manager**, shown in *Figure 1*, and then click **Plot**.

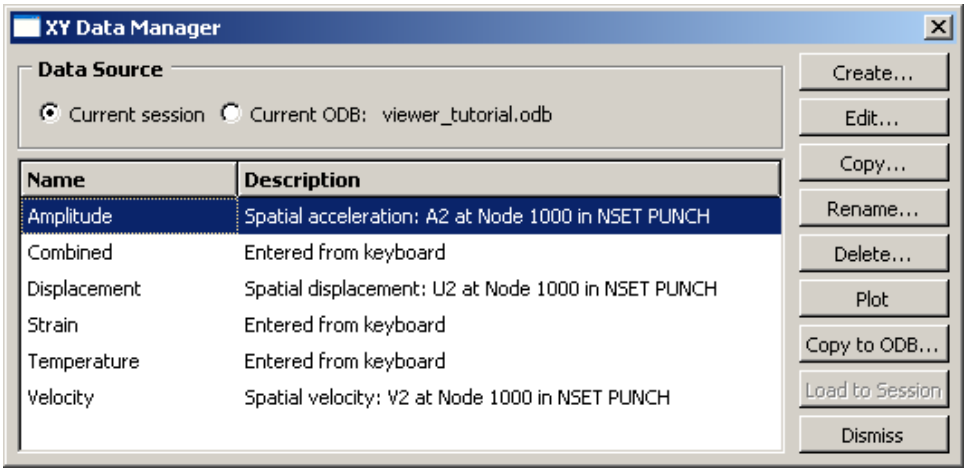

Figure 1: Single item selected.

Some functions allow you to operate on more than one item. For example, if you wanted to delete the first two data objects in the manager shown in *Figure 1*, you could select them both and then click **Delete**.

To select a single item from a list, you need only click that item in the dialog box. To select a single item from a table, click the table row heading. To select multiple items, you can use the following techniques:

Selecting consecutive items from a list or table

Click the first item of interest from a list or row heading from a table and then, while continuing to hold down mouse button 1, drag the cursor over the remaining items. Release the mouse button when all of the items of interest are selected. For example, consecutive items are selected in *Figure 2*.

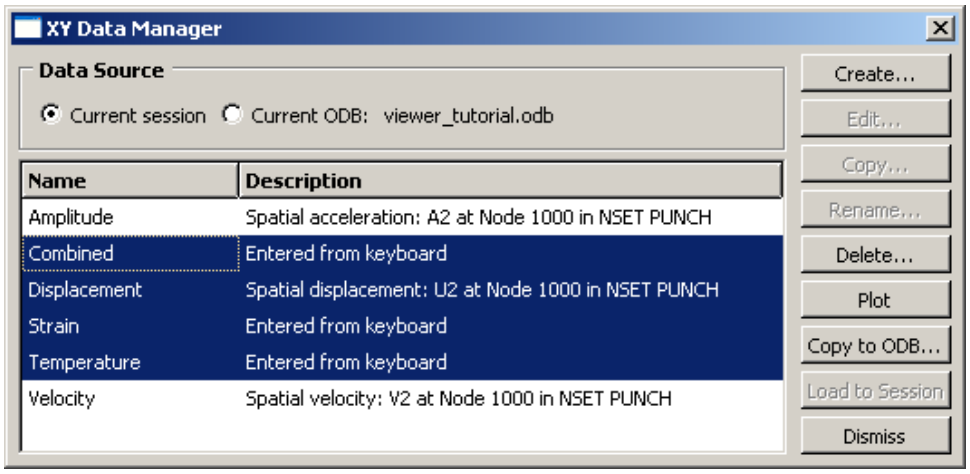

Figure 2: Consecutive items selected.

Another way to select consecutive items is to click the first item of interest from a list or row heading from a table and then **[Shift] + Click** the last item of interest. All items between the first and the last are selected automatically.

Selecting nonconsecutive items from a list or table

Click the first item of interest from a list or row heading from a table and then **[Ctrl] + Click** any other items you want to select. For example, nonconsecutive items are selected in *Figure 3*.

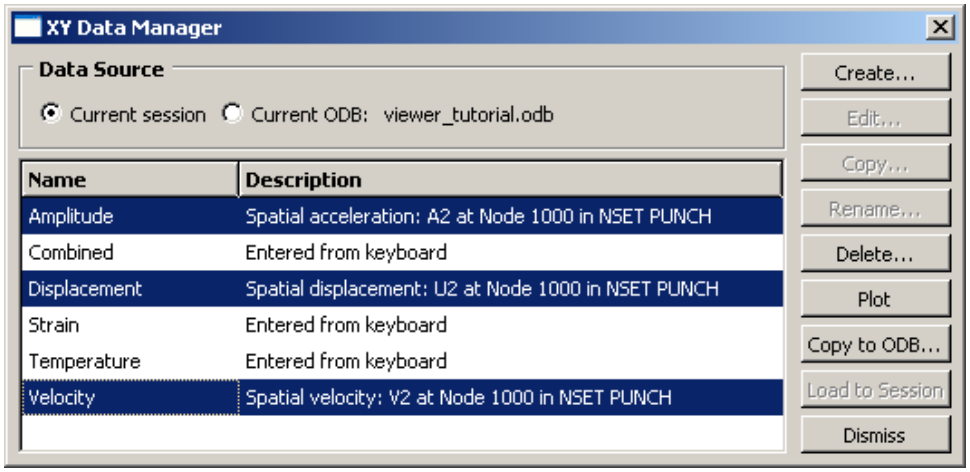

Figure 3: Nonconsecutive items selected.

Canceling a selection

You can **[Ctrl] + Click** previously selected items to remove them from your selection. For example, if you **[Ctrl] + Click**`Displacement` in the list shown in *Figure 3*, that data object is no longer selected, as shown in *Figure 4*.

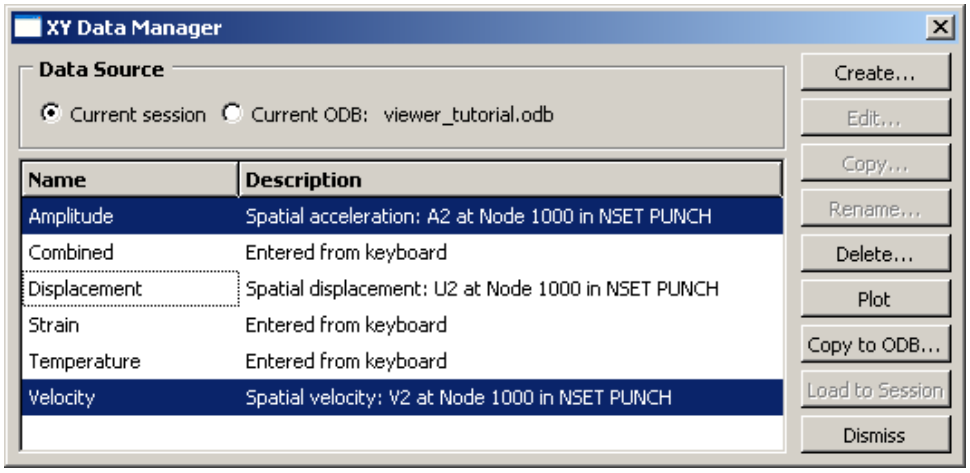

Figure 4: Individual item removed from selection.

Certain functions in a dialog box may become unavailable when you select multiple items. For example, the **Edit**, **Copy**, and **Rename** functions in the **Data Manager** shown in *Figure 4* are valid only for individual data objects. When you select multiple data objects, these three functions become unavailable.

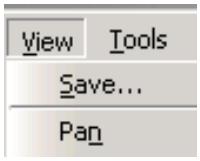
Using keyboard shortcuts

You can use the keyboard instead of the mouse to perform most actions within the Abaqus/CAE main window and dialog boxes. The following actions have keyboard shortcuts:

Context-sensitive help

Press **[F1]** to display context-sensitive help concerning the currently selected object in the Abaqus/CAE main window or dialog box. For more information on using **[F1]** for context-sensitive help, see *Displaying context-sensitive help*.

Menus



You can display a particular menu by pressing the **[Alt] +** key in combination with the underlined character in that menu's name. For example, the letter `V` is underlined in the **View** menu in the main menu bar:

Therefore, you can type **[Alt] + V** to display the **View** menu.

Menu items

Once the menu is displayed, you can select a particular menu item by continuing to press the **[Alt] +** key and pressing the underlined character in that menu item's name. For example, the letter `n` is underlined in **Pan** in the **View** menu:

Therefore, you can type **[Alt] + V** to display the **View** menu and then, without releasing the **[Alt] +** key, type `n` to select **Pan**.

Model Tree and Results Tree

The Model Tree and Results Tree contain keyboard shortcuts that allow you to navigate through the tree and toggle its display on and off. For more information, see *The Model Tree*.

Understanding and using toolboxes and toolbars

This section explains how to use the toolbox windows and toolbars to perform common functions within a module or toolset or on the canvas.

In this section:

- *What are toolboxes and toolbars?*
- *Using toolboxes and toolbars that contain hidden icons*

What are toolboxes and toolbars?

Toolboxes and toolbars are collections of icons that provide quick access to commonly used Abaqus/CAE functions. For example, the Visualization module toolbox contains icons representing the tools used to generate different kinds of plots. The Visualization module toolbox is shown in *Figure 1*. All module toolboxes are available immediately to the left of the drawing area as soon as you enter the module.

Figure 1: The Visualization module toolbox.

Toolbars also contain collections of icons to access Abaqus/CAE functions. Toolbars provide access to supporting functions that help you save, manipulate, and make selections from a model; whereas toolboxes contain functions critical to creating or changing a model. In addition to tool icons, toolbars may also contain lists of options related to a tool. For example, the color mapping list in the **Color Code** toolbar contains various methods for coloring the objects displayed in the current viewport. You can also customize toolbar contents, move toolbars to new locations, or close them (for more information, see *The Customize toolset*). Toolboxes cannot be moved or hidden.

To obtain a short description of a tool, place the cursor over that tool for a moment; a small box containing a description, or "tooltip," will appear. Tooltips are not available for icons that appear dimmed; to get information on those icons, use *context-sensitive help* instead.

Additional information

- *Understanding and using toolboxes and toolbars*

Using toolboxes and toolbars that contain hidden icons

In some toolboxes, such as the Job module toolbox, all tool icons are immediately visible; however, most toolboxes contain hidden icons to conserve space. Since there is more space above the canvas, and since you can move or hide toolbars to meet your needs, most toolbars do not contain hidden icons.

Any icon that includes a small triangle in its lower right corner conceals a group of icons whose function is closely related to that of the visible icon.

1. Click and hold any icon that includes a triangle in its lower right corner.

   Icons for all the tools that are closely related to the original icon appear. For example, *Figure 1* shows the top portion of the Part module toolbox with all of the icons revealed that are used for creating round or chamfered corners.

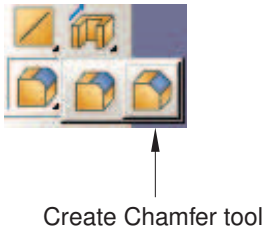


Figure 1: Part module toolbox with round and chamfer icons displayed.

2. Drag the cursor to the desired icon, and release the mouse button.

   The selected icon replaces the icon that was visible originally, and you can begin using the corresponding tool immediately.

Managing objects

Managers are dialog boxes you use to manage all objects of a given type associated with the current model or session; examples of such objects include materials, parts, steps, display groups, and *X*–*Y* data objects.

In addition, you can use the **Model Manager** to manage the models contained in the current model database. This section describes basic and step-dependent managers and how you can use them in Abaqus/CAE.

In this section:

- *What are basic managers?*
- *What are step-dependent managers?*
- *Suppressing and resuming objects*
- *Understanding the status of an object in a step*
- *Terms describing object status*
- *Modifying the history of a step-dependent object*
- *Understanding modified step-dependent objects*
- *What happens when deleted objects are referred to?*
- *Managing objects using manager dialog boxes*
- *Managing objects using manager menus*
- *Copying step-dependent objects using manager dialog boxes*
- *Changing the status of an object in a step*
- *Editing step-dependent objects*

What are basic managers?

Basic managers consist of a list of objects and a series of buttons; you use the buttons to perform tasks on the objects you select from the list or to add new objects to the list.

Figure 1 shows the **Material Manager**, which is an example of a basic manager used in Abaqus/CAE.

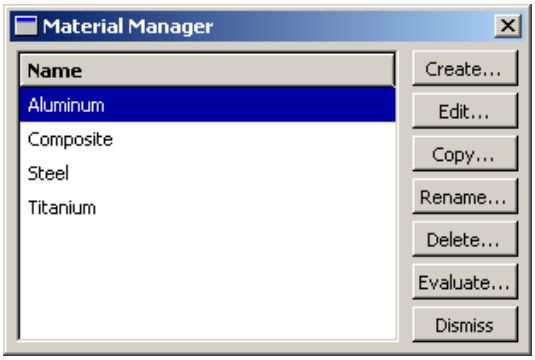

Figure 1: The Material Manager.

The list box on the left shows all the materials that you have defined within the context of the current model. You use the buttons on the right to create new material definitions and to edit, copy, rename, and delete existing material definitions. The **Dismiss** button is used to close the manager dialog box.

Often, the manager provides more information about an object than just its name; for example, in the Job module, the **Job Manager** provides information about currently executing jobs and provides buttons that allow you to write input files, submit jobs, monitor the analysis, or view output files for a given job. The **Job Manager** is shown in *Figure 2*.

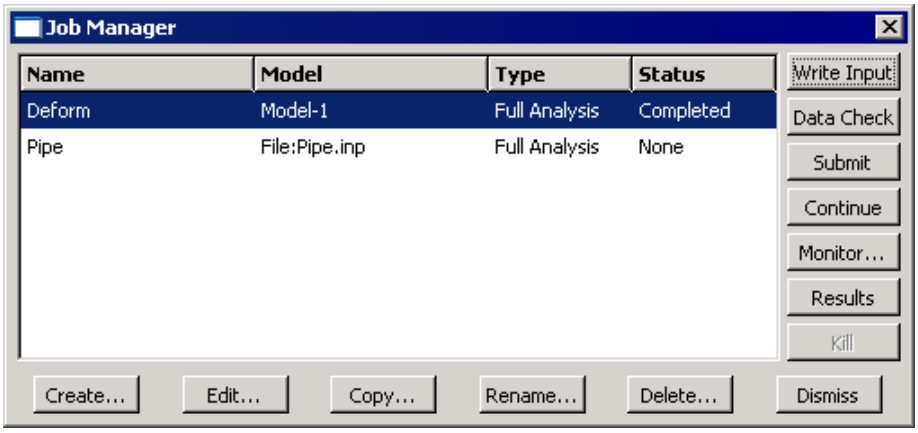

Figure 2: The Job Manager.

Most tasks you can perform with a manager can also be performed using the pull-down menus available from the main menu bar; for example, *Figure 3* shows the menu items that correspond to the **Job Manager**.

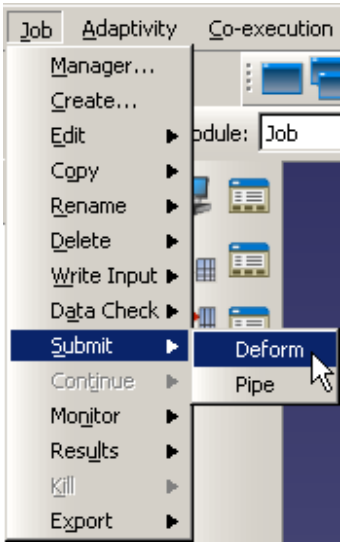

Figure 3: Menu items that correspond to the Job Manager.

After you select a management operation from the main menu bar, the procedure is exactly the same as if you had clicked the corresponding button inside the manager dialog box. In addition, most of the tasks you can perform with a manager can be performed by clicking mouse button 3 on an object in the Model Tree. For more information, see *Working with the Model Tree and the Results Tree*.

The decision whether to use menus, dialog boxes, or the Model Tree is yours. In general, menus are more convenient if you are performing isolated operations; the advantages of manager dialog boxes become apparent when you are performing several operations in sequence, when you need to browse through a long list of objects, or when you need quick access to the additional information that is displayed by some managers. The Model Tree provides you with a graphical overview of your model and allows you to perform operations without changing modules. In addition, the Model Tree allows you to use drag-select to select multiple items; for example, you can select multiple sets to merge or multiple parts to delete.

Additional information

- *Managing objects*
- *What are step-dependent managers?*

What are step-dependent managers?

Like the basic managers described in *What are basic managers?*, step-dependent managers contain a list of all of the objects of a certain type that you have created, as well as **Create**, **Edit**, **Copy**, **Rename**, and **Delete** buttons that you can use to manipulate existing objects and to create new ones.

However, the types of objects that appear in step-dependent managers are those that you can create and, in some cases, modify, suppress, and deactivate in particular analysis steps. Therefore, unlike basic managers, step-dependent managers contain additional information concerning the history of each object listed in the manager. Step-dependent managers display how these objects propagate from one step to another during the course of an Abaqus analysis. (For information on steps and multiple-step analyses, see *Defining an Analysis*.)

The following step-dependent managers exist in Abaqus/CAE:

In the Load module:

- **Load Manager**
- **Boundary Condition Manager**
- **Predefined Field Manager**

In the Interaction module:

- **Interaction Manager**

In the Step module:

- **Field Output Requests Manager**
- **History Output Requests Manager**
- **Adaptive Mesh Constraint Manager**

For example, the **Load Manager** is shown in *Figure 1*.

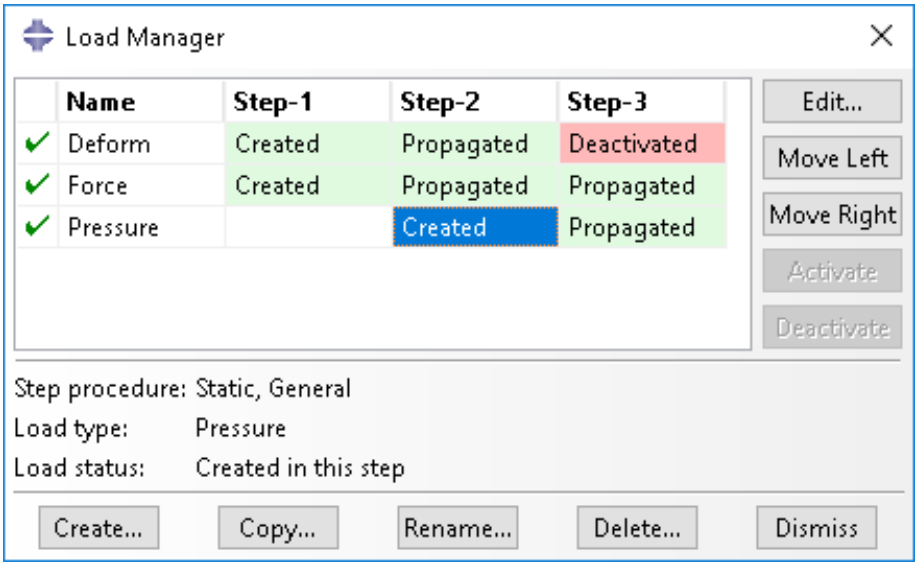

Figure 1: The Load Manager.

This manager displays an alphabetical list of existing loads along the left side of the dialog box. The names of all the steps in the analysis appear along the top of the dialog box in the order of execution. The table formed by these two lists displays the status of each load in each step. (For information on creating and deleting steps, see *The Step module*.)

If you click one of the cells in the table, that cell becomes highlighted, and the following information related to the cell appears in the legend at the bottom of the manager:

- The type of analysis procedure carried out in the step in that column.
- Information about the step-dependent object in that row.
- The status of the step-dependent object in that step (the same information that appears in the cells of the table except in more detail in some cases).

You can use the icons in the column along the left side of the manager to suppress objects or to resume previously suppressed objects for an analysis. For more information, see *Suppressing and resuming objects*.

The buttons along the right side of the manager allow you to manipulate objects in the steps that you select. For example, if you click **Edit** in the Load Manager shown above, an editor appears in which you could modify the load named `Force` in `Step-1`. The other buttons—**Move Left**, **Move Right**, **Activate**, and **Deactivate**—allow you to change the status of an object in a particular step.

Note: The **Activate** and **Deactivate** buttons are not available in the **Predefined Field Manager**.

For more information, see *Modifying the history of a step-dependent object*, *Changing the status of an object in a step*, and *Editing step-dependent objects*.

You can resize the columns of the table by dragging the dividers between the column headings to the right or left. You can also increase the size of the dialog box by dragging the sides of the box. If the analysis includes many steps or many step-dependent objects, increasing the size of the dialog box allows you to view more rows and columns without having to use the scroll bars.

Additional information

- *The output request managers*
- *Managing objects in the Interaction module*
- *Managing prescribed conditions*

Suppressing and resuming objects

When performing an analysis, you may want to study the effects of different combinations of objects, such as loads, or you may want to temporarily exclude an object from the model, such as excluding a boundary condition or a constraint in a design analysis. You can create a model that includes all of the objects and then suppress the objects that you want to exclude from the model prior to the analysis. Suppressed objects are not written to the input file and are treated as deleted objects. You should review your model for any references to suppressed objects. For more information, see *What happens when deleted objects are referred to?*.

You can suppress step-dependent objects, constraints (in the Interaction module), section assignments (in the Property module), and features. After you create a suppressible object, the manager dialog box displays a green check mark in the column along the left side of the manager next to the name of the object. You can suppress an object from the manager by clicking the green check mark next to the object. For example, if you click the green check mark to the left of the load named `Force` in the Load Manager shown in *Figure 1*, the icon changes to a red "X" and the cells displaying the status of the load in each step are shaded gray to indicate that the load is suppressed, as shown in *Figure 1*.

Note:

There is no manager associated with features; you can suppress or resume features using the popup menus in the Model Tree.

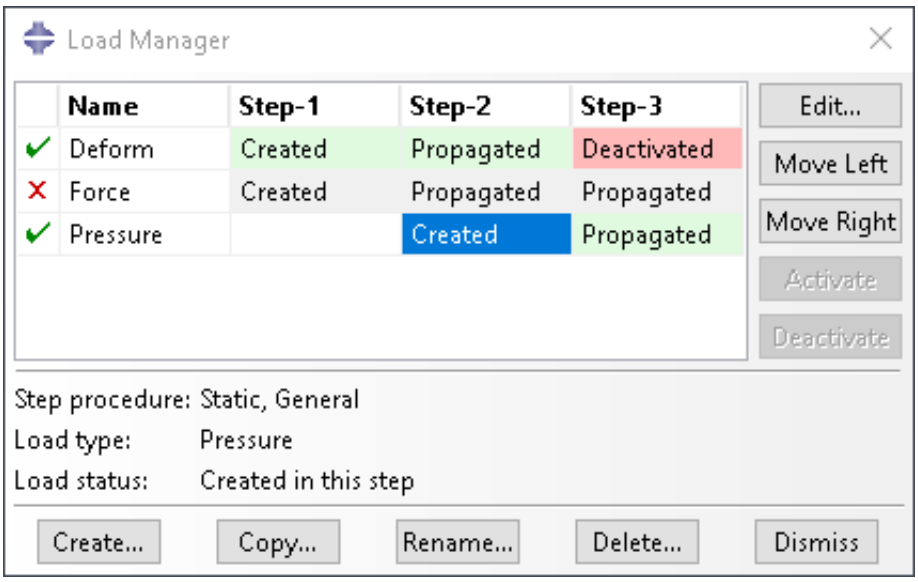

Figure 1: The Load Manager indicates that the load named `Force` is suppressed.

You can also select **Suppress->*object*** in the appropriate menu from the main menu bar to suppress an object. For example, to suppress the load named `Force` shown in *Figure 1*, you would select **Load->Suppress->Force** from the main menu bar of the Load module.

You cannot edit suppressed objects; however, you can copy, rename, and delete them. Symbols for suppressed objects are not displayed in the viewport.

You can resume an object that was previously suppressed. If you attempt to resume an object that is not valid for a given procedure type, Abaqus/CAE displays an error message. You can use the manager or the **Resume** menu item from the main menu bar to resume the object. In the manager, click the red "X" to change the icon back to a green check mark and to remove the cell shading. Symbols for resumed objects are displayed in the viewport.

You can also use the Model Tree to suppress or resume an object by clicking mouse button 3 on the object and selecting **Suppress** or **Resume** from the menu that appears. The Model Tree displays a red "X" next to an object to indicate that it is suppressed. For more information, see *The Model Tree*.

Additional information

- *The output request managers*
- *Managing objects in the Interaction module*
- *Managing prescribed conditions*

Understanding the status of an object in a step

A model can contain a sequence of analysis steps. When you create an object in a step, that object may or may not continue to be active in any of the following steps. The activity (or inactivity) of an object in any particular step is called its “status” in that step.

For example, *Figure 1* shows the status of a load in a series of general static analysis steps.

	Step 1	Step 2	Step 3	Step 4	Step 5	Step 6
Load 1	Created	Propagated	Modified	Propagated	Deactivated	Deactivated

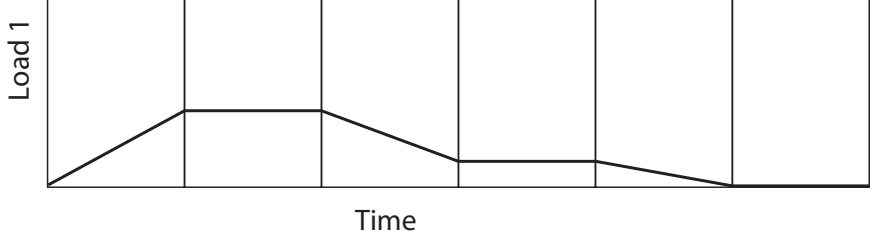

Figure 1: The analysis history of a load.

The load in this example is created in Step 1; therefore, the status of the load in Step 1 is `Created`. Since Step 1 is a general static step, the load's magnitude is ramped up over the course of the step. If the load continues to be active in Step 2, its status in Step 2 is `Propagated` and its magnitude remains constant throughout that step. If you edit the load in Step 3, its status in Step 3 becomes `Modified` and its magnitude ramps to the new value over the course of the step. If the modified version of the load continues to be active in Step 4, its status in Step 4 (as in Step 2) is `Propagated` and the value is constant. If you deactivate the load in Step 5, its status in Step 5 is `Deactivated` and its magnitude ramps down to zero. The load remains deactivated in Step 6.

For detailed explanations of the terms used to describe object status, see *Terms describing object status*.

Additional information

- *What are step-dependent managers?*

Terms describing object status

Abaqus/CAE uses the following terms to describe the status of objects in particular steps:

Created

The object was created and becomes active in this step. The point in the step at which a prescribed condition becomes active depends on the amplitude variation associated with that step. For more information, see "Prescribed conditions" in *Defining an Analysis*.

Computed

The analysis products will compute the value of the object in this step.

Modified

The definition of the object has been modified in this step. The variation of a prescribed condition over the course of the step depends on the amplitude variation associated with that step.

Propagated

The object was created, modified, or computed in an earlier step of the analysis and continues to be active in this step.

Deactivated

The object has been deactivated in this step or in a previous step. It will remain deactivated in all subsequent steps until you reactivate it. You cannot deactivate an object in the step in which it was created. The point in the step at which a prescribed condition becomes inactive depends on the amplitude variation associated with that step. For more information, see "Prescribed conditions" in *Defining an Analysis*.

You cannot deactivate predefined fields; a deactivated status for a predefined field means that the field has been reset to the value specified in the initial step. The point in the step at which an object resumes its initial value depends on the amplitude variation associated with that step. For more information, see "Prescribed conditions" in *Defining an Analysis*.

N/A

The object does not have any effect on the calculations for this step.

The following terms apply only in linear perturbation steps:

Built into base state

Any active object created in a preceding general analysis step will be part of the base state and cannot be changed during the linear perturbation step.

Propagated from base state

Objects created in a previous general step will be part of the base state for this procedure but can be modified or deactivated by the user.

Deactivated from base state

Objects created in a previous general step are deactivated in this linear perturbation step. The deactivated state applies only to the linear perturbation step and does not propagate to the remaining steps.

For information on linear perturbation steps, see *General and Perturbation Procedures*.

The following term applies only in modal dynamics steps:

Built into modes

Boundary conditions that are active in a preceding frequency analysis step are used in the calculation of modes and will therefore be built into the modes for mode-based linear perturbation procedures and subspace dynamic procedures. During these mode-based and subspace dynamic procedures the boundary condition cannot be changed.

For information on modal dynamics steps, see *Transient Modal Dynamic Analysis*.

Figure 1 shows the color codes assigned to various object statuses. The table cells in step-dependent managers are colored accordingly to indicate the object status.

Color codes	Statuses
	Created
	Computed
	Modified
	Propagated
	Deactivated
	N/A
	Built into base state
	Modified from base state
	Propagated from base state
	Deactivated from base state
	Built into modes

Figure 1: Color codes for object statuses.

Modifying the history of a step-dependent object

You can modify the analysis history of an object by using the five buttons aligned along the right side of the step-dependent manager: **Edit**, **Move Left**, **Move Right**, **Activate**, and **Deactivate**. (For information on how to use these buttons, see *Changing the status of an object in a step*.) The use of these buttons may be restricted depending on the nature of each step and the status of the object in the steps.

The following list describes the rules for modifying the history of a step-dependent object:

Changing the step in which an object becomes active

You can change the step in which an object becomes active by moving the `Created` status to that step. You can move the `Created` status of an object to any previous general step, or you can move the `Created` status to the following general step if its status in the following step is `Propagated`.

For example, you could select the `Created` status of Load1 in the load manager table below.

	Step 1	Step 2	Step 3	Step 4	Step 5
Load1		Created	Propagated	Propagated	Propagated

If you moved the `Created` status to Step 1, the table would change as shown below.

	Step 1	Step 2	Step 3	Step 4	Step 5
Load1	Created	Propagated	Propagated	Propagated	Propagated

If you moved the `Created` status to Step 3, the table would change as shown below.

	Step 1	Step 2	Step 3	Step 4	Step 5
Load1			Created	Propagated	Propagated

Note:

If an object is created in a linear perturbation step, its `Created` status cannot be moved.

Modifying an object

You can modify an object when its status is `Propagated`; the object's status in that step changes to `Modified`.

Moving the modifications of an object to another step

You can transfer the modifications of an object to another step by moving the object's modified status to that step. You can move the `Modified` status of an object to the previous general step or to the following general step if the status of the object in those steps is `Propagated`.

For example, you could select the `Modified` status of Load1 in the load manager table below.

	Step 1	Step 2	Step 3	Step 4	Step 5
Load1		Created	Propagated	Modified	Propagated

If you moved the `Modified` status to Step 3, the table would change as shown below.

	Step 1	Step 2	Step 3	Step 4	Step 5
Load1		Created	Modified	Propagated	Propagated

If you moved the `Modified` status to Step 5, the table would change as shown below.

	Step 1	Step 2	Step 3	Step 4	Step 5
Load1		Created	Propagated	Propagated	Modified

Deactivating an object

You can deactivate an object when its status is `Propagated` or `Modified`; the object's status in that step is shown as `Deactivated`, and the object is inactive in any following steps.

Note:

You cannot deactivate predefined fields using the **Predefined Field Manager**; you must select **Reset to initial** in the predefined field editor (for example, see *Defining a temperature field*).

Warning:

If you deactivate an object in a step in which its status is `Modified`, the modifications to the object are lost. If you later reactivate the object in that step, the original propagated version of the object becomes active in that step and in all subsequent steps.

Reactivating an object

You can reactivate an object that has a `Deactivated` status; however, the **Activate** button is available only in the step in which the object is first deactivated (for example, Step 3 in the following table).

	Step 1	Step 2	Step 3	Step 4	Step 5
Load1	Created	Propagated	Deactivated		

When you reactivate the load in the example above, its status in Step 3 and in all following steps changes to `Propagated`.

The following rules apply to linear perturbation steps:

Deactivating a boundary condition whose status is `Propagated from base state`

You can deactivate an object whose status is `Propagated from base state`; the object's status in the linear perturbation step changes to `Deactivated from base state`. The status `Propagated from base state` cannot be moved to other steps.

Reactivating a boundary condition whose status is `Deactivated from base state`

You can reactivate an object whose status is `Deactivated from base state`; the object's status in the linear perturbation step changes to `Propagated from base state`. The status `Propagated from base state` cannot be moved to other steps.

Objects whose status is `Built into base state`

The status `Built into base state` cannot be changed directly.

For information on linear perturbation steps, see *General and Perturbation Procedures*.

For information on the propagating behavior of output requests from general and linear perturbation analysis steps, see *Propagation of output requests*.

You can use the Model Tree to view the status of a step-dependent object, to edit the object, and to deactivate and reactivate the object. However, you must use the step-dependent manager to modify the history of an object by moving it right or left in the sequence of steps. For more information, see *The Model Tree*.

Additional information

- *What are step-dependent managers?*

Understanding modified step-dependent objects

When you edit an object in the step in which it was created, you change the definition of the object in all of the steps in which it is active. In some cases you can also edit an object in steps in which its status is `Propagated` or `Modified`. In these cases the object's definition varies according to the analysis step.

The effects of editing a step-dependent object are summarized below.

If the status of the object is `Created` in the selected step:

- Modifications that you make to the object in this step become effective in this step and propagate through all subsequent steps in which the condition is active unless you modify the object again in a later step.
- The status of the object remains `Created` in the selected step and also remains unchanged in all subsequent steps. For more information, see *Understanding the status of an object in a step*.

If the status of the object is `Propagated` or `Modified` in the selected step:

- Modifications that you make to the object in this step become effective in this step and propagate through all subsequent steps in which the object is active.
- The status of the object becomes (or remains) `Modified` in this step and remains unchanged in all other steps. (In other words, if the status of the object in the following step was `Propagated` before modification, its status in the following step remains `Propagated` after modification.) For example, the load applied over a sequence of general static analysis steps in *Figure 1* has been modified in Step 3; the modifications remain in effect in Step 4 even though the status in Step 4 is `Propagated`. For more information, see *Understanding the status of an object in a step*.
- When you modify the data in any editor other than the Interaction editor, Abaqus/CAE indicates in the editor which data have been modified. These indications disappear if you change the data in the editor back to their original values.

In some cases you cannot edit a particular aspect of an object's definition because it must be consistent for the analysis to proceed correctly. For example, although you can modify the magnitude of a load in any analysis step, you cannot modify the region to which the load is applied. The areas in an editor that specify this kind of restricted data are unavailable in all steps except the one in which the object was created.

Additional information

• *What are step-dependent managers?*

What happens when deleted objects are referred to?

You should take care when deleting or renaming objects, such as materials and amplitudes, that may be referred to by other objects. For example, if you delete or rename a material, the sections that refer to the material become inconsistent. To resolve the missing reference, you can edit the section and refer to a new material, or you can create a new material with the same name as the deleted material.

Table 1 lists objects that are commonly referred to by other objects.

Table 1: Objects that are commonly referred to by other objects.

This object	Can be referred to by these types of objects
Material	Section
Profile	Section, skin
Section	Section assignment
Interaction	Output request, contact controls
Interaction property	Interaction
Amplitude	Load, predefined field, boundary condition, interaction
Connector section	Connector section assignment
Region (set or surface)	Boundary condition, predefined field, load, interaction, constraint, connector section assignment, output request, section assignment, beam section orientation, material orientation, output request, DOF monitor, adaptive mesh domain
Load	Load case, output request
Boundary condition	Load case
Datum coordinate system	Boundary condition, connector section assignment, material orientation, constraint
Datum plane	Load
Datum axis	Load
Datum point	Constraint
Part instance	Constraint
Part	Part instance

Parts and part instances behave slightly differently. If you delete a part after you have instanced the part in the Assembly module, Abaqus/CAE suppresses the part instance in the assembly. You can delete the instance from the assembly. Alternatively, if you then create a new part that uses the same name, you can unsuppress the part instance to include it in the assembly. In addition, if you rename a part or a datum, objects that refer to the part or datum refer to the new name; and, as a result, the reference does not become inconsistent.

Managing objects using manager dialog boxes

Abaqus/CAE provides you with a set of managers that list all the objects defined in the current model or session such as parts, stand-alone sketches, materials, sections, steps, display groups, and *X–Y* data objects. In addition, the **Model Manager** lists all the models defined in the current model database.

Note:

For more information on specific managers and where they are located, see the documentation for the particular module in which you are interested.

Use the buttons in the manager dialog box to manage the list of objects.

1. To display a manager, do one of the following:
   - To display a manager associated with a module, select **Manager** from the appropriate menu on the main menu bar. For example, to display the **Section Manager** while you are working in the Property module, select **Section->Manager** from the main menu bar.
   - To display a manager associated with a toolset, select **Tools->*Toolset*->Manager** from the main menu bar. For example, to display the **Set Manager**, select **Tools->Set->Manager** from the main menu bar.
   - To display a step-dependent manager associated with an object in the Model Tree, click mouse button 3 on the object and select **Manager** from the menu that appears.
   - To display the **Model Manager**, select **Model->Manager** from the main menu bar.

   The manager appears and displays a list of objects in the current model or session. The list contains the name of each object and, in some cases, information about each object. For example, the **Part Manager** lists the name of each part, its status, its type, and the modeling space in which it was created.
2. To manage an existing object, select the object or objects of interest from the list in the manager and then click the appropriate button. (For example, to delete an object, select that object's name from the list and then click **Delete**.)

   In most cases a dialog box appears; for example, when you click **Rename**, the dialog box asks for the new name of the selected object.
3. If a dialog box appears, provide the requested information and click **OK**.
4. Click **Dismiss** to close the manager.

Tip: You can also use the menus in the main menu bar to manage objects. For more information, see *Managing objects using manager menus*.

Additional information

• *Managing objects using manager menus*

Managing objects using manager menus

Like managers, pull-down menus from the main menu bar allow you to manage all the objects defined in the current model or session.

1. From the main menu bar, select one of the following:

   - To manage objects associated with a module, select the manager menu items in the appropriate menu in the main menu bar. For example, to edit a material in the Property module you would select **Material->Edit->*material of your choice*** from the main menu bar.
   - To manage objects associated with a toolset, select the appropriate manager menu items in the **Tools** menu. For example, to delete a set, you would select **Tools->Set->Delete->*set of your choice*** from the main menu bar.
   - To manage all the models defined in the current model database, select the manager menu items in the **Model** menu in the main menu bar. For example, to copy a model, you would select **Model->Copy->*model of your choice*** from the main menu bar.

   In most cases a dialog box appears; for example, when you rename an object, a dialog box appears that asks for the new name of the object.

2. If a dialog box appears, provide the requested information and click **OK**.

Tip: You can also use manager dialog boxes to manage objects. For more information, see *Managing objects using manager dialog boxes*.

Additional information

• *Managing objects using manager dialog boxes*

Copying step-dependent objects using manager dialog boxes

You use the **Copy** button in manager dialog boxes to copy a step-dependent object such as a load, boundary condition, interaction, predefined field, output request, or adaptive mesh constraint. You can copy an object from any step to any other valid step.

1. Open the appropriate manager, as described in *Managing objects using manager dialog boxes*.
2. Select the object you want to copy by clicking in the corresponding table cell.
3. Click **Copy**.

   The corresponding **Copy *Object*** dialog box appears.
4. Enter a name for the new object.
5. Choose the destination step from the **Step** list. By default, the object is copied into the step in which it was created.
6. Click **OK**.

   The object is copied to the selected destination step.

If the destination step type is different from the type of step in which the object was originally created, Abaqus/CAE may need to modify the object to make it compatible with the new step. For example, if a load was created in a static (general) step and you copy it into a steady-state dynamics (linear perturbation) step, Abaqus/CAE will add an imaginary component to the load value. Conversely, if a load from a steady-state dynamics step is copied to a static step, the imaginary component will be removed.

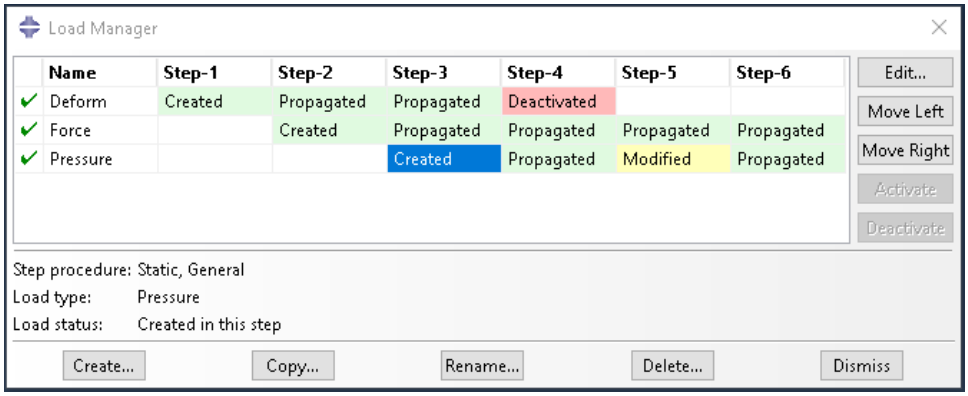
In addition, when you copy an object to a step other than the step in which it was created, any modifications made to the original object in one of its propagated states will be ignored in the copy.

Abaqus/CAE prevents you from copying an object into a step type where the object type is invalid. Abaqus/CAE also prevents you from copying a suppressed object or copying to a suppressed step.

Changing the status of an object in a step

Step-dependent managers contain buttons that you can use, under certain circumstances, to alter the status of an object in a particular step. These buttons are labeled **Move Left**, **Move Right**, **Activate**, and **Deactivate**.

Whether or not you can change the status of an object in a step depends on the step's procedure and the object's status in the step. The manager allows you to make only valid changes to the history of an object. If the operation of one of the buttons would cause an invalid change in status, that button becomes unavailable. For more information, see *Modifying the history of a step-dependent object*.



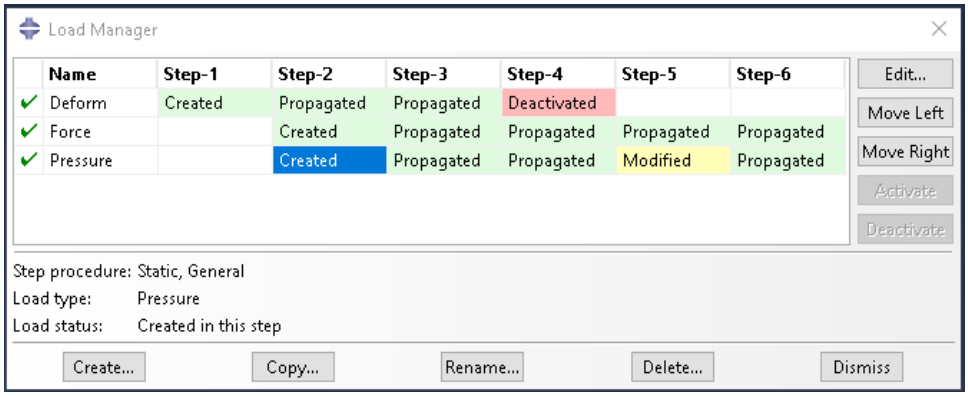
The following list describes techniques for manipulating the status of a step-dependent object:

To select the status that you want to change:

Click in the cell that is located in the row of the object of interest and in the column of the step of interest.

The status of the object in that step becomes highlighted, and, in most cases, some or all of the buttons on the right side of the dialog box become available. The availability of the buttons depends on the status of the object in the current step, in the preceding step, and in the following step.

For example, the `Created` status of **Pressure** in `Step-3` is selected in the figure below:

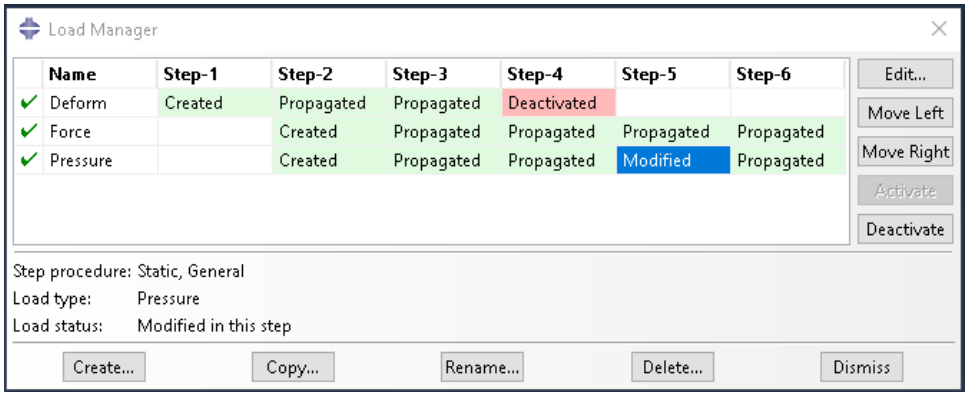


Use the buttons that become available to manipulate the status of the object in the step that you have chosen, as described below.

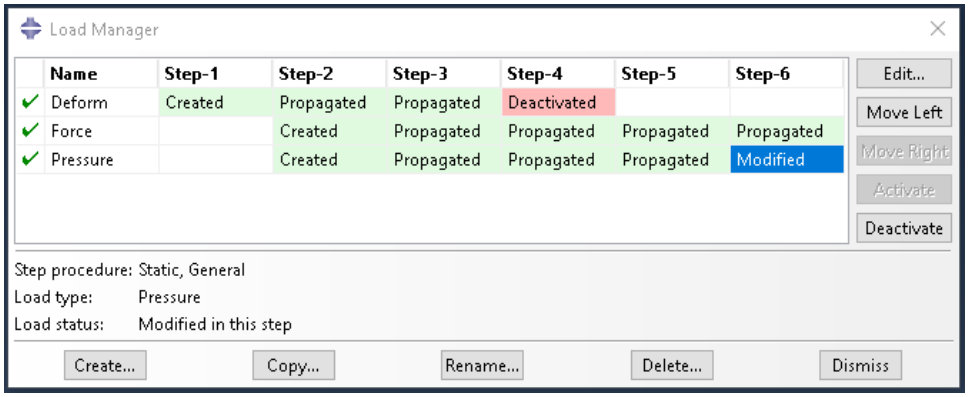
To move the status in the selected step to the preceding step:

Click **Move Left** to move the highlighted status from the selected to the preceding step.

For example, the `Created` status of **Pressure** in `Step-3` is selected in the history shown above. If you clicked **Move Left**, the history would change as shown below:



The `Created` status of **Pressure** moves to `Step-2` and is replaced by `Propagated` in `Step-3`.

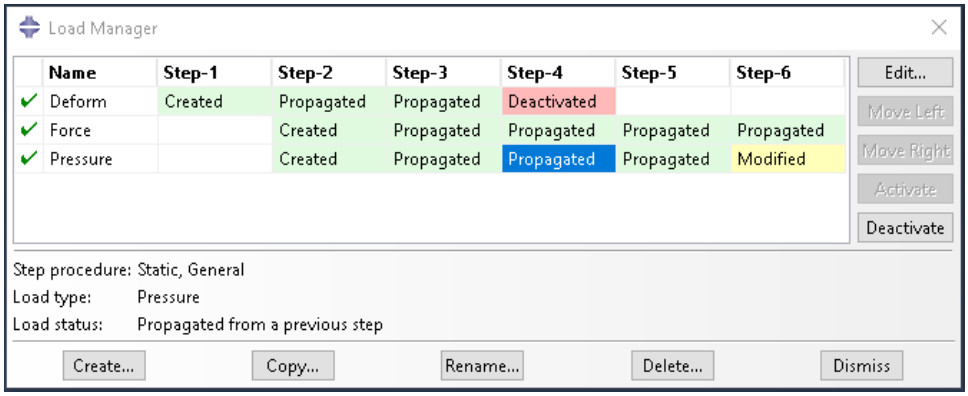


To move the status in the selected step to the following step:

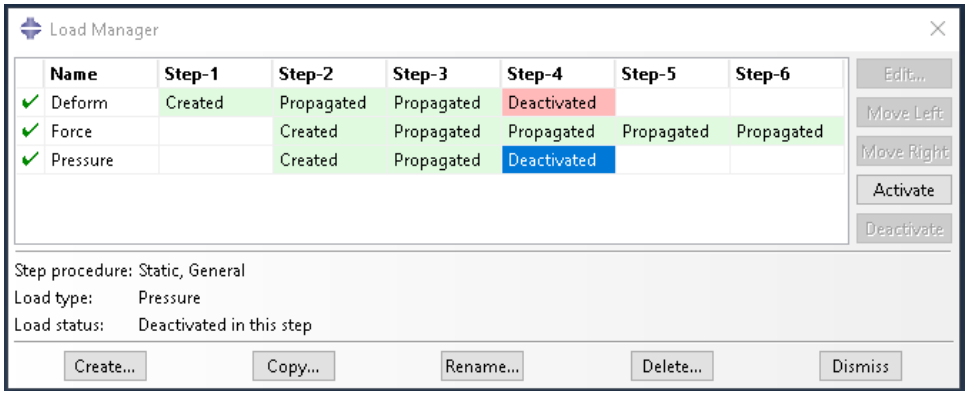
Click **Move Right** to move the highlighted status from the selected step to the following step.

In the history shown below, for example, the `Modified` status of **Pressure** in `Step-5` is selected.

If you clicked **Move Right**, the history would change as shown below:



The `Modified` status of **Pressure** moves to `Step-6` (indicating that the modifications to **Pressure** become effective in `Step-6`), and `Modified` is replaced by `Propagated` in `Step-5`.



To deactivate the object in the selected step:

Click **Deactivate** to deactivate the object in the selected step.

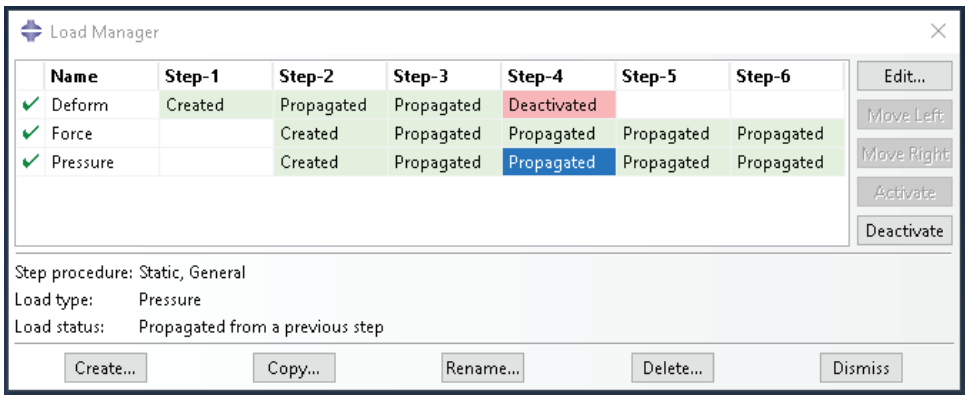
In the history shown below, for example, the `Propagated` status of **Pressure** in `Step-4` is selected.

If you clicked **Deactivate**, the history would change as shown below:

The `Propagated` status of **Pressure** in `Step-4` changes to `Deactivated`, and the pressure is inactive in all subsequent steps.

Note:

You cannot deactivate predefined fields using the **Predefined Field Manager**; you must select **Reset to initial** in the predefined field editor (for example, see *Defining a temperature field*).



Warning:

If you deactivate an object in a step in which its status is `Modified`, the modifications to the object are lost. If you later reactivate the object in that step, the original, unmodified version of the object becomes active in that step and in all subsequent steps.

To reactivate the object in the selected step:

Click **Activate** to reactivate the object in the selected step.

In the history shown above, for example, the `Deactivated` status of **Pressure** in `Step-4` is selected. If you clicked **Activate**, the history would change as shown below:

The `Deactivated` status of **Pressure** changes to `Propagated` in `Step-4` and in any following steps.

Note:

The **Activate** button is available only in the step in which an object is first deactivated.

You can use the Model Tree to view the status of a step-dependent object, to edit the object, and to deactivate and reactivate the object. However, you must use the step-dependent manager to modify the history of an object by moving it right or left in the sequence of steps. For more information, see *The Model Tree*.

Additional information

- *What are step-dependent managers?*

Editing step-dependent objects

You can use either menus, managers, or the Model Tree to edit step-dependent objects in a particular step.
You cannot edit suppressed objects; you must resume the object before editing. For more information, see *Suppressing and resuming objects*. (For information about the status of modified objects, see *Understanding modified step-dependent objects*.)

Additional information

- *What are step-dependent managers?*
- *Suppressing and resuming objects*
- *Understanding modified step-dependent objects*
- *Understanding symbols that represent prescribed conditions*
- *Editing the region to which a prescribed condition is applied*

Edit step-dependent objects using menus

1. From the main menu bar, select **Edit->*object of your choice*** from the appropriate menu. For example, if you want to edit a load in the Load module, select **Load->Edit->*load of your choice***.

   The appropriate editor appears. The region to which the object is applied becomes highlighted in the current viewport.

2. In the editor, modify the object definition as desired, and click **OK**.

Edit step-dependent objects using managers

1. In the manager, locate the cell of interest. The cell is located in the row of the object that you want to modify and in the column of the step of interest.
2. In the manager, double-click the cell.

   Note:

   Alternatively, you can click the cell of interest and then click **Edit**.

   The appropriate editor appears. Abaqus/CAE highlights the region to which the object is applied.

3. In the editor, modify the object definition as desired, and click **OK**.

Edit step-dependent objects using the Model Tree

1. In the Model Tree select the object of interest.
2. Click mouse button 3 on the object and select **Edit** from the menu that appears

   The appropriate editor appears. Abaqus/CAE highlights the region to which the object is applied.

3. In the editor, modify the object definition as desired, and click **OK**.

Working with the Model Tree and the Results Tree

The Model Tree and Results Tree are convenient tools for navigating and managing your models and analysis results.

You can use the Model Tree to view a model and the items that it contains, and you can use the Results Tree to display analysis results from output databases as well as session-specific data such as *X*–*Y* plots. Both trees provides shortcuts to much of the functionality of the main menu bar, the module toolboxes, and the various managers. This section describes both the Model Tree and Results Tree.

In this section:

- *The Model Tree*
- *The Results Tree*
- *Using popup menus in the Model Tree and the Results Tree*
- *Changing the view of the model*

The Model Tree

The Model Tree provides a visual description of the hierarchy of items in a model.
For example, *Figure 1* shows the appearance of the Model Tree after completing the tutorial for a cantilever beam in *Creating and Analyzing a Simple Model in Abaqus/CAE*.

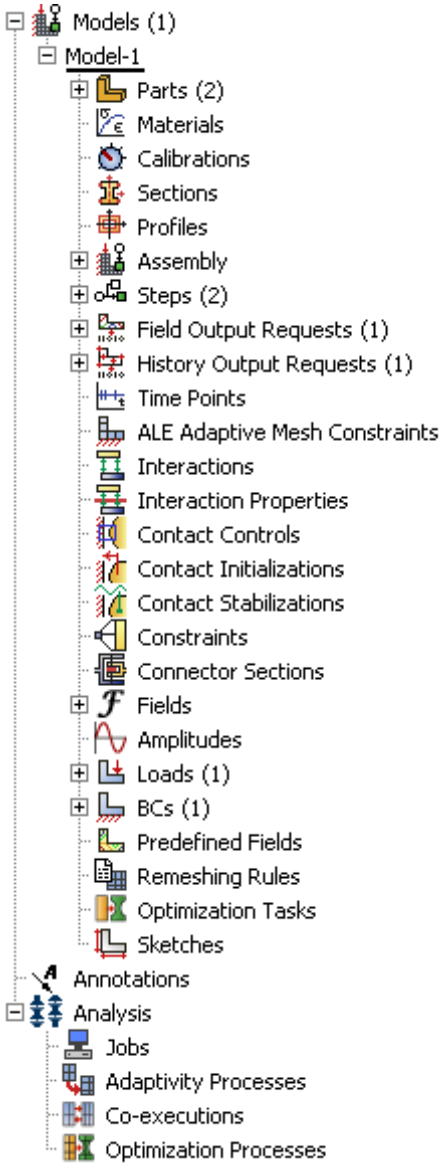


Figure 1: The Model Tree after completing the cantilever beam tutorial.

The Model Tree shares the left side of the Abaqus/CAE interface with the Results Tree and, in the Property module only, a material library. You can click the **Model**, **Results**, or **Material Library** tab to toggle the display between the Model Tree, the Results Tree, and a material library. See *The Results Tree*, and *Using material libraries*, respectively, for more information about the Results Tree and material libraries. In addition, the tip button at the top of the Model Tree provides a quick summary of the functionality of the Model Tree and Results Tree along with a summary of the keyboard shortcuts described at the end of this section.

A complete Abaqus/CAE model contains all of the information required to perform an analysis; for example, all of the parts, materials, steps, and loads and the meshed representation of the assembly. A model also contains the jobs that are submitted to the Abaqus analysis products. For more information, see *What does an Abaqus/CAE model contain?*. All of these items are represented in the Model Tree.

Items in the Model Tree are represented by small icons; for example, the **Steps** icon, . In addition, parentheses next to an item indicate that the item is a container, and the number in the parentheses indicates the number of items in the container. You can click on the "plus" and "minus" signs in the Model Tree to expand and collapse a container. The right and left arrow keys perform the same operation.

For example, the **Steps** container contains all the steps in your model. In the example shown in *Figure 1* expanding the **Steps** container reveals that the model contains two steps—the **Initial** step and the **BeamLoad** step. Expanding the **BeamLoad** step, as shown in *Figure 2*, reveals that the step has four containers, each of which contains a single item—**Field Output Requests**, **History Output Requests**, **Loads**, and **BCs**.

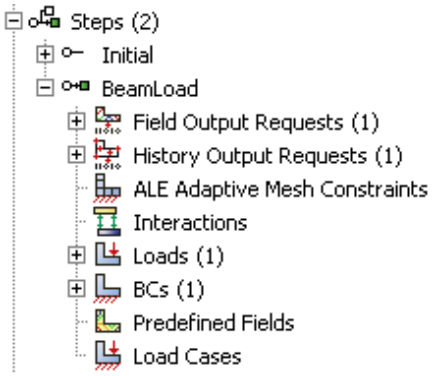

Figure 2: Containers in the BeamLoad step.

In addition, the step contains four empty containers—**ALE Adaptive Mesh Constraints**, **Interactions**, **Predefined Fields**, and **Load Cases**. You cannot delete an empty container from the Model Tree, although you can hide empty containers from view (see *Changing the view of the model*). Finally, expanding the **Loads** container, as shown in *Figure 3*, reveals a single load called **Pressure** that was created in this step.

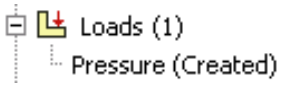

Figure 3: The load in the Loads container.

The arrangement of the containers and items in the Model Tree reflects the order in which you are likely to create your model. A similar logic governs the order of modules in the module menu—you create parts before you create the assembly, and you create steps before you create loads. This arrangement is fixed—you cannot move items in the Model Tree. For more information, see *What is a module?*.

Abaqus/CAE underlines the current objects in the Model Tree and displays them in the context bar. The model you are working on is a current object. The current part or the current step is also a current object. When you select an item in the Model Tree, Abaqus/CAE highlights that item in the current viewport if the selected item belongs to the current objects. For example, if you select a load, Abaqus/CAE highlights the load in the current viewport if it was applied in the current step of the current model. Containers are not highlighted.

You can select multiple items in the Model Tree, and Abaqus/CAE highlights each of those items if they belong to the current objects. For example, you can select an interaction and a load in the current step of the current model, and Abaqus/CAE highlights both the interaction and the load in the assembly. As you move the cursor over an item, the Model Tree displays some information about the item, as shown in *Figure 4*. In most cases the same information is available from the item's manager.

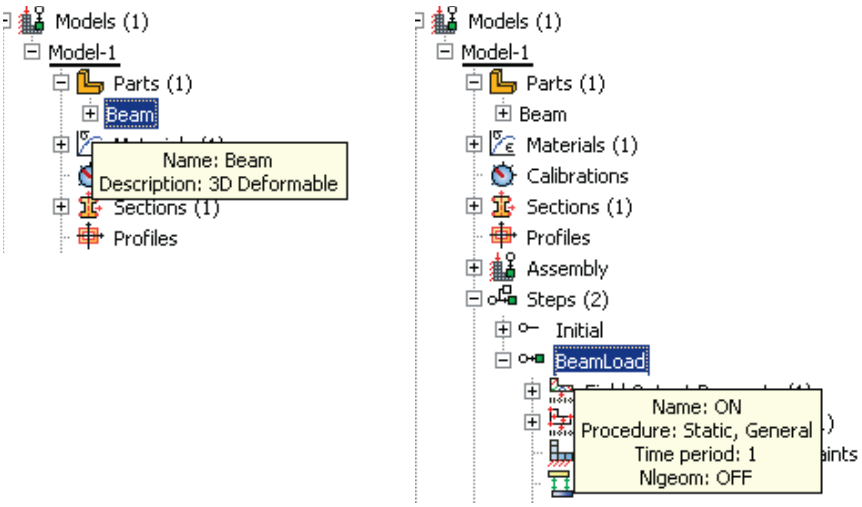

Figure 4: The Model Tree displays information about the item under the cursor.

Pressing an alphabetic key (a–z) when the cursor is in the Model Tree selects the first item in the tree with a name beginning with that character. Pressing subsequent keys continues to match characters in an item's name. *Table 1* describes all of the keyboard shortcuts that are available for navigation in the Model Tree; you can use these shortcuts to navigate in the Results Tree as well.

Table 1: Keyboard shortcuts in the Model Tree and Results Tree.

Keyboard shortcut	Action
[Home]	Go to top of Model Tree or Results Tree
[End]	Go to bottom of Model Tree or Results Tree
Up arrow	Move up one item
Down arrow	Move down one item
Right arrow	Expand branch or move down one item
Left arrow	Collapse branch or move up one item
[Del]	Delete item
[F2]	Apply a *filter* to a container

The Model Tree provides most of the functionality of the main menu bar and the module managers. For example, if you double-click on the **Parts** container, you can create a new part (the equivalent of selecting **Part->Create** from the main menu bar). If you double-click on a part's feature, you can edit the feature (the equivalent of selecting **Feature->Edit** from the main menu bar).

You can drag the divider between the Model Tree and the canvas to change the width of the Model Tree. In addition, you can toggle off the display of the Model Tree by selecting **View->Show Model Tree** from the main menu bar. Pressing **[Ctrl] + T** has the same effect. To switch to the Results Tree, click the **Results** tab.

Step-dependent objects are objects that can be propagated between steps; for example, loads and interactions. For more information, see *What are step-dependent managers?*. Text next to a step-dependent object in the Model Tree, such as **(Created)** and **(Propagated)**, indicates the status of the object. You can use the Model Tree to change the status of a step-dependent object by clicking mouse button 3 on the object and selecting an action from the menu that appears. The actions correspond to those available in the step-dependent managers. For more information, see *Understanding modified step-dependent objects*.

You can use the Model Tree to suppress a feature, a constraint (in the Interaction module), a section assignment (in the Property module), or a step-dependent object by clicking mouse button 3 on the item and selecting **Suppress** from the menu that appears. A red "X" appears next to the item in the Model Tree to indicate that it is suppressed. You can resume the item by clicking mouse button 3 on the item and selecting **Resume**. Abaqus/CAE removes the red "X" from the Model Tree to indicate that the item is no longer suppressed. The same information is displayed in the managers. For more information, see *Suppressing and resuming objects*.

The Results Tree

The Results Tree provides a visual description of the output data available in your session, including all open output databases and session-specific data such as *X–Y* data and *X–Y* plots. In addition, the Results Tree enables you to navigate to viewable content in the current model database, such as the loads specified in one step of a particular model. This tool shares the left side of the Abaqus/CAE interface with the Model Tree and, in the Property module only, a material library. You can click the **Model**, **Results**, or **Material Library** tab to toggle the display between the Model Tree, the Results Tree, and a material library. (For more information on material libraries, see *Using material libraries*.) The Results Tree also uses all of the same keyboard and navigational shortcuts as the Model Tree; see *Table 1* for more information.

Figure 1 shows the appearance of the Results Tree after completing an analysis of the tutorial for the hinge model in *Using Additional Techniques to Create and Analyze a Model in Abaqus/CAE*. The **Output Databases** container displays all the output database files that are currently open in your session. In the example shown in *Figure 1* the **Output Databases** container is expanded and reveals that only one output database is open—the **PullHinge** output database.

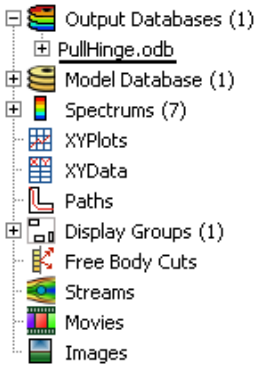

Figure 1: The Results Tree after completing an analysis of the hinge model tutorial.

Expanding **PullHinge**, as shown in *Figure 2*, reveals that this output database has the following containers: **History Output**, **Steps**, **Instances**, **Materials**, **Sections**, **Element Sets**, **Node Sets**, and **Surface Sets**. In addition, the output database contains two empty containers—**Session Coordinate Systems** and **ODB Coordinate Systems**. You cannot delete an empty container from the Results Tree, although you can hide empty containers from view (see *Changing the view of the model*).

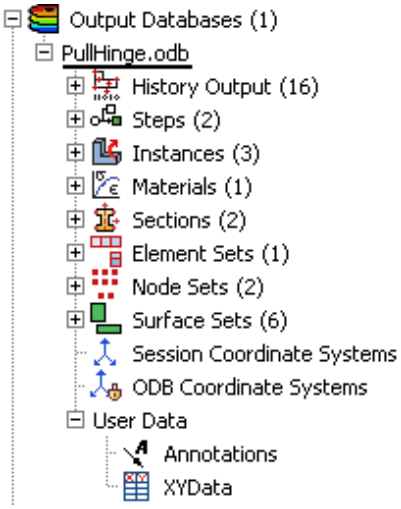

Figure 2: The containers in the PullHinge output database.

Expanding the **History Output** container, as shown in *Figure 3*, reveals the sixteen output variables for which history output was requested in this analysis. Each variable listing also describes the region for which history output was requested; in this example every history output request was made for the whole model. You can click any of the history output variables in the Results Tree to plot the selected variable in the current viewport.

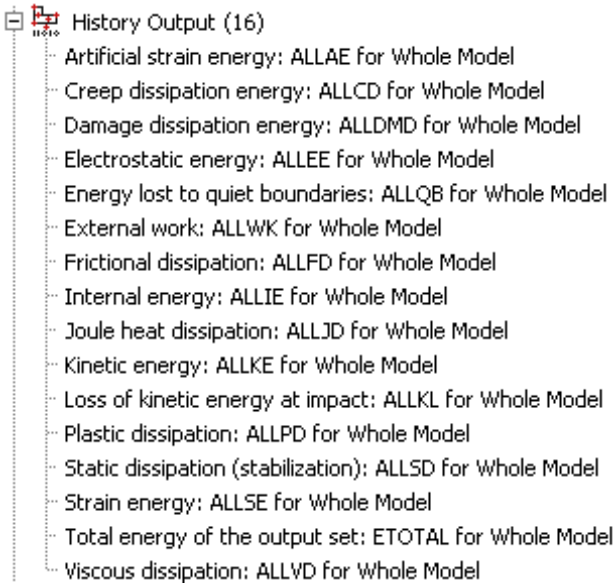

Figure 3: The History Output container of the Results Tree.

Each output database also includes a **Steps** container, which includes containers for each step in the output database and within the steps, every frame in the output database. You can use the Results Tree to display the model at any frame of the analysis, to activate or deactivate steps or frames in the analysis, or to display field output at the selected frame.

The **Model Database** container displays all the models in the current model database. You can expand each model to select the step with data that you want to investigate and to display or hide individual part instances. *Figure 4* shows the hinge model with its **Steps** and **Instances** containers expanded.

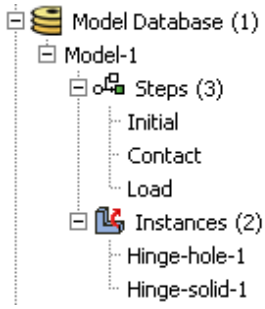

Figure 4: The Model Database container of the Results Tree.

The other containers in the Results Tree provide shortcuts to data that persist only during your session. By using these shortcuts, you can create and manage contour spectrums; create and edit *X–Y* data and display *X–Y* plots, create and manage paths and display groups; and upload and display background images and movies.

Using popup menus in the Model Tree and the Results Tree

Much of the power of the Model Tree and Results Tree comes from the popup menu that appears when you click mouse button 3 on an item. For example, *Figure 1* shows the effect of clicking mouse button 3 on the **Parts** container in the Model Tree.

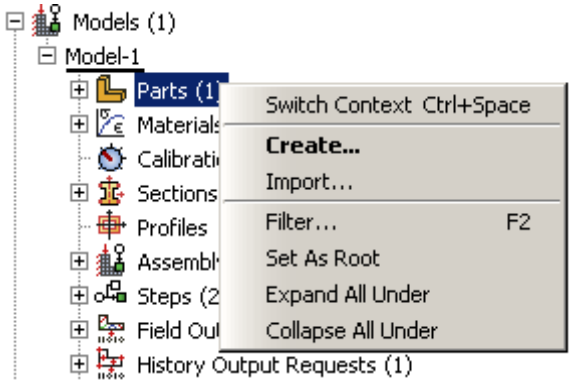

Figure 1: Clicking mouse button 3 on the Parts container in the Model Tree.

The **Create** menu item appears in bold font in *Figure 1* because it is the default action. Double-clicking an item or selecting an item and pressing **[Enter]** invokes the default action. In most cases if an item is a container, the default action is to create a new item in the container. Similarly, if an item is not a container, the default action is to edit the item. For example, if you double-click the **Parts** container, Abaqus/CAE displays the **Create Part** dialog box and allows you to create a new part; if you double-click one of the parts within the container, Abaqus/CAE displays the **Edit Part** dialog box and allows you to edit the part you selected.

Some of the commands in the popup menu appear with all items in the Model Tree and Results Tree; other commands appear only with specific items or with items in one of the two trees. For example, the **Switch Context** command appears with all items in the Model Tree and Results Tree, including containers. The following commands appear with all containers in the Model Tree and Results Tree:

Switch Context

If you select **Switch Context**, Abaqus/CAE makes the item current. In the Model Tree, where appropriate, Abaqus/CAE also switches to the module in which you can edit the item. For example, if you click mouse button 3 on the **Materials** container and select **Switch Context**, Abaqus/CAE switches to the Property module. For more information, see *What is a module?*. In the Results Tree you can also switch the context to an item in another output database.

Selecting a container and pressing **[Ctrl][Space]** have the same effect as selecting **Switch Context** from either tree.

Filter

When you select **Filter**, Abaqus/CAE prompts you for a string of characters next to the container's name. After you press **[Enter]**, Abaqus/CAE filters the contents of the container and displays only those items that match the specified character string. The filter is case-sensitive. For details on valid filtering syntax, click the tip button

at the top of the Model Tree or Results Tree. *Figure 2* shows the effect of filtering a container.

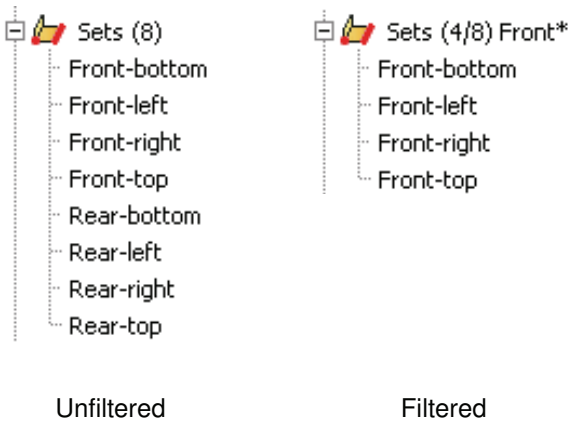

Figure 2: Filtering a container in the Model Tree.

Items that are hidden by a filter cannot be manipulated from the Model Tree or Results Tree; however, these items are not removed from the model or output database. When a filter is in effect, the numbers in parentheses next to the container name indicate the number of visible items in the container followed by the total number of items (visible and hidden) in the container (see *Figure 2*). The filter string appears to the right of these numbers. To remove a filter, select **Filter** for the appropriate container, delete the filter string, and press **[Enter]**.

Filters can be applied only to individual containers and persist only during your session. Selecting a container and pressing **[F2]** have the same effect as selecting **Filter** from either tree.

Set As Root

If you select **Set As Root**, Abaqus/CAE moves the container to the pull-down menu above the Model Tree or Results Tree and displays everything under the selected container. For more information, see *Changing the view of the model*.

Expand All Under

If you select **Expand All Under**, Abaqus/CAE expands all of the containers and items inside the selected container.

Collapse All Under

If you select **Collapse All Under**, Abaqus/CAE collapses all of the containers and items inside the selected container.

Group Children

When a container includes more than 30 items, Abaqus/CAE automatically groups the items into sets of 30. If you toggle off the **Group Children** option, Abaqus/CAE removes the groupings and lists all of the items on the same level in the container.

Selecting a container and pressing **[Ctrl][G]** have the same effect as selecting **Group Children** from either tree.

Many popup menu commands appear only with specific items. In the Model Tree these commands mirror the actions that you can perform with that item's manager; for example, create, edit, delete, rename, suppress, and resume. In the Results Tree some popup menus provide Boolean operators that enable you to control the display of items in the current viewport. These Boolean operators are the same five commands that are available for controlling display groups: replace, add, remove, intersect, and either. See *Understanding display group Boolean operations*, for more information.

Some menu commands are specific to one container in the Model Tree or Results Tree; for example, clicking mouse button 3 on a step allows you to toggle the **Nlgeom** setting, clicking mouse button 3 on a job allows you to submit the job for analysis, and clicking mouse button 3 on a history output variable allows you to add another variable to the existing plot. When you become familiar with the Model Tree and Results Tree, you will find that you can quickly perform most of the actions that are found in the main menu bar, the module toolboxes, and the various managers.

Changing the view of the model

If you select **Set As Root** from a container's popup menu, Abaqus/CAE displays everything under the selected container in the Model Tree or Results Tree and displays the name of the container in the menu above the tree. This option is useful if, for example, you have a complex model or output database and correspondingly complex Model Tree or Results Tree. You can use **Set As Root** to simplify the Model Tree or Results Tree by displaying only the portion that you are working on. For example, *Figure 1* shows a view of the Model Tree on the left and contrasts it with the effect of setting the **Materials** container as the root.

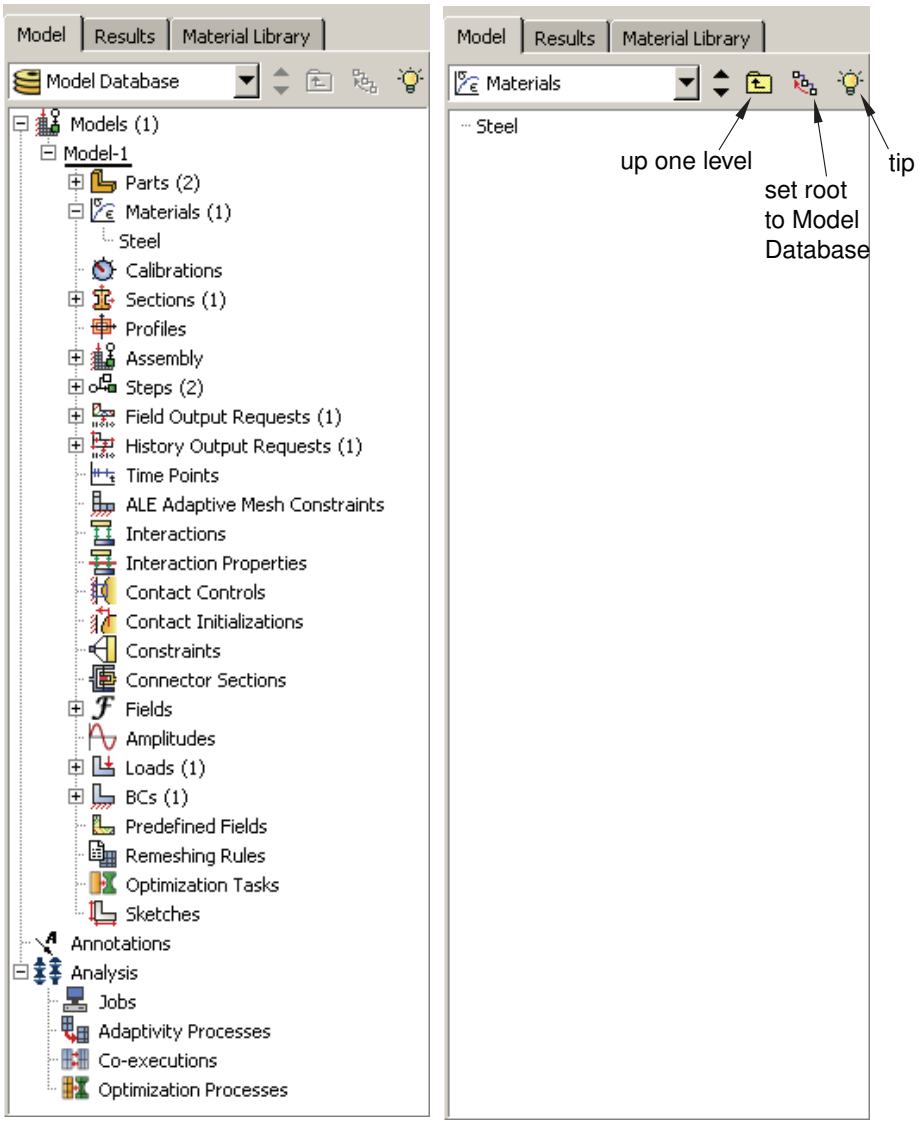

Figure 1: The effect of Set As Root on the Model Tree.

When you change the default root container, you can use the menu above the Model Tree and Results Tree to move up through its levels. In addition, Abaqus/CAE activates two icons above the Model Tree or Results Tree, as shown in *Figure 1*: the **Set Root to Model Database** icon in the Model Tree, the **Set Root to Session Data** icon in the Results Tree, and the **Up One Level** icon in both trees.

- The **Set Root to Model Database** icon  returns the Model Tree to the default view that shows **Model Database** at the top of the tree. The **Set Root to Session Data** icon  returns the Results Tree to the default view that shows **Session Data** at the top of the tree.
- The **Up One Level** icon  moves the root of the Model Tree or Results Tree up one level; for example, from the **Materials** container up one level to the **Beam** model that contains the **Materials** container.

If you click mouse button 3 on the background of the Model Tree or Results Tree, Abaqus/CAE displays a popup menu with the following options:

Show Empty Containers

By default, Abaqus/CAE displays all of the containers in the Model Tree and Results Tree, whether or not they have items in them. By turning off the **Show Empty Containers** option, you can suppress the display of containers without any items in them. If you perform an action in Abaqus/CAE that adds an item to a previously empty container (for example, creating an interaction using the Interaction module toolbox), the container and item will reappear in the Model Tree or Results Tree. For a container to be suppressed from view, it must be completely empty; even if all items in a container are hidden because of a filter (see *Using popup menus in the Model Tree and the Results Tree*), that container is not suppressed by the **Show Empty Containers** option.

The state of the **Show Empty Containers** option persists between Abaqus/CAE sessions.

Expand All

If you select **Expand All**, Abaqus/CAE expands all of the containers and items in the Model Tree or Results Tree.

Collapse All

If you select **Collapse All**, Abaqus/CAE collapses all of the containers in the Model Tree or Results tree, leaving only top-level containers and items visible.

Set Root to Displayed Object

If you select **Set Root to Displayed Object**, the container corresponding to the part visible in the current viewport becomes the root of the Model Tree (as described above). If an assembly is visible in the current viewport, the **Assembly** container for the appropriate model becomes the root of the Model Tree.

This option is available only in the Model Tree.

Set Root to Model Database

If you select **Set Root to Model Database**, Abaqus/CAE returns the Model Tree to the default view that shows **Model Database** at the top of the tree. This option has the same effect as the **Set Root to Model Database** icon .

This option is available only in the Model Tree.

Set Root to Session Data

If you select **Set Root to Session Data**, Abaqus/CAE returns the Results Tree to the default view that shows **Session Data** at the top of the tree. This option has the same effect as the **Set Root to Session Data** icon  . This option is available only in the Results Tree.

Understanding Abaqus/CAE GUI settings

GUI settings are always saved automatically to a binary file in your home directory called `abaqus_2026.gpr` when you exit Abaqus/CAE. For more information, see *Working with abaqus_2026.gpr files*.

These GUI settings include the following:

- The size and location of the main window.
- The size and location of a particular dialog box; for example, the **Open Database** and **Create Part** dialog boxes.
- The location, orientation, and visibility of individual toolbars.
- Custom toolbars.
- Customized keyboard shortcuts.
- The size of the message area and command line interface.
- Whether the Model Tree and Results Tree are displayed. The width of the tree area is also stored.
- Bookmarks to directories that you created when opening a file.

You cannot edit the `abaqus_2026.gpr` file; however, you can delete it to restore the default GUI and display options settings.

Warning:

Deleting the `abaqus_2026.gpr` file resets all of the GUI settings listed above. You cannot restore the settings from a deleted `abaqus_2026.gpr` file except by recreating them manually in Abaqus/CAE.

Managing viewports on the canvas

The canvas can be thought of as an infinite screen or bulletin board on which you post viewports; you can imagine the canvas extending beyond the main window and your monitor.

The visible portion of the canvas is called the drawing area, and you can increase its size by increasing the size of the main window. You can display the drawing area full screen using the **View** menu; you can also press **[F11]** to toggle between full screen mode and normal mode.

You can position viewports anywhere on the canvas, and you can drag them outside the drawing area. When viewports are positioned outside the drawing area, you can cascade or tile the viewports to bring them back into view. Viewports are not part of a model and are not saved between sessions.

This chapter explains how to create and manipulate viewports, text annotations, and arrow annotations.

In this section:

- *Understanding viewports*
- *Manipulating viewports and viewport annotations*
- *Displaying the drawing area in full screen mode*
- *Working with viewports*
- *Working with viewport arrow and text annotations*
- *Linking viewports for view manipulation*
- *Working with background images and movies in viewports*

Understanding viewports

Viewports are areas on the canvas where you can display models or analysis results. You can add arrow and text annotations to draw attention to or explain features within a viewport. You can create and manipulate viewports, text, and arrows using the **Viewport** menu.

In this section:

- *What is a viewport?*
- *What are arrow and text annotations?*

What is a viewport?

While the canvas can be thought of as an infinite screen or bulletin board, viewports are simply display areas posted onto that screen on which you can display models or analysis results. You can have many viewports on the canvas. A viewport is similar to other windows on your workstation in that it can be moved, resized, minimized, and maximized; and it can overlap other viewports on the canvas. For more information, see *Working with viewports*.

You can easily create and delete viewports and control their size, position, and appearance. *Figure 1* illustrates how you might use several viewports to view the results from your analysis.

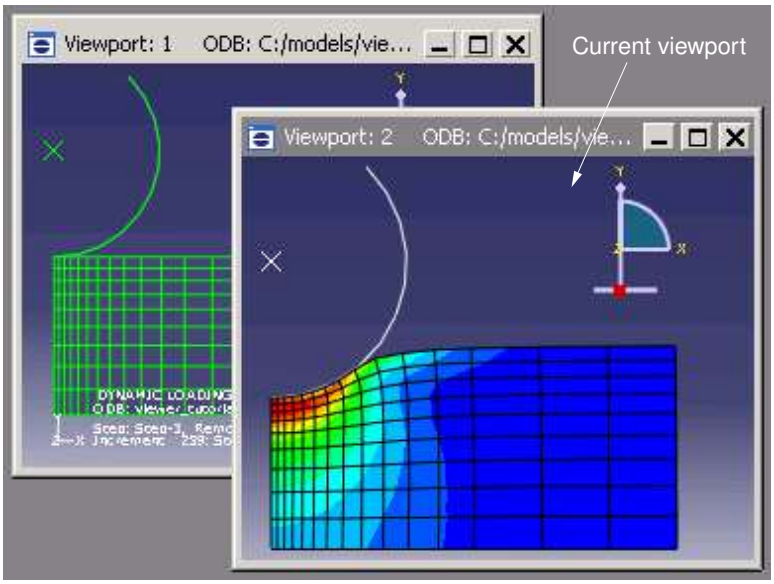

Figure 1: Working with multiple viewports.

The *view manipulation tools*, such as zoom and rotate, operate on the viewport that contains the cursor. Other operations interact with the current viewport or with all viewports on the canvas.

The current viewport

To change the contents of a viewport, you must first designate the desired viewport as current. The current viewport is indicated by a dark gray title bar. All work takes place within the current viewport. To choose another viewport as the current viewport, click on the border or title bar. The selected viewport moves in front of other viewports on the canvas, and the title bar color changes to blue. The title bar reverts to dark gray when you select an Abaqus/CAE tool or menu.

Note:

On Windows platforms you can customize the colors used by Abaqus/CAE. For more information, see *Common customizations on Windows platforms*.

All viewports are associated with a certain model and module. When you create a new model or open an existing model or output database, that model becomes associated with the current viewport. You can create different viewports and associate each one with a different model, so designating each viewport as current results in

switching between the associated models. Similarly, you can work in multiple modules simultaneously by designating a new viewport as current before entering a different module.

Additional information

• *Components of the main window*

What are arrow and text annotations?

Arrow and text annotations are arrows and text strings that you create in a viewport to enhance the appearance and clarity of displayed models or results. You can create arrow annotations and text annotations independently, and you can create arrows and text together to automatically position text at the end of an arrow. The positions of annotations in a viewport are controlled by anchor points. You define each anchor point based on viewport geometry or model coordinates; the method you choose determines how Abaqus/CAE moves the annotations. If you manipulate the viewport, Abaqus/CAE repositions any annotations anchored to viewport geometry; similarly, if you manipulate the model, Abaqus/CAE moves any annotations anchored to the model. *Figure 1* shows the use of arrows and text to describe details of a model.

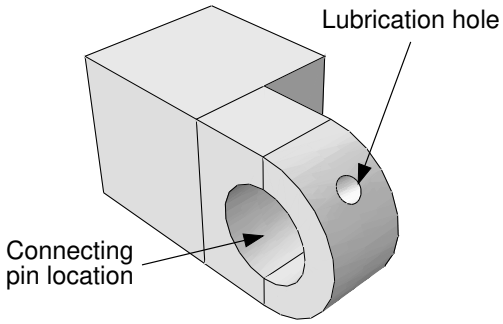

Figure 1: Arrow and text annotations.

Annotation editing operations require you to first select one or more annotations. Use the **Edit Annotations** tool from the **Viewport** toolbar to select arrow or text annotations from the current viewport. Abaqus/CAE highlights selected arrow or text annotations along with their anchor points, as shown in *Figure 2*.

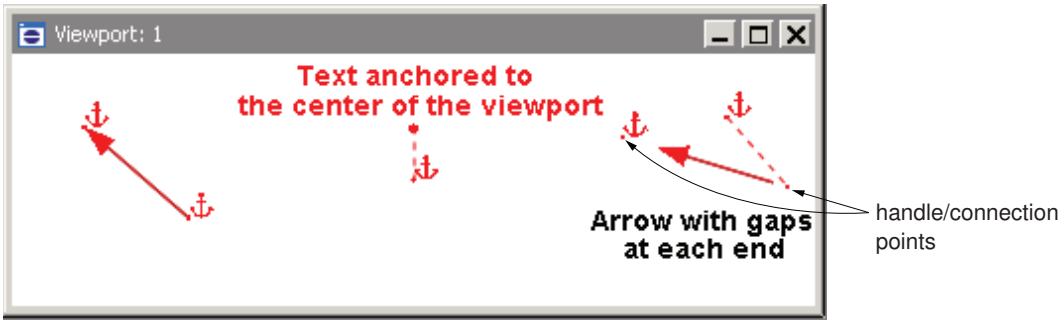

Figure 2: Selected annotations: an arrow with no offsets, text with an offset, and an arrow with gaps at both ends and an offset between the tail and its anchor point.

Anchor points are shown as a small dot with an anchor symbol placed nearby. Dashed lines indicate an offset between the anchor point and the annotation; circular “handles” are the anchor connection points—if there is no offset, the connection point and anchor point are the same.

Arrow annotations have two anchor points (you can use the same coordinates for both points). You can add a gap between the arrow ends and the connection points. Adding a gap is comparable to leaving a space between dimension lines and object lines in the Sketcher or in a CAD drawing; it can increase the clarity of your annotation. Text annotations have a single anchor point. You can change the offsets by dragging the connection points, or the entire annotation, in the viewport.

Do not confuse the viewport annotations that you can create with the viewport annotations generated by Abaqus/CAE. The generated viewport annotations include the view orientation triad; the 3D compass; and, in the Visualization module, the legend, the title block, and the state block. You can modify some display aspects of the generated annotations,

but you cannot modify their contents. For more information, see *Customizing viewport annotations*. In contrast, you have full control of all attributes related to arrow and text annotations including their colors, line styles, line thicknesses, arrowheads, fonts, anchor points, and any offsets between the anchor points and the annotations.

Abaqus/CAE saves arrow and text annotations in model and output databases; however, viewports are not saved. As a result, the arrow and text annotations in a database are not associated with a viewport. When you subsequently open a database that contains annotations, you must use the **Annotation Manager** to display a selected annotations in the current viewport. The **Annotation Manager** also allows you to copy annotations from a model database to an output database and vice versa. You cannot create annotations in a model database from the Visualization module; open the model database in a different module if you want to create annotations for it.

- *Working with viewports*
- *Working with viewport arrow and text annotations*

Manipulating viewports and viewport annotations

This section explains how to manipulate viewports and viewport annotations using the options provided in the **Viewport** menu, the **Viewport** toolbar, and the **Annotation Manager**.

In this section:

- *Managing viewports and viewport annotations from the main menu bar*
- *Managing viewports and viewport annotations from the Viewport toolbar*
- *The Annotation Manager*

Managing viewports and viewport annotations from the main menu bar

Use the **Viewport** menu, located on the main menu bar, to create, delete, modify, link, or rearrange viewports and to create or edit viewport annotations—both those that you create and those generated by Abaqus/CAE. If you prefer, you can select **View->Toolbars->Viewport** from the main menu bar to display a toolbar containing most of the functionality of the items in the **Viewport** menu.

The **Viewport** menu and toolbar allow you to do the following:

- *Create* a viewport.
- *Edit* options for generated viewport annotations (triad, legend, title block, and state block).
- Create an *arrow* annotation.
- Create a *text* annotation.
- Create a *combined arrow and text* annotation.
- Edit *arrow* and *text* annotations.
- Open the **Annotation Manager** to manipulate arrow and text annotations.

  Note:

  The **Annotation Manager** provides several unique management functions; for more information, see *The Annotation Manager*.

- Open the **Viewport Annotation Options** to show or hide all annotations and to manipulate the viewport annotations generated by Abaqus/CAE.
- *Link* viewports.

In addition, the **Viewport** menu lists all the viewports in the session and allows you to delete the current viewport.

Additional information

• *Managing viewports on the canvas*

Managing viewports and viewport annotations from the Viewport toolbar

To display the **Viewport** toolbar, + select **View**->**Toolbars**->**Viewport** from the main menu bar. *Figure 1* describes the tools available from the **Viewport** toolbar.

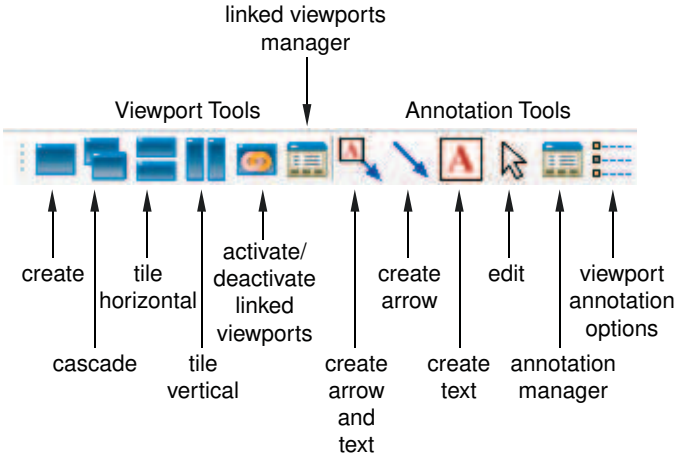

Figure 1: The Viewport toolbar.

Additional information

• *Managing viewports on the canvas*

The Annotation Manager

The **Annotation Manager** is similar to other manager dialog boxes in Abaqus/CAE. It allows you to do the following:

- Create *arrow*, *text*, or *combined arrow and text* annotations.
- Edit an *arrow* or *text* annotation.
- Copy or rename an annotation.
- Delete annotations.

In addition, the **Annotation Manager** allows you to perform the following tasks that are *not* available from the **Viewport** menu or toolbar:

- Select the source—model database (**MDB**) or output database (**ODB**)—of annotations to manage.
- Plot model database or output database annotations in the current viewport.
- Hide model database or output database annotations in the current viewport.
- Copy annotations from a model database to an output database and vice versa.
- Highlight annotations in the viewport.
- Rearrange the order of arrow and text annotations in the list.

You can display the **Annotation Manager** by selecting **Viewport->Annotation Manager** from the main menu bar or  in the **Viewport** toolbar. The **Annotation Manager** is shown in *Figure 1*.

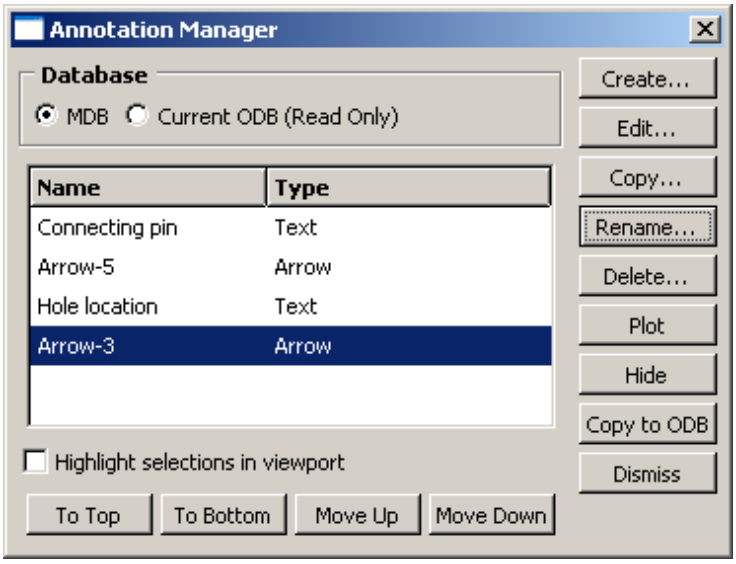

Figure 1: The Annotation Manager.

For detailed instructions on using the **Annotation Manager** to create, edit, and manipulate annotations, see the following sections :

- *Annotating viewports*
- *Editing arrow annotation attributes*
- *Editing text annotation attributes*
- *Plotting annotations in the current viewport*
- *Copying viewport annotations to another database*

- *Rearranging the annotation list order*

Additional information

- *Managing viewports on the canvas*

Displaying the drawing area in full screen mode

The drawing area is the visible portion of the canvas. You can display the drawing area in full screen mode. If you are in the Visualization module, the **Animation Controls** are available as a separate toolbar; otherwise, no menu bars or toolbars are accessible in full screen mode. To make a toolbar accessible in full screen mode, you can click and drag the toolbar's grip to “undock” the toolbar prior to switching modes.

1. From the main menu bar, select **View->Full Screen**.

   Tip: You can also press **[F11]** to toggle between full screen mode and normal mode.

   The drawing area enlarges to fill the entire screen.

2. Click the restore button in the title bar to return the drawing area to its previous size.

Additional information

• *Managing viewports on the canvas*

Working with viewports

This section explains how to create and manage viewports and how to modify their appearance.

In this section:

- *Creating new viewports*
- *Selecting viewports*
- *Moving viewports*
- *Resizing viewports*
- *Minimizing, maximizing, restoring, or deleting a viewport*
- *Cascading viewports*
- *Tiling viewports*

Creating new viewports

You can create new viewports at any time; there is no limit to the number of viewports or their position on the canvas.

From the main menu bar, select **Viewport->Create**.

Abaqus/CAE creates a new viewport in the drawing area. This viewport becomes the current viewport.

The new viewport size and position depend on the size of the current viewport and the drawing area. If the current viewport is maximized, Abaqus/CAE automatically maximizes the new viewport.

 **Tip:** You can also create a new viewport by clicking  in the **Viewport** toolbar.

Additional information

• *Managing viewports on the canvas*

Selecting viewports

Most of your interactions with the model—such as sketching a part, positioning a load, assembling part instances, generating a mesh, and customizing a plot state—take place in the current viewport. In addition, if you have multiple viewports displayed on the canvas, the current viewport indicates the model you are working on (the current model) and the module you are working in (the current module).

There are several ways that you can select a new viewport to be the current viewport:

- Click on the border or title bar of an existing viewport.
- Select an existing viewport from the list in the **Viewport** menu.
- Use **[Ctrl][Tab]**—or select **Next** or **Previous** from the **Viewport** menu—to cycle through all the viewports on the canvas.

  Note:

  On Linux platforms **[Ctrl][Tab]** is used to switch applications; **[Ctrl][F6]** is an alternative keyboard shortcut.

- Create a new viewport.

The current viewport has a dark gray title bar as shown in the following figure:

1. Move the cursor onto the border of the viewport.

   If the viewport is hidden, you may need to move other viewports to expose the one you want to select. For more information, see *Moving viewports*.

2. Click mouse button 1.

   The viewport becomes the current viewport; the viewport also becomes selected and its title bar changes to blue to indicate that it is the selected viewport. If you click on a tool or menu, the viewport remains current but the title bar reverts to dark gray.

   Note:

   On Windows platforms you can customize the colors used by Abaqus/CAE. For more information, see *Common customizations on Windows platforms*.

Additional information

- *Cascading viewports*
- *Tiling viewports*
- *Managing viewports on the canvas*

Moving viewports

You can move a selected viewport to any location on the canvas. This may be necessary to expose hidden viewports or simply to reduce clutter in the drawing area. To move a viewport, click anywhere on the viewport title bar and then drag it to the desired position.

1. Place the cursor anywhere on the viewport title bar.
2. Click mouse button 1, and + drag the cursor to the new location.

   The cursor changes to a four-headed arrow  . An outline of the viewport indicates its new position as you drag.
3. Release mouse button 1.

   The viewport moves to the new location, and it becomes the current viewport (if it was not previously).

Additional information

- *Selecting viewports*
- *Managing viewports on the canvas*

Resizing viewports

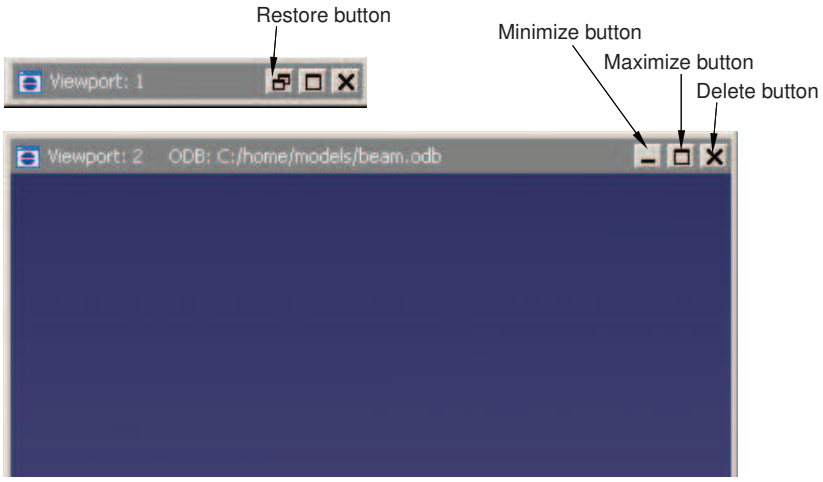
You can change the size and shape of a viewport by dragging its borders.

1. Place the cursor anywhere on the viewport border that you want to move.

   The cursor changes to a set of opposing arrows. The direction of the arrows is dependent on the relative position between the cursor and the viewport.

2. Click mouse button 1, and + drag the cursor to change the position of the borders.
3. Release mouse button 1.

   The viewport is displayed with the new size, and it becomes the current viewport (if it was not previously).



Additional information

- *Selecting viewports*
- *Managing viewports on the canvas*

Minimizing, maximizing, restoring, or deleting a viewport

Minimize, maximize, restore, and delete buttons are located in the top right corner of each viewport.

These buttons appear as shown in the following figure:

If necessary, **Tile** or **Cascade** viewports to reveal the minimize, maximize, restore, and delete buttons.

The minimize button

When you click the minimize button, the viewport reduces to an abbreviated title bar in a default location toward the lower left of the drawing area. The minimize button changes to a restore button that is retained, along with the maximize and delete buttons, in the title bar. If you move a minimized viewport, the new location will be saved as its minimized location for the duration of the Abaqus/CAE session.

The maximize button

When you click the maximize button, the viewport changes size and position to fill the canvas. The maximize button changes to a restore button and is moved, along with the minimize and delete buttons, to the right side of the main menu bar. The maximized viewport becomes the current viewport and is moved to the front of the canvas, hiding any other viewports in the drawing area. The information in the viewport title bar is displayed in the Abaqus/CAE title bar.

The delete button

When you click the delete button or select **Viewport->Delete Current** from the main menu bar, the viewport is deleted from the canvas. You cannot restore a deleted viewport. If there is only one viewport on the canvas, Abaqus/CAE does not allow you to delete it. If you have created additional viewports on the canvas, Abaqus/CAE deletes the current viewport and selects one of the other viewports to be the current viewport. You cannot control which viewport Abaqus/CAE selects to be current.

The restore button

The restore button replaces either the minimize button or maximize button, whichever you used most recently. When you click the restore button, Abaqus/CAE returns the viewport to its previous size and location. The restore

button reverts to the minimize or maximize button that it had replaced. The restored viewport becomes the current viewport and is moved to the front of the canvas, hiding any other viewports in the drawing area.

Additional information

- *Working with viewports*
- *Managing viewports on the canvas*

Cascading viewports

You can arrange the viewports on the canvas in a cascading pattern. This may be useful to expose hidden viewports or simply to reduce clutter in the drawing area. Abaqus/CAE arranges the viewports so that the title bars are visible but the contents may be hidden by another viewport.

1. Use the **Minimize** button in the upper right corner of a viewport to minimize any viewports that you do not want to cascade.
2. From the main menu bar, select **Viewport->Cascade**.

   Abaqus/CAE sets all the non-minimized viewports to the same size and arranges them from the upper left corner toward the lower right corner of the drawing area. The current viewport is always positioned at the front of the canvas; all other viewports are arranged in numerical order. Minimized viewports are positioned in front of any cascaded viewports except the current viewport.

Tip: You can also cascade non-minimized viewports by clicking  in the **Viewport** toolbar.

Additional information

- *Minimizing, maximizing, restoring, or deleting a viewport*
- *Managing viewports on the canvas*

Tiling viewports

You can arrange the viewports on the canvas in a tile pattern. This may be useful to expose hidden viewports or simply to reduce clutter in the drawing area. Abaqus/CAE arranges the viewports so that the contents are visible but parts of the title bars may be hidden.

1. Use the **Minimize** button in the upper right corner of a viewport to minimize any viewports that you do not want to tile.
2. Do one of the following:

   - From the main menu bar, select**Viewport**->**Tile Horizontally** to tile the viewports while retaining the largest possible horizontal dimension.
   - From the main menu bar, select**Viewport**->**Tile Vertically** to tile the viewports while retaining the largest possible vertical dimension.

   Abaqus/CAE sets all the non-minimized viewports to the same size and arranges them to fill the drawing area. All tiled viewports are arranged in numerical order. Minimized viewports are positioned in front of any tiled viewports except the current viewport.

Tip: You can also tile non-minimized viewports by clicking  or  in the **Viewport** toolbar.

Additional information

• *Managing viewports on the canvas*

Working with viewport arrow and text annotations

This section explains how to create, modify, and manage arrow and text annotations.

In this section:

- *Annotating viewports*
- *Creating an arrow annotation*
- *Creating a text annotation*
- *Creating combined arrow and text annotations*
- *Manipulating annotations in the current viewport*
- *Editing arrow annotation attributes*
- *Editing text annotation attributes*
- *Plotting annotations in the current viewport*
- *Hiding annotations in the current viewport*
- *Copying viewport annotations to another database*
- *Rearranging the annotation list order*

Annotating viewports

Abaqus/CAE provides three types of viewport annotations that you can use to annotate models or results: text strings, arrows, and a combination arrow and text annotation. You use the **Viewport** menu to create these annotations, and you can position them anywhere on the viewport. *Figure 1* shows text strings and arrows used to annotate a model. Arrow and text annotations are anchored to points in the viewport. The anchor points define the position of the annotation with respect to either the viewport size and shape or a point in the model coordinates. When you manipulate the model or resize the viewport, the annotations follow the position of their anchor points.

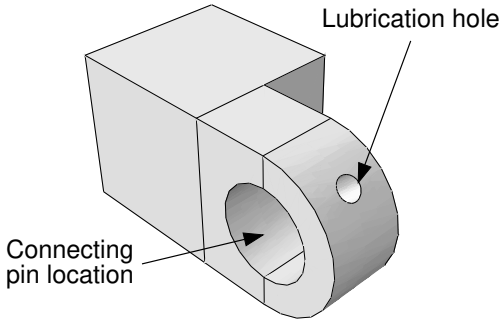


Figure 1: Arrow and text annotations.

Viewport arrow and text annotations are saved with the model database or with the output database when you exit the Abaqus/CAE session. You can also copy annotations from a model to an output database and vice versa.

Warning: You can always create or copy annotations to an output database; however, you can save them only if you opened the database with write privileges.

Text

Text annotations can consist of any characters that can be displayed using the fonts available on your workstation. Abaqus/CAE does not restrict the length or number of text lines in an annotation. However, you must take the size of the viewport into consideration when creating text annotations; the text should fit in the desired viewport location. You can place text anywhere on the viewport, and you can move a text annotation or change its anchor point after you have created it. Each text annotation can be displayed using different fonts, colors, and backgrounds, but you cannot change these attributes within a single text annotation.

Arrows

You can create arrows anywhere in the viewport; typically, an arrow will connect a text annotation to a point in model coordinates. Arrows can have one of several different line thicknesses, line styles, and endpoint styles and can be displayed in any color available on your workstation. You can use one or two anchor points to control the position of an arrow annotation. For example, you can anchor the arrowhead to a point on the model and the tail to a viewport location so that when the model is manipulated the arrow still points to the desired feature but the tail is stationary. You can modify and move an arrow after you have created it.

Arrow and text combination

You can create a combined arrow and text annotation. This method uses a reduced set of options to create an arrow annotation, anchored at the arrowhead, with a text annotation positioned at the arrow's tail. This creation method is provided to simplify the addition of information about specific parts of a model or results. You cannot edit the annotations' position during creation, except by using the **Previous** button ( ) in the prompt area.

However, once you create them, the arrow and text are saved independently; so you can edit them using all the options available for each annotation type.

In addition to the viewport annotations that you can create, Abaqus/CAE generates some annotations to provide the context of the view in a viewport. Abaqus/CAE generates the 3D compass and the view triad to show the orientation of the model in the viewport; in the Visualization module the legend, the title block, and the state block are generated to indicate various aspects of the analysis results in the viewport. The **Viewport Annotation Options** dialog box allows you to show or hide all viewport annotations—yours and those generated by Abaqus/CAE—you can also use it to edit the attributes of the generated annotations. For more information, see *Customizing viewport annotations*.

Additional information

- *What are arrow and text annotations?*
- *Creating an arrow annotation*
- *Creating a text annotation*
- *Creating combined arrow and text annotations*
- *Customizing viewport annotations*

Creating an arrow annotation

You can create an arrow to help annotate the contents of a viewport, and you can place the arrow anywhere on the viewport. Typically, you would use a *combined arrow and text annotation* to connect a text annotation to an object in a viewport, but you may want to add individual arrows if a text annotation applies to multiple locations or if you want full control over the anchor points and position without editing the arrow after you create it.

1. From the main menu bar, select **Viewport->Create Annotation->Arrow**.

   Tip: You can also create an arrow annotation by clicking  in the ***Viewport*** *toolbar*.

   An anchor symbol appears in the viewport. The default anchor point changes as you create new annotations in the session. If this is the first arrow annotation, the anchor point is in the lower left corner of the viewport.

2. If desired, click **Change Anchor** in the prompt area and do one of the following:

   - Choose a new anchor point in the viewport.
   - Select a viewport corner or center point from the list in the prompt area.
   - Click **Pick From Model** in the prompt area, and select a node or vertex or enter the coordinates of the desired anchor point.

     Note:

     If you anchor an annotation to a node or vertex, Abaqus/CAE uses the model coordinates of the selected point; the annotation will not follow model deformation in the Visualization module.

3. Choose one of the following options to position the endpoint of the arrow:

   - To position the endpoint on the current anchor point, click **On Anchor** in the prompt area.
   - To position the endpoint anywhere on the viewport, move the cursor to the desired position, and + click mouse button 1.

   By default, Abaqus/CAE creates an arrowhead at the first endpoint; the second endpoint does not have a symbol.

4. Repeat Steps 2 and 3 to anchor and position the second endpoint of the arrow annotation.

   Abaqus/CAE opens an **Arrow Editor** dialog box.

5. Complete the information in the **Arrow Editor** dialog box to finalize the arrow annotation.

   For more information, see *Editing arrow annotation attributes*.

6. Click **Preview** to view your changes in the viewport.
7. To finish creating your arrow annotation, click **OK**.

   Abaqus/CAE updates your changes in the viewport, closes the editor, and begins creating another arrow annotation starting at Step 2.

8. To stop creating arrow annotations, click mouse button 2 in the viewport or the  button in the prompt area.

Additional information

- *What are arrow and text annotations?*
- *The Annotation Manager*
- *Manipulating annotations in the current viewport*
- *Editing arrow annotation attributes*

Creating a text annotation

You can create one or more lines of text to annotate the contents of a viewport and place them anywhere on the viewport. Typically, you would use a *combined arrow and text annotation* to connect a text annotation to an object in a viewport, but you may also add text annotations to provide a title or other general information that applies to the entire model or results in the viewport.

1. From the main menu bar, select **Viewport->Create Annotation->Text**.

   Tip: You can also create a text annotation by clicking  in the ***Viewport*** *toolbar*.

   An anchor symbol appears in the viewport with the annotation `Text-n`. The default anchor point changes as you create new annotations in the session. If this is the first text annotation, the anchor point is in the lower left corner of the viewport.

2. If desired, click **Change Anchor** in the prompt area and do one of the following:

   - Choose a new anchor point in the viewport.
   - Select a viewport corner or center point from the list in the prompt area.
   - Click **Pick From Model** in the prompt area, and select a node or vertex or enter the coordinates of the desired anchor point.

     Note:

     If you anchor an annotation to a node or vertex, Abaqus/CAE uses the model coordinates of the selected point; the annotation will not follow model deformation in the Visualization module.

3. Choose one of the following options to position the text annotation in the viewport:

   - To position the text on the current anchor point, click **On Anchor** in the prompt area.
   - To position the text anywhere on the viewport, move the cursor to the desired position, and + click mouse button 1.

   Abaqus/CAE opens a **Text Editor** dialog box.

4. Complete the information in the **Text Editor** dialog box to finalize the text annotation.

   For more information, see *Editing text annotation attributes*.

5. Click **Preview** to view your changes in the viewport.
6. To finish creating your text annotation, click **OK**.

   Abaqus/CAE updates your changes in the viewport, closes the editor, and begins creating another text annotation starting at Step 2.

7. To stop creating text annotations, click mouse button 2 in the viewport or the  button in the prompt area.

Additional information

- *What are arrow and text annotations?*
- *The Annotation Manager*
- *Manipulating annotations in the current viewport*

- *Editing text annotation attributes*

Creating combined arrow and text annotations

You can create an arrow and a text annotation at the same time to relate the text to a particular feature or result in the viewport.
This method creates an arrow annotation with the anchor point at the arrowhead and a separate text annotation anchored at the same location and positioned at the arrow's tail. During creation, your annotation options are limited; for example, you cannot offset the arrowhead from the anchor point or select a second anchor point for the tail of the arrow (the text position).

Once you create them, Abaqus/CAE saves the arrow and text annotations independently so that you can edit them using all the options available for each annotation type as described in *Editing arrow annotation attributes*, and, *Editing text annotation attributes*, respectively. Since they are not linked, you can also move the arrow and text independently.

Tip: To move an arrow and text annotation while keeping the same relative positions, select both annotations and position the text in the desired location, then select only the arrow to edit the arrowhead position.

Additional information

- *What are arrow and text annotations?*
- *Manipulating annotations in the current viewport*

Create combined arrow and text annotations

1. From the main menu bar, select **Viewport->Create Annotation->Arrow & Text**.

   Tip: You can also create an arrow and text annotation by clicking in the ***Viewport*** *toolbar*.

2. Select the arrow target by choosing a model node or vertex in the viewport or entering model coordinates in the prompt area.

   Abaqus/CAE displays the anchor symbol and arrowhead at the selected point and the default text string `Text-n` appears at the cursor position.

3. Position the text on the viewport; move the cursor to the desired text position and click mouse button 1.

   Abaqus/CAE displays the **Arrow & Text Editor** dialog box.

4. Complete the information in the **Arrow & Text Editor** dialog box to finalize both annotations.

   Click **Preview** at any time to see your changes in the viewport; click **OK** to save the arrow and text annotations and to close the **Arrow & Text Editor**.

Edit the text

1. Click the **Text** tab in the **Arrow & Text Editor**, if it is not already selected.
2. To display or suppress a box outlining the text, toggle **Show bounding box**. The bounding box visually separates the text from the underlying model or results.
3. Type the desired text.

   When typing a text annotation, you can use standard mouse and keyboard editing techniques such as backspace, copy, and paste; press **[Enter]** to start a new line.

4. To customize the background, click one of the following:

   - **Match viewport** to match the background to the viewport color.
   - **Transparent** to eliminate the background and show only the text.

- **Other color** to reveal other background color options.

If you selected **Other color**:

a. Click the color sample .

Abaqus/CAE displays the **Select Color** dialog box.

b. Use one of the methods in the **Select Color** dialog box to select a new color. For more information, see *Customizing colors*.

c. Click **OK** to close the **Select Color** dialog box.

The color sample changes to the selected color.

5. Customize the text font.

a. Click **Set Font**.

The **Select Font** dialog box appears.

b. Use the **Select Font** dialog box to choose the font characteristics you want. For more information, see *Customizing fonts*.

c. When you are done, click **OK** to implement your changes and to close the **Select Font** dialog box.

6. Choose the text color.

a. Click the color sample .

Abaqus/CAE displays the **Select Color** dialog box.

b. Use one of the methods in the dialog box to select a new color. For more information, see *Customizing colors*.

c. Click **OK** to close the **Select Color** dialog box.

The color sample changes to the selected color.

7. Choose **Left**, **Center**, or **Right** justification to arrange the text within the bounding box area.

Edit the arrow

1. Click the **Arrow** tab in the **Arrow & Text Editor**, if it is not already selected.

2. Select the desired line style; you can choose a solid line or several styles of dashed line for your arrow.

3. Select the desired line thickness.

Note:

Changing the line thickness also changes the size of the arrowheads.

4. Select the desired arrowhead symbol.

5. Choose the arrow color.

a. Click the color sample .

Abaqus/CAE displays the **Select Color** dialog box.

b. Use one of the methods in the dialog box to select a new color. For more information, see *Customizing colors*.

c. Click **OK** to close the **Select Color** dialog box.

The color sample changes to the selected color.

Manipulating annotations in the current viewport

To manipulate viewport arrow and text annotations, you must first select them. Use **Viewport->Edit Annotations** from the main menu bar to select arrow or text annotations from the current viewport.

Note:

To manipulate the viewport annotations generated by Abaqus/CAE, use the **Viewport Annotations Options** dialog box (for more information, see *Customizing viewport annotations*").

You can move, copy, edit, hide, or delete the selected annotations. You can also rearrange the order that Abaqus/CAE uses to display annotations; the order determines which annotation will be "in front" if viewport or model manipulations cause more than one annotation to appear in the same location.

1. From the main menu bar, select **Viewport->Edit Annotations**.

   Tip: You can also edit an annotation by clicking  in the ***Viewport*** *toolbar*.

2. Click an arrow or text annotation to select it. To select additional annotations, **[Shift] + Click** instead of clicking. For more information, see *Selecting objects within the current viewport*.

   Abaqus/CAE highlights the selected annotations and their anchor points. Circular handles are the anchor connection points; they appear near each end of a selected arrow and at the reference point of a selected text annotation. Dashed lines indicate an offset between the anchors and the handles.

3. Do one of the following:

To move or copy annotations:

If you selected text or multiple annotations, drag your selection to move it around the viewport. Press **[Ctrl]** before releasing mouse button 1 to copy the annotations instead of moving them. If you selected a single arrow annotation, drag the arrow shaft to move the arrow. You can drag annotations anywhere on the viewport, even outside the viewable area. Moving or copying annotations in the viewport does not change their anchor points.

To move or copy the ends of an arrow annotation:

If you selected a single arrow annotation, notice that the circular handles are larger than when you select multiple annotations; this indicates that you can move each end of the arrow independently. Drag one of the circular handles to lengthen, reduce, or reorient the arrow. Press **[Ctrl]** before releasing mouse button 1 to create radial copies of the arrow instead of moving it. You can drag the endpoint anywhere on the viewport, even outside the viewable area. Moving or copying an arrow by dragging an endpoint does not change the arrow's anchor points.

To edit an annotation:

Double-click an arrow or text annotation to open the **Arrow Editor** or **Text Editor** dialog box, respectively. If you prefer, you can also click mouse button 3 and select **Edit** from the popup menu.

- For an arrow annotation you can change the line style, line weight, or color; and you can change the offset, arrowhead style, and anchor point for each end of the arrow, as well as add a gap between the handle positions and the arrow endpoints. For more information, see *Editing arrow annotation attributes*.

- For a text annotation you can edit the text; show or hide a box around the text; change the background color, font, font color, justification, and rotation; or change the reference point, anchor point, and offset. For more information, see *Editing text annotation attributes*.

To hide selected annotations:

Click mouse button 3, and select **Hide** from the menu that appears.

Abaqus/CAE removes the selected annotations from the current viewport. To show the annotations again, you can plot them from the ***Annotation Manager***. You can also hide or plot annotations by selecting them in the Model Tree, clicking mouse button 3, and selecting the desired option from the menu that appears.

To delete selected annotations:

Press `Backspace` or `Delete`. Abaqus/CAE displays a warning dialog box; click **Yes** to delete the annotations.

Abaqus/CAE deletes the selected annotations from both the current viewport and the associated database.

To rearrange the display order of annotations:

By default, Abaqus/CAE displays viewport annotations in the order that they are created or plotted in the viewport; the last annotation created or plotted will appear in front of any preexisting annotations. Changes in the display order will not affect the current view unless two or more annotations appear in the same location. All viewport annotations are displayed in front of the model.

Click mouse button 3, and select **Bring to Front**, **Send to Back**, **Bring Forward**, or **Send Backward** from the popup menu to change the display order. Alternatively, to move a single annotation to the front, plot it again from the ***Annotation Manager***.

Additional information

- *What are arrow and text annotations?*
- *The Annotation Manager*

Editing arrow annotation attributes

You can change the following attributes of arrow annotations:

- Name (use the **Annotation Manager** to rename existing annotations).
- Line thickness and line style.
- Color.
- Anchor point and offset for each end.
- Endpoint style.
- Gap between the endpoint and the arrowhead or tail position.

If you are creating a new annotation, Abaqus/CAE applies many of your customizations not only to the current annotation but also to any new annotations you subsequently create. If you are editing an existing annotation, Abaqus/CAE applies your changes only to the selected annotation.

You can also copy an arrow annotation and its attributes and edit them to create a new arrow annotation. For more information, see *The Annotation Manager*.

1. Use one of the following methods to access the **Arrow Editor** dialog box:
   - Select an arrow annotation from the **Annotation Manager**, and click **Edit**.
   - Select **Viewport->Edit Annotations** or  in the ***Viewport** toolbar*, and double-click an arrow annotation in the viewport.
   - Create a new arrow annotation in the viewport; Abaqus/CAE opens the editor after you select the endpoints in the viewport.
2. If you are creating a new annotation, you can edit the name of the arrow.
3. Select the desired line style; you can choose a solid line or several styles of dashed line for your arrow.
4. Select the desired line thickness.

    **Note:**

   Changing the line thickness also changes the size of the arrowheads.

5. Choose the arrow color.
   a. Click the color sample .

      Abaqus/CAE displays the **Select Color** dialog box.
   b. Use one of the methods in the dialog box to select a new color. For more information, see *Customizing colors*.
   c. Click **OK** to close the **Select Color** dialog box.

      The color sample changes to the selected color.
6. Click the **Start Point** tab or the **End Point** tab.

   Abaqus/CAE highlights the selected point and its anchor point in the viewport.
7. Select a new anchor point; the following methods are available:

    **Tip:** To avoid changing the position of the annotation, use the **Pick Anchor** button to change the anchor point and recalculate the **Offset** between the anchor point and the annotation.

Predefined

Select this method to anchor the annotation to a predefined point of viewport geometry. The available points are the viewport corners, the center, and the midpoint of each edge. The anchor point definition changes if you modify the viewport shape.

% Viewport X, Y

Select this method to anchor your annotation to a point based on the position of the lower left viewport corner and the viewport size. Enter the anchor point as a percentage of the total width and height of the current viewport. As with the **Predefined** method, the anchor point definition changes if you modify the viewport shape.

Model point X, Y, Z

Select this method to anchor your annotation to a point on the model. Enter the model coordinates of the new anchor point in the text field. The anchor point definition, and any annotation linked to it, changes if you manipulate the model. For example, if you rotate the model in the viewport, the anchor point and the arrow endpoint will rotate with it.

Pick Anchor button

Select this method to change the anchor point without changing the current position of the annotation.

Abaqus/CAE hides the **Arrow Editor** dialog box and prompts you to select a point from the viewport. Alternatively, you can pick one of the predefined viewport points from the list in the prompt area or click **Pick From Model** to pick a model node or vertex from the viewport or to enter the coordinates of a model point in the prompt area.

Each selection type corresponds to one of the preceding anchor point selection methods. After you make your selection, the **Arrow Editor** dialog box reappears with your selection indicated in the appropriate anchor selection method and the offset value recalculated for the new anchor point.

8. Enter new *X*- and *Y*-values to change the **Offset**, in millimeters, between the endpoint and its anchor point.

   Note:

   After you close the **Arrow Editor**, you can also change the **Offset** by dragging each endpoint, or the entire arrow, in the viewport. For more information, see *Manipulating annotations in the current viewport*.

9. Select the desired arrowhead symbol.

   The defaults are a plain line for the **Start Point** and a filled arrow for the **End Point**.

10. If desired, add a **Gap** between the endpoint position and the start or end of the arrow annotation. Adding a gap is comparable to leaving a space between dimension lines and object lines in the Sketcher or in a CAD drawing; it can increase the clarity of your annotation. For example, you can indicate a specific point on a model and add a gap so that the arrowhead does not obscure the point.
11. Repeat Steps 7–10 to edit the remaining endpoint of the arrow.
12. Click **Apply** to see your changes in the viewport.

Note:

Once you have applied your changes in the viewport, you cannot recover the original settings except by recreating the annotation or editing the options again.

13. Click **OK** to close the **Arrow Editor**.

Additional information

- *What are arrow and text annotations?*
- *The Annotation Manager*

Editing text annotation attributes

You can change the following attributes of text annotations:

- Name (use the **Annotation Manager** to rename existing annotations).
- Bounding box display.
- Background color.
- Font style and color.
- Justification.
- Rotation angle.
- Reference point location and offset.
- Anchor point location.

If you are creating a new annotation, Abaqus/CAE applies many of your customizations not only to the current annotation but also to any new annotations you subsequently create. If you are editing an existing annotation, Abaqus/CAE applies your changes only to the selected annotation.

You can also copy a text annotation and its attributes and edit them to create a new text annotation. For more information, see *The Annotation Manager*.

1. Use one of the following methods to access the **Text Editor** dialog box:
   - Select a text annotation from the **Annotation Manager**, and click **Edit**.
   - Select **Viewport->Edit Annotations** or  in the ***Viewport** toolbar*, and double-click a text annotation in the viewport.
   - Create a new text annotation in the viewport; Abaqus/CAE opens the editor after you select the text position in the viewport.
2. If you are creating a new annotation, you can edit the name of the text annotation.
3. To display or suppress a box outlining the text, toggle **Show bounding box**. The bounding box visually separates the text from the underlying model or results.
4. Type the desired text.

   When typing a text annotation, you can use standard mouse and keyboard editing techniques such as backspace, copy, and paste; press **[Enter]** to start a new line.
5. To customize the background, click one of the following:
   - **Match viewport** to match the background to the viewport color.
   - **Transparent** to eliminate the background and show only the text.
   - **Other color** to reveal other background color options.

   If you selected **Other color**:

   a. Click the color sample .

   Abaqus/CAE displays the **Select Color** dialog box.

   b. Use one of the methods in the **Select Color** dialog box to select a new color. For more information, see *Customizing colors*.

   c. Click **OK** to close the **Select Color** dialog box.

   The color sample changes to the selected color.

6. Customize the text font.
   a. Click **Set Font**.

      The **Select Font** dialog box appears.

   b. Use the **Select Font** dialog box to choose the font characteristics you want. For more information, see *Customizing fonts*.
   c. When you are done, click **OK** to implement your changes and to close the **Select Font** dialog box.
7. Choose the text color.
   a. Click the color sample .

      Abaqus/CAE displays the **Select Color** dialog box.

   b. Use one of the methods in the dialog box to select a new color. For more information, see *Customizing colors*.
   c. Click **OK** to close the **Select Color** dialog box.

      The color sample changes to the selected color.
8. Choose **Left**, **Center**, or **Right** justification to arrange the text within the bounding box area.
9. Enter a rotation angle (in degrees) to orient the text; 0° is horizontal.

   Abaqus/CAE rotates the text counterclockwise about the **Reference Point**.
10. Click the **Location** tab.
11. Select a new **Reference Point**.

    The reference point is the point where a text annotation is attached to its anchor point; Abaqus/CAE also uses the reference point as the center of rotation if you rotate the text. The following methods are available:

Predefined

Select this method to use a predefined point of the text bounding box geometry as the reference point. The available points are the bounding box corners, the center, and the midpoint of each edge. The definition of the reference point changes if you modify the annotation text.

% Text X, Y

Select this method to define the reference point based on the position of the lower left bounding box corner and the bounding box size. Enter the reference point as a percentage of the total width and height of the text bounding box. As with the **Predefined** method, the reference point definition changes if you modify the text.

Note:

Abaqus/CAE determines the lower left corner position based on a 0° rotation angle. If you rotate the text, the corner position is also rotated accordingly.

Tip: You can select a reference point outside of the bounding box by entering values less than 0% or greater than 100%.

12. Enter new *X*- and *Y*-values to change the **Offset**, in millimeters, between the reference point and the anchor point.

Note:

After you close the **Text Editor**, you can also change the offset by dragging the text annotation in the viewport. For more information, see *Manipulating annotations in the current viewport*.

13. Select a new anchor point; the following methods are available:

Tip: To avoid changing the position of the annotation, use the **Pick Anchor** button to change the anchor point and recalculate the **Offset** between the anchor point and the annotation.

Predefined

Select this method to anchor the annotation to a predefined point of viewport geometry. The available points are the viewport corners, the midpoint of each edge, and the center of the viewport. The anchor point definition changes if you modify the viewport shape.

% Viewport X, Y

Select this method to anchor your annotation to a point based on the position of the lower left viewport corner and the viewport size. Enter the anchor point as a percentage of the total width and height of the current viewport. As with the **Predefined** method, the anchor point definition changes if you modify the viewport shape.

Model point X, Y, Z

Select this method to anchor your annotation to a point on the model. Enter the model coordinates of the new anchor point in the text field. The anchor point definition, and any annotation linked to it, changes if you manipulate the model. For example, if you rotate the model in the viewport, the anchor point and the arrow endpoint will rotate with it.

Pick Anchor button

Select this method to change the anchor point without changing the current position of the annotation.

Abaqus/CAE hides the **Arrow Editor** dialog box and prompts you to select a point from the viewport. Alternatively, you can pick one of the predefined viewport points from the list in the prompt area or click **Pick From Model** to pick a model node or vertex from the viewport or to enter the coordinates of a model point in the prompt area.

Each selection type corresponds to one of the preceding anchor point selection methods. After you make your selection, the **Text Editor** dialog box reappears with your selection indicated in the appropriate anchor selection method and the offset value recalculated for the new anchor point.

14. Click **Apply** to see your changes in the viewport.

Note:

Once you have applied your changes in the viewport, you cannot recover the original settings except by recreating the annotation or editing the options again.

15. Click **OK** to close the **Text Editor**.

Additional information

- *What are arrow and text annotations?*
- *The Annotation Manager*

Plotting annotations in the current viewport

When you open a database that contains saved viewport annotations or create a new viewport for an open database, Abaqus/CAE does not automatically display your viewport arrow or text annotations. You can use the **Annotation Manager** to plot arrow and text annotations in the current viewport; you can also select the annotations in the Model Tree, click mouse button 3, and select **Plot** from the menu that appears.

Annotations generated by Abaqus/CAE are displayed according to the settings in the **Viewport Annotation Options** dialog box (for more information, see *Customizing viewport annotations*").

1. From the main menu bar, select **Viewport->Annotation Manager**.

   Tip: You can also display the **Annotation Manager** dialog box by clicking  from the ***Viewport*** *toolbar*.

2. Click the **MDB** or **ODB** radio button to select the source of the annotations to be plotted.
   a. If you have more than one output database open or are otherwise uncertain of the database files involved, position the cursor over the **MDB** or **ODB** radio button to display a tooltip containing the database path and file name.
   b. If necessary, change the active output database by displaying the desired database in the current viewport. Alternatively, you can open a new viewport to display the database or close all the other output databases.

   Abaqus/CAE lists the annotations available in the selected database.

3. Select annotations from the list in the dialog box (for more information, see *Selecting multiple items from lists and tables*).

   Tip: Toggle on **Highlight selections in viewport** to preview the selected annotations.

4. Click **Plot**.

   Abaqus/CAE plots the selected annotations in the current viewport.

Additional information

- *What are arrow and text annotations?*
- *The Annotation Manager*

Hiding annotations in the current viewport

If there are arrow and text annotations obscuring the model view in the viewport, you can use the **Annotation Manager** to hide them.

Annotations generated by Abaqus/CAE are displayed according to the settings in the **Viewport Annotation Options** dialog box (for more information, see *Customizing viewport annotations*").

1. From the main menu bar, select **Viewport->Annotation Manager**.

   Tip: You can also display the **Annotation Manager** dialog box by clicking  from the ***Viewport*** *toolbar*.

2. Click the **MDB** or **ODB** radio button to select the source of the annotations to be hidden.
   a. If you have more than one output database open or are otherwise uncertain of the database files involved, position the cursor over the **MDB** or **ODB** radio button to display a tooltip containing the database path and file name.
   b. If necessary, change the active output database by displaying the desired database in the current viewport. Alternatively, you can open a new viewport to display the database or close all the other output databases.

   Abaqus/CAE lists the annotations available in the selected database.

3. Select annotations from the list in the dialog box (for more information, see *Selecting multiple items from lists and tables*).

   Tip: Toggle on **Highlight selections in viewport** to preview the selected annotations.

4. Click **Hide**.

   Abaqus/CAE hides the selected annotations in the current viewport.

Additional information

- *What are arrow and text annotations?*
- *The Annotation Manager*

Copying viewport annotations to another database

You can copy viewport annotations that you created from a model database (**MDB**) to an output database (**ODB**), and vice versa. You cannot copy annotations from one output database to another. Annotations generated by Abaqus/CAE contain model- and results-specific information; this information is automatically available in every database and cannot be copied (for more information, see *Customizing viewport annotations*").

1. From the main menu bar, select **File->Open** to open the desired model database and output database (`.cae` and `.odb`) file.

   Note:

   You do not need to have write privileges for the database files to copy annotations; however, if you do not have write privileges, you cannot save the copied annotations.

2. From the main menu bar, select **Viewport->Annotation Manager**.

   Tip: You can also display the **Annotation Manager** by clicking from the ***Viewport** toolbar*.

3. Click the **MDB** or **ODB** radio button to select the source of the annotations to be copied.
   a. If you have more than one output database open or are otherwise uncertain of the database files involved, position the cursor over the **MDB** or **ODB** radio button to display a tooltip containing the database path and file name.
   b. If necessary, change the active output database by displaying the desired database in the current viewport. Alternatively, you can open a new viewport to display the database or close all the other output databases.

   Abaqus/CAE lists the annotations available in the selected database.

4. Select annotations from the list in the dialog box (for more information, see *Selecting multiple items from lists and tables*).

   Tip: Toggle on **Highlight selections in viewport** to preview the selected annotations.

5. Click the **Copy to MDB** or **Copy to ODB** button.

   Abaqus/CAE copies the selected annotations.

Additional information

- *What are arrow and text annotations?*
- *The Annotation Manager*

Rearranging the annotation list order

You can change the order of viewport annotations in the **Annotation Manager** list. Changing the order allows you to keep related annotations—such as text and an arrow that annotate the same area—together in the list. If you plot the multiple selections from the **Annotation Manager** list to a viewport, the display order is driven by the list order; that is, the annotation at the top of the list will also be in front of all the other annotations in the viewport. However, you can change the display order of annotations in each viewport independently, either by plotting individual annotations from the **Annotation Manager** or by selecting an annotation, clicking mouse button 3, and using the options in the popup menu. (For more information, see *Manipulating annotations in the current viewport*.)

1. From the main menu bar, select **Viewport->Annotation Manager**.

   Tip: You can also display the **Annotation Manager** by clicking  from the ***Viewport*** *toolbar*.

2. Select annotations from the list in the dialog box (for more information, see *Selecting multiple items from lists and tables*).

   Tip: Toggle on **Highlight selections in viewport** to preview the selected annotations.

3. Use the buttons along the bottom of the **Annotation Manager** to rearrange the list.

   Note:

   The **Move Up** and **Move Down** buttons are not available if you select multiple annotations from the list.

   Abaqus/CAE moves the selected annotations within the list.

- *The Annotation Manager*
- *Manipulating annotations in the current viewport*

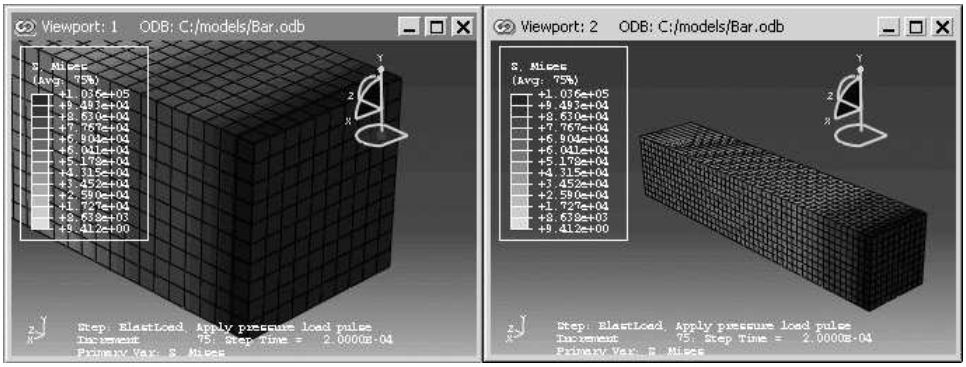
Linking viewports for view manipulation

This section explains how to link multiple Abaqus/CAE viewports for synchronized view manipulation.

In this section:

- *Using linked viewports*
- *Linking viewports*

Using linked viewports



Linked viewports enable you to manipulate your view of objects in different viewports simultaneously. When you manipulate an object in one linked viewport using any of the view manipulation tools described in *Manipulating the view and controlling perspective*, Abaqus/CAE performs the same action in all linked viewports in your session.

Abaqus/CAE allows only one set of linked viewports, so every viewport in your session is either independent or a part of the group of linked viewports. When you change the view in an independent viewport, Abaqus/CAE changes the view in that viewport only.

When using the standard view manipulation tools (see *Understanding the view manipulation tools*), the manipulations in the linked viewports are not dependent on the view orientation in each viewport. For example, panning the view to the left will pan the view to the left in all linked viewports, regardless of different view orientations in each viewport. When manipulating the view using the 3D compass (see *The 3D compass*), the manipulations in the linked viewports are dependent on the view orientation in each viewport. For example, panning the view along the *X*-axis will pan the view along the *X*-axis in all linked viewports; the view orientation in each viewport determines the direction of motion.

You can activate or deactivate viewport linking for your session from the **Viewport** menu, the **Viewport** toolbar, or the **Linked Viewports Manager**. If this option is deactivated, all viewports in your session are independent. By default, if this option is activated, all viewports in your session are linked. In the bottom portion of the **Linked Viewports Manager**, you can toggle off a viewport's checkbox to exclude it from the group of linked viewports. From the **Linked Viewports Manager**, you can control which characteristics the linked viewports share. By default, all of the characteristics are shared. Several of the linked viewport options are available in all modules; some of the options, such as displaying the same plot state in all linked viewports, are applicable only in the Visualization module.

Abaqus/CAE indicates linked viewports with a red chain link icon that appears on the left side of the viewport title bar, as shown in the two viewports below.

Additional information

- *Using the view manipulation tools*
- *Understanding plot states and plot customization*

Linking viewports

You can control which viewports in your Abaqus/CAE session will be linked and the characteristics that the linked viewports will share.

Several of the linked viewport options are available in all modules; some of the options, such as displaying the same plot state in all linked viewports, are applicable only in the Visualization module.

1. Link viewports using one of the following methods:

   - From the main menu bar, select**Viewport->Link Viewports**.

     Tip: You can activate or deactivate linked viewports by clicking  in the *Viewport toolbar*.

   - From the main menu bar, select**Viewport->Linked Viewports Manager** and toggle on **Link viewports**.

     Tip: You can also display the **Linked Viewports Manager** by clicking  in the *Viewport toolbar*.

2. By default, all of the characteristics of the viewports are shared in linked viewports. From the **Options** portion of the **Linked Viewports Manager**, you can control which characteristics are shared.

   - Toggle on **Animation** to use the same animation settings in the linked viewports. After linking, when animation is started or stopped, the animation state of the current viewport will be applied to all viewports that are linked to the current one. This option applies only in the Visualization module.
   - Toggle on **Display groups** to perform selected display group operations simultaneously in all linked viewports. If you select specific items for the display group by names or labels, the same display group operation is performed in all linked viewports that share the items specified. This option applies only in the Visualization module.
   - Toggle on **Field output** to display results for the same field output variable in the linked viewports. When you change the field output variable for one of the linked viewports, Abaqus/CAE displays the newly selected field output variable in all viewports with output databases that contain that field output variable. This option applies only in the Visualization module.
   - Toggle on **Frames** to set the step and frame in the linked viewports. This option applies only in the Visualization module.
     - Select **Frame navigation** to set the step and frame in the linked viewports using the **ODB Frame** buttons (**First**, **Previous**, **Next**, and **Last**). For example, **Next** increments the frame number currently displayed in each of the linked viewports.
     - Select **Frame selection** to set the linked viewports to the same step and frame number by making a selection in the **Step/Frame** dialog box or the **Frame Selector**.
   - Toggle on **Plot options** to display the same plot options in the linked viewports. This option applies only in the Visualization module.
   - Toggle on **Plot states** to display the same plot state or states in the linked viewports. This option applies only in the Visualization module.
   - Toggle on **Rotation centers** to use a common center of rotation across all linked viewports.

- Toggle on **Section points** to share section point selection across viewports. Linking section point selection by category occurs only if all the section categories in the current viewport are present in the other linked viewports; for envelope plots, this restriction does not exist. This option applies only in the Visualization module.
- Toggle on **View cuts** to display the same view cuts in all linked viewports. This option applies only in the Visualization module.
- Toggle on **View manipulations** to enable simultaneous view manipulations in the linked viewports.
- Toggle on **Viewport annotation options** to display viewport annotations in the same way across all linked viewports. When you display, hide, or customize the display of a viewport annotation such as the legend in the **Viewport Annotation Options** dialog box, Abaqus/CAE applies that change across all linked viewports.
- Toggle on **XY data from history output** to share *X–Y* data created from history output across viewports. This option applies only in the Visualization module.

Use **Select All** to select all the options and **Unselect All** to clear all the selected options.

3. By default, all viewports in your session are linked when you link viewports. From the **Linked Viewports** portion of the **Linked Viewports Manager**, deselect the viewports that you want to remain independent.
4. If you made changes in the **Linked Viewports Manager**, click **OK** to apply your changes and to close the manager.

   The linked viewports exhibit the shared behavior you specified in the **Options** selections.

Working with background images and movies in viewports

This section explains how to display images and movies in the background of Abaqus/CAE viewports.

In this section:

- *Using background images and movies*
- *Displaying a background image*
- *Displaying and customizing a background movie*
- *Customizing the appearance of background images and movies*

Using background images and movies

You can customize the viewports in your session by displaying an image or movie in the viewport background. Both background images and movies are viewport-specific, so you can display a different image or movie in each viewport in your session. Background images persist in a viewport as you change modules, while background movies appear in the Visualization module only. Abaqus/CAE displays images and movies on top of the existing viewport background, so if you have customized the color of the viewport background, the image or movie might obscure some or all of the custom background color.

You can use background images to help you while you create your model; for example, an image of a completed prototype can help you to align part instances in an assembly. Alternatively, a background image can serve as a watermark or display a logo when you generate images of your model.

Note: In the Sketch module you can display a second background image that can help you sketch parts more effectively. Abaqus/CAE displays the Sketcher background image on top of the module-wide background image when the Sketch module is selected and hides the Sketcher background image in all other modules. See *Managing images in the Sketcher background*.

Background movies can help you to compare the results of an Abaqus analysis with experimental results. For example, if you display a background movie that shows deformation in a prototype, you can animate the results from a similar Abaqus analysis and compare the animations in a single viewport.

Before you can display an image or movie in the viewport background, you must add the file to your Abaqus/CAE session. To add an image from the **Image/Movie Options** dialog box, click

; then enter a name for the image or movie and provide its location. Images in the session are available in all modules, while movies are available in the Visualization module only. Both images and movies persist for your session only; they are not saved to the model database or output database.

Abaqus/CAE supports background images in the following formats: Bitmap (`.bmp`), PNG (`.png`), GIF (`.gif`), JPEG (`.jpg`, `.jpeg`), TIFF (`.tif`), XPM (`.xpm`), PCX (`.pcx`), ICO (`.ico`), TGA(`.tga`), and RGB (`.rgb`).

Abaqus/CAE supports background movies that satisfy the following two criteria:

- The movie file's format must be supported on your Abaqus/CAE platform. For Linux systems Abaqus/CAE supports MP4 format (`.mp4`), Audio Video Interleave format (`.avi`), QuickTme format (`.mov`), and animated GIF format (`.gif`). For Windows systems Abaqus/CAE supports MP4, AVI, QuickTime, and animated GIF formats, as well as Mpeg movie format (`.mpeg`, `.mpg`, `.mlv`, `.wm`) and Windows Media Format (`.asf`, `.wmv`, `.wm`).
- The codec used to create the background movie file must be one of the codecs available for creating movie files in Abaqus/CAE. For example, you can display a QuickTime movie file in the viewport background only if it was created using one of the three codecs available for QuickTime movie creation in Abaqus/CAE: Raw 8, Raw 24 or RLE 24. The available codecs for creating each movie file format in Abaqus/CAE are described in *Choosing the animation file format*.

Additional considerations for selecting the codec used to create the background movie file:

- You need to create the movie file with a codec whose 64-bit version is available and installed on your computer so it can be read by Abaqus/CAE.
- Codecs on one computer might differ from the ones available on other computers. In particular, a movie file created on a 32-bit system using a 32-bit codec might not open in Abaqus/CAE if the 64-bit version of the codec is unavailable on that system.

- If the codec to read an AVI file is not installed on your computer, Abaqus/CAE reports information about the unsupported compression format and the color depth (number of color bits in a pixel).
- Third-party software is available to convert to RLE or RAW AVI format, which can be read by Abaqus/CAE.

Additional information

• *Choosing background colors*

Displaying a background image

The viewport background image that you select is displayed in the current viewport only, and it remains visible in that viewport as you change modules. Because background images are viewport-specific, you can display different images in each viewport that either help you with different tasks or enable you to distinguish viewports more quickly.

While the module-wide background image appears in all modules, its appearance may be obscured by the Sketcher background image (in the Sketch module) or the background movie (in the Visualization module). When active, each of these viewport decorations are displayed on top of the module-wide background image in the selected module. You can also include the background image in a printout of a viewport; see *Selecting which part of the image to print*, for more information.

1. From the main menu bar, select **View->Image/Movie Options**.

   The **Image/Movie Options** dialog box opens with the **Image** page selected.
2. Toggle **Show image** to display or hide the background image in the viewport.
3. Select an image file to display:
   - To display an image that has been defined for your session, expand the **Image name** list and select the image name.
   - To add a new image, click ; then enter a name and specify a file location in the dialog box that appears. You can either enter the file location directly in the **File Name** field or click  to navigate to it in the **Select Image File** dialog box.
4. Click **OK** to apply your changes and to close the **Image/Movie Options** dialog box.

   If desired, you can also customize the scale, positioning, or translucency of the background image; see *Customizing the appearance of background images and movies*.

Additional information

- *Displaying and customizing a background movie*
- *Customizing the appearance of background images and movies*

Displaying and customizing a background movie

You can display some or all of a movie file in the viewport background. Background movies appear in the Visualization module only and, when active, they are displayed on top of the viewport background image. If you print a viewport when the background movie is active, Abaqus/CAE displays the current frame of the movie in the background of the printed image.

This section describes how to display an image using the **Image/Movie Options** dialog box. Alternatively, you can display and customize background movies from the **Movies** container in the Results Tree or from the **Movie Manager** dialog box. To display the movie manager, select **Tools->Movie->Manager**.

1. From the main menu bar, select **View->Image/Movie Options**. In the **Image/Movie Options** dialog box that appears, click the **Movie** tab.
2. Toggle **Show movie during animation** to display or hide the background movie while animations are playing.
3. Select a movie file to display:
   - To display a movie that has been defined for your session, expand the **Movie name** list and select the movie name.
   - To add a new movie, click ; then enter a name and specify a file location in the dialog box that appears. You can either enter the file location directly in the **File Name** field or click  to navigate to it in the **Select Movie File** dialog box.

     For newly added movies, the **Edit Movie** dialog box appears.
4. If desired, customize the movie's active frames from the **Edit Movie** dialog box:
   - Activate or deactivate frames at the beginning and end of the movie. You can either drag the **Active Frames** sliders or enter frame numbers in the **Start** and **End** fields to change these values.
   - Toggle on **Preview changes in viewport** to change the background movie's length dynamically as you adjust its active frames. When this option is not selected, the background movie's active frames do not change until you click **Apply** or **OK**.
   - Toggle on **Show movie only** to hide model data in the viewport. In some cases the model data can obscure the background movie, making movie editing difficult.
5. If desired, customize the movie's timeline from the **Edit Movie** dialog box. If you select a frame-based animation as the background movie, you can change the movie's starting frame and ending frame; if you select a time-based animation, you can change the movie's starting time and ending time. To change the ending value, expand the appropriate field under the **End** column and select **Specify**. Abaqus/CAE then allows you to enter a value in this field.
6. Click **OK** to apply your changes and to close the **Image/Movie Options** dialog box.

   If desired, you can also customize the scale, positioning, or translucency of the background movie; see *Customizing the appearance of background images and movies*.

Additional information

- *Displaying a background image*
- *Customizing the appearance of background images and movies*

Customizing the appearance of background images and movies

You can customize the appearance of a background image or movie by repositioning it in the viewport, by stretching or compressing it in the *X*- or *Y*-direction, and by adjusting its level of translucency. These customization options are available for both images and movies, but their settings are separate; for example, if you change the *X*-axis scale setting for background images, the same setting for background movies in the Visualization module remains unchanged.

1. From the main menu bar, select **View->Image/Movie Options**.

   The **Image/Movie Options** dialog box appears with the **Image** tab selected by default. To customize background movies, click the **Movie** tab.

2. Toggle **Show image** on the **Image** page or **Show movie during animation** on the **Movie** page to activate the customization options.
3. Select one of the **Position and scale** options for your background image or movie:

Fit to viewport

This option positions the background image or movie in the center of the viewport and scales it to the **Width** or **Height** of the current viewport. In addition, you can select the **Best** option, which scales either the background movie in the direction that causes the lesser amount of deformation to the image.

Auto-align

This option enables you to align the background image or movie in one of nine positions in the viewport: its center, any of the four corners, or centered along any of the four edges. Expand the **Alignment** list, then select one of the options from the graphical depictions of alignment in the list.

Manual

This option enables you to reposition the background image at a location other than the center of the viewport. Click **Manual**, then enter in the **Origin** field the location at which you want to position the lower left corner of the background image.

4. For **Auto-align** or **Manual** scaling, you can specify the amount of scaling along either axis. Specify the **X scale** or **Y scale** for the background image or movie. The default scale values are 1; increase the scale to stretch the image or movie along the selected axis, or decrease the value to compress it along the selected axis.
5. Drag the **Translucency** slider to the percentage of translucency you want. This setting changes the translucency of the background image or movie and, at values less than 1.00, blends it with the displayed model. A value of 0.00 is transparent, and a value of 1.00 is opaque, with the image appearing to be in the background. By default, background images or movies and models are displayed with opaque translucency.
6. Click **OK** to apply your changes and to close the **Image/Movie Options** dialog box.

Manipulating the view and controlling perspective

This chapter describes the view options, the view manipulation tools, the 3D compass, and the perspective tools, all of which control a camera that creates the view in a viewport.
The view options allow you to switch between two camera modes and numerically control some of their properties. The view manipulation tools and 3D compass control the camera to position, orient, and magnify objects in the view; you can also select custom views such as front and back, as well as define your own views. The perspective tools control whether Abaqus/CAE displays your model with or without perspective; using perspective gives a more realistic appearance for three-dimensional models.

In this section:

- *Understanding camera modes and view options*
- *Understanding the view manipulation tools*
- *The 3D compass*
- *Customizing the view triad*
- *Controlling perspective*
- *Using the view manipulation tools*
- *Using the 3Dconnexion motion controllers with Abaqus/CAE*

Understanding camera modes and view options

This section describes the camera modes used to create views in Abaqus/CAE.

In this section:

- *Camera modes and view terminology*
- *Using view options to control the camera*

Camera modes and view terminology

A view is a two-dimensional representation—a camera image—of your model or analysis results, displayed in a viewport. Abaqus/CAE uses a single camera to create the view in each viewport. You can choose from two camera modes to create the desired view of your model or results. The default mode allows you to position the camera anywhere outside the model. The movie mode allows you to position the same camera inside the model as well as outside it. In addition, the movie mode provides you with two clipping planes that you can use to eliminate objects from the view when they are too close to, or too far from, the camera. The view depth is not limited in default mode; objects in the view may be directly in front of the camera or at a distance that makes them too small for you to see in the viewport.

View manipulation tools are available so that you can fully utilize both camera modes. All view manipulation tools can be used in either camera mode, but an "alternate mode" of some view manipulation tools is intended primarily for use in movie mode. For example, the magnify tool allows you to magnify the current view without moving the camera; the alternate mode of this tool moves the camera closer to the model. The effects of both view manipulations appear identical; but when used in the default camera mode, the alternate mode stops working if the camera "hits" the outer edge of the model. In movie mode you can use the alternate mode of the magnify tool to move the camera into and through the model. The view manipulation tools are described in *Understanding the view manipulation tools*.

Figure 1 shows the two camera modes. The shaded areas in the figure represent the visible space—the view—in each camera mode.

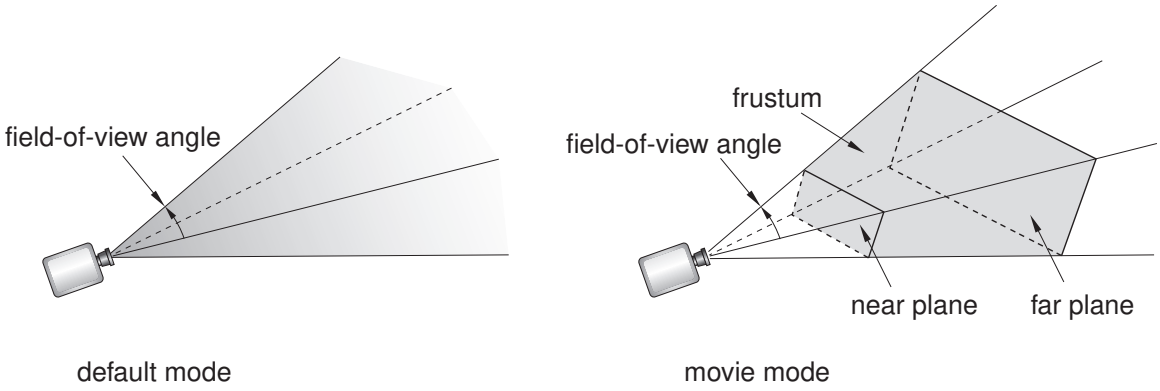

Figure 1: The default mode and movie mode camera views.

The camera terms that follow are used to describe the view that you see in a viewport:

Camera target

The camera target is a point in space that controls how the camera moves during most view manipulations. For all default views the camera target coincides with the center point of all objects in the view. The camera target moves away from the center of all objects when you use the alternate mode of the pan, rotate, and magnify view manipulation tools.

Frustum

The frustum is the three-dimensional space visible with the movie camera mode. The camera position forms the apex of a pyramid created by a left, right, top, and bottom plane (the same as it does in the default mode). To create the frustum, two additional planes are added to the default view, the near plane and the far plane. Only those objects (or portions of objects) that are within the frustum are visible in movie camera mode.

Field-of-view angle

The field-of-view angle is the larger of the angles between the left and right or the top and bottom planes that form the sides of the view. The angle that is used depends on the shape of the frustum (effectively the shape of the viewport); in both images of *Figure 1* the angle between the left and right planes is larger; therefore, this angle is indicated as the field-of-view angle. The field-of-view angle applies to both the default camera mode and the movie camera mode; changing the angle is comparable to adjusting the zoom on a stationary camera to expand or shrink the camera image.

The magnify, box zoom, and auto-fit view manipulation tools all change the field-of-view angle to resize the view in the viewport. See *Understanding the view manipulation tools*, for more information about these tools.

Near plane

The near plane lies perpendicular to the camera direction and is effective only in the movie camera mode. The distance from the camera to the near plane is the closest distance that an object can be to the camera and still remain in the view. The view from the default camera includes objects at any distance, as if the near plane were positioned directly in front of the camera lens.

The near plane is a clipping plane; it removes model surfaces and edges from view without cutting through the model. In the Visualization module you can cut the model such that interior surfaces are visible; for more information, see *Cutting through a model*.

Far plane

Like the near plane, the far plane lies perpendicular to the camera direction and is effective only in the movie camera mode. The distance from the camera to the far plane is the farthest distance that an object can be from the camera and still remain in the view. The view from the default camera includes objects at any distance, as if the far plane were positioned an infinite distance from the camera lens.

The far plane is a clipping plane; it removes model surfaces and edges from view without cutting through the model. In the Visualization module you can cut the model such that interior surfaces are visible; for more information, see *Cutting through a model*.

You use the view options, view manipulation tools, and perspective tools to change the camera mode settings or to change the relationship between the camera, the camera target, and the object that you are viewing. The current settings of these tools and options define the current view.

Using view options to control the camera

Use the view options to control the current camera mode and other options that you cannot set using the view manipulation tools.

Select **View->View Options** from the main menu bar to access the view options for the current viewport, as shown in *Figure 1*.

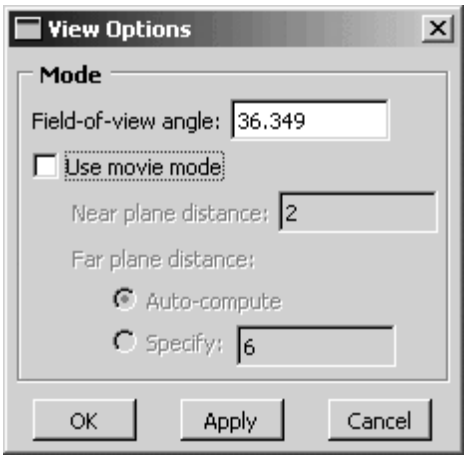

Figure 1: The View Options dialog box.

You can use the **View Options** dialog box to control:

- The field-of-view angle (effectively, the magnification of the current view).
- The camera mode (movie mode allows you to move the camera into and through the model).
- The distance from the movie mode camera to the near plane (the closest distance an object can be to the camera while remaining in the view).
- The distance from the movie mode camera to the far plane (the farthest distance an object can be from the camera while remaining in the view).

Note:

Specifying the near plane and far plane distance can improve the display performance for large models by excluding from view any portion of the model that lies beyond the specified range.

In the Visualization module the **View Options** dialog box also includes **Camera Movement** options. You can make the camera follow the motion of a local coordinate system and choose whether the camera also follows the rotation of the selected coordinate system. If movie mode is on, you can position the camera on the origin of the selected coordinate system. For more information on the view options in the Visualization module, see *Customizing camera movement*.

1. Select **View->View Options** from the main menu bar.

   The **View Options** dialog box appears.

2. If desired, change the **Field-of-view angle** to resize the view in the viewport:

   - Decrease the angle to magnify the view
   - Increase the angle to reduce the view

3. Toggle **Use movie mode** on or off to switch between the default and movie camera mode.

Activating the movie camera mode does not change the current view. However, if you apply the default camera mode (toggle off **Use movie mode**), you will see one of the following effects:

- If the model lies entirely within the frustum, the current view does not change.
- If a portion of the model is cut off by the near or far plane, that portion reappears in the view and Abaqus/CAE resets the near plane and far plane distances to include the entire object in the view the next time you activate movie mode.
- If the movie mode camera is positioned inside the model, the camera moves “back” along the current view direction so that the entire model is in front of the camera. Abaqus/CAE adjusts the field-of-view angle to display the model in a size similar to that in the movie mode view and resets the near plane and far plane distances to include the entire object in the view the next time you activate movie mode.

Tip: Use the *cycle* view manipulation tool to return to the previous view.

4. If desired, adjust the **Near plane distance**.

   Abaqus/CAE removes from view any objects, or portions of objects, that lie between the movie mode camera and the near plane.

5. If desired, click **Specify** and adjust the **Far plane distance**.

   By default, Abaqus/CAE automatically computes the far plane distance, setting it to a value beyond the farthest point in the model and adjusting it when you manipulate the view so that no part of the model is excluded from view. If you specify a distance, Abaqus/CAE removes from view any objects, or portions of objects, that lie beyond that distance from the camera.

6. + Click **OK** to implement your changes and to close the dialog box.

   Your changes are saved for the duration of the session.

Additional information

- *Camera modes and view terminology*
- *Understanding the view manipulation tools*

Understanding the view manipulation tools

This section describes basic concepts you should understand before using the view manipulation tools.

In this section:

- *The view manipulation tools*
- *The pan view tool*
- *The rotate view tool*
- *The magnify tool*
- *The box zoom tool*
- *The auto-fit tool*
- *The cycle tool*
- *Custom views*
- *Numerically specifying a view*

The view manipulation tools

The camera position, orientation, and zoom factor combine to define the view of an object in the viewport. Your view of the assembly, as well as each of your parts, is positioned relative to a default Cartesian coordinate system, and the orientation of this default coordinate system within a viewport is indicated by the view triad. By default, an isometric view is used when a module first displays a three-dimensional part or assembly.

You can manipulate the view using the pan, rotate, magnify, box zoom, and auto-fit tools on the View Manipulation toolbar to control the relative positions of the camera, the camera target, and the model or results that you are viewing. For example, you might want to pan and zoom a contour plot to view an area of stress concentration. The view manipulation tools allow you to perform the following operations:

-  Move the view horizontally and vertically; that is, *pan* the view.
-  *Rotate* the view.
-  *Magnify* or reduce the view.
-  *Zoom* in to a selected area of the view.
-  *Rescale* the view to fill the viewport; that is, auto-fit the view.
-  *Cycle* through previous views.

Other types of view manipulations can be performed using the 3D compass; for more information, see *The 3D compass*.

You can click mouse button 3 to access the following view manipulation tools:

- **Set As Rotation Center**: Set the center of rotation at the position of the mouse click, which can be at any location in the viewport.
- **Use Default Rotation Center**: Clear a previously set center of rotation.
- **Center View**: Center the view at the position of the mouse click.

When an *X*–*Y* plot is displayed in the viewport, you can use the view manipulation tools to change the view of the *X*–*Y* curves. Because *X*–*Y* plots are two-dimensional, the rotate tool is disabled when the current viewport displays an *X*–*Y* plot.

Clicking a view manipulation tool puts you into the corresponding view manipulation mode. You then manipulate the view in a particular viewport by moving the cursor to that viewport and dragging or clicking as necessary. In addition, the pan, rotate, and magnify tools have alternate modes that you can access by holding the **[Shift]** key in conjunction with the normal use of these tools. The alternate modes of these tools are intended for use in the movie camera mode, but they can also be used in the default mode. For more information about camera terminology and the view modes, see *Understanding camera modes and view options*. To exit a view manipulation mode, do one of the following:

- Click mouse button 2.
- Click the cancel button  in the prompt area.
- Click the view manipulation tool again.
- Click any other view manipulation tool.

You can use the view manipulation tools as many times as necessary to reach the desired view, and you can perform the view manipulation in any viewport, regardless of what is being displayed. Abaqus/CAE stores the eight most recent

views from each viewport, and you can use the cycle view manipulation tool to cycle backward and forward through these views.

When you use the move, rotate, magnify, zoom, or rescale tools in a viewport that is linked to other viewports, Abaqus/CAE manipulates the view of objects in the linked viewports as well. For more information, see *Linking viewports for view manipulation*.

By default, Abaqus/CAE displays the image using the current render style (wireframe, filled, hidden line, or shaded) while you manipulate the view of an object. Alternatively, you can change the **Drag mode** in the **Graphics Options** dialog box to display the image as a simple wireframe while you manipulate the view; this mode allows faster manipulation of very large models in the shaded render style. The view reverts to the original render style when you complete a manipulation.

If you prefer to use menus rather than the tools on the View Manipulation toolbar, you can access all of the view manipulation tools through the **View** menu on the main menu bar. In addition, you can apply predefined and user-defined views using the Views toolbar, and you can numerically specify a precise view using the dialog box that appears when you select **View->Specify** from the main menu bar. For more information on custom and numerically specified views, see *Custom views*, and *Numerically specifying a view*, respectively.

Alternatively, you can enter three of the view manipulation modes by using a combination of keyboard and mouse actions.

- To rotate the view, press **[Ctrl][Alt]**, and hold down mouse button 1.
- To pan the view, press **[Ctrl][Alt]**, and hold down mouse button 2.
- To magnify or reduce the view, press **[Ctrl][Alt]**, and hold down mouse button 3.

Add **[Shift]** to any of these combinations to access the alternate modes of these tools. For example, press **[Shift][Ctrl][Alt]** and hold mouse button 3 to access the alternate mode of the magnify tool and move the camera closer to or farther from the objects in the view. The **[Shift]** key has no effect on the view manipulation tools when you are not using alternate modes. To exit a view manipulation mode after using one of the preceding actions, simply release the mouse button.

You can reconfigure these keyboard and mouse combinations to mimic the view manipulation interfaces used by five other common CAD applications by selecting **Tools->Options** from the main menu bar. See *Using view manipulation shortcuts*, for more information.

Additional information

- *Using the view manipulation tools*
- *Understanding camera modes and view options*

The pan view tool

When a model is displayed in the viewport and the pan mode is set, the position of your view of the model changes as you click and then drag the cursor, and a rubberband line indicates the amount of translation.

When you select the pan tool and the viewport in which to work, Abaqus/CAE enters pan mode, as indicated by the cursor.

Panning the view is comparable to moving the camera over a snapshot of the model, as shown in *Figure 1*; the snapshot moves in the viewport but any faces of the model that were hidden in the original camera position remain hidden as you pan.

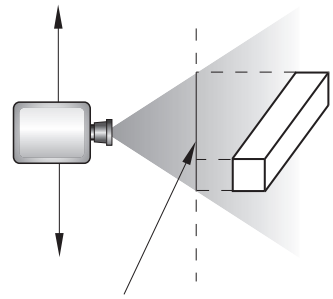

Figure 1: Panning the view.

The alternate mode of the pan tool, accessed by holding **[Shift]** while performing the manipulation, creates a more realistic camera view. Instead of a snapshot of the model, you pan the camera over the real model. Faces of the model that were hidden at the original camera position are exposed as you move the camera over the model, as shown in *Figure 2*.

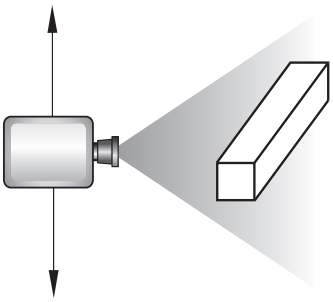

Figure 2: Panning the view in alternate mode.

Note:

If perspective is not on, the alternate mode of pan works identically to the standard pan tool.

For both modes of the pan tool, the initial location of the cursor is not important, as long as you place it within the viewport. Cursor motion is limited only by the physical bounds of your monitor, and panning will continue even if you move the cursor outside the viewport or window.

When an *X–Y* plot is displayed in the viewport, you can change your view of the *X–Y* curves in the plot by clicking and dragging the cursor in the grid. Abaqus/CAE updates the values in the axes as you manipulate your view of the *X–Y* data.

Additional information

- *The view manipulation tools*
- *Panning the view*
- *Understanding camera modes and view options*

The rotate view tool

In the rotate mode the cursor changes to two curved arrows, and a large circle appears in the viewport. To define the center of rotation, you can enter its coordinates directly or select a point from the viewport. Otherwise, Abaqus/CAE will rotate the view about the center of the viewport.

When you select the rotate tool and the viewport in which to work, Abaqus/CAE enters rotate mode. If you select a center of rotation by selecting a position from the viewport or entering coordinates, that rotation center position overrides the view center and remains selected until you select a new rotation center, display a different object, or choose the default rotation center. Your view of the model rotates as you drag the cursor, and a rubberband line indicates the amount and the direction of rotation. As you rotate your view of the model, the view triad indicates the orientation of the global coordinate system.

Note:

Abaqus/CAE disables the rotate tool when an *X*–*Y* plot is displayed in the current viewport.

The circle that is drawn when you enter rotate mode represents the silhouette of an imaginary sphere that surrounds the object. When you drag the mouse inside the circle, you might imagine that you are actually rotating the sphere, as you would a trackball. Your model is attached to the center of the sphere, so that rotating the sphere causes your view of the model to rotate as well.

You determine the axis of rotation as you move the cursor over the surface of the imaginary sphere. The rubberband line represents the intersection of a cutting plane with the sphere's surface, and the rotation axis is normal to this cutting plane. The angle of rotation is equal to the angle made by the rubberband line on the sphere's surface, so that dragging all the way across the circle produces a 180° rotation. *Figure 1* illustrates the imaginary sphere and a rubberband line being dragged across its surface.

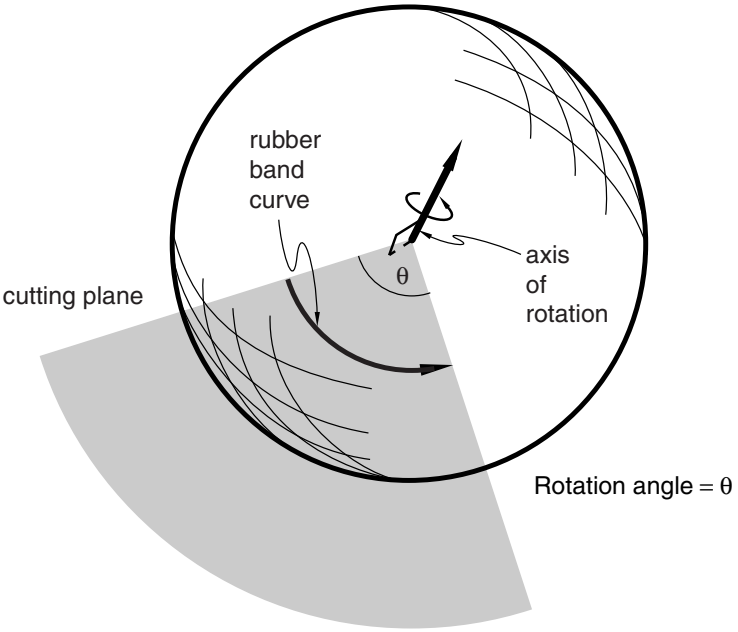

Figure 1: The rotate tool.

When you drag outside the circle, the rubberband line is superimposed on the edge of the circle, and your view of the object simply rotates about an axis normal to the screen and passing through the center of the circle. In the same way as it does for dragging inside the circle, the rubberband line represents the angle through which the object has rotated.

Using the default mode of view rotation is comparable to rotating the camera around the view center or selected center of rotation, as shown in *Figure 2*.

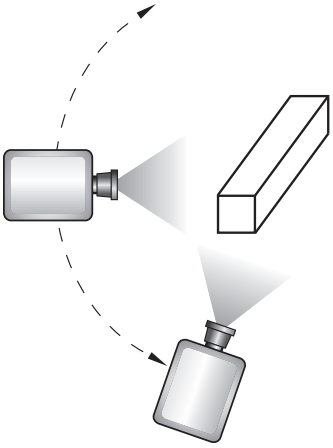

Figure 2: Rotating the camera about the target or selected center of rotation.

The alternate mode of the rotate tool, accessed by holding **[Shift]** while performing the manipulation, rotates the camera about itself, as shown in *Figure 3*. This moves the camera target and frustum without regard to the position of objects in the original view. Rotating the camera about itself is most useful when you are in movie mode and the camera is positioned inside the model. In this position, moving the camera target and frustum brings different portions of the interior of the model into view.

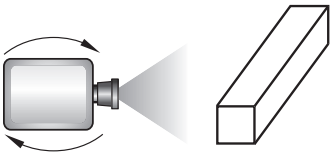

Figure 3: Rotating the camera about itself.

Note:

If you have selected a point as the center of rotation, your selection overrides the alternate mode of rotation.

In either mode, it is usually easier to obtain a desired rotation by performing a sequence of smaller rotations rather than one large one. If you need to abandon the rotation and return to a known orientation, use either the predefined views in the Views toolbar or the cycle view tool . Using any of the predefined views will also reset the camera target to the center of the model.

Because *X*–*Y* plots are two-dimensional, Abaqus/CAE disables the rotate tool when an *X*–*Y* plot is displayed in the current viewport.

Additional information

- *The view manipulation tools*
- *Rotating the view*
- *Understanding camera modes and view options*

The magnify tool

When you drag the cursor along the positive direction while in magnify mode, your view of the model or plot expands within the viewport, and a rubberband line indicates the relative magnification. Similarly, when you drag the cursor along the negative direction, your view of the model or plot contracts, and a rubberband line indicates the relative reduction.

When you select the magnify tool and the viewport in which to work, Abaqus/CAE enters magnify mode, as indicated by the magnify cursor . The positive and negative directions depend on your settings in the view manipulation options (see *Using view manipulation shortcuts*). If you are using the default Abaqus/CAE configuration for view manipulations, the positive direction is to the right and the negative direction is to the left. If you are using a nondefault configuration for view manipulations, the positive direction is upward and the negative direction is downward. To reflect the configuration settings, the rubberband line is horizontal for the default configuration and vertical for nondefault configurations.

The dragging action must start in the viewport, but you can continue to drag within the limits of your monitor. You can also drag repeatedly to achieve the desired view. The magnify tool recognizes only the horizontal (for the default configuration) or vertical (for nondefault configurations) component of your dragging motion, as indicated by the rubberband line. Consequently, you can achieve finer control by dragging diagonally across the screen, since this results in a smaller component of the cursor's motion in the effective direction than dragging the same distance along the effective direction.

Using the default mode of the magnify tool, as its name suggests, magnifies the view; as shown in *Figure 1*, the camera does not move with respect to the objects in the view. The magnification is caused by changing the field-of-view angle, the same method you use when changing the zoom on a stationary camera.

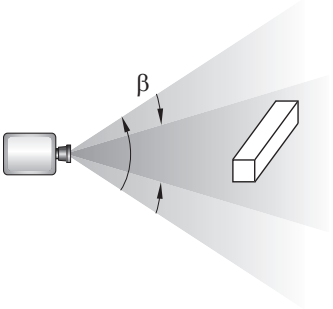

Figure 1: Magnifying the view.

The alternate mode of the magnify tool, accessed by holding **[Shift]** while performing the manipulation, keeps the field of view constant and moves the camera towards or away from the objects in the view, as shown in *Figure 2*.

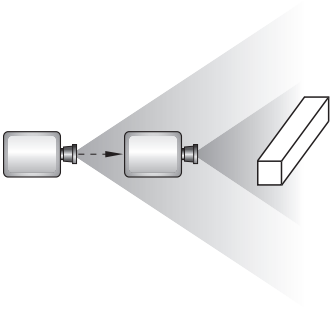

Figure 2: Moving the camera closer to the model.

Moving the camera in this manner is most useful when movie mode is on. Then your view is not limited; you can move the camera through the model such that any parts that you do not want to see are removed by the near or far planes or are actually behind the camera. If you are not using movie mode, the camera can move forward only until it reaches the outer limits of the model.

When an *X–Y* plot is displayed in the viewport, you can magnify your view of the data to focus in on a particular component of an *X–Y* curve. Abaqus/CAE updates the values in the axes as you change the magnification of the *X–Y* plot.

If you lose track of your position, you can use the *auto-fit* tool  to rescale the view to fit the viewport. Using the auto-fit tool also resets the camera target to the center of the model.

Additional information

- *The view manipulation tools*
- *Magnifying or reducing the view*
- *Understanding camera modes and view options*

The box zoom tool

You use the box zoom tool to select a rectangular area of your model or plot; Abaqus/CAE enlarges your view of the selected portion of your model or plot to fill the viewport.

When you select the box zoom tool  and the viewport in which to work, Abaqus/CAE enters box zoom mode, as indicated by a crosshair-shaped cursor. For *X*–*Y* plots, Abaqus/CAE enlarges your view of the selected *X*–*Y* curves and updates the axis values to match the data that you select.

Additional information

- *The view manipulation tools*
- *Zooming in to a selected area of the view*

The auto-fit tool

The View Manipulation toolbar contains an auto-fit tool.

Use the auto-fit tool  from the View Manipulation toolbar to quickly adjust your view of the model so that the model or model plot fills the viewport and is centered within it. When you fit a view of a model, the orientation does not change, as indicated by the view triad.

When you auto-fit an *X–Y* plot, the auto-fit tool resets the values in the axes to their specified minimum and maximum values; see *Customizing X–Y plot axes*. The auto-fit tool does not necessarily fill the viewport with the *X–Y* plot, because the chart options may dictate that the plot occupy only part of the viewport; see *Customizing X–Y plot appearance*, for more information about the chart sizing and positioning options.

Auto-fitting occurs in the current viewport as soon as you click the auto-fit tool. If you have more than one viewport, select the viewport that you want to rescale to make it the current viewport before selecting the auto-fit tool.

A separate option, **Auto-fit after rotations**, is available when you select **View->Graphics Options** from the main menu bar. You use this option to control whether or not Abaqus/CAE automatically rescales the view to fit the viewport as you rotate. For more information on using this option, see *Rotating the view*.

Additional information

- *The view manipulation tools*
- *Rescaling the view to fit the viewport*

The cycle tool

You can cycle through the eight most recent views in each viewport.

When you select the cycle tool  and the viewport in which to work, Abaqus/CAE enters cycle mode, as indicated by a cursor in the form of a two-way arrow.

To cycle through previous views, click in the viewport whose view you want to change. To control the direction of cycling, click **Backward** or **Forward** in the prompt area. The default is to cycle backward. After you cycle backward to the oldest available view, continued clicking has no effect. Similarly, after you cycle forward to the most recent view, continued clicking has no effect.

Additional information

- *The view manipulation tools*
- *Cycling through views*

Custom views

The Views toolbar allows you to apply a custom view to the model in the selected viewport. (A view is the combination of the position, orientation, and zoom factor of the model in the viewport.)

Note:

The Views toolbar is not visible in the Abaqus/CAE main window by default. To display the Views toolbar, select **View->Toolbars->Views** from the main menu.

Custom views include seven predefined views (such as front and back) and up to four user-defined views.

Predefined views

Predefined views are based on the six faces of an imaginary cube and an isometric view. The view triad indicates the orientation of this imaginary cube within a viewport. *Figure 1* illustrates the six predefined cube face views.

Note:

Predefined views have no effect when an *X*–*Y* plot is displayed in the current viewport.

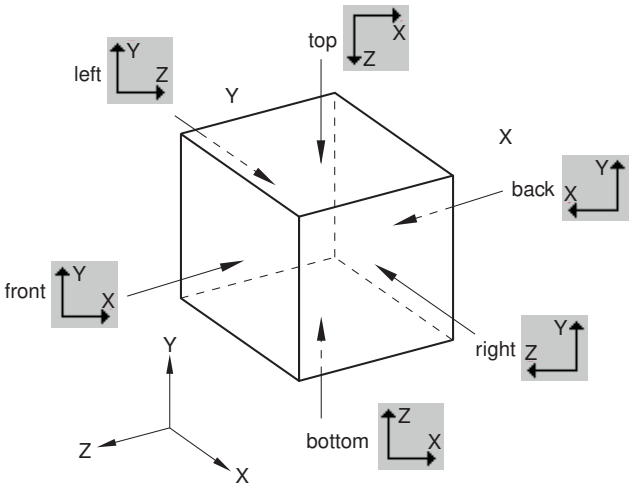

Figure 1: Predefined views.

User-defined views

You can use the view manipulation tools to position your view of a model in a viewport and then click in the Views toolbar to save the view as one of four user-defined views. You can use this saved view to restore the object in the viewport to a known orientation, and you can apply a saved view to other viewports. By default, saved views are not stored between sessions. If you want to retain a saved view for subsequent sessions, save it to an XML file, to the model database, or to an output database. For more information, see *Managing session objects and session options*.

The view consists of three components: orientation, zoom factor, and position. You can choose whether or not all three of these components are saved using the **Scale & Position** options, as follows:

Auto-fit

When you save a view after choosing this option, only the orientation is saved. When you apply a view saved with this option, the saved orientation is applied, but the zoom factor and position are adjusted to make the view fit the viewport.

Save current

When you save a view after choosing this option, the orientation, the zoom factor, and the position are all saved. When you apply a view saved with this option, the saved orientation, zoom factor, and position are all applied to the object in the viewport. To compare different objects in different viewports by placing the viewports side-by-side and applying a known orientation, zoom factor, and position to each, choose the **Save current** option.

Additional information

- *The view manipulation tools*
- *Applying custom views*
- *Saving a user-defined view*

Numerically specifying a view

You can bypass the view manipulation tools and specify a particular view numerically. Specifying a view is useful if you want to reproduce a particular view between Abaqus/CAE sessions or if numerically specifying a view is simpler and more convenient than applying a series of view manipulations.

Select **View->Specify** from the main menu bar to specify a view.

Tip: You can also specify a view by double-clicking the 3D compass.

You can use the following methods to specify your view:

Rotation Angles

Enter three angles (θ_1, θ_2, θ_3) representing the angles through which your view of the model rotates about the screen or model 1-, 2-, and 3-axes, respectively. Rotations are interpreted in the order (θ_1, θ_2, θ_3), and a positive angle represents a right-handed rotation about the axis. If you previously specified a nondefault center of rotation while using the rotate view tool (see *The rotate view tool*), the specified rotations will also be about this point. You must choose one of the following modes to apply the rotation:

- **Increment About Model Axes**. When you choose **Increment About Model Axes**, Abaqus/CAE simply applies the rotation to the current view. *Figure 1* shows the result of applying an incremental model axes rotation of 90, 0, 0 from the isometric view.

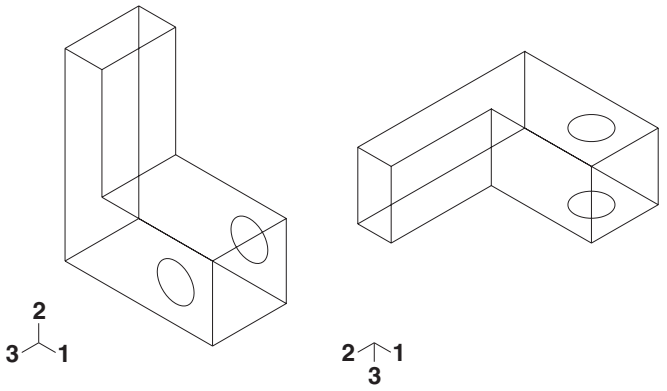

Figure 1: Specifying an incremental model axes rotation angle.

- **Increment About Screen Axes**. The screen *X*-axis is horizontal, the *Y*-axis is vertical, and the *Z*-axis is out of the screen. The origin of the screen axes is the camera target. In most cases the camera target coincides with the center of the viewport, but some view manipulation methods can move the camera target (for more information, see *Camera modes and view terminology*). When you choose **Increment About Screen Axes**, Abaqus/CAE simply applies the rotation to the current view. *Figure 2* shows the result of applying an incremental screen axes rotation of 90, 0, 0 from the isometric view.

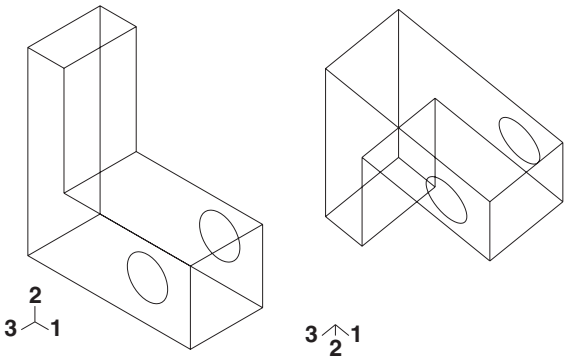

Figure 2: Specifying an incremental screen axes rotation angle.

- **Total Rotation From (0,0,1)**. When you choose **Total Rotation From (0,0,1)**, Abaqus/CAE first rotates the view to the default position (a view looking down the 3-axis with the 1- and 2-axes in the plane of the screen) and then applies the desired rotation. *Figure 3* shows the result of applying a total rotation of 90, 0, 0 from the isometric view.

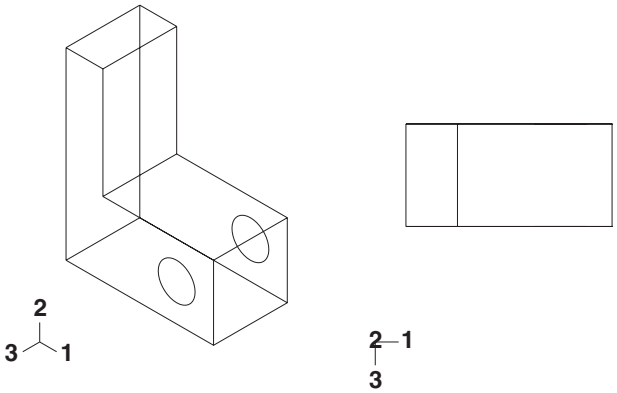

Figure 3: Specifying a total rotation angle.

Viewpoint

When you choose **Viewpoint**, you enter three values representing the 1-, 2-, and 3-position of an observer. Abaqus/CAE constructs a vector from the origin of the model to the position that you specify and rotates your view of the model so that this vector points out of the screen. *Figure 4* shows the result of applying a viewpoint of 1, 1, 1 (an isometric view) and a viewpoint of 1, 0, 0.

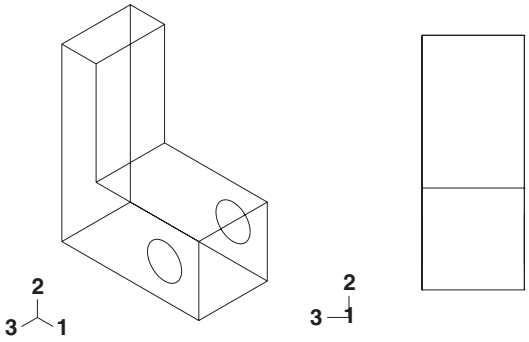

Figure 4: Specifying a viewpoint.

When you use the **Viewpoint** method to specify a view, you can also specify the **Up vector**. Abaqus/CAE positions your view of the model so that this vector points upward. *Figure 5* shows the result of applying an up vector of 0, 1, 0 and an up vector of 0, −1, 0 to an isometric view. The **Up vector** must not equal the **Viewpoint** vector.

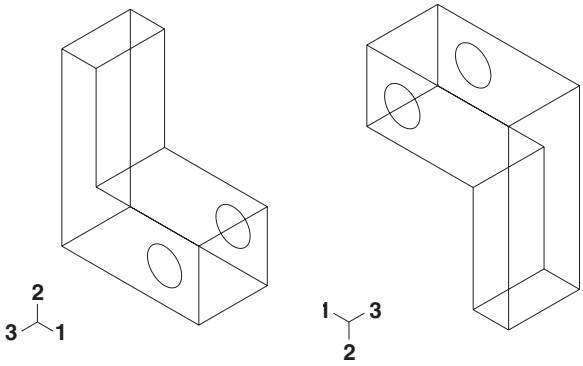

Figure 5: Specifying an Up vector.

Zoom

Enter a value representing a magnification factor. A value greater than 1 expands your view of the model in the viewport; for example, a **Zoom factor** of 2 doubles the size of your view of the model. A value between 0 and 1 contracts your view of the model in the viewport; for example, a value of 0.25 contracts your view of the model to a quarter of its original size. The value must be greater than zero.

You must choose one of the following methods to apply the zoom:

- **Absolute**. When you choose **Absolute**, Abaqus/CAE first fits the view to the viewport and then applies the desired **Zoom factor**.
- **Relative**. When you choose **Relative**, Abaqus/CAE applies the **Zoom factor** to the current view.

Pan

Enter values that Abaqus/CAE uses to **Pan** your view of the model by a specified horizontal and vertical distance. Abaqus/CAE moves the view relative to its current postion in the viewport. The values that you enter correspond to fractions of the viewport dimensions; the first value represents horizontal motion and the second value represents vertical motion. A positive first value moves your view of the model toward the right edge of the viewport, and

a positive second value moves your view of the model toward the top of the viewport. For example, if the viewport is 200 mm wide and 100 mm tall and you enter values of 0.5, −0.1 in the **Fraction of viewport to pan (X,Y)** field, Abaqus/CAE positions your view of the model 100 mm toward the right and 10 mm down from its current position.

- *Applying a specified view*

The 3D compass

This section describes the basic functions and features of the 3D compass.

In this section:

- *About the 3D compass*
- *Rotating the view using the 3D compass*
- *Panning the view using the 3D compass*
- *Predefined views for the 3D compass*
- *Customizing the 3D compass*

About the 3D compass

The 3D compass is a viewport annotation that appears in the upper right-hand corner of a viewport.

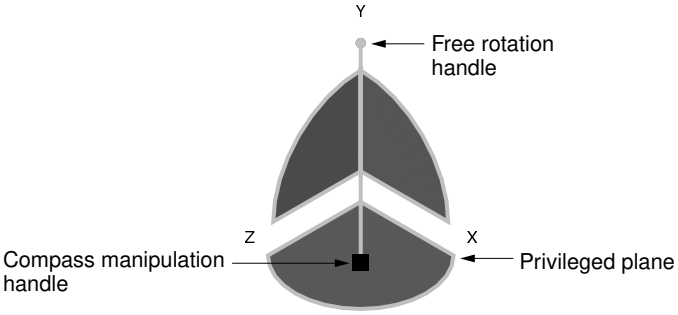

Figure 1: The 3D compass.

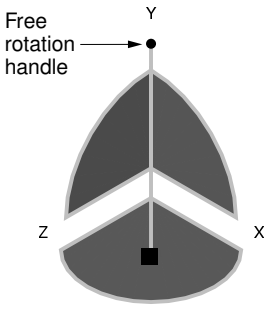
The 3D compass in Abaqus/CAE is based on the 3D compass used in CATIA V5. The 3D compass indicates the orientation of the model in the viewport, similar to the view triad. Unlike the view triad, you can manipulate the orientation of the 3D compass by clicking and dragging on it. When you manipulate the 3D compass, the viewport camera pans or rotates to change the viewport orientation accordingly. The behavior of the compass view manipulations is identical to the compass view manipulation behavior in CATIA V5.

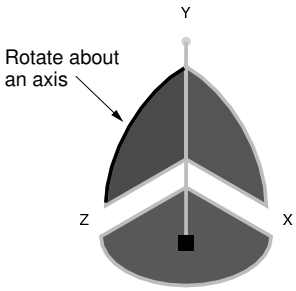


The 3D compass is a helpful shortcut for certain view manipulation options since it is available in all modules and during all procedures; you do not need to enter a view manipulation mode to change the viewport orientation using the 3D compass.

Rotating the view using the 3D compass

The 3D compass allows you to rotate the view of a model using two different methods: you can rotate freely in all directions, or you can constrain the manipulation to rotation about a specific axis. In both cases the model view rotates about the current center of rotation for the viewport, as defined by the rotate tool (see *The rotate view tool*).

Free rotation



To rotate a model in any direction, click and drag the free rotation handle on the 3D compass:

As you drag the mouse, the compass rotates about its pivot in the direction of the mouse motion (the pivot point coincides with the compass manipulation handle). The rotation is dependent on the direction of the mouse motion, not on the location of the pointer; in other words, the compass continues to rotate as long as you continue to drag. As the orientation of the compass changes, the view of the model changes accordingly.

Rotation about an axis

You can also rotate a model about a specified axis, thereby maintaining a constant orientation in a particular direction during the manipulation. To rotate about an axis, click and drag one of the three arcs along the perimeter of the 3D compass:

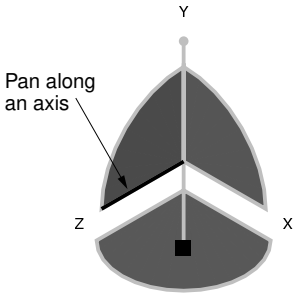
As you drag the mouse, the compass rotates about the axis that is perpendicular to the plane subtended by the selected arc (the *X*-axis in the above example). The rotation is dependent on the location of the pointer. As you drag the mouse, the path of the pointer in the viewport is projected onto the selected compass arc. The compass rotates according to this projected path. As the orientation of the compass changes, the view of the model changes accordingly.

Additional information

- *What is a viewport?*
- *Camera modes and view terminology*
- *The rotate view tool*

Panning the view using the 3D compass

The 3D compass allows you to pan the view of a model using two different methods: you can pan along a specified axis, or you can pan within a specified plane.

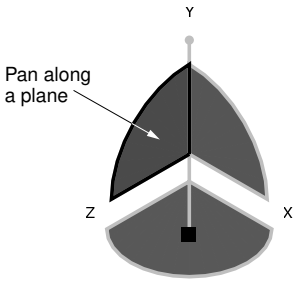


The pan manipulations performed with the 3D compass are different than the manipulation performed with the standard pan view tool (see *The pan view tool*). The standard pan tool moves the camera laterally in front of the model; the camera is constrained to move only in a plane parallel to the viewport. The panning planes for the 3D compass are not necessarily parallel to the viewport. As a result, panning with the compass behaves like a combination of the standard pan and zoom tools in their alternate modes: the camera moves both laterally across the model and perpendicularly toward or away from the model. The orientation of the compass and model view does not change during pan manipulations.

Note:

As with the alternate mode of the standard pan view tool, panning the view with the 3D compass also translates the viewport's center of rotation along with the camera. See *The rotate view tool*, for information about the center of rotation.

Panning along an axis



To pan the view along an axis, click and drag any of the straight axes on the 3D compass:

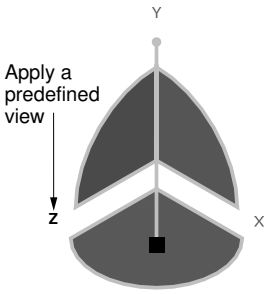
As you drag the mouse, the path of the pointer in the viewport plane is projected onto the selected compass axis (the *Z*-axis in the above example). The camera moves according to this projected linear path.

Panning along a plane

To pan the view along a plane, click and drag any of the quarter-circular faces on the 3D compass:

As you drag the mouse, the path of the pointer in the viewport plane is projected onto the selected compass plane (the *Y*–*Z* plane in the above example). The camera moves according to this projected path.

Additional information



- *What is a viewport?*
- *Camera modes and view terminology*
- *The pan view tool*

Predefined views for the 3D compass

You can use the 3D compass to quickly set the viewpoint to one of six predefined views. You can also access the **Specify View** dialog box through the compass.

Predefined views

The predefined views correspond to the three planes of the 3D compass. To apply a predefined view, click the label for any of the axes on the 3D compass:

The view is adjusted so that the selected axis (the *Z*-axis in the above example) is perpendicular to the plane of the viewport. Clicking the same axis label again flips the view orientation to the opposite side of the viewport plane. In other words, clicking the same axis label repeatedly oscillates the view between the front and back side of the displayed model.

The six predefined views associated with the 3D compass are identical to the predefined views in the Views toolbar.

Numerically specifying a view

Double-clicking anywhere on the 3D compass opens the **Specify View** dialog box. You can use this method to numerically specify a viewpoint or camera location. See *Numerically specifying a view*, for more information.

Additional information

- *What is a viewport?*
- *Camera modes and view terminology*
- *Custom views*
- *Numerically specifying a view*

Customizing the 3D compass

To customize the look and orientation of the 3D compass, click mouse button 3 on the compass and select an option from the menu that appears. You can perform the following customizations:

Edit

Select **Edit** to display the **Specify View** dialog box and numerically specify a custom view orientation. See *Numerically specifying a view*, for details on specifying custom view orientations.

Tip: You can also double click the 3D compass to display the **Specify View** dialog box.

Change the privileged plane

The base of the compass (which contains the compass manipulation handle) is called the privileged plane. By default, the *X*–*Z* plane is the privileged plane in Abaqus/CAE. The privileged plane can be helpful in determining the "correct" orientation of a model in the viewport. In the default isometric orientation of the compass, the privileged plane appears at the bottom and the free rotation handle appears at the top; the axis from the privileged plane to the free rotation handle in effect indicates the "up" direction for the model.

If the *Y*-axis does not correspond to the "up" direction in a model, you can change the privileged plane to any of the three major planes in the compass. For example, select **Make XY the Privileged Plane** to set the *X*–*Y* plane as the privileged plane. Changing the privileged plane only reconfigures the shape of the 3D compass, as indicated in *Figure 1*; the view orientation and the predefined views in the Views toolbar are not changed.

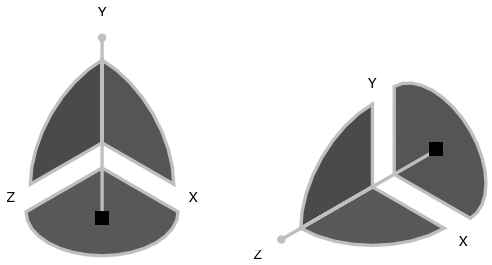


Figure 1: Changing the privileged plane from the *X*–*Z* plane (left) to the *X*–*Y* plane (right).

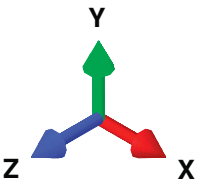
Hide



Select **Hide** to remove the 3D compass from the viewport display. To resume the display of the 3D compass, you must use the viewport annotation options (select **Viewport->Viewport Annotation Options** from the main menu). For information on controlling the visibility of viewport annotations, see *Using viewport annotation options*.

Help

Select **Help** to display a help window with documentation on using the 3D compass.

Customizing the view triad

The view triad, shown below, is a set of three perpendicular axes that indicate the orientation of your view of the model currently being displayed. The *X*, *Y*, and *Z* labels correspond to the 1-, 2-, and 3-directions, respectively. As you rotate your view of the model, the triad changes to indicate the new orientation. For more information on using the rotate tool, see *Rotating the view*.

The view triad and the 3D compass both indicate the view orientation, and they are always aligned with each other. You can directly manipulate the 3D compass orientation in the viewport, thereby changing the view of the model (see *The 3D compass*). The view triad acts only as a reference; it rotates with the 3D compass, but it cannot be directly manipulated.

You can use the **Viewport->Viewport Annotation Options** menu item to request or suppress the display of the triad and to control the triad's size, position, and appearance. You can also control the triad's labels, including their color and font.

1. From the main menu bar, select **Viewport->Viewport Annotation Options**.

   The **Viewport Annotation Options** dialog box appears.

2. Toggle **Show triad** to display or suppress the triad in the current viewport.

   When **Show triad** is toggled on, triad options become available.

3. Click the **Triad** tab.

   Abaqus/CAE displays the triad view options.

4. Enter the **Triad size** as a percentage of the viewport size. When you resize the viewport, the size of the triad changes accordingly. The minimum allowable triad size is 1% of the viewport, and the maximum allowable triad size is 50% of the viewport.

5. Enter percentage values for the triad X and Y positions in the **% Viewport X** and **% Viewport Y** boxes, respectively.

   A value of 0 for **% Viewport X** moves the triad origin to the extreme left of the viewport while a value of 100 moves it to the extreme right. A value of 0 for **% Viewport Y** moves the triad origin to the extreme bottom of the viewport, while a value of 100 moves it to the extreme top.

6. Choose the color of the triad labels:

   a. Click the color sample .

      Abaqus/CAE displays the **Select Color** dialog box.

   b. Use one of the methods in the **Select Color** dialog box to select a new color. For more information, see *Customizing colors*.

   c. Click **OK** to close the **Select Color** dialog box.

      The color sample changes to the selected color.

7. Click the arrow next to the **Labels** field and select either numerical or alphabetical labeling for the triad.

   The specified style appears in the **Labels** field.

8. Click **Set Label Font** to set the font type, size, and style using the dialog box that appears.
9. + Click **Apply** to implement your changes.
   Your changes are saved for the duration of the session.

Additional information

- *Using graphics display options*
- *Customizing viewport annotations*

Controlling perspective

Perspective representation accurately depicts the spatial relationship of three-dimensional objects in a two-dimensional plane. In other words, a three-dimensional model on your screen appears more realistic when perspective is turned on. Alternatively, parallel lines in the model appear parallel when perspective is turned off. Perspective affects all plots except *X–Y* plots, applies in all modules, and is turned on by default.

- To turn perspective on, select the  icon located in the View Options toolbar or select **View**->**Perspective** from the main menu bar.
- To turn perspective off, select the  icon located in the View Options toolbar or select **View**->**Parallel** from the main menu bar.

Your changes apply only to the current viewport and are saved for the duration of the session.

Additional information

• *Manipulating the view and controlling perspective*

Using the view manipulation tools

This section provides details of using the tools in the View Manipulation toolbar that allow you to manipulate the position, orientation, and scaling of the model or *X*–*Y* plot within a viewport.
When the viewport you manipulate is linked to other viewports, Abaqus/CAE also changes the view within every linked viewport in your session.

In this section:

- *Centering the view*
- *Panning the view*
- *Rotating the view*
- *Magnifying or reducing the view*
- *Zooming in to a selected area of the view*
- *Rescaling the view to fit the viewport*
- *Cycling through views*
- *Applying custom views*
- *Saving a user-defined view*
- *Applying a specified view*

Centering the view

Click mouse button 3 in the viewport to access the option to center the view.

You can also use the auto-fit tool  from the View Manipulation toolbar to quickly pan and magnify or reduce a view so that the view fills the viewport and is centered within it.

1. Position the cursor in the viewport at the location to be used to center the view, and click mouse button 3.
2. From the menu that appears, select **Center View**.

   Abaqus/CAE shifts the position that you selected to the center of the viewport.

Additional information

- *Linking viewports for view manipulation*
- *The view manipulation tools*
- *Rescaling the view to fit the viewport*

Panning the view

You can use the View Manipulation toolbar to move the view horizontally and vertically within the viewport.

Use the pan tool  from the View Manipulation toolbar to move the view horizontally and vertically within the viewport. Hold **[Shift]** while using the pan tool to access the alternate pan mode. The alternate mode shifts the view perspective as you pan the view, creating a more realistic image (for more information, see *The pan view tool*).

If the current viewport is linked to other viewports, Abaqus/CAE also moves the view of objects within all linked viewports in your session. For more information, see *Linking viewports for view manipulation*.

1. From the View Manipulation toolbar, click the pan tool  to enter pan mode.

    **Tip:** You can also select **View->Pan** from the main menu or press **[F2]**.

2. Position the cursor in the viewport whose view you want to change.

   The cursor changes to a four-headed arrow: 

3. Drag the cursor in any direction until you obtain the desired view.

   The position of your view of the model or *X*–*Y* plot in the viewport changes as you drag the cursor, and a rubberband line indicates the amount of translation.

    **Note:**

   The initial location of the cursor is not important, as long as you place it within the viewport. Cursor motion is limited only by the physical bounds of your monitor, and panning will continue even if you move the cursor outside the viewport or window.

4. Repeat Steps 2 and 3 until you achieve the desired view.
5. To exit pan mode, do one of the following:
   - Click mouse button 2.
   - Click the cancel button  in the prompt area.
   - Click the pan tool.
   - Click any other view manipulation tool.

    **Tip:** Use the *cycle* view manipulation tool to return to the previous view.

Additional information

- *Linking viewports for view manipulation*
- *The pan view tool*
- *The view manipulation tools*
- *Using the view manipulation tools*

Rotating the view

You can use the rotate tools to access several modes for manipulating views within the viewport.

Use the rotate tool  from the View Manipulation toolbar to rotate the view within the viewport. Hold **[Shift]** while using the rotate tool to access the alternate rotate mode. The alternate mode rotates the camera about itself instead of rotating it about the view center or the selected rotation center. The alternate mode is most useful when you use movie camera mode and position the camera inside of the model so that the model is surrounding the camera (for more information, see *The rotate view tool*). You can also specify a point in each viewport or select a location in each viewport to use as the center of rotation. Using the **Auto-fit after rotations** option in the **Graphics Options** dialog box, you can control whether or not Abaqus/CAE rescales your model to fit the viewport as you rotate.

 **Note:**

You cannot rotate *X*–*Y* plots.

If the current viewport is linked to other viewports, Abaqus/CAE also rotates objects within all linked viewports in your session. For more information, see *Linking viewports for view manipulation*.

Additional information

- *Linking viewports for view manipulation*
- *The rotate view tool*
- *The view manipulation tools*
- *Rescaling the view to fit the viewport*

Rotate the view

1. From the View Manipulation toolbar, click the rotate tool  to enter rotate mode.

    **Tip:** You can also select **View->Rotate** from the main menu or press **[F3]**.

2. By default, Abaqus/CAE rotates the view about the center of the viewport. You can change the center of rotation using one of the following methods:

   - Position the cursor at any location on the model or in the viewport, click mouse button 3, and select **Set As Rotation Center**.
   - Click **Select** in the prompt area. Select the center of rotation from the highlighted vertices in the viewport or enter coordinates to specify a point. In the Visualization module you can select a node and the center of rotation will remain on that node in both undeformed and deformed model states.

     When using this method, you can select a center of rotation only when there is existing geometry in the viewport. If you are working in the Sketcher, sketched points will not be available for selection.
   - Click mouse button 3 and select **Use Default Rotation Center**, or select **Use Default** in the prompt area to return to the default (center of viewport) rotation method.

   Your selected center of rotation persists in the viewport until you display another object in the viewport, select a new center of rotation, or return to the default rotation method.

3. Position the cursor in the viewport whose view you want to change.

   A large circle appears in the viewport and the cursor changes to a right facing arrow. If you selected a center of rotation in the viewport, it is highlighted.

4. Drag the cursor in any direction.

   The view rotates as you drag the cursor, and a rubberband line indicates the amount and direction of rotation.

   Tip: It is usually easier to achieve the desired orientation by performing a sequence of small rotations rather than a single large rotation.

   To rotate the view about the normal to the screen, move the cursor outside the circle and drag it clockwise or counterclockwise.

5. Repeat Steps 2, 3, and 4 until you achieve the desired views.
6. To exit rotate mode, do one of the following:
   - Click mouse button 2.
   - Click the cancel button  in the prompt area.
   - Click the rotate tool.
   - Click any other view manipulation tool.

   Tip: Use the *cycle* view manipulation tool to return to the previous view.

Rescale the view to fit the viewport as you rotate

1. From the main menu bar, select **View->Graphics Options**.

   The **Graphics Options** dialog box appears.
2. Toggle **Auto-fit after rotations** on to automatically rescale the view to fit the viewport as you rotate; toggle it off to disable automatic rescaling during rotation.
3. Click **OK** to implement your changes and close the dialog box.

   Your changes are saved for the duration of the session.

Magnifying or reducing the view

You can use the View Manipulation toolbar to change the scale of the view in the viewport.

Use the magnify tool  from the View Manipulation toolbar to change the scale of the view in the viewport. Hold **[Shift]** while using the magnify tool to access the alternate magnify mode. The alternate mode moves the camera closer to or farther from the objects in the view instead of changing the magnification. The alternate mode is most useful when you use movie camera mode (for more information, see *The magnify tool*).

Your configuration settings for the view manipulation options affect the behavior of the magnify tool. If you are using the default Abaqus/CAE view manipulation configuration, the magnify tool operates by dragging the cursor horizontally: dragging to the right zooms in and dragging to the left zooms out. In all other view manipulation configurations, the magnify tool operates by dragging the cursor vertically: dragging upward zooms in and dragging downward zooms out. See *Using view manipulation shortcuts*, for more information.

If your mouse has a wheel as mouse button 2, you can also change the scale of the view by scrolling up or down when the cursor is in the viewport. For *X*–*Y* plots the effect of this scrolling depends on the location of the cursor:

- When the cursor is within the *X*–*Y* plot grid, the *X*–*Y* plot will retain its aspect ratio as you magnify or reduce the view of the *X*–*Y* curves in the plot.
- When the cursor is placed on one of the axes, Abaqus/CAE stretches or compresses the *X*–*Y* plot along the axis you select. This functionality enables you to adjust your view of *X*–*Y* plots that exhibit much more change along one axis than the other.

If the current viewport is linked to other viewports, Abaqus/CAE also changes the scale of the view within all linked viewports in your session. For more information, see *Linking viewports for view manipulation*.

1. From the View Manipulation toolbar, click the magnify tool  to enter magnify mode.

    **Tip:** You can also select **View->Magnify** from the main menu or press **[F4]**.

2. Position the cursor in the viewport whose view you want to change.

   The cursor changes to a magnifying glass: 

3. Drag the cursor to change the view. The direction in which you drag depends on your view manipulation configuration settings. You can change these settings by selecting **Tools->Options** from the main menu bar and selecting a setting from the **View Manipulation Options** tabbed page.

   - If you are using the default view manipulation configuration, drag the cursor to the right of the starting point to magnify the view (zoom in). Drag the cursor to the left of the starting point to reduce the view (zoom out).
   - If you are using a nondefault view manipulation configuration, drag the cursor above the starting point to magnify the view (zoom in). Drag the cursor below the starting point to reduce the view (zoom out).

   Abaqus/CAE draws a rubberband line from the starting point as you drag the cursor across the screen. The rubberband line indicates the amount of zooming that has been applied, which is proportional to the component of your dragging motion in the effective direction.

4. Repeat Steps 2 and 3 until you achieve the desired view.
5. To exit magnify mode, do one of the following:

   - Click mouse button 2.

- Click the cancel button  in the prompt area.
- Click the magnify tool.
- Click any other view manipulation tool.

 **Tip:** Use the *cycle* view manipulation tool to return to the previous view.

Additional information

- *Linking viewports for view manipulation*
- *The magnify tool*
- *The view manipulation tools*
- *Using the view manipulation tools*

Zooming in to a selected area of the view

You can use the View Manipulation toolbar to enlarge the view so that a selected area fills the viewport.

Use the box zoom tool  from the View Manipulation toolbar to enlarge the view so that a selected area fills the viewport. If the current viewport is linked to other viewports, Abaqus/CAE enlarges the view in the linked viewports by the same factor. For more information, see *Linking viewports for view manipulation*.

1. From the View Manipulation toolbar, click the box zoom tool  to enter zoom mode.

    **Tip:** You can also select **View->Box Zoom** from the main menu or press **[F5]**.

2. Position the cursor in the viewport whose view you want to change.
   The cursor shape changes to crosshairs.
3. Position the cursor at one corner of the area to be enlarged.
4. Drag the cursor to the opposite corner.
   A rectangle indicates the area to be enlarged.
5. Release mouse button 1.
   The area defined by the rectangle enlarges to fill the viewport.
6. Repeat Steps 2 through 5 as many times as necessary to achieve the desired view.
7. To exit box zoom mode, do one of the following:
   - Click mouse button 2.
   - Click the cancel button  in the prompt area.
   - Click the box zoom tool.
   - Click any other view manipulation tool.

    **Tip:** Use the *cycle* view manipulation tool to return to the previous view.

Additional information

- *Linking viewports for view manipulation*
- *The box zoom tool*
- *The view manipulation tools*
- *Using the view manipulation tools*

Rescaling the view to fit the viewport

The View Manipulation toolbar contains a tool that rescales the view to fit the viewport.

Use the auto-fit tool  from the View Manipulation toolbar to quickly pan and magnify or reduce a view so that the view fills the viewport and is centered within it. When you fit a view, the orientation remains fixed, as indicated by the view triad. If the rescaled viewport is linked to other viewports, Abaqus/CAE magnifies or reduces the view in those viewports by the same factor. For more information, see *Linking viewports for view manipulation*.

From the View Manipulation toolbar, click the auto-fit tool  to enter auto-fit mode.

 **Tip:** You can also select **View->Auto-fit** from the main menu or press **[F6]**.

If you have only one viewport, Abaqus/CAE immediately scales the view to fit the viewport without changing the orientation, centers the view within the viewport, and exits fit mode. If you have more than one viewport, select the auto-fit tool and then place the cursor over the viewport you want to rescale. Click in the viewport to auto-fit; Abaqus/CAE rescales the view and exits fit mode.

 **Tip:** Use the *cycle* view manipulation tool to return to the previous view.

For information on how to automatically rescale the view to fit the viewport during rotation, see *Rotating the view*.

Additional information

- *Linking viewports for view manipulation*
- *The auto-fit tool*
- *The view manipulation tools*
- *Using the view manipulation tools*

Cycling through views

You can use the View Manipulation toolbar to cycle through previous views.

Use the cycle tool  from the View Manipulation toolbar to cycle through previous views; Abaqus/CAE saves the eight most recent views for each viewport.

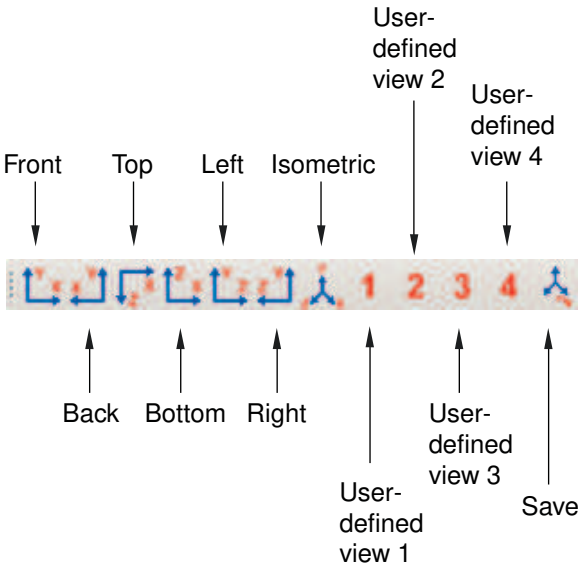
If the current viewport is linked to other viewports, Abaqus/CAE also cycles through the views in all linked viewports in your session. For more information, see *Linking viewports for view manipulation*.

1. From the View Manipulation toolbar, click the cycle tool  to enter cycle mode.

    **Tip:** You can also select **View->Previous Views** from the main menu or press **[F7]**.

2. Position the cursor in the viewport whose view you want to change (the cursor changes to a two-way arrow); then click.
3. To control the direction of cycling, click **Backward** or **Forward** in the prompt area. The default is to cycle backward.
4. Repeat Steps 2 and 3 as many times as necessary to achieve the desired views.

   After you cycle backward to the oldest available view, continued clicking has no effect. Similarly, after you cycle forward to the most recent view, continued clicking has no effect.
5. To exit cycle mode, do one of the following:
   - Click mouse button 2.
   - Click the cancel  or **Done** button in the prompt area.
   - Click the cycle view tool.
   - Click any other view manipulation tool.



Additional information

- *Linking viewports for view manipulation*
- *The cycle tool*
- *The view manipulation tools*
- *Using the view manipulation tools*

Applying custom views

Use the Views toolbar to orient, scale, and position a view to one of seven predefined or four user-defined settings.

To display the Views toolbar, select **View->Toolbars->Views** from the main menu; the Views toolbar is illustrated in the following figure:

The following custom views are available:

- **Front**, **Back**, **Top**, **Bottom**, **Left**, and **Right**: equivalent to observing the model from the six sides of a cube.
- **Iso**: an isometric view. This is the default orientation for three-dimensional models.
- **User1**, **User2**, **User3**, and **User4**: four user-defined views. See *Saving a user-defined view*, for a description of how to save a user-defined view.

If the current viewport is linked to other viewports, Abaqus/CAE also applies the same custom view to all linked viewports in your session. For more information, see *Linking viewports for view manipulation*.

1. If it is not visible already, display the Views toolbar by selecting **View->Toolbars->Views** from the main menu.

   Abaqus/CAE displays the Views toolbar.

2. From the Views toolbar, click the desired tool.

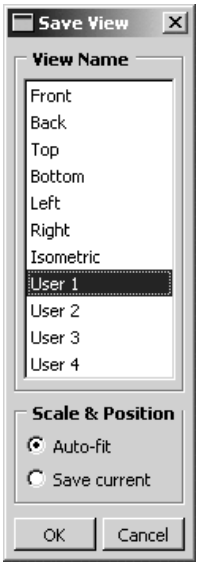
   If you have only one viewport, Abaqus/CAE immediately applies the selected view and unselects it from the Views toolbar. If you have more than one viewport, place the cursor over the viewport whose view you want to change. The cursor changes to a triad; click, and Abaqus/CAE applies the selected view to that viewport.

   Note:

   When you apply a view that was saved with the **Auto-fit** option selected, the view adopts the orientation of the saved view and immediately rescales it to fill the viewport. When you apply a view that was saved with the **Save current** option selected, the view adopts the orientation, zoom factor, and position of the saved view.

3. Repeat Step 2 as many times as necessary to achieve the desired view.

Tip: Use the *cycle* view manipulation tool to return to the previous view.



Additional information

- *Linking viewports for view manipulation*
- *Custom views*
- *Saving a user-defined view*
- *The view manipulation tools*
- *Using the view manipulation tools*

Saving a user-defined view

You can use the Views toolbar to open the **Save Views** dialog box and save a user-defined view.

Use the save tool  in the Views toolbar to open the **Save Views** dialog box and save a user-defined view. The **Save Views** dialog box is illustrated in the following figure:

Use the **Scale & Position** options to determine whether the saved view contains zoom factor and position information.

1. From the main menu bar, select **View->Save**.

    **Tip:** You can also save a view by clicking the  tool in the Views toolbar.

   If you have only one viewport, Abaqus/CAE immediately opens the **Save View** dialog box. If you have more than one viewport, click in the viewport whose view you want to save; Abaqus/CAE then opens the **Save View** dialog box.

2. From the **Save View** dialog box, choose the desired **Scale & Position** behavior:

   - Choose **Auto-fit** to save only the orientation of the view. When you apply a view saved with this option, the saved orientation is applied, but the scaling factor and position are adjusted to make the view fill the viewport.
   - Choose **Save current** to save the orientation, the zoom factor, and the position of the view. When you apply a view saved with this option, the saved orientation, scaling factor, and position are all applied.

3. In the **View Name** list in the **Save Views** dialog box, click the name of the tool you will use to recall this view.

   If you overwrite one of the six custom views—front, back, top, bottom, left, right—the other five views still retain their original definitions; that is, they do *not* become rotated to positions orthogonal to your saved view.

4. From the **Save View** dialog box, click **OK**.

Abaqus/CAE saves the definition of the view you selected. The view is saved only for the duration of the current session; the saved view will not be available the next time you run Abaqus/CAE.

Additional information

- *Linking viewports for view manipulation*
- *Custom views*
- *Applying custom views*
- *The view manipulation tools*
- *Using the view manipulation tools*

Applying a specified view

Select **View->Specify** from the main menu bar to specify a view. You can choose from the following methods to specify the view:

Rotation Angles

You can specify the angles through which Abaqus/CAE will rotate your view of the model about the model or screen 1-, 2-, and 3-axes. You can also choose to rotate your view of the model from an absolute position (a "Front" view) or from the current position.

Viewpoint

You can specify the coordinates of a vector along which an observer views your model. You can also orient the global 1-, 2-, and 3-axes within the viewport by specifying a vector representing the "up" direction.

Zoom

You can specify a zoom factor that expands or contracts the view. You can also choose to zoom the view relative to an absolute size of the objects in the viewport (the default size with a zoom factor of one applied) or relative to the current size of the objects in the viewport.

Pan

You can specify movement of the view in the 1- and 2-directions. The values correspond to fractions of the viewport horizontal and vertical dimensions and are relative to the current view.

For a more detailed explanation, see *Numerically specifying a view*.

If the current viewport is linked to other viewports, Abaqus/CAE also applies the specified view to all linked viewports in your session. For more information, see *Linking viewports for view manipulation*.

1. From the main menu bar, select **View->Specify**.

   Tip: You can also specify a view by double-clicking the 3D compass.

   Abaqus/CAE displays the **Specify View** dialog box.

2. From the **Specify View** dialog box, select the desired **Method** and do one of the following:

   - If you selected the **Rotation Angles** method, enter the rotation angles about the *X*-, *Y*-, and *Z*-axes (θ_x, θ_y, θ_z); a positive number corresponds to a counterclockwise rotation about each axis.

     Use the **Mode** button to specify how Abaqus/CAE is to apply your rotation:

     - Choose **Increment About Model Axes** to apply the rotation to the model axes of the current view.
     - Choose **Increment About Screen Axes** to apply the rotation to the screen axes of the current view. The screen *X*–axis is horizontal, the *Y*–axis is vertical, and the *Z*–axis is out of the screen. The origin of the screen axes is the center of the viewport.
     - Choose **Total Rotation From (0,0,1)** to first rotate the view to the default position (a view looking down the 3-axis with the 1- and 2-axes in the plane of the screen) and then apply the rotation.

- If you selected the **Viewpoint** method, enter the *X*-, *Y*-, and *Z*-coordinates of the viewpoint vector and the coordinates of the up vector.
- If you selected the **Zoom** method, enter the zoom factor and choose either **Absolute** or **Relative** magnification. A zoom factor greater than one expands your view of the model, and a zoom factor between zero and one contracts your view of the model.
- If you selected the **Pan** method, enter the values indicating how you want to position your view of the model relative to the current view. The values are fractions of the viewport dimensions; the first value represents horizontal motion, and the second value represents vertical motion.

3. Click **OK** to apply your specified view and to close the **Specify View** dialog box.

Tip: Use the *cycle* view manipulation tool to return to the original view.

Using the 3Dconnexion motion controllers with Abaqus/CAE

http://www.3dconnexion.com/ manufactures a variety of view manipulation devices that are popular with users of CAE and CAD systems. One example of their devices is the SpaceBall that is illustrated in *Figure 1*.

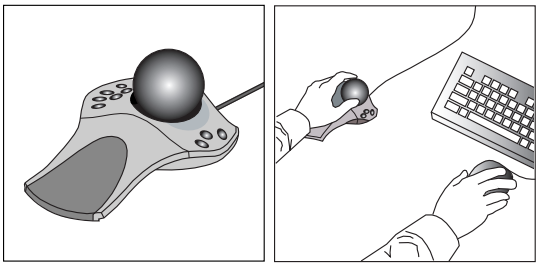

Figure 1: The 3Dconnexion SpaceBall.

You can use a 3Dconnexion motion controller together with the mouse to interact more efficiently with Abaqus/CAE. You can use the motion controllers to manipulate the view of your model with one hand while using the mouse to select from the model with the other hand. The motion controllers operate on whatever is under the cursor; for example, a part or a deformed plot in a viewport or a scrollbar in a dialog box. If neither a viewport nor a scrollbar is under the cursor, the motion controller operates on the current viewport.

You can change the center of rotation of an object if you use the motion controller in conjunction with the rotate view manipulation tool. By default, both the rotate tool and the motion controller rotate an object about the center of the viewport. However, you can select the center of rotation for both the rotate tool and the motion controller by positioning the cursor in the viewport at the location to be used as the center of rotation, clicking mouse button 3, and selecting **Set As Rotation Center**. Alternatively, if you click the rotate tool in the View Manipulation toolbar, a **Select** button appears in the prompt area. If you click on this button, you can select the center of rotation from a vertex or node in the viewport. The motion controller continues to use the specified rotation center even after you exit the rotate mode. For more information, see *The rotate view tool*.

In addition, Abaqus provides a set of "Application Functions" that are available through the standard 3Dconnexion user interface. These functions provide shortcuts to the view manipulation, view, and display tools. You can map these functions to the programmable buttons that are built into the 3Dconnexion motion controllers.

On Windows platforms Abaqus provides the following functions:

Movie Mode

Toggle between the default and alternate rotation modes. The default mode is comparable to rotating the camera around the camera target or selected center of rotation; the alternate mode rotates the camera about itself instead of about the camera target. You can also toggle on the alternate rotation mode if you hold down the **[Shift]** key while using the rotate view manipulation tool. For more information, see *Camera modes and view terminology*; *Using view options to control the camera*; and *The rotate view tool*.

Decrease Abaqus Sensitivity

Decrease the sensitivity of the 3Dconnexion motion controller. This setting applies only when manipulating the view in Abaqus/CAE.

Increase Abaqus Sensitivity

Increase the sensitivity of the 3Dconnexion motion controller. This setting applies only when manipulating the view in Abaqus/CAE.

Reset Abaqus Sensitivity

Restore the sensitivity of the 3Dconnexion motion controller to its default setting.

Auto-fit

Fit the model into the viewport. This is the same functionality as the auto-fit  view manipulation tool. For more information, see *The auto-fit tool*.

Keep in View

Keep the model in view during rotate and pan. When you are manipulating the view with the motion controller, toggling on this function prevents you from moving the target of the camera out of the viewport. Similarly, if you have changed the center of rotation, this option prevents you from moving the center out of the viewport.

Zoom to Cursor

Replace rotate and pan with zoom. If you press mouse button 2 and manipulate the motion controller, Abaqus/CAE disables the normal pan and rotate modes and replaces them with a mode that only zooms in or out from the area below the mouse cursor. If you release mouse button 2, the normal pan and rotate modes are restored. This behavior is enabled by default. You can use this function to toggle between the two modes.

Wireframe/Shaded

Toggle between wireframe and shaded render style. This is the same functionality as the wireframe  and shaded  icons located in the Render Style toolbar. For more information, see *Choosing a render style*.

Perspective

Toggle between perspective and parallel views. This is the same functionality as the perspective  and parallel  icons located in the View Options toolbar. For more information, see *Controlling perspective*.

Manipulate Layers

Manipulate all layers or the current layer. If you have created an overlay plot of results in the Visualization module, you can use this function to toggle between applying view manipulations to all the layers or to only the current layer. For more information, see *Manipulating the view for an overlay plot*.

Page Up

Page up in a scrollable dialog box. If the dialog box allows only horizontal scrolling, this button moves the page to the right.

Page Down

Page down in a scrollable dialog box. If the dialog box allows only horizontal scrolling, this button moves the page to the left.

Set Rotation Center

Set the center of rotation at the position of the mouse.

Clear Rotation Center

Clear a previously set center of rotation.

Set View Center

Center the view at the position of the mouse.

On Linux platforms Abaqus also provides a set of “Application Functions” that are available through the standard 3Dconnexion user interface. You should select Abaqus from the list of **Applications**. If Abaqus is not listed, you should select **XWindow Driver Version 2.0/3.0**.

The default mapping of the programmable buttons on Linux platforms is shown in the following table:

Button	Meaning
4	Movie mode
5	Decrease sensitivity
6	Increase sensitivity
7	Reset sensitivity
8	Auto-fit
9	Keep in view
A	Zoom to cursor ON/OFF
B	Wireframe/Shaded

The button mapping is fixed for the Abaqus application. However, 3Dconnexion allows you to reassign the buttons to use the standard functionality provided by their driver. For more information, see the Linux version of the 3Dconnexion documentation.

Selecting objects within the viewport

This chapter explains how to select objects that appear within a viewport, such as nodes, elements, vertices, edges, faces, and cells.

Selecting dialog box options is discussed in *Interacting with dialog boxes*. Selecting viewports is discussed in *Selecting viewports*.

In this section:

- *Understanding selection within viewports*
- *Selecting objects within the current viewport*
- *Using the selection options*

Understanding selection within viewports

This section describes the objects that you can select in a viewport and explains what these objects represent.

In this section:

- *What objects can you select from the viewport?*
- *What is a selection group?*
- *Understanding the correspondence between geometric and physical objects*

What objects can you select from the viewport?

Selecting an object within the current viewport is one of the most common tasks you have to perform during the modeling process. In the course of various procedures you may need to select geometric objects (vertices, edges, faces, cells, and datums) or discrete objects (nodes and elements) by picking them directly from the viewport. *Figure 1* shows these different object types.

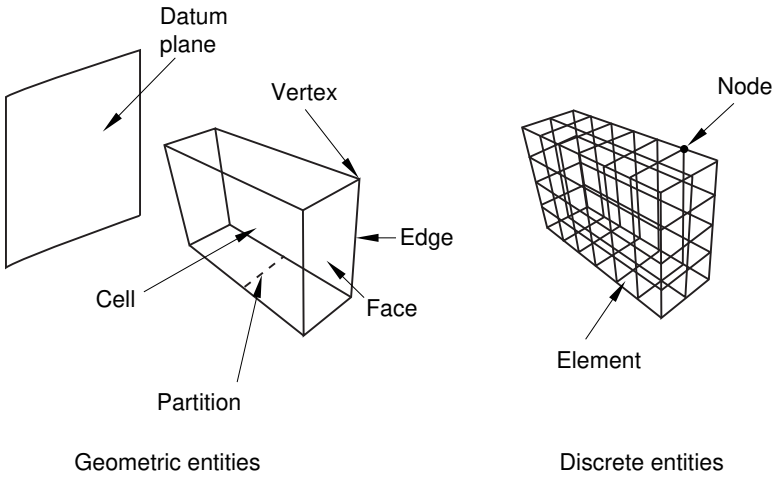

Figure 1: Object types that you can select.

You can select objects in the viewport during certain procedures, such as those listed below:

- Creating sets and surfaces
- Partitioning a part instance
- Editing a feature
- Seeding a part instance for meshing
- Creating or editing a display group composed of elements or nodes
- Color coding elements in your model
- Creating a node list path through your model
- Creating a load

You can also select objects in the viewport in advance of selecting a procedure. If you make selections prior to selecting a procedure, Abaqus/CAE does not limit your selections. When you select a procedure, Abaqus/CAE filters any selections that you made and keeps only those selections that are appropriate for the procedure. For more information, see *Selecting objects before choosing a procedure*.

If you select objects as part of a procedure, in most circumstances Abaqus/CAE only allows you to select objects that are appropriate for the current procedure. For example, the first step in partitioning an edge is selecting the edge of interest. Therefore, at this point in the procedure you can select only an edge; you cannot select a cell, a face, or a vertex. Messages in the prompt area guide you through the steps of a procedure and indicate which types of objects are available for selection. You can select only objects that are part of the current display group.

In some circumstances Abaqus/CAE cannot determine which objects are appropriate for selection and does not limit your selection. For example, when you are creating a set, you can select from cells, faces, edges, and vertices to include in the set and Abaqus/CAE allows you to select any of these objects. If you make an ambiguous selection from the viewport during a procedure, Abaqus/CAE allows you to cycle through the available objects until the desired object is selected. This ambiguity is described in *Cycling through valid selections*. You may find it easier to use the selection filters to limit the type of object you can select. For more information, see *Using the selection options*.

Many procedures to define attributes (interactions, constraints, loads, boundary conditions, predefined fields, and engineering features) allow you to select objects from the viewport to identify the region on which to apply the attribute. The default behavior for these procedures is to create a set or surface that contains the selected objects. You can change this behavior by toggling off the option to create a set or surface in the prompt area. A default name is provided in the prompt area, but you can enter a new name.

Additional information

- *Understanding selection within viewports*
- *Selecting objects within the current viewport*

What is a selection group?

You can copy entities (vertices, edges, faces, or cells) that are highlighted in the viewport into a temporary storage area called a selection group. Abaqus/CAE saves the selection group for the duration of a session. Rather than manually reselecting the same entities during a subsequent selection procedure, you can paste the selection group into your selection. For example, you can copy all of the small faces highlighted by the **Geometry Diagnostics** query tool into a selection group. You can then paste the same selection group into your selection when you are using the Geometry Edit toolset to repair small faces.

When you paste a group into your selection, you can choose from selection groups and from display groups. Selection groups are designed to be a temporary convenience for the user, and they do not appear with display groups in the Display Groups toolset. You can create any number of display groups. In contrast, Abaqus/CAE saves a maximum of five selection groups. Abaqus/CAE overwrites the existing selection groups if you create more than five selection groups.

After you have selected the desired entities, you create a selection group by clicking mouse button 3 in the viewport and selecting **Copy** from the menu that appears. Abaqus/CAE copies all of the highlighted entities into a selection group. You paste a selection group to your current selection by clicking mouse button 3 in the viewport and selecting **Paste** from the menu that appears. Abaqus/CAE displays the **Paste to Selection** dialog box, and you can select one or more of the existing selection groups to paste to your current selection. When you paste a group, Abaqus/CAE appends the entities in the group to any other entities that you have already selected.

Note:

You cannot create or use selection groups if you are selecting objects in advance of selecting a procedure.

Understanding the correspondence between geometric and physical objects

When you select geometric objects in a viewport, it is important to understand what physical structure each object represents. The geometric objects that make up a model—cells, faces, edges, and vertices—can represent different physical structures depending on the space in which they are embedded.

For example, beams and other wire parts are represented by edges in the geometric model (see *Figure 1*).

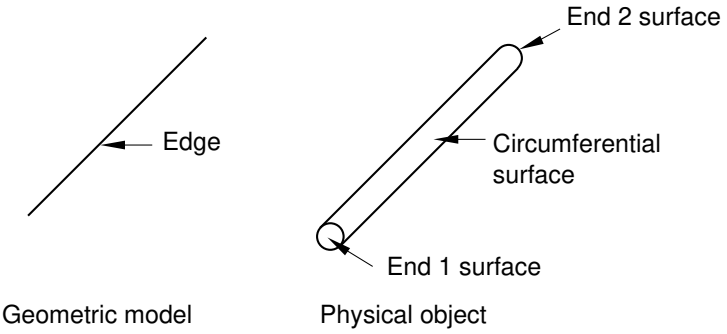

Figure 1: Selecting wire parts.

The end surfaces of these parts are represented by the vertices on either side of the edge, and the circumferential surface is represented by the line joining the vertices. To select a wire part, you can click the edge, and, if necessary, Abaqus/CAE prompts you to specify the surface of interest.

Likewise, axisymmetric shells are also represented by edges in the geometric model (see *Figure 2*).

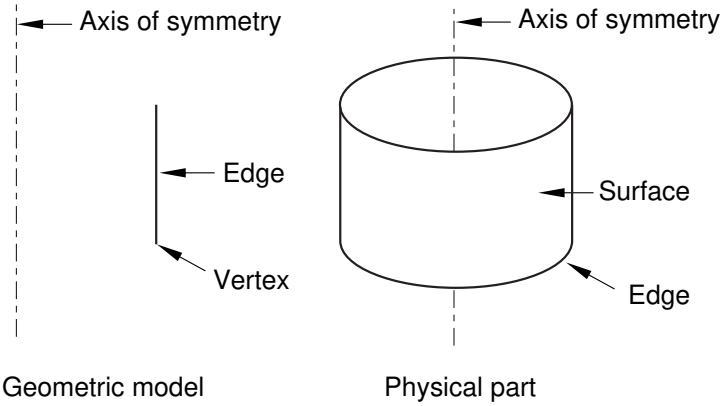

Figure 2: Selecting axisymmetric shells.

You can select the axisymmetric shell by clicking the edge in the viewport, and, if necessary, Abaqus/CAE prompts you to specify either the inside surface or the outside surface of the shell. You must select either the inside or the outside surface if you are applying a prescribed condition or contact definition to the surface. For example, if you want to apply a pressure load to a shell, you must specify which side of the shell should receive the load.

For more information on selecting surfaces, see *Specifying a particular side or end of a region*. For more information on modeling space, see *The relationship between parts and features*, and *Part modeling space*.

Additional information

- *Understanding selection within viewports*
- *Selecting objects within the current viewport*

Selecting objects within the current viewport

This section describes techniques that you can use for selecting one or more objects in the current viewport.

In this section:

- *Selecting and unselecting individual objects*
- *Drag-selecting multiple objects*
- *Using the angle and feature edge method to select multiple objects*
- *Using the face curvature method to select multiple faces*
- *Using the topology method to select multiple elements*
- *Using the limiting angle, layer, and analytic methods to select multiple element faces*
- *Adding adjacent objects to a selection*
- *Combining selection techniques*
- *Excluding objects from your selection*
- *Cycling through valid selections*
- *Using groups while selecting entities*
- *Selecting interior surfaces*

Selecting and unselecting individual objects

Selecting and unselecting objects in the current viewport are straightforward operations that use standard methods. For more information on selecting viewports, see *Selecting viewports*.

Preselection highlighting allows you to preview which object Abaqus/CAE will select if you click at the current cursor location. In addition, preselection in the Sketcher uses a secondary cursor to indicate the exact position and type of entity that will be selected. (For more information on Sketcher preselection, see *The Sketcher cursors and preselection*.)

You will use the following three selection operations most frequently:

Click to select an object

To select a single object from the current viewport, move the cursor to the object and click mouse button 1.

- To select a point, click the corresponding point marker. The point marker changes color when selected. Vertices that you can select are marked by small, filled circles; and datum points are marked by small, unfilled circles. (See *Understanding the role of datum geometry*, for information on datum points.) Edge midpoints and arc centers that you can select are marked by small diamonds.

  Note:

  Some of the selection markers that appear when you are using the Sketch module are different from those described here. For information on selecting objects while using the Sketch module, see *The Sketcher cursors and preselection*.

- To select an edge, click the edge while positioning the cursor away from any vertex. Selected edges are highlighted.
- To select a face, click the face while positioning the cursor away from any edge or vertex. Selected faces are highlighted with a grid pattern. (The grid pattern is unrelated to mesh element location.)
- To select a cell, click any of its faces. All edges of selected cells are highlighted.

If you are unable to select the desired objects, you can use the **Selection** toolbar to change the selection behavior. For more information, see *Using the selection options*.

Once you select an object, any objects previously selected in the current viewport are unselected automatically.

If your current procedure, options, and cursor position do not clearly specify one object for preselection, Abaqus/CAE highlights all of the potential selections and adds ellipsis marks (...) next to the cursor arrow to indicate an ambiguous preselection. If you accept an ambiguous preselection or otherwise make an ambiguous selection, use the buttons in the prompt area to make your final selection. For more information, see *Cycling through valid selections*.

[Shift] + Click to select additional objects

To select an additional object, move the cursor to the object and **[Shift] + Click**. Your original selection remains highlighted, and the newly selected object becomes highlighted.

An alternative method for selecting multiple objects is to drag a rectangle around the objects. For more information, see *Drag-selecting multiple objects*.

[Ctrl] + Click to unselect objects

To unselect an object, move the cursor to the object and **[Ctrl] + Click**. To unselect all objects, click an unused region of the current viewport.

When you have finished selecting and unselecting items in the viewport, click mouse button 2 to confirm your selection. You can use the selection option tools to adjust the shape of the drag-select region. You can also choose which objects are selected by the drag-select region. The selection option tools are located in the **Selection** toolbar. For more information, see *Modifying the shape of the drag-select region*, and *Choosing which objects are selected by the drag-select region*.

Additional information

- *Understanding selection within viewports*
- *Selecting objects within the current viewport*
- *The Sketcher cursors and preselection*
- *Using the chain method to select edges in the Sketcher*

Drag-selecting multiple objects

Most prompts ask you to select just one object from the current viewport. However, some tasks allow you to select one or more objects; for example, the Set toolset allows you to select several objects of the same type and group them into sets. You can select multiple objects using the **[Shift] + Click** method described in *Selecting and unselecting individual objects*. An additional method for selecting multiple objects is to drag a rectangle around those objects. You can use the selection option tools to adjust the shape of the drag-select region. You can also choose which objects are selected by the drag-select region. The selection option tools are located in the **Selection** toolbar. For more information, see *Modifying the shape of the drag-select region*, and *Choosing which objects are selected by the drag-select region*.

1. Imagine a rectangle that encloses only the objects you want to select.
2. Click at one corner of the rectangle and, while continuing to press the mouse button, drag until you have enclosed all the objects.
3. Release the mouse button.

   All the valid objects inside or crossing the rectangle are highlighted.
4. Click mouse button 2 to indicate that you have finished selecting objects.

Sometimes it is convenient to use a combination of the **[Shift] + Click** and drag-select selection techniques. For more information, see *Combining selection techniques*.

Tip: If you select multiple objects and then want to unselect one or more of them, **[Ctrl] + Click** the objects you want to unselect. To unselect all the objects, click in an unused area of the viewport.

Additional information

- *Selecting objects within the current viewport*
- *Selecting and unselecting individual objects*
- *Cycling through valid selections*
- *Using the chain method to select edges in the Sketcher*

Using the angle and feature edge method to select multiple objects

In complicated models selecting individual faces or edges from geometry or selecting element faces or nodes from a mesh can be time consuming and prone to error. For example, when creating a surface from a mesh, you must select the individual element faces that make up the surface and append them to your selection. To speed up the selection process, Abaqus/CAE provides the angle and feature edge methods for selecting multiple faces, edges, elements, element faces, or nodes.

When you are performing a task in which you must pick more than one face or edge from geometry or more than one element, element face, or node from a mesh, Abaqus/CAE displays a field in the prompt area. The field allows you to choose between three selection methods—**individually**, **by angle**, and **by feature edge**, as shown in *Figure 1*.

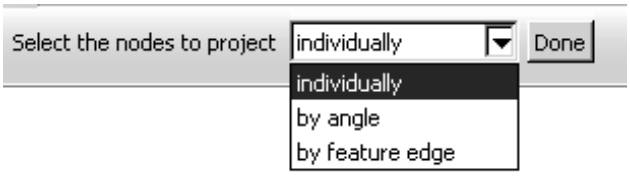

Figure 1: Choose the selection method from the field in the prompt area.

Individually

Selecting individual objects is described in *Selecting and unselecting individual objects*.

By angle

Selecting objects using the angle method is a two-step process:

1. In the prompt area, you enter an angle (from 0° to 90°).
2. From the part or assembly, you select a face, edge, element face, or node.

The angle must be greater than the angle through which adjacent edges or faces must rotate to create the geometry as if it was being formed by bending a straight wire or folding a series of faces. Abaqus/CAE starts from the selected geometry and selects all adjacent geometry until the angle you entered is met or exceeded.

For example, to select the edges of a regular hexagon, enter an angle greater than 60° (since each adjacent edge must be rotated 60° to form the shape from a straight wire), and select one of the edges. Abaqus/CAE then selects every adjacent edge since none of the angles is equal to or exceeds the angle that you entered.

Figure 2 illustrates how the angle method allows you to select all the elements around the flange of an exhaust manifold mesh.

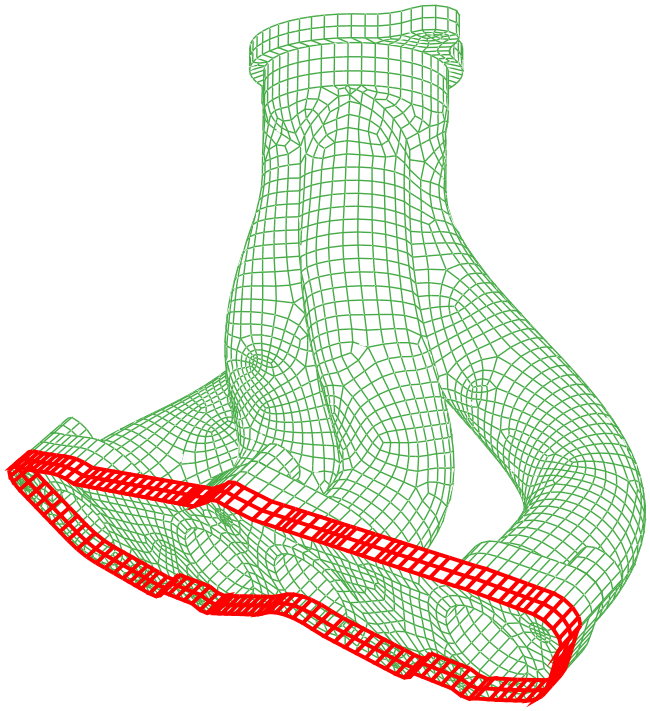

Figure 2: Enter an angle and select an element to select an entire face.

In the Sketch module, the angle method is available only when you are selecting objects from the underlying part or assembly. When you are selecting edges in the sketch, the chain method replaces the angle method. Use the chain method to select a group of edges that are connected end-to-end, like the links of a chain. For more information on the chain method, see *Using the chain method to select edges in the Sketcher*.

By feature edge

The feature edge method is also a multistep process:

1. In the prompt area, you enter an angle (from 0° to 90°).
2. Abaqus/CAE identifies all the feature edges in your model by finding all the element edges where the angle between two adjacent element faces is greater than the angle specified.
3. From the mesh, you select an element edge or node.
4. Abaqus/CAE follows the feature edge that passes through the selected element edge or node. The feature edge is truncated if another feature edge intersects it at an angle greater than the angle specified in Step 1.
5. Abaqus/CAE selects all the elements or nodes along the feature edge.

Figure 3 illustrates how the feature edge method allows you to select all the nodes along the edges of a flange of an exhaust manifold mesh.

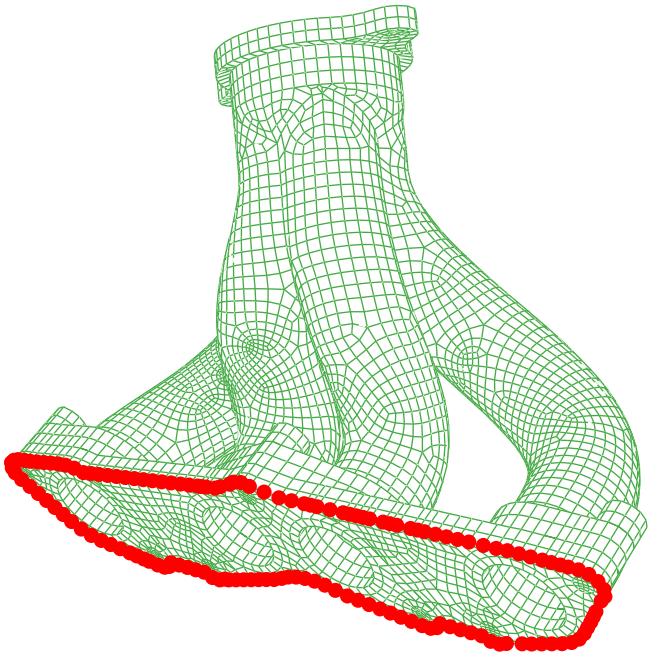

Figure 3: Enter an angle and select a segment of an edge to select adjacent nodes.

After you use the angle or feature edge methods, you can click the **individually** method in the prompt area and **[Shift] + Click** on individual faces, edges, elements, element faces, or nodes to append them to your selection. You can also **[Ctrl] + Click** on items to unselect them. In addition, you can continue to use the angle and feature edge methods and use **[Shift] + Click** to append faces, edges, elements, element faces, or nodes to your selection. You can keep the same angle, or you can change the angle while you continue to append items. For more information, see *Combining selection techniques*.

Additional information

- *Selecting objects within the current viewport*
- *Understanding selection within viewports*

Using the face curvature method to select multiple faces

In addition to selecting objects by the angle between them, you can select multiple faces from a part based on the curvature of the faces. When you are performing a task that allows you to pick more than one geometric face, Abaqus/CAE displays a field in the prompt area. The field allows you to choose between the three selection methods—**individually**, **by face angle**, and **by face curvature**, as shown in *Figure 1*.

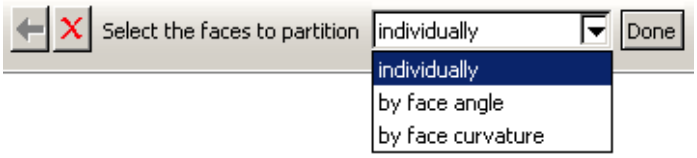

Figure 1: Choose the selection method from the field in the prompt area.

The angle selection method is described in *Using the angle and feature edge method to select multiple objects*.

The face curvature method is available during procedures that select faces. If a procedure accepts object types other than faces, you can change the object type in the **Selection** toolbar to **Faces** to access the face curvature method.

Select a face from the part or assembly. Abaqus/CAE selects all connected faces that have similar curvature along both principal directions and are joined at an angle of less than 20°. If you select a flat face, Abaqus/CAE adds any adjoining flat faces that lie in the same plane. Disconnected faces that share similar curvature are not selected, nor are faces that share similar curvature but have significantly different face normals at the edge where they meet. *Figure 2* shows two rounded faces selected using the face curvature method.

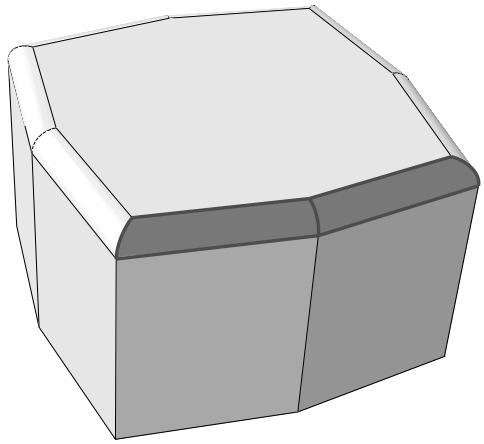

Figure 2: Select a single curved face to select adjoining faces with similar curvature.

After you use the face curvature method, you can click the **individually** method in the prompt area and **[Shift] + Click** on individual faces to append them to your selection. You can also **[Ctrl] + Click** on items to unselect them. In addition, you can continue to use the face curvature method and use **[Shift] + Click** to append faces to your selection. For more information, see *Combining selection techniques*.

Additional information

- *Understanding selection within viewports*
- *Selecting objects within the current viewport*

Using the topology method to select multiple elements

You can select multiple elements based on the connection of a row or layer of elements. When you are performing a task that allows you to pick more than one element, Abaqus/CAE displays a field in the prompt area. The field allows you to choose between the four selection methods—**individually**, **by angle**, **by feature edge**, and **by topology**, as shown in *Figure 1*.

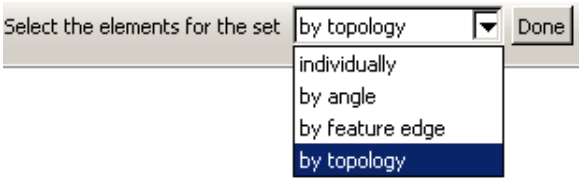

Figure 1: Choose the selection method from the field in the prompt area.

The angle and feature edge selection methods are described in *Using the angle and feature edge method to select multiple objects*.

The topology method is available during most procedures that select elements. If a procedure accepts object types other than elements, you can change the object type in the **Selection** toolbar to **Elements** to access the topology method.

The topology method is designed for use with two- and three-dimensional structured meshes. Select an element face from the mesh, and Abaqus/CAE selects all the elements connected to it in a row through the mesh. Select an element edge from the mesh, and Abaqus/CAE selects all the elements in a layer starting with the element faces that share the selected edge. *Figure 2* shows selection of an interior row on the left and an interior layer on the right.

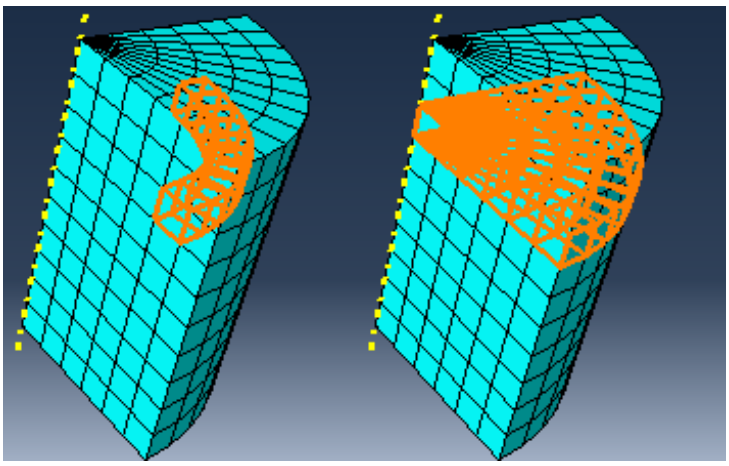

Figure 2: Using the topology method to select a row or a layer of elements.

You can use the topology method to select elements from other mesh types, but without the clearly defined rows or layers of a structured mesh, the selections may be unpredictable. In some cases, such as with a tetrahedral mesh, topology selection may be limited to only the elements that share the face or edge you select.

After you use the topology method, you can select other methods in the prompt area and **[Shift] + Click** to append more elements to your selection. You can also **[Ctrl] + Click** on items to unselect them. In addition, you can continue to use the topology method and use **[Shift] + Click** to append elements to your selection. For more information, see *Combining selection techniques*.

Additional information

- *Understanding selection within viewports*

- *Selecting objects within the current viewport*

Using the limiting angle, layer, and analytic methods to select multiple element faces

When you are selecting orphan element faces to create geometry (for more information, see *Create face from element faces*), Abaqus/CAE displays a field in the prompt area. The field allows you to choose between five selection methods—**individually**, **by angle**, **by limiting angle**, **by layer**, and **by analytic**, as shown in *Figure 1*.

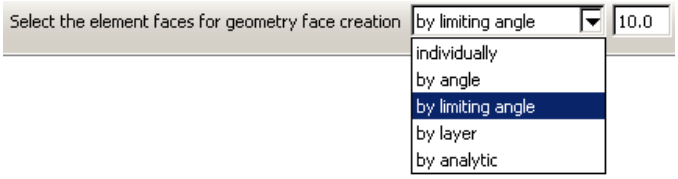

Figure 1: Choose the selection method from the field in the prompt area.

The angle selection method is described in *Using the angle and feature edge method to select multiple objects*. The limiting angle, layer, and analytic methods are available only while selecting orphan element faces to create new geometric faces.

By limiting angle

Selecting objects using a limiting angle is a two-step process:

1. In the prompt area, you enter an angle (from 0° to 90°).
2. From the part or assembly, you select an orphan element face.

The angle must be greater than the total angle between the selected element face and the element faces connected to it. Abaqus/CAE starts from the selected geometry and selects all adjacent geometry until the angle between the selected face and the last face in the series of adjacent faces meets or exceeds the angle you entered. *Figure 2* shows selection of element faces with a limiting angle of 45°, and one of the vertical element faces below the rounded area is picked.

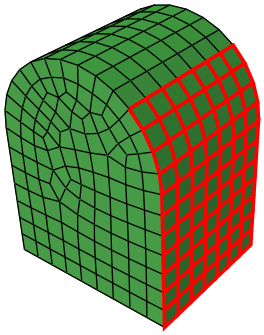

Figure 2: A limiting angle of 45° with a selected vertical face.

Increasing the limiting angle to its maximum of 90° would select the faces up to the top of the rounded section. In contrast, using the angle method with an angle of 13° or more would continue the selection around the rounded portion and down the far side since the angle between each adjacent face is less than 13°.

By layer

Selecting objects using the layer method is a two-step process:

1. In the prompt area, you enter a number of layers.
2. From the part or assembly, you select an orphan element face.

Abaqus/CAE starts from the selected face and selects layers of adjacent element faces around it in all directions. Selection continues around corners and other features until the number of layers is reached or until there are no more adjacent orphan element faces.

Figure 3 illustrates the selection of three layers of orphan shell element faces around a starting face and the resulting geometric face.

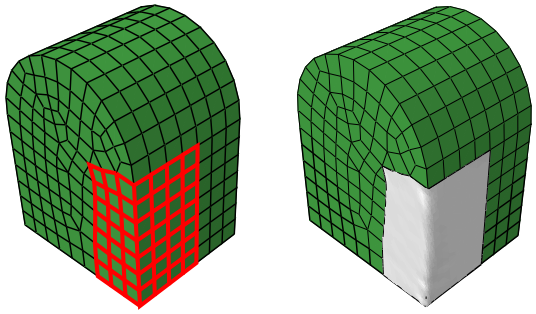

Figure 3: Face layer selection and creation of a geometric face.

As shown in *Figure 3*, layer selection can traverse sharp corners and other model features that would normally signify the end of a geometric face. In most cases you should preserve logical model edges and other features by creating separate faces. Otherwise, the resulting geometry may be difficult to repair and mesh.

Note:

When you are working with solid orphan elements, selections that include multiple faces from the same orphan element are not acceptable for the creation of a single geometric face.

By analytic

The analytic selection method for orphan element faces is based on the recognition of basic shapes in analytic geometry (such as planes, cylinders, cones, spheres, and tori), or portions of these shapes. Analytic selection attempts to recognize the logical boundaries of a set of orphan element faces that would make a recognizable geometric face.

Figure 4 illustrates analytic selection of orphan element faces. A spherical section of element faces is highlighted; this selection could not be made using any of the other selection options for multiple objects.

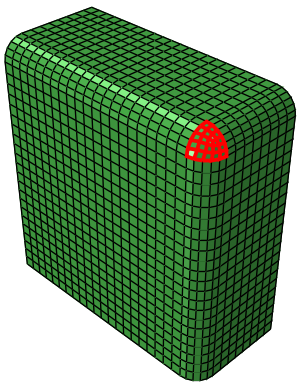

Figure 4: Analytic geometry selection.

After you use any of the above methods, you can select other methods in the prompt area and **[Shift] + Click** to append more elements to your selection. You can also **[Ctrl] + Click** on items to unselect them. In addition, you can continue to use the current method and use **[Shift] + Click** to append elements to your selection. For more information, see *Combining selection techniques*.

Additional information

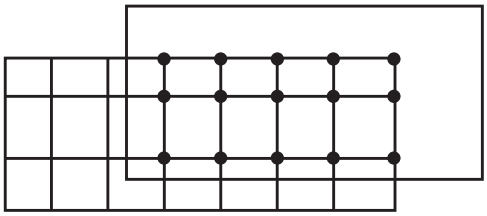
- *Understanding selection within viewports*
- *Selecting objects within the current viewport*
- *Create face from element faces*

Adding adjacent objects to a selection

If you have already selected one or more objects, you can expand your selection to include all adjacent objects of the same type. Adding adjacent objects is an alternative to using drag-select or the angle method (see *Drag-selecting multiple objects*, and *Using the angle and feature edge method to select multiple objects*, respectively) to quickly select multiple objects. Selecting adjacent objects allows you to expand your selection in all directions, regardless of the shape of surrounding features or the angle at which objects are joined. It also allows you to pick multiple areas of interest in a model and expand the selection set in each area at the same time.

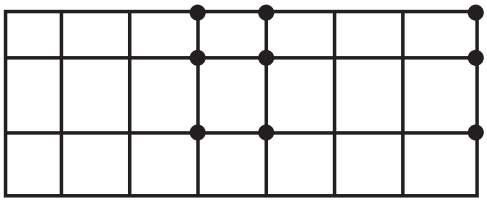
To add adjacent objects to the current selection, click mouse button 3 over an existing selected object and select **Add Adjacent Entities**. Abaqus/CAE expands your selections to all adjacent objects of the same type, including objects that are not included in the current display. If necessary, Abaqus/CAE adds the newly selected objects to the current display group to make them visible. Adjacent objects are defined in terms of the currently selected entities as follows:

- Edges that share a common vertex with one or more selected edges
- Vertices that share a common edge with one or more selected vertices
- Faces that share a common vertex or edge with one or more selected faces
- Nodes that share a common edge with one or more selected nodes
- Elements that share a common element edge or node with a selected element



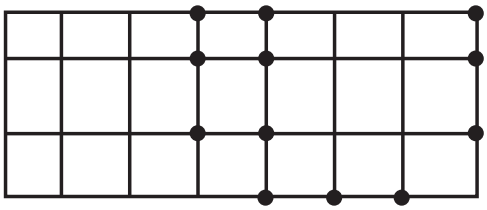
Additional information

• *Selecting objects within the current viewport*
• *Using the chain method to select edges in the Sketcher*



Combining selection techniques

There are times when it is convenient to use a combination of the methods for selecting and unselecting objects. For example, you can drag-select a group of nodes while creating a node set using the Set toolset. You can then **[Ctrl] + Click** individual nodes to unselect them and **[Shift] + Click** additional nodes to add them to your selection. A combination of the three techniques is illustrated below:



1. First, you use drag-select to select a group of nodes.

2. Then, you use **[Ctrl] + Click** to unselect individual nodes.

3. Finally, you use **[Shift] + Click** to add nodes to your set and then click mouse button 2 to indicate you have finished selecting.

You may find it useful to adjust the view orientation to make particular items in the viewport more accessible. You can adjust the view orientation at any point during the selection process. For information on the view manipulation tools, see *Manipulating the view and controlling perspective*.

Tip: To unselect all the objects, click an unused part of the current viewport.

Additional information

- *Selecting objects within the current viewport*
- *Selecting and unselecting individual objects*
- *Drag-selecting multiple objects*
- *Using the chain method to select edges in the Sketcher*

Excluding objects from your selection

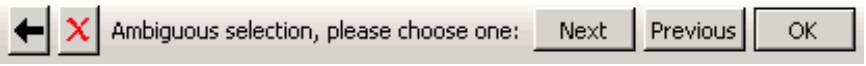
When you select an object from the viewport, your selection includes all the entities of lower dimensionality that are associated with the object. For example, if you select a cell, your selection includes all the faces, edges, and vertices associated with the cell. Similarly, if you select an edge, your selection includes all the vertices associated with the edge. In some circumstances you may want to exclude the entities of lower dimensionality from your selection. For example, if you select an edge to include in a set, you may not want the set to contain the vertices at each end of the edge. Excluding entities of lower dimensionality from your selection may solve any problems that you encounter with overconstraints.

1. Select all the objects using a combination of select, drag-select, **[Ctrl] + Click**, and **[Shift] + Click**.
   Abaqus/CAE highlights the selected objects in red.
2. **[Ctrl] + Click** an object to exclude it from your selection.
   Abaqus/CAE highlights the excluded objects in purple.

Additional information

- *Selecting objects within the current viewport*
- *Selecting and unselecting individual objects*
- *Cycling through valid selections*
- *Using the chain method to select edges in the Sketcher*

Cycling through valid selections



In some cases Abaqus/CAE is unable to differentiate between the object you have selected and other nearby or related objects. This ambiguity can arise as follows:

- Imagine a small square surrounding the cursor. When you click an object, any other valid objects of the same type that fall inside this square are also considered to be possible selections. For example, if you select an edge that is positioned very close to another edge, Abaqus/CAE may consider both edges to be possible selections.

  The size of the square is independent of the monitor size, the viewport size, and the dimensions of the model. It also remains constant when you zoom in and out on your model. Therefore, you can select a specific object in the viewport more precisely by zooming in on your model to increase the distance between objects.
- If your model is three-dimensional, imagine a line that is perpendicular to the screen and that passes through the cursor and into the model. When you select an object, any valid objects of the same type that intersect this line are considered to be possible selections. (Rotating your model may remove some of the ambiguity.)

Abaqus/CAE reduces the potential for ambiguity by filtering your selection against the current procedure whenever possible. For example, if you are partitioning a cell, Abaqus/CAE prompts you to select the cell to partition. When you make a selection, Abaqus/CAE considers only cells to be a valid selection. Conversely, if you are creating a geometry set, Abaqus/CAE considers cells, faces, edges, and vertices to be a valid selection and the potential for ambiguity is increased. In addition, preselection highlighting allows you to see exactly which object would be selected before you make the selection. Moving the cursor around the viewport may remove the ambiguity in the selection and result in Abaqus/CAE highlighting the object of your choice. If the ambiguity remains, Abaqus/CAE changes the cursor, adding ellipsis marks (...) to the right of the arrow, and highlights all the possible selections.

When your selection is ambiguous, Abaqus/CAE displays buttons in the prompt area that allow you to cycle through all of the possible selections, as shown here:

Use the **Next** and **Previous** buttons to cycle forward and backward through all of the objects in the viewport that are possible selections; each object becomes highlighted in turn. When the object of your choice is highlighted, click **OK** or click mouse button 2 to confirm your selection. (You can also click mouse button 3 in the current viewport to reveal a menu of the options in the prompt area.)

Additional information

• *Selecting objects within the current viewport*

Using groups while selecting entities

You can append groups of entities to your selection to speed up the process of selecting many entities from the viewport. The group can be a display group, or it can be a temporary selection group. You can click mouse button 3 on the viewport and do the following:

- Create a selection group by copying entities (vertices, edges, faces, or cells) that are highlighted in the viewport into a selection group.
- Append to your selected entities by pasting the entities stored in a selection group or a display group into your current selection.

Selecting interior surfaces

You can use the selection tools to select an interior surface of a model; for example, when you create a surface or when you select a region using the solid offset mesh tool.

1. In the **Selection** toolbar, toggle on the **Select From Interior Entities** tool .

   Note:

   The **Select From Interior Entities** tool is hidden by default. For more information, see *Using toolboxes and toolbars that contain hidden icons*.

2. Select the interior surface from the viewport.

Additional information

- *Understanding and using toolboxes and toolbars*
- *Understanding selection within viewports*
- *Selecting objects within the current viewport*
- *Filtering your selection based on the position of the object*
- *What is a surface?*
- *Specifying a particular side or end of a region*

Using the selection options

Abaqus/CAE provides a set of tools that can make it easier and more efficient for you to select entities from the viewport.
The selection tools are located in the **Selection** toolbar. The available options depend on the current selection procedure; some options can be used to preselect entities outside of a procedure.

This section describes the selection options.

In this section:

- *Available selection options*
- *Filtering your selection based on the type of object*
- *Filtering your selection based on the position of the object*
- *Highlighting objects prior to selection*
- *Modifying the shape of the drag-select region*
- *Choosing which objects are selected by the drag-select region*
- *Selecting objects before choosing a procedure*

Available selection options

When you are prompted to select an object from the viewport, Abaqus/CAE provides selection tools that can make it easier and more efficient for you to make the desired selection.

Use the **Selection** toolbar to configure the selection options. *Figure 1* shows the layout of the selection tools. Selection tools appear dimmed if they are not valid for the current procedure.

Figure 1: The Selection toolbar.

Additional information

- *Components of the toolbars*
- *Using dimmed dialog box and toolbox components*
- *Selecting objects within the current viewport*
- *Using the selection options*

Filtering your selection based on the type of object

To help you select the desired entities (such as vertices, edges, faces, nodes, and elements) from the current viewport, Abaqus/CAE provides a set of filters that you can use to limit your selection based on the type of object.
For example, if you are creating a set that contains only surfaces, you can limit your selection to only faces—other objects, such as vertices and edges, will not be selected.

The object filters are listed in the **Selection** toolbar. Abaqus/CAE configures the filter list based on the current procedure. If you have not started a selection procedure, Abaqus/CAE lists some commonly used filters (for more information on selecting objects outside of a procedure, see *Selecting objects before choosing a procedure*).

You can press **[Ctrl] + A** to select all objects in the current viewport based on the active selection filter. The view is rescaled to fit the viewport to clearly display the selected objects, which are highlighted in the viewport. For example, if edge objects are selected in the filter and you press **[Ctrl] + A**, all edges visible in the viewport are selected. You cannot customize the **[Ctrl] + A** keyboard shortcut.

If the current viewport contains an Abaqus/CAE part or part instance, you can select one of the following filters:

All

All objects except skins and stringers.

Cells

All volumes, such as cells and elements.

Faces

All planar objects, such as faces, datum planes, and element faces.

Edges

All edge objects, such as edges, datum axes, and element edges.

Vertices

All point objects, such as vertices, datum points, and nodes.

Elements

All elements.

Nodes

All nodes.

Datums

All datum objects, such as datum planes, datum axes, and datum points.

Features

All feature objects.

Ref points

All reference points.

The list of available filters is updated as you change modules or selection procedures, and additional filters (such as **Instances**, **Skins**, and **Stringers**) are displayed where applicable. By default, Abaqus/CAE selects from all objects but excludes skins and stringers. You can select a skin or stringer from the viewport only after you select the appropriate filter.

Similarly, if you are selecting orphan elements in the current viewport (to assign an element type, for example), you can select one of the following filters:

- All
- Zero-dimensional elements
- One-dimensional elements
- Two-dimensional elements
- Three-dimensional elements
- Skins
- Stringers

By default, Abaqus/CAE selects from all elements except skins and stringers.

• *Using the selection options*

Filtering your selection based on the position of the object

The selection tools allow you to choose from which objects to select, based on their positions in the viewport. The **Selection** toolbar contains all of the selection tools.

The following position-based selection tools are available only after you start a procedure that requires object selection (position-based selection is not available outside of a procedure):

Objects closest to the screen

 Toggle on this tool to select only the objects closest to the front of the screen. This tool is toggled on by default.

If you toggle off this tool, Abaqus/CAE allows you to cycle through all of the possible selections. Use the **Next** and **Previous** buttons in the prompt area to cycle forward and backward through all of the objects in the viewport that are possible selections; each object becomes highlighted in turn. For more information, see *Cycling through valid selections*.

This filter applies to native vertices, edges, faces, and cells and to orphan nodes and orphan elements.

Interior and exterior objects

Choose one of the following filters:

-  Select objects located both outside and inside a part.
-  Select only objects located on the outside of a part. In most cases this tool is selected by default.
-  Select only objects located on the inside of a part.

• *Using the selection options*

Highlighting objects prior to selection

When you are selecting objects from the viewport and you stop moving the cursor, Abaqus/CAE highlights the object that would be selected at the cursor position.
This behavior, called “preselection,” allows you to see exactly which object would be selected before you make the selection. If the current selection options make more than one object available, Abaqus/CAE changes the cursor, adding ellipsis marks (...) to the right of the arrow, and highlights all the possible selections. The position and type filtering that you choose for selection also applies to preselection.

Toggle off the **Allow Preselection During Picking** tool  in the **Selection** toolbar to turn off preselection highlighting for procedures in the current session. This tool is toggled on by default.

Note:

Preselection highlighting may be delayed for large models; toggling off preselection may improve the display speed.

- *Using the selection options*

Modifying the shape of the drag-select region

The selection tools allow you to change the shape of the drag-select region.

From the **Selection** toolbar, choose one of the following:

Rectangle

 Click to indicate one corner of the rectangle, and drag the cursor to the second corner. This tool is selected by default.

Circle

 Click to indicate the center of the circle, and drag the cursor to a point on the circumference.

Polygon

 Click to indicate one vertex of the polygon, and drag the cursor to the second vertex. You then continue to click on each vertex of the polygon. Click mouse button 2 to indicate you have finished entering vertices. There is no limit to the number of vertices in the polygon.

- *Using the selection options*

Choosing which objects are selected by the drag-select region

The selection tools allow you to choose which objects are selected by the drag-select region.

From the **Selection** toolbar, choose one of the following:

Inside

 Select only the objects that fall inside the drag-select region.

Inside and crossing

 Select only the objects that fall inside or cross the drag-select region. This tool is selected by default.

Crossing

 Select only the objects that cross the drag-select region.

Outside and crossing

 Select only the objects that fall outside or cross the drag-select region.

Outside

 Select only the objects that fall outside the drag-select region.

• *Using the selection options*

Selecting objects before choosing a procedure

You can select objects from the current viewport before choosing a procedure to work with them.

You can use the **Selection** toolbar 

to toggle *selection* and to limit viewport selections based on the type of object. The **Selection** tool is the first tool in the toolbar; it is available only when there are no active procedures running in a viewport. By default, selection is active and viewport object types are not limited. You can select multiple objects using any of the methods described in *Combining selection techniques*. Toggle off object selection to prevent selecting objects when you are not in a procedure.

Note:

Preselection highlighting may be delayed for large models; toggling off selection may improve the display speed by preventing preselection and selection unless you first choose a procedure that requires object selection.

When you select a procedure after selecting objects from the viewport, Abaqus/CAE applies the selection filters for the procedure. For example, if you selected a vertex, a face, and an edge, then started a procedure that can accept only vertices, Abaqus/CAE accepts the selected vertex, cancels the selection of the face and edge, and begins the procedure with the second step. Similarly, if you select a procedure that requires a single object selection and you have already selected multiple valid objects, Abaqus/CAE accepts the first valid selection and cancels the remaining selections. If Abaqus/CAE cannot determine which object you selected first, it will cancel all selections and begin the procedure at the first step.

If a procedure includes multiple selection steps, objects that you select before the procedure can be used only to complete the first selection step. Any subsequent selection steps require you to select new objects interactively from the viewport or, if applicable, use saved selection groups. You cannot save selections made prior to the start of a procedure.

- *Using the selection options*

Configuring graphics display options

This chapter explains how you can configure the graphics display options in Abaqus/CAE.

In this section:

- *Using graphics display options*
- *Using display lists*
- *Using antialiasing*
- *Choosing a highlight method*
- *Choosing a translucency mode*
- *Controlling drag mode*
- *Choosing background colors*

Using graphics display options

When you start a session, Abaqus detects the graphics hardware installed on your system and sets the graphics options accordingly. If your graphics hardware is not supported by Abaqus/CAE or if you wish to override the default graphics options, you can use the **Graphics Options** dialog box to tune display performance.

Abaqus/CAE applies the settings to all viewports and saves the settings for the duration of the session. To use the customized settings each time you start an Abaqus/CAE session, modify the environment file (`abaqus_v6.env`). For additional information on the environment file, see the *Abaqus Configuration Guide*.

Note: Recommended settings for recently introduced graphics adapters are available from the **Support** page at *www.3ds.com/simulia*.

You can also use the **Graphics Options** dialog box to do the following:

- Choose the appearance of your model during rotation, pan, or zoom view manipulations. The appearance is related to the render style and can be set to **Fast (wireframe)** or **As is**.
- Choose whether Abaqus/CAE will auto-fit the image to the current viewport after you rotate the view. Automatically fitting the image to the viewport is equivalent to clicking the auto-fit tool  in the View Manipulation toolbar. Auto-fit adjusts your view of the model so that the model fills the viewport and is centered within it. The orientation remains fixed, as indicated by the view triad.
- Choose whether Abaqus/CAE will optimize the display of translucent objects for performance, for accuracy, or for a level in between.
- Choose the viewport background color. Your selected color will be applied to all viewports in the current session of Abaqus/CAE.

1. From the main menu bar, select **View->Graphics Options**.

   The **Graphics Options** dialog box appears.

2. Select one of the following options:

   - Tune performance using options for display lists, highlight method, and translucency mode.
   - Choose the display mode while you drag objects in the viewport.
   - Enable or disable the automatic fitting of your view to the viewport after rotations.
   - Choose the background color of the viewports.

Additional information

- *Using display lists*
- *Choosing a highlight method*
- *Choosing a translucency mode*
- *Controlling drag mode*
- *Choosing background colors*

Using display lists

Display lists help you display repeated images faster. When display lists are enabled, every drawing operation is recorded in a list that can be quickly replayed if necessary. This results in faster image refreshes on most systems but requires graphics memory to record each drawing operation. Display lists are not used at all in the Visualization module (Abaqus/Viewer). In Abaqus/CAE display lists are usually enabled; you should disable them if you experience memory problems or a degradation of graphics performance while displaying exceptionally large models.

1. Locate the display lists options.

   From the main menu bar, select **View->Graphics Options**.

   Abaqus/CAE displays the **Graphics Options** dialog box.

2. From the **Hardware** options, toggle **Use display lists** on or off to control the use of display lists for images. This option has no effect in the Visualization module.

   When **Use display lists** is on, you may notice a brief delay the first time an image is drawn; this occurs because Abaqus/CAE must construct the display lists. Subsequent drawing of the image is faster.

3. Click **OK** to implement your changes and to close the dialog box.

   Your changes are saved for the duration of the session.

Additional information

- *Choosing a highlight method*
- *Choosing a translucency mode*
- *Controlling drag mode*
- *Choosing background colors*

Using antialiasing

Abaqus/CAE uses antialiasing to improve the display of curved and diagonal lines on models. Antialiasing is enabled on compliant systems, and you can toggle off this option to improve performance for some systems.

1. Locate the graphics options.

   From the main menu bar, select **View->Graphics Options**.

   Abaqus/CAE displays the **Graphics Options** dialog box.
2. From the **Hardware** options, toggle on **Anti-alias lines** to enable antialiasing or toggle it off to disable antialiasing.
3. Click **OK** to implement your changes and to close the dialog box.

   Your changes are saved for the duration of the session.

Additional information

- *Using display lists*
- *Controlling drag mode*
- *Choosing background colors*

Choosing a highlight method

The highlight method controls how Abaqus/CAE displays highlighting in the viewport while you interact with the model. The effect of changing the highlight method is most apparent when you use the view manipulation tools to rotate the model or while sketching a profile in the Sketch module. **Hardware Overlay** provides the best graphics performance; however, this option is not supported by all graphics adapters.

In most circumstances you should not have to change the default highlight method setting. When you start a session, Abaqus/CAE detects the graphics hardware installed on your system and selects the appropriate highlight method. However, if you are using a graphics adapter that is not supported, the default setting selected by Abaqus/CAE may not be optimal.

1. Locate the highlight method options.

   From the main menu bar, select **View->Graphics Options**.

   Abaqus/CAE displays the **Graphics Options** dialog box.

2. From the **Highlight method** menu, select one of the following:

   - **Hardware Overlay**. This option appears only if it is supported by the graphics adapter on your system. It uses graphics hardware to display the highlighting layer. If your workstation supports this option, choosing **Hardware Overlay** provides the optimum quality and performance.
   - **XOR**. This option uses software to emulate the highlighting layer. Choosing the **XOR** option uses a Boolean pixel operation to simulate the drawing operations but can produce different colors depending on the color of the underlying pixels.
   - **Software Overlay**. This option also uses software to emulate the highlighting layer and provides good quality at reasonable performance. However, on some systems selecting this option results in poor performance.
   - **Blend**. The Blend method combines the color of the underlying pixel with the desired color producing an approximation of the transient graphics. You should choose this option only if none of the other options are satisfactory. Performance and quality may be affected if you choose the **Blend** option.

3. Click **OK** to implement your changes and to close the dialog box.

   Your changes are saved for the duration of the session.

Additional information

- *Using display lists*
- *Choosing a translucency mode*
- *Controlling drag mode*
- *Choosing background colors*

Choosing a translucency mode

The translucency mode controls the speed and accuracy with which Abaqus/CAE displays translucent objects in the viewport. The effect of changing the translucency mode is most apparent when you use the view manipulation tools to manipulate the display of the model. The **Fast** setting provides the best graphics performance, while the **Accurate** setting provides the best rendering of translucent objects.

In most circumstances you should not have to change the default translucency method setting. When you start a session, Abaqus/CAE detects the graphics hardware installed in your system and selects the appropriate translucency mode. However, if you are using a less capable graphics adapter, the default setting selected by Abaqus/CAE may not be optimal for your models.

1. Locate the translucency mode options.

   From the main menu bar, select **View->Graphics Options**.

   Abaqus/CAE displays the **Graphics Options** dialog box.

2. Drag the **Translucency mode** slider to the setting that you want. For some graphics cards, Abaqus/CAE supports three intermediate translucency mode settings between **Fast** and **Accurate**; for others, Abaqus/CAE supports only one intermediate setting between these two options.
3. Click **OK** to implement your changes and to close the dialog box.

   Your changes are saved for the duration of the session.

Additional information

- *Using display lists*
- *Choosing a highlight method*
- *Controlling drag mode*
- *Choosing background colors*

Controlling drag mode

Drag mode controls the appearance of your model during rotation, pan, or zoom view manipulations. Drag mode can be set to **Fast (wireframe)** or **As is**.

Fast (wireframe)

When you set drag mode to **Fast (wireframe)**, a wireframe outline is drawn during the view manipulation. **Fast (wireframe)** is the default drag mode setting on compliant systems.

As is

When you set drag mode to **As is**, everything displayed in the window will continue to be displayed during the view manipulation. On older or slower systems the display may lag behind movement of the mouse while you manipulate the view, especially if the model is complex. For newer systems with graphics hardware acceleration the **As is** setting can be accommodated without significant loss of performance.

Set the drag mode to **As is** to observe the model during the view manipulation; for example, to locate areas of high stress concentration as you rotate a contour plot.

In addition, you can choose whether Abaqus/CAE will auto-fit the image to the current viewport after you rotate the view. Automatically fitting the image to the viewport is equivalent to clicking the auto-fit tool  in the View Manipulation toolbar. Auto-fit adjusts your view of the model so that the model fills the viewport and is centered within it. The orientation remains fixed, as indicated by the view triad.

1. Locate the drag mode options.

   From the main menu bar, select **View->Graphics Options**.

   Abaqus/CAE displays the **Graphics Options** dialog box.
2. From the **View Manipulation** field, select **Fast (wireframe)** or **As is** drag mode.
3. If desired, toggle on **Auto-fit after rotations**.
4. Click **OK** to implement your changes and to close the dialog box.

   Your changes are saved for the duration of the session.

Additional information

- *Using display lists*
- *Choosing a highlight method*
- *Choosing a translucency mode*
- *Choosing background colors*

Choosing background colors

The appearance of your models is affected by the difference in contrast between the model colors and the colors in the viewport background. You can improve this contrast by changing the color or colors displayed in the viewport background. Abaqus/CAE provides two color selections: you can display a single color that floods the entire viewport background, or you can create a gradient background that blends two different colors.

Abaqus/CAE implements your background color selections for every viewport in your session.

1. Locate the background color options.

   From the main menu bar, select **View->Graphics Options**.

   Abaqus/CAE displays the **Graphics Options** dialog box.

2. From the **Viewport Background** field, select one of the following:

   - **Solid** to choose one color for the viewport background
   - **Gradient** to choose the top and bottom colors used to draw the background as a gradual blend from the top of the viewport to the bottom of the viewport

3. Select the viewport background color or colors.

   a. Click a color sample .

   Abaqus/CAE displays the **Select Color** dialog box.

   b. Use one of the methods in the **Select Color** dialog box to select a new color. For more information, see *Customizing colors*.

   c. Click **OK** to close the **Select Color** dialog box.

   The color sample changes to the selected color.

   d. For gradient backgrounds you can select both the top and bottom colors directly; or you can select the top color, then click **Auto-Select** to have Abaqus/CAE select the bottom color based on a variation of the top color.

   e. Sketches or X–Y plots may not display clearly with a gradient background. For these views Abaqus/CAE displays a solid background even when you have specified a gradient background. To disable this behavior, toggle off **Allow override**.

4. Click **OK** to implement your changes and to close the dialog box.

   Abaqus/CAE implements your background color selections for every viewport in your session. Your changes are saved for the duration of the session.

Printing viewports

This chapter describes how you send an image of selected viewports either directly to a printer or to a file.

For more information on configuring printers, see the *Abaqus Configuration Guide*.

In this section:

- *Understanding printing*
- *Controlling the destination and appearance of printed images*

Understanding printing

Abaqus/CAE allows you to take a snapshot of one or more viewports and their contents and to send the image either directly to a printer or to a file for later use; for example, to include in a presentation, embed in a printed report, or display in an HTML document.
Additional options allow you to select the appearance of viewports in the resulting image, as well as the color, resolution, and size of the image.

This section describes basic concepts you should understand before sending output to a printer or to a file.

In this section:

- *Printed image formats*
- *Windows and PostScript image layout*
- *Windows printer image size*
- *EPS, TIFF, PNG, and SVG image size*
- *Hard-copy image quality*
- *Importing Abaqus/CAE images into other software products*

Printed image formats

You can print images directly to a printer or save images in several file formats.

Abaqus/CAE allows you to print images directly to a Windows printer. The printer driver creates and sends the necessary information to the printer in whatever format is required.

If Windows printer drivers are not available or if you are using another platform, you can use a print command to create and send a PostScript file directly to a PostScript printer. You can also save images in a Portable Network Graphics (PNG), Scalable Vector Graphics (SVG), Tag Image File Format (TIFF), PostScript (PS), or Encapsulated PostScript (EPS) file. The following list describes these file formats:

PNG

Portable Network Graphics (PNG) is an industry standard for storing raster images. The use of PNG files has been popularized by the World Wide Web, and PNG images are displayed by most popular web browsers running on a variety of operating systems. A PNG file consists of color information and a compressed raster representation of the image. By default, Abaqus/CAE limits PNG images of viewports to 8-bit color (256 colors). However, you can also use 24-bit color (on Windows) or the system color setting (on Linux).

SVG

Scalable Vector Graphics (SVG) is an industry-standard vector graphics language written in XML.

TIFF

Tag Image File Format (TIFF) is a well-established raster image format that is recognized by many software applications. The TIFF format supports both color and greyscale. By default, Abaqus/CAE limits TIFF images of viewports to 8-bit color (256 colors). However, you can also use 24-bit color (on Windows) or the system color setting (on Linux).

PostScript

PostScript is the recognized standard for desktop publishing. PostScript is actually a programming language whose instructions and data are usually stored in an ASCII format that can be transferred easily between operating systems. The PostScript format is used when you use a print command to print to a PostScript printer or when you save the image in a PostScript file. When you select the PostScript format, Abaqus/CAE generates either a compressed raster representation or a vector representation of your image. For efficiency when producing raster images, you should minimize the size of your image and limit the resolution of the image to, at most, the resolution of the device on which the image is to be printed or displayed.

Encapsulated PostScript

Encapsulated PostScript (EPS) is a variation of PostScript that describes a single graphic designed to be included in a larger document without modification. EPS files are identical to PostScript files except for some information that describes the size and positioning of the image. As a result, the above discussion about vector and raster representations of your image applies equally to the EPS format. Most word processing and graphics applications support the inclusion of EPS files.

Additional information

- *Controlling the destination and appearance of printed images*

Windows and PostScript image layout

When you print a snapshot of selected viewports directly to a Windows printer or to a PostScript printer or file, the layout of the image is determined by the available page size, the orientation, and the aspect ratio of the viewports:

Available page size

The available page size is calculated from the total page size and the margin information that you supply, as illustrated by the sample dimensions shown in *Figure 1*.

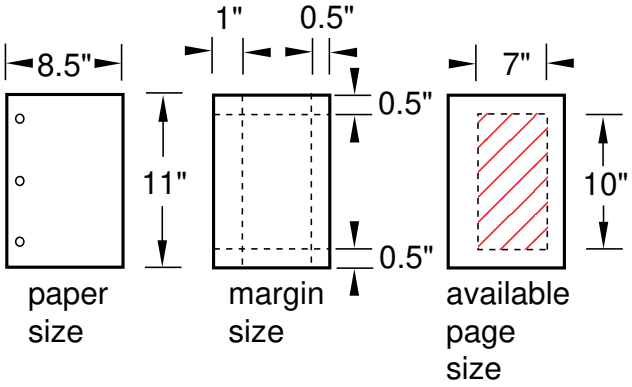

Figure 1: The available page size.

The total page size is determined by the paper size. For a Windows printer, click the **Printer Properties** button in the **Print** dialog box to open the **Document Properties** dialog box and change the paper size. For a PostScript printer or file, click the **Postscript Format Options** button in the **Print** dialog box to change the paper size.

Orientation

The orientation of your page can be either portrait or landscape.

Aspect ratio

The aspect ratio is the ratio between the overall width and the overall height of the viewports that you select for printing. Abaqus/CAE always maintains the aspect ratio of the objects, as shown in *Figure 2*. You can control the aspect ratio by manipulating the viewports on the canvas before printing them.

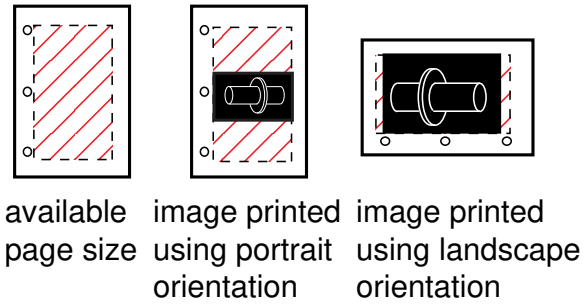

Figure 2: Scaling the objects to maintain the aspect ratio.

The default method for determining the image size on Windows printers—the only method for determining the image size on PostScript printers and files—scales the image to fit the aspect ratio and the available page size.

For detailed instructions, see *Customizing the image sent to a Windows printer*, and *Customizing the image sent to a PostScript printer or file*.

Additional information

- *Controlling the destination and appearance of printed images*
- *EPS, TIFF, PNG, and SVG image size*

Windows printer image size

When you print a snapshot of selected viewports directly to a Windows printer, the image size is determined by one of three methods:

Fit to page

Use this method to scale the printed image to fit within the available page size. This method is used by default.

Use size on screen

Use this method to match the printed image size to the current size on the canvas. If the image size exceeds the available page size, you must resize the image, change the page size or margins, or select a different method to print your image.

Use settings

Use this method to specify the size of the printed image directly. You specify either the width or the height, and Abaqus/CAE adjusts the other dimension to maintain the image aspect ratio. If the image exceeds the available page size, you must resize the image, change the page size or margins, or select a different method to print the image.

Additional information

- *Customizing the image sent to a Windows printer*
- *Controlling the destination and appearance of printed images*
- *Windows and PostScript image layout*
- *EPS, TIFF, PNG, and SVG image size*

EPS, TIFF, PNG, and SVG image size

When you print a snapshot of selected viewports to an Encapsulated PostScript (EPS), TIFF, PNG, or SVG format file, Abaqus/CAE determines the size of the image based on the size you specify and the overall aspect ratio of the viewports. You can control the aspect ratio by manipulating the viewports on the canvas.

In the options dialog box (**EPS Options**, **TIFF Options**, **PNG Options**, or **SVG Options**) you can choose one of the following methods to specify the size of the printed image:

- Use the size of the image on the screen. (Abaqus/CAE indicates the current image size in the options dialog box.) This method is the default.
- Set the width or height. You specify only one dimension; Abaqus/CAE computes the other dimension to maintain the aspect ratio of the viewports. When you are creating an EPS-format file, you specify the width or height in either inches or millimeters. When you are creating a TIFF, PNG, or SVG format file, you specify the width or height in screen pixels; increasing the number of pixels increases the image size.

Additional information

- *Windows and PostScript image layout*
- *Controlling the destination and appearance of printed images*

Hard-copy image quality

When you print a snapshot of selected viewports directly to a PostScript printer or save it in a PostScript or Encapsulated PostScript (EPS) file, Abaqus/CAE creates either a vector or raster representation of the image (for more information, see *Printed image formats*).

Vector representation images are resolution independent, so their quality depends only on the resolution of your printer.

For PostScript and EPS images, you can use the **Resolution** field in the corresponding options dialog box to specify the resolution of the image you save or print. At higher resolution, raster images appear to be smoother and less jagged. Low-resolution vector images may have holes if scaled to a larger size.

Although a higher resolution image has higher quality, more data are required to define the image; the resulting file can consume a large amount of disk space. A lower resolution image will normally print and display faster. In general, you should select the lowest resolution that still produces an acceptable image. You may want to save a lower resolution image while you produce draft copies of your work and switch to a higher resolution for the finished version.

The resolution of your printer sets an upper limit on the printed image resolution. For example, if you save an image at a resolution of 600 dots per inch (dpi) and print it on a printer that has a resolution of 300 dpi, the printed image will have a resolution of only 300 dpi.

Raster representation image quality may also be affected by changes you make to the image with external software after the image has been created, such as scaling and rotation. Scaling and rotation may distort a raster image. Consequently, before you print a raster representation of your image, you should adjust the viewports on your canvas to match the dimensions and orientation that will appear in the final application. Scaling and rotation do not distort or diminish the quality of vector representation images.

For vector representation PostScript and EPS images, you can use the **Shading Quality** field in the corresponding options dialog box to specify the quality of the lighting on curved surfaces in the image. This option does not affect the image resolution or the file size. A finer shading quality will produce an image closer to the raster representation. A coarser shading quality will normally print and display faster. Similar to the resolution for raster images, you should select the coarsest shading quality that still produces an acceptable image.

Vector PostScript and EPS images do not support translucency; all translucent or transparent objects will appear opaque when printed using vector PostScript or EPS format.

Additional information

- *Understanding printing*
- *Controlling the destination and appearance of printed images*

Importing Abaqus/CAE images into other software products

Many popular software applications, such as word processors, allow you to import files containing graphic images generated by Abaqus/CAE; and most of these applications allow you to preview the imported image. In addition, if you are using a Windows system, you can use **[Ctrl] + C** to copy the image in the current viewport to the system clipboard and **[Ctrl] + V** to paste it into another application. Windows stores the image in the clipboard in a bitmap (`.bmp`) format at the resolution of the screen. Although the image quality will be satisfactory when viewed online, it may be unacceptable when printed. If you expect to print an image, you should save it in PostScript or Encapsulated PostScript format.

Controlling the destination and appearance of printed images

This section describes the options available for controlling the destination and appearance of printed images.

In this section:

- *Printing to a printer or to a file*
- *Selecting which part of the image to print*
- *Choosing the color of your image*
- *Choosing the destination of your image*
- *Customizing the image sent to a Windows printer*
- *Customizing the image sent to a PostScript printer or file*
- *Customizing the image saved in an Encapsulated PostScript file*
- *Customizing the image saved in TIFF, PNG, or SVG files*

Printing to a printer or to a file

Abaqus/CAE allows you to print a snapshot of one or more viewports on the canvas and to send the image either directly to a printer or to a file for later use; for example, to include in a presentation, embed in a printed report, or display in an HTML document. The printed image will reproduce the layering of viewports on the canvas; that is, if one viewport obscures another on the canvas, the obscured portion will not appear in the printed image. You can select the format of the printed image; and additional options allow you to select the appearance of viewports in the resulting image, and the color, resolution, orientation, and size of the image.

To create a printed image, select **File->Print** from the main menu bar. To configure your image, use the **Print** dialog box that appears. For detailed help on the items within the dialog box, request context-sensitive help on the individual items.

When you have finished selecting options, click **OK** in the **Print** dialog box to send the image to the selected destination. Abaqus/CAE closes the **Print** dialog box, sends the image to the selected destination, and saves your print options for the duration of the session.

Additional information

- *Understanding printing*
- *Controlling the destination and appearance of printed images*

Selecting which part of the image to print

When you print an image directly to a printer or to a file, you can use the **Print** dialog box to select which viewports on the canvas to include in the printed image. You can select the following:

All or current viewports

Select **All Viewports** to print all viewports on the canvas. Viewports that are on the canvas but are not visible because they are outside the drawing area will still be printed. If viewports are overlaid, the printed image will reproduce the layering on the canvas; that is, if one viewport obscures another, the obscured portion will not appear in the printed image. By default, Abaqus/CAE prints all the viewports on the canvas.

Select **Current Viewport** to print the most recently used viewport only. See *Selecting viewports*, for more information on selecting viewports.

Note:

Minimized viewports are not printed, regardless of your selections in the **Print** dialog box.

Viewport decorations

Toggle on **Print viewport decorations (if visible)** to select whether your image will include viewport decorations. Decorations are defined as the viewport border and the viewport title.

Viewport backgrounds

Toggle on **Print viewport backgrounds** to control the appearance of a viewport's background in your printed image. When this option is selected and viewport background images or movies are active, Abaqus/CAE includes the viewport background image or the current frame of the movie in the background of the printed image. If **Print viewport backgrounds** is active but viewport background images or movies are inactive, Abaqus/CAE displays the viewport background colors in the background.

The **Print viewport backgrounds** option is available only when you *choose either a greyscale or a color image*; when you choose black and white, Abaqus/CAE always prints a black image on a white background.

Note:

Printing without the viewport background (so that the background appears transparent or white) usually produces the most attractive hard-copy image.

Viewport compass

Toggle on **Print viewport compass (if visible)** to include the 3D compass in your printed image. If the compass is not currently visible in a viewport (see *Customizing the 3D compass*), the compass will not appear in the printed image regardless of the setting for this option.

1. From the main menu bar, select **File->Print**.

    **Tip:** You can also click  in the File toolbar.

   The **Print** dialog box appears.

2. From the **Print** field at the top of the dialog box, select either:

- **All Viewports** to print all viewports, even if they lie outside the drawing area.
- **Current Viewport** to print the viewport that you manipulated most recently.

3. Toggle **Print viewport decorations (if visible)**.

   When **Print viewport decorations (if visible)** is on, all viewport titles and borders that are visible on the canvas will be printed.

   When **Print viewport decorations (if visible)** is off, none of the viewport titles or borders will be printed. To print the current viewport without the border, you must toggle this option off.

4. Toggle **Print viewport backgrounds**.

   When **Print viewport backgrounds** is on, your image will inherit the background color or background images of viewports on your monitor.

   When **Print viewport backgrounds** is off, the appearance of viewport backgrounds depends on the format you choose for your image:

   - When you choose **PS** (PostScript) or **EPS** (Encapsulated PostScript) format or print directly to a Windows printer, viewports in your image will have a white background.
   - When you choose **TIFF**, **PNG**, or **SVG** format, viewports in your image will have a transparent background.

5. Toggle **Print viewport compass (if visible)**.

   When **Print viewport compass (if visible)** is on, any 3D compass that is currently visible in a viewport will appear in your printed image.

   When **Print viewport compass (if visible)** is off, the 3D compass will not appear anywhere in your printed image.

6. When you have finished with the **Print** dialog box, click **OK** to generate the desired output.

   Abaqus/CAE generates the output and closes the **Print** dialog box. Your settings in the **Print** dialog box are saved for the duration of the session.

Additional information

• *Understanding printing*
• *Controlling the destination and appearance of printed images*

Choosing the color of your image

When you print an image from the canvas directly to a printer or a file, you can use the **Print** dialog box to select the color of your image. The following color options are available:

Black&White

Use this option to print black images on a white background. This option is useful for printing wireframe and hidden-line images of parts, assemblies, and meshes, including any partitions and datum geometry. You can also print black and white images of undeformed and deformed shape plots. When you choose **Black&White**, Abaqus/CAE always prints a black image on a white background, and the viewport background is printed as either transparent or white. This option should not be used for printing images that depend heavily on color, such as contour plots.

Greyscale

Use this option to print greyscale versions of color images, where each color is approximated by a shade of gray. (Abaqus/CAE converts each color to one of 256 true shades of gray.) This option is useful for printing color images, such as contour plots, to a black and white laser printer. To improve the appearance of images sent to a printer, you may want to print viewports with the background turned off (so that it appears white or transparent).

Color

Use this option to print an approximation of the colors you see. If you try to print a color image to a black and white printer, the printer converts the colors to shades of gray.

By default, Abaqus/CAE uses up to 256 different colors for raster printed images (PNG, TIFF, and raster-format PostScript). However, for *TIFF or PNG* printed images you can choose to allow more colors, which increases the file size but allows the image to more closely match the display. For more information, see *Customizing the image saved in TIFF, PNG, or SVG files*.

1. From the main menu bar, select **File->Print**.

    **Tip:** You can also click  in the File toolbar.

   The **Print** dialog box appears.

2. From the **Rendition** text box in the **Settings** field, select one of the following color options:
   - Select **Black&White** to create a black image on a white background.
   - Select **Greyscale** to print a greyscale approximation of a color image.
   - Select **Color** to print a color approximation of the colors on your screen.

3. When you have finished with the **Print** dialog box, click **OK** to generate the desired output.

   Abaqus/CAE generates the output and closes the **Print** dialog box. Your settings in the **Print** dialog box are saved for the duration of the session.

Additional information

- *Understanding printing*
- *Controlling the destination and appearance of printed images*

Choosing the destination of your image

You can choose to send an image directly to a printer, or you can save the image in a file.

If you send the image directly to a printer, you can select the Windows printer that you want to use. If you are on another platform or if there are no printer drivers on your Windows system, Abaqus/CAE selects the PostScript format, and you can specify the print command. Additional options allow you to choose the number of copies, paper size, orientation, margins, image quality, and whether or not to include the date and SIMULIA logo.

If you choose to save the image in a file, you must provide a file name and select one of the following file formats:

PNG

Select **PNG** if you want to incorporate the saved image in a separate document; for example, an HTML file for display on the World Wide Web. Additional options for this format allow you to specify the size of the image. For more information, see *Customizing the image saved in TIFF, PNG, or SVG files*.

SVG

Select **SVG** if you want to incorporate the saved image in a separate document; for example, an HTML file for display on the World Wide Web. Additional options for this format allow you to specify the size of the image. For more information, see *Customizing the image saved in TIFF, PNG, or SVG files*.

TIFF

Select **TIFF** if you want to incorporate the saved image in a separate document; for example, a word processing file. Additional options for this format allow you to specify the size of the image. For more information, see *Customizing the image saved in TIFF, PNG, or SVG files*.

PostScript

Select PostScript (**PS**) if you want the saved image to be identical to the image that Abaqus/CAE would print to a PostScript printer. Additional options for this format allow you to choose the paper size, orientation, margins, and resolution of your image, and whether or not to include the date and SIMULIA logo. For more information, see *Customizing the image sent to a PostScript printer or file*.

Encapsulated PostScript

Select Encapsulated PostScript (**EPS**) if you want to incorporate the saved image in a separate document; for example, a word processing file. Additional options for this format allow you to specify the size and resolution of the image. For more information, see *Customizing the image saved in an Encapsulated PostScript file*.

1. From the main menu bar, select **File->Print**.

   
   Tip: You can also click  in the File toolbar.

   The **Print** dialog box appears.

2. From the **Destination** buttons in the **Settings** field, select one of the following:

   #### Printer

   Choose **Printer** to send your image to a printer. On Windows systems you can select from a list of installed printers, similar to other Windows programs. On other systems, or on Windows systems that do not have a printer driver installed, you can type a print command in the **Print**

command text field. This command should be the same command that you would use at your workstation to print a PostScript file. Do not include a file name in the print command; Abaqus/CAE automatically appends the file name to your command. See your systems administrator for details on the valid commands at your site.

Whether you select a printer or enter a print command, click the arrows in the **Copies** field to set the desired number of copies to print, or type the number of copies you want into the text field. You can print up to 100 copies. If desired, click **Page Setup** and the **Printer Properties** button (for Windows printers) or the **Postscript Format Options** button (for systems using a print command) to specify the page size, printed image quality, and other options.

File

Choose **File** to send your image to a file. There are two ways to supply the file name:

File name

Type the name in the **File name** text field. You can type any characters that are legal Windows or Linux file names; for example, on a Windows system:

- `stressfield.png`
- `..\..\nozzle\presentation\injector_mesh`
- `~\pump\actuator\strainpattern.eps`

If you do not type a file extension, Abaqus/CAE will append an extension (`.png`, `.svg`, `.tif`, `.ps`, or `.eps`) to the file name.

Select

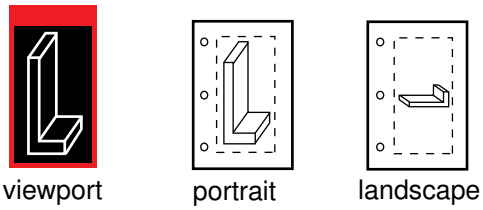
Use the **Select** button to supply a file name using the standard file browser. For more information on file selection, see *Using file selection dialog boxes*.

3. If you selected to print the image to a file, click the arrow next to the **Format** field to select a **PNG**, **SVG**, **TIFF**, PostScript (**PS**), or Encapsulated PostScript (**EPS**) format file. If desired, click the respective options button to specify additional options.
4. When you have finished with the **Print** dialog box, click **OK** to generate the desired output.

   Abaqus/CAE generates the output and closes the **Print** dialog box. Your settings in the **Print** dialog box are saved for the duration of the session.

Additional information

- *Printed image formats*
- *Hard-copy image quality*
- *Controlling the destination and appearance of printed images*



Customizing the image sent to a Windows printer

When you print viewports on the canvas directly to a Windows printer, you can use the **Page Setup** dialog box to customize the resulting printed image.

You can configure the following:

Orientation

You can choose either **Portrait** or **Landscape** orientation. Portrait and landscape orientations are illustrated in the following figure:

Units

You can choose either **Inch** or **Millimeter** units. Your selection determines the units used for the **Image Size** and **Margins** settings that also appear in this dialog box.

Quality

You can select from three levels of quality. Each setting limits the maximum file size that is sent to the printer:

- **Coarse** limits the file to 2 megabytes,
- **Medium** limits the file to 10 megabytes, and
- **Fine** limits the file to 50 megabytes.

The quality level works in conjunction with the image size and the printer settings to determine the resolution of the printed image.

Note:

Click the **Printer Properties** button in the **Print** dialog box to access the printer settings.

Date and logo

By default, Abaqus/CAE includes the date and time and the Abaqus/CAE logo across the top of an image sent directly to a Windows printer. You can choose to remove the date and time or the logo from your output.

Image Size

You can choose one of three methods to determine the size of the printed image:

- **Fit to page** fits the selected image within the current page size and margins.
- **Use size on screen** prints the image as it appears on the screen. Parts of the image that do not fit within the current page size and margins are cut off in the printed output.

- **Use settings below** allows you to enter a width or height; Abaqus/CAE adjusts whichever dimension you do not edit to preserve the current aspect ratio.

Margins

You can provide the **Top**, **Bottom**, **Left**, and **Right** margins. Abaqus/CAE computes the maximum image size as the page size minus the margins. You can specify zero-width margins; however, printers cannot print to the edge of the paper and typically have margins of at least 0.25 inches (6 mm). The page size is set in the printer settings.

Note:

Click the **Printer Properties** button in the **Print** dialog box to access the printer settings.

Abaqus/CAE maintains the margins you specify regardless of the orientation of the paper. For example, assume you chose a **Portrait** image and entered a value for the **Top** margin. If you now choose a **Landscape** image, Abaqus/CAE uses the value you entered for the **Top** margin to compute the **Left** margin. Similarly, the value you entered for the **Right** margin becomes the **Top** margin.

You can also use the **Print** dialog box to set the number of copies to print and to access specific settings for the selected printer. Click the **Printer Properties** button to open the ***printer name*** **Document Properties** dialog box. The available printer settings are determined by the installed printer driver and configuration, not by Abaqus/CAE.

For more information, see *Windows and PostScript image layout*, and *Hard-copy image quality*.

1. From the main menu bar, select **File->Print**.

    **Tip:** You can also click  in the File toolbar.

   The **Print** dialog box appears.
2. From the **Destination** radio buttons, choose **Printer**.
3. From the **Printer** list, select the name of the printer that you want to use.
4. Click the arrows to the right of the **Copies** text field to increase or decrease the number of copies to print or type the number directly in the text field. You can print 1 to 100 copies.
5. From the lower-right corner of the **Print** dialog box, click **Page Setup**.

   The **Page Setup** dialog box appears.
6. From the **Orientation** field, choose the paper orientation.
7. From the **Units** field, choose the units to use for the image size and margins.
8. From the **Quality** field, click the arrow and select **Coarse**, **Medium**, or **Fine** image quality.
9. If desired, toggle off **Print date** to remove the date and time from your output.
10. If desired, toggle off **Print SIMULIA logo** to remove the logo from your output.
11. From the **Image Size** field, choose the size for your printed image.
12. From the **Margins** field, type the **Top**, **Bottom**, **Left**, and **Right** margins (in the units that you selected previously).
13. Click **OK** to save your customization settings and to close the **Page Setup** dialog box.
14. If desired, click the **Printer Properties** button in the **Print** dialog box to open the **Document Properties** dialog box to access options specific to your printer.

Note:

The **Document Properties** dialog box is a Windows dialog box, not part of Abaqus/CAE. If you have questions regarding the information in this dialog box, you should address them to your system administrator or consult the documentation for your printer or printer driver.

15. When you have finished with the **Print** dialog box, click **OK** to generate the desired output.

    Abaqus/CAE generates the output and closes the **Print** dialog box. Your settings in the **Print** dialog box are saved for the duration of the session.

Additional information

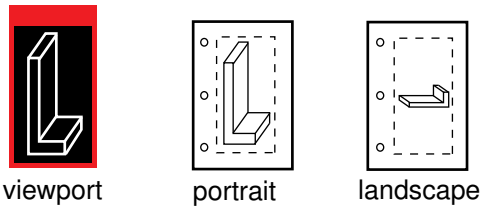
- *Controlling the destination and appearance of printed images*

Customizing the image sent to a PostScript printer or file

When you print viewports on the canvas to a PostScript file or directly to a PostScript printer, you can use the **PostScript Options** dialog box to customize the resulting printed image.



You can configure the following:

Paper Size

You can choose from a list of standard page sizes.

Orientation

You can choose either **Portrait** or **Landscape** orientation. Portrait and landscape orientations are illustrated in the following figure:

Margins

You can provide the **Top**, **Bottom**, **Left**, and **Right** margins. Abaqus/CAE computes the maximum image size as the page size minus the margins. You can specify zero-width margins; however, printers cannot print to the edge of the paper and typically have margins of at least 0.25 inches (6 mm). Abaqus/CAE maintains the margins you specify regardless of the orientation of the paper. For example, assume you chose a **Portrait** image and entered a value for the **Top** margin. If you now choose a **Landscape** image, Abaqus/CAE uses the value you entered for the **Top** margin to compute the **Left** margin. Similarly, the value you entered for the **Right** margin becomes the **Top** margin.

Text Rendering

You can specify how you want text in the viewports to appear in the printed image. You can either use PostScript fonts or request that text characters be output as small bitmaps.

Resolution

You can select from a list of standard resolutions. (For more information, see *Printed image formats*.) The maximum effective resolution of a raster PostScript image is limited to the resolution of the device on which the image will be displayed. By default, Abaqus/CAE sets the resolution of a PostScript image to 150 dpi. To save disk space, you should select the minimum acceptable resolution when generating raster PostScript images. For more information, see *Hard-copy image quality*.

Image Format

You can choose either **Vector** (default) or **Raster** format. Vector images are scalable and resolution independent. Raster (or bitmap) images are pixelated and resolution dependent and tend to decrease in quality when they are scaled.

Shading Quality

For vector images you can choose how fine curved surfaces will be shaded.

Date and logo

By default Abaqus/CAE includes the date and time and an Abaqus/CAE logo across the top of a PostScript image. You can choose to remove the date and time or the logo from your output.

If you are printing to a PostScript printer, the **Print** dialog box also allows you to type a printer command and set the number of copies to print.

For more information, see *Windows and PostScript image layout* and *Hard-copy image quality*.

1. From the main menu bar, select **File->Print**.

   Tip: You can also click in the File toolbar.

   The **Print** dialog box appears.
2. From the **Destination** radio buttons, choose **Printer** to send your image to a PostScript printer or **File** to send your image to a PostScript file.
3. If you are sending your image to a PostScript printer:
   a. In the **Print command** text field, type the print command.
   b. Click the arrows to the right of the **Copies** text field to increase or decrease the number of copies to print or type the number directly in the text field. You can print 1 to 100 copies.
4. If you are sending your image to a PostScript file:
   a. In the **File name** text field, type the file name or click to select the file name from the standard file browser.
   b. From the **Format** field, select **PS**.
5. From the bottom of the **Print** dialog box, click the **Postscript Format Options** button.

   The **PostScript Options** dialog box appears.
6. From the **Paper Size** field, select a standard page size.
7. From the **Orientation** field, choose the paper orientation.
8. From the **Margins** field, type the **Top**, **Bottom**, **Left**, and **Right** margins in inches.
9. From the **Text Rendering** field, choose one of the following:
   - Choose **Always use PostScript printer fonts** to print only font families that are commonly available on a PostScript printer (Courier, Helvetica, Times, and Symbol). Any other font is replaced by Courier, the default font.
   - Choose **Use PostScript printer fonts when available** to print any viewport text that appears in Courier, Helvetica, Times, or Symbol font. Text in any other font is output as small bitmaps for each character. This option requires more processing and results in a larger PostScript file. No fonts are replaced by the default font.
   - Choose **Always use displayed fonts (WYSIWYG)** to output all characters as small bitmaps.
10. From the **Resolution** field, click the arrow and select from the list of resolutions.
11. From the **Image Format** field, select **Vector** or **Raster**.
12. For vector images, select the **Shading Quality**.

13. If desired, toggle off **Print date** to remove the date and time from your output.
14. If desired, toggle off **Print SIMULIA logo** to remove the logo from your output.
15. Click **OK** to save your PostScript customization settings and to close the **PostScript Options** dialog box.
16. When you have finished with the **Print** dialog box, click **OK** to generate the desired output.

    Abaqus/CAE generates the output and closes the **Print** dialog box. Your settings in the **Print** dialog box are saved for the duration of the session.

Additional information

- *Windows and PostScript image layout*
- *Controlling the destination and appearance of printed images*

Customizing the image saved in an Encapsulated PostScript file

When you print viewports to an **EPS** (Encapsulated PostScript) file, you can customize the resulting image.

The **Encapsulated PostScript Options** dialog box allows you to configure the following:

Image Size

You can save an image that is the same size as the image on the screen, or you can specify the size of the image in inches or millimeters. You specify either the width or the height; Abaqus/CAE calculates the other dimension to maintain the aspect ratio of the viewports.

Text Rendering

You can specify how you want text in the viewports to appear in the printed image. You can use either PostScript fonts or request that text characters be output as small bitmaps.

Resolution

You can select from a list of standard resolutions. (For more information, see *Printed image formats*.) The maximum effective resolution of a raster representation EPS image is limited to the resolution of the device on which the image will be displayed. By default, Abaqus/CAE sets the resolution of an EPS image to 150 dpi. To save disk space, you should select the minimum acceptable resolution when generating raster PostScript images. For more information, see *Hard-copy image quality*.

Image Format

You can choose either **Vector** (default) or **Raster** format. Vector images are scalable and resolution independent. Raster (or bitmap) images are pixelated and resolution dependent and tend to decrease in quality when they are scaled.

Shading Quality

For vector images you can choose how fine curved surfaces will be shaded.

1. From the main menu bar, select **File->Print**.

   Tip: You can also click in the File toolbar.

   The **Print** dialog box appears.
2. From the **Destination** radio buttons, choose **File**.
3. In the **File name** text field, type the file name or click to select the file name from the standard file browser.
4. From the **Format** field, select **EPS**.
5. From the bottom of the **Print** dialog box, click the **Encapsulated Postscript Format Options** button.

   The **Encapsulated PostScript Options** dialog box appears.
6. From the **Image Size** field, choose one of the following:
   - Choose **Use size on screen** to save an EPS image that is the same size as the overall width and height of the viewports that you select for printing. Abaqus/CAE displays the resulting size to the right of the **Use size on screen** radio button.

- Choose **Use settings below** to specify the width or height of the resulting image in either inches or millimeters.

7. From the **Text Rendering** field, choose one of the following:
   - Choose **Always use PostScript printer fonts** to print only font families that are commonly available on a PostScript printer (Courier, Helvetica, Times, and Symbol). Any other font is replaced by Courier, the default font.
   - Choose **Use PostScript printer fonts when available** to print any viewport text that appears in Courier, Helvetica, Times, or Symbol font. Text in any other font is output as small bitmaps for each character. This option requires more processing and results in a larger PostScript file. No fonts are replaced by the default font.
   - Choose **Always use displayed fonts (WYSIWYG)** to output all characters as small bitmaps.
8. From the **Resolution** field, click the arrow and select from the list of resolutions.
9. From the **Image Format** field, select **Vector** or **Raster**.
10. For vector images, select the **Shading Quality**.
11. Click **OK** to save your customization settings and to close the **Encapsulated PostScript Options** dialog box.
12. When you have finished with the **Print** dialog box, click **OK** to generate the desired output.

    Abaqus/CAE generates the output and closes the **Print** dialog box. Your settings in the **Print** dialog box are saved for the duration of the session.

Additional information

• *Printed image formats*
• *Controlling the destination and appearance of printed images*

Customizing the image saved in TIFF, PNG, or SVG files

When you print viewports to a TIFF, PNG, or SVG format file, you can customize the resulting image. You can save an image that is the same size as the image on the screen, or you can specify the size of the image in pixels.

For more information, see *EPS, TIFF, PNG, and SVG image size* and *Printed image formats*.

1. From the main menu bar, select **File->Print**.

   Note:

   You can also click  in the File toolbar.

   The **Print** dialog box appears.

2. In the **File name** text field, type the file name or click  to select the file name from the standard file browser.
3. From the **Format** field, select **TIFF**, **PNG**, or **SVG**.
4. From the bottom of the **Print** dialog box, click the **TIFF Format Options**, **PNG Format Options**, or **SVG Format Options** button.

   The appropriate dialog box appears.

5. From the **Image Size** field, choose one of the following:

   - Choose **Use size on screen** to save an image that is the same size as the overall width and height of the viewports that you select for printing. Abaqus/CAE displays the resulting size to the right of the **Use size on screen** radio button.
   - Choose **Use settings below** to specify the width or height of the resulting image in units of pixels. Abaqus/CAE computes the other dimension to maintain the aspect ratio of the viewports. The maximum allowed image dimension (width or height) is 4096 pixels.

6. Click **OK** to save your customization settings and to close the dialog box.
7. For color PNG and TIFF images, you can use the default 8-bit color depth (256 colors) or toggle off **Reduce to 256 colors** to use more colors, which increases the file size but allows the image to more closely match the display.

   If you do not use the default setting, the number of colors available for an image depends on the system type and settings. For Windows systems, Abaqus/CAE uses 24-bit color (1.67 million colors). For Linux systems, Abaqus/CAE uses the same color setting as the display.

8. When you have finished with the **Print** dialog box, click **OK** to generate the desired output.

   Abaqus/CAE generates the output and closes the **Print** dialog box. Your settings in the **Print** dialog box are saved for the duration of the session.

Working with Abaqus/CAE Model Databases, Models, and Files

Almost every modeling operation you perform while working in an Abaqus/CAE module contributes to the definition of a model in a model database.
This part describes Abaqus/CAE models and model databases, the files created by the modeling process, and how you work with these models and files.

In this section:

- *Understanding and working with Abaqus/CAE models, model databases, and files*
- *Importing and exporting geometry data and models*

Understanding and working with Abaqus/CAE models, model databases, and files

This chapter discusses models and model databases and describes the various files that Abaqus/CAE generates and reads.

A finished model contains all the data that Abaqus/CAE needs to create and submit the analysis to Abaqus/Standard or Abaqus/Explicit. Models are stored in a model database.

In this section:

- *What is an Abaqus/CAE model database?*
- *What is an Abaqus/CAE model?*
- *Accessing an output database on a remote computer*
- *Understanding the files generated by creating and analyzing a model*
- *Abaqus/CAE command files*
- *Using the File menu*
- *Managing model and output databases*
- *Managing models*
- *Managing session objects and session options*
- *Controlling the input file generated by Abaqus/CAE*
- *Managing macros*

What is an Abaqus/CAE model database?

A model database (file extension `.cae`) stores models and analysis jobs. (For more information on analysis jobs, see *Understanding analysis jobs*.) You can have multiple model databases stored on your workstation or network, but Abaqus/CAE can work on only one of them at any time. A model database can contain more than one model; if you plan to work on multiple models simultaneously, they must be stored in one model database. The model database in use is known as the current model database; Abaqus/CAE displays the name of the current model database across the top of the main window, as shown in *Figure 1*.

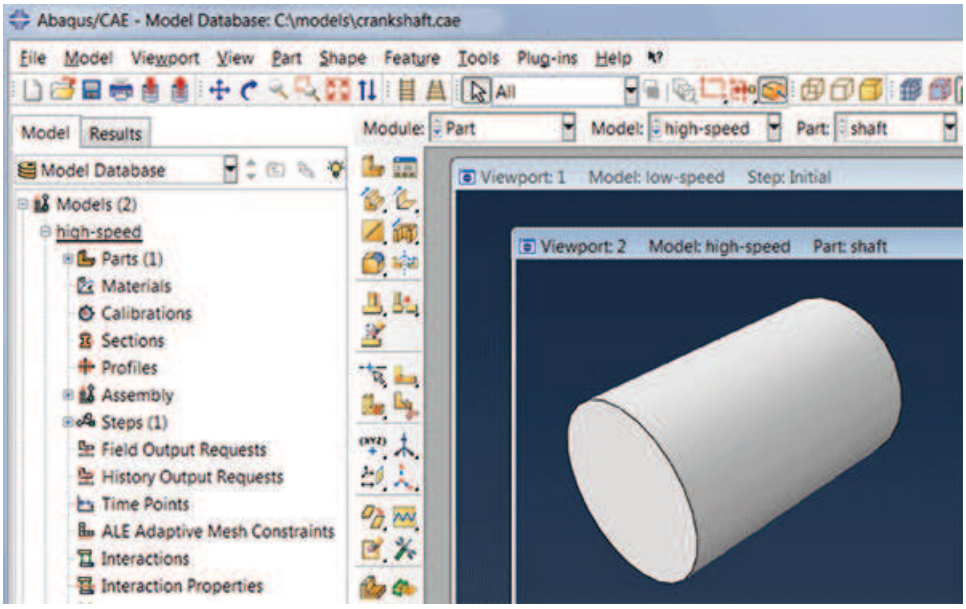

Figure 1: Abaqus/CAE displays the model database name and the model name.

When you first start Abaqus/CAE, the **Start Session** dialog box allows you to either create a new, empty model database or to open an existing model database. Anything you create or define in Abaqus/CAE is stored in this model database. You save the contents by selecting **File->Save** or **File->Save As** from the main menu bar.

Abaqus/CAE never saves the model database unless you perform an explicit save operation; there is no timer-based automatic saving, for example. However, while you work on your model, Abaqus/CAE maintains a record of all the operations that changed the model database. Although you may not have saved the model database, you can always replay the operations that replicate its current state. For more information on recreating the model database, see *Recreating an unsaved model database*. Abaqus/CAE is backward compatible and can open model databases created by previous releases of Abaqus/CAE.

After you begin an Abaqus/CAE session, you can open an existing model database by selecting **File->Open** from the main menu bar, or you can create a new model database by selecting **File->New**. If you open or create another model database after you have made changes to the current one, Abaqus/CAE asks if you want to save the changes before it closes the current model database.

You can open a model database in the Visualization module to probe or query its nodes and elements and to plot contours or symbols for selected attributes. For more information, see *Understanding the role of the Visualization module*.

Additional information

- *Understanding and working with Abaqus/CAE models, model databases, and files*
- *Managing model and output databases*

What is an Abaqus/CAE model?

This section describes an Abaqus/CAE model.

In this section:

- *What does an Abaqus/CAE model contain?*
- *What are the model attributes?*

What does an Abaqus/CAE model contain?

An Abaqus/CAE model contains the following kinds of objects:

- parts
- materials and sections
- assembly
- sets and surfaces
- steps
- loads, boundary conditions, and fields
- interactions and their properties
- meshes

A model database can contain any number of models so that you can keep all models related to a single problem in one database. (For more information, see *What is an Abaqus/CAE model database?*.) You can open multiple models from the model database at the same time, and you can work on different models in different viewports. The viewport title bar (if visible) displays the name of the model associated with the viewport. The model associated with the current viewport (indicated by a red border) is called the current model, and there is only one current model. *Figure 1* shows two viewports displaying two different models (`high-speed` and `low-speed`) in the same model database (`crankshaft.cae`); the current viewport in *Figure 1* is displaying the `high-speed` model.

You use the **Model Manager** or the **Model** menu items from the main menu bar to create and manage your models. You use the **Model** list located in the context bar to switch to a different model in the current model database.

You can create a copy of a model within a model database; in addition, you can copy the following objects between models:

- Sketches
- Parts (part sets are also copied)
- Instances
- Materials
- Sections (including connector sections)
- Profiles
- Amplitudes
- Interaction properties

For detailed instructions, see *Manipulating models within a model database*, and *Copying objects between models*.

You can also import a model from another model database file, which creates a full copy of the model in the current model database. For more information, see *Importing a model from an Abaqus/CAE model database*.

Abaqus/CAE checks that your model is complete when you submit it for analysis. For example, if you request a dynamic analysis, you must specify the density of the materials so that the mass and inertia properties of the model can be calculated. If you did not provide a material density in the Property module, the Job module reports an error; for more information, see *Monitoring the progress of an analysis job*.

In some modules Abaqus/CAE does not support functionality from Abaqus/Standard or Abaqus/Explicit that you may want to include in the analysis. You may be able to add such functionality by using the **Keywords Editor** to edit the Abaqus keywords associated with a model. Select **Model->Edit Keywords->*model name*** from the main menu bar to start the **Keywords Editor**. (You can review the keywords supported by Abaqus/CAE by selecting **Help->Keyword Browser** from the main menu bar.)

You can specify that a model uses information from a previous analysis. When you submit the model for analysis, Abaqus/CAE continues the analysis from a selected step. For more information, see *Configuring restart output requests*, and *Restarting an analysis*.

What are the model attributes?

The model attributes describe characteristics of a model and are stored with a model in the model database.

The following list describes the attributes of an Abaqus/CAE model:

- Description. If you have many similar models in a model database, you can use the description to distinguish between the models. The description that you enter is stored with the model attributes; the description is written above the header of the input file but is not written to the output database. For more information, see *Adding descriptions to your Abaqus/CAE model*.
- Type. You can choose between a **Standard & Explicit** model (the default) or an **Electromagnetic** model. Once you select a model type, Abaqus/CAE filters the set of options available in the main menu bar, toolboxes, and Model Tree so that they are appropriate to your model type selection.
- Physical constants for the model. You can enter values for the **Absolute zero temperature** and the **Stefan-Boltzmann constant**. These values are needed to specify surface emissivity and radiation conditions in heat transfer analyses.

  You can also enter a value for the **Universal gas constant**, and you can choose an option from the **Specify acoustic wave formulation** list.
- Restart information that will start the analysis using data from a previous analysis. You can specify the following:
  - The name of the job from which Abaqus/CAE will read the restart information.
  - The name of the step from which Abaqus/CAE will restart the analysis.
  - The increment or the interval of the step from which Abaqus/CAE will restart the analysis.

  For more information, see *Restarting an analysis* and *Restarting an Analysis*.
- Submodel information that will be used to drive submodel boundary conditions or loads in the model. You can specify the following:
  - The job from which the global solution will be used to drive the submodel boundary conditions or loads.
  - Whether a shell global model will be used to drive a solid submodel.

  For more information, see *Submodeling*.
- Model instance information. You can control whether constraints, connector section assignments, and surface-to-surface contact and self-contact interactions defined in the initial step will be copied to the current working model when you create model instances from this model. For more information, see *Working with model instances*.

Select **Model->Edit Attributes->*model name*** from the main menu bar to edit the attributes of the selected model.

Additional information

- *Specifying model attributes*

Accessing an output database on a remote computer

This section describes how you can create and start a network connector.
You can use the network connector to navigate the directory structure on a remote host and to access a remote output database.

In this section:

- *What is a network ODB connector?*
- *How secure is the access to a network ODB connector?*
- *Tuning the cache size to increase the performance of a network ODB*

What is a network ODB connector?

A network ODB connector creates a connection to a remote machine and allows you to access a remote output database. For example, you can submit an analysis to a high-performance Linux system and view the results on a local Windows workstation while the analysis is still running.

You can create a network ODB connector from any platform—Windows or Linux. However, the network ODB server must reside on a Linux platform; you cannot access an output database that resides on a remote Windows system. You can access only a remote output database; you cannot access a remote model database.

Select **File->Network ODB Connector->Create** from the main menu bar to create a connection with a directory on a remote host. When you are creating a network ODB connector, you can use Abaqus/CAE to automatically start the network ODB server and to establish the communication port numbers on the host and remote systems. Alternatively, you can start the network ODB server manually from the command line using the **abaqus networkDBConnector** execution procedure. If you start the server from the command line, you enter the communication port number returned by the execution procedure when you subsequently create the network ODB connector. For more information, see *Network Output Database File Connector*.

After you create a network ODB connector, you must start it by selecting **File->Network ODB Connector->Start->*Connector name*** from the main menu bar. The remote system must have Abaqus installed for Abaqus/CAE to establish the network connection. For more information, see *Creating a network ODB connector*, and *Managing network ODB connectors*.

After you create and start a network connector, you can use it to navigate the directory structure on a remote host. When you select **File->Open** from the main menu bar to open a database from Abaqus/CAE, a **Network connectors** entry appears under **Directory** in the file selection dialog box. The entry appears regardless of whether you are trying to open an output database or a model database; however, you cannot use a network connector when opening a model database. For more information, see *Using file selection dialog boxes*.

The network connector allows you to do the following:

- Open a remote output database in read-only mode, and view the contents of the output database using the Visualization module. For more information, see *Opening a model database or an output database*.

  The behavior of the Visualization module does not change when the output database is remote; for example, you can view the output database while the analysis is running on a remote machine, and more than one user can view the output database. However, you cannot click **Results** in the **Job Manager** to open the remote output database associated with a remote analysis.
- Import a part from a remote output database. For more information, see *Importing parts*.
- Import a model from a remote output database. For more information, see *Importing a model from an output database*.
- Upgrade a remote output database.

After most Visualization module operations and during animations, Abaqus/CAE monitors the output database for updated results and updates the current viewport accordingly. If you are displaying data from a remote output database, the performance of Abaqus/CAE may be degraded if the time taken to monitor the database over the network is significant. To increase the performance, you can reduce the frequency with which Abaqus/CAE monitors the output database for updates or you can disable the monitoring. For more information, see *Controlling results caching*.

How secure is the access to a network ODB connector?

Abaqus/CAE maintains a secure connection to the network ODB connector by generating a key that is passed back and forth between the server and the client. If a file called `.abaqus_net_passwd` is present in your home directory on the remote server, Abaqus/CAE uses the password in the file for authentication instead of the key generated by Abaqus/CAE. Abaqus/CAE checks that you are the only user with permission to read and write to the password file. In addition, you must update the file after 30 days, and the password must be at least eight characters long. Abaqus uses password files to authenticate the connection between the client and the server if you start the network ODB server manually. These files are described in *Network Output Database File Connector*.

Tuning the cache size to increase the performance of a network ODB

When you start an Abaqus/CAE session, a cache is created in the scratch file directory. Abaqus/CAE uses this cache for local data storage when you use a network ODB connector to read from a remote output database. The cache greatly increases the performance of the Visualization module in Abaqus/CAE when accessing data from the remote output database.

Abaqus/CAE allows the cache to grow to a size that is sufficient to contain all of the data in all of the open remote output databases. However, Abaqus/CAE limits the cache size to 80% of the total free space in the directory. For example, if the scratch directory has 35 gigabytes of unused space, Abaqus/CAE will allow the cache to grow to 28 gigabytes. Alternatively, you can limit the size of the cache using the **nodb_cache_limit** parameter in the Abaqus environment file, `abaqus_v6.env`. You must set the **nodb_cache_limit** parameter to the number of megabytes to which the cache size will be limited. For example,

```
nodb_cache_limit=20000
```

will set the maximum cache size to 20 gigabytes. Abaqus/CAE uses this cache space only as needed during a session, and the actual cache size may be significantly less than the limit you specified. The minimum value of **nodb_cache_limit** is 500, indicating that the cache size is limited to 500 megabytes. If you set the maximum cache size to be greater than the available free space, Abaqus/CAE reduces it to a value that is equal to the available free space.

Abaqus/CAE uses the cache to increase its performance when reading data from a remote output database. The speed at which data can be accessed over a network is significantly lower than the speed at which data can be accessed from a local disk drive. As a result, the performance of remote output databases will be significantly slower than the performance of a local output database. The cache reduces this performance difference by retaining data that have been transferred over the network, thereby reducing the need for data transfer over the network. However, if the cache is not large enough, Abaqus/CAE will have to transfer more data over the network and performance will suffer.

In most cases you will not have to tune the size of the cache using the **nodb_cache_limit** parameter. However, you may have to reduce the size of the cache if it is consuming too much disk space and reducing the speed of other applications on your system. Similarly, you may have to increase the size of the cache if it is too small to support all of your remote output databases and the performance of Abaqus/CAE is degraded. If you cannot increase the size of the cache, you should close some of your remote output databases.

If the desired cache size is larger than the space available in the scratch file directory, you can move the scratch file directory to a larger disk drive using the Abaqus**scratch** environment file parameter. For more information, see *Environment File Settings*, and *Managing Memory and Disk Resources*.

Understanding the files generated by creating and analyzing a model

When you start a session and begin defining your model, Abaqus/CAE generates the following file:

The replay file (*abaqus* . `rpy`)

The replay file contains Abaqus/CAE commands that record almost every modeling operation you perform during a session. For more information, see *Replaying an Abaqus/CAE session*.

When you select **File->Save** from the main menu bar and save the model database, Abaqus/CAE saves the following files:

The model database file (*model_database_ name* . `cae`)

The model database file contains models and analysis jobs. For more information, see *What is an Abaqus/CAE model database?*.

The journal file (*model_database_ name* . `jnl`)

The journal file contains the Abaqus/CAE commands that will replicate the model database that was saved to disk. For more information, see *Recreating a saved model database*.

When you continue to work on your model, Abaqus/CAE continues to record your actions in the replay file. In addition, Abaqus/CAE saves the following file:

The recover file (*model_database_ name* . `rec`)

The recover file contains the Abaqus/CAE commands that will replicate the version of the model database in memory. The model database recovery file contains only the commands that changed the model database since you last saved it. For more information, see *Recreating an unsaved model database*.

When you submit a job for analysis, Abaqus/Standard and Abaqus/Explicit create a set of files; for a complete list of these files, see *File Extension Definitions*. The following list describes some of the files that Abaqus/Standard and Abaqus/Explicit create and their relationship to Abaqus/CAE:

Input files (*job_name* . `inp`)

Abaqus/CAE generates an input file that is read by Abaqus/Standard or Abaqus/Explicit when you submit a job for analysis. For more information, see *Basic steps for analyzing a model*.

Output database files (*job_name* . `odb`)

Output database files contain the results from your analysis. You use the Step module's *output request managers* to choose which variables are written to the output database during the analysis and at what rate. An output database is associated with the job you submit from the Job module; for example, if you named your job `FrictionLoad`, the analysis creates an output database called `FrictionLoad.odb`.

When you open an output database, Abaqus/CAE loads the Visualization module and allows you to view a graphical representation of the contents. You can also import a part from an output database as a mesh. You can save *X–Y* data objects to an output database file if you open the file with write permission; otherwise, you cannot modify the contents of the output database once it has been created.

The output database lock file (*job_name*`.lck`)

The lock file (*job_name*`.lck`) is written whenever an output database file is opened with write access, including when an analysis is running and writing output to an output database file. The lock file prevents you from having simultaneous write permission to the output database from multiple sources. It is deleted automatically when the output database file is closed or when the analysis that creates it ends.

The restart file (*job_name*`.res`)

The restart file is used to continue an analysis that stopped before it was complete. You use the Step module to specify which analysis steps should write restart information and how often. If you are using Abaqus/Explicit, the restart information you supply in the Step module controls the data written to the state file (*job_name*`.abq`). For more information, see *Configuring restart output requests*.

The data file (*job_name*`.dat`)

The data file contains printed output from the analysis input file processor, as well as printed output of selected results written during the analysis. Abaqus/CAE automatically requests that the default printed output for the current analysis procedure be generated at the end of each step; you cannot use Abaqus/CAE to exert any additional control over the contents of the data file.

The message file (*job_name*`.msg`)

The message file contains diagnostic or informative messages about the progress of the solution. You can control the diagnostic information that is output to the message file using the Step module. For more information, see *Diagnostic printing*.

The status file (*job_name*`.sta`)

The status file (*job_name*`.sta`) contains information about the progress of the analysis. In addition, you use the Step module to request that the value of a single degree of freedom at a single node be output to the status file. For more information, see *Degree of freedom monitor requests*.

The results file (*job_name*`.fil`)

The results file contains selected results from the analysis in a format that can be read by other applications, such as postprocessing programs. A submodel analysis can read the global model results from either an output database or a results file. By default, an analysis from Abaqus/CAE does not create a results file. For more information, see *Submodeling*, and *Submodeling*.

Note:

The errors and warnings that Abaqus/Standard and Abaqus/Explicit write to the data, message, and status files while analyzing a job can be monitored by the Job module; for more information, see *Monitoring the progress of an analysis job*.

When you open an output database file in the Visualization module and create new field output variables (see *Creating and saving new field output*, for more information), Abaqus/CAE generates the following file:

The scratch output database file (*job_name*`.ods`)

The scratch output database file (*job_name*`.ods`) contains a "session step" in which field output variables that you create (by operating on either fields or frames) are saved. This file is deleted automatically when the original output database file (from which the field output originates) is closed or when the Abaqus/CAE session ends.

In most cases the files generated by Abaqus/CAE are written to the work directory. The work directory is the directory from which you started the Abaqus/CAE session unless you changed the directory by selecting **File->Set Work Directory** from the main menu bar. For more information, see *Setting the work directory*.

Abaqus/CAE command files

This section describes the command files that you can use to reproduce your work and to customize Abaqus/CAE.

In this section:

- *Replaying an Abaqus/CAE session*
- *Recreating a saved model database*
- *Recreating an unsaved model database*
- *Creating and running your own scripts*
- *Creating and running a macro*
- *Customizing your Abaqus/CAE environment*

Replaying an Abaqus/CAE session

Almost every operation that you perform in Abaqus/CAE is recorded automatically in the replay file (`abaqus.rpy`) in the form of Abaqus Scripting Interface commands. Executing the replay file is equivalent to replaying the original sequence of operations including any redundant procedures and any mistakes and subsequent corrections that you made. The replay file also includes canvas operations, such as creating a new viewport.

Abaqus/CAE retains the five most recent versions of the replay file. The most recent version of the replay file is called `abaqus.rpy`; it is created when you start a session. The four older versions have a number appended to the end of the file name; the file name with the lowest number indicates the oldest replay file, and the file name with the highest number indicates the second most recent replay file.

You can execute the commands in a replay file when you start Abaqus/CAE or during a session; however, the result may be different if the replay file generates an error.

From the Abaqus execution procedure

To run a replay file from the Abaqus execution procedure, type `abaqus cae` (or `abaqus viewer`) `replay=replay_file_name.rpy`. If executing the replay file generates an error, Abaqus/CAE ignores the error and continues to the next command in the replay file. As a result, Abaqus/CAE always attempts to execute every command in the replay file. You cannot use the `replay` option to execute a script with control flow statements. For more information, see *Abaqus/CAE Execution*.

During an Abaqus/CAE session

To run a replay file during a session, select **File->Run Script** from the main menu bar. If the replay file generates an error, Abaqus/CAE stops executing the replay file and displays an error message in the command area. It is recommended that you run a replay file from the Abaqus execution procedure.

You can also execute a replay file using the Abaqus Python development environment (AbaqusPDE). The Abaqus Scripting Interface commands in the replay file must be run in the kernel workspace in the AbaqusPDE. For more information on the AbaqusPDE, see *The Abaqus Python Development Environment*.

Recreating a saved model database

When you save a model database (by selecting **File**->**Save** or **File**->**Save As** from the main menu bar), Abaqus/CAE also saves a model database journal file (*model_database_name*`.jnl`) containing the Abaqus Scripting Interface commands that will recreate the model database. Should the saved model database become corrupted, you can recreate it by starting Abaqus/CAE with the recover option. (Type `abaqus cae recover=model_database_name.jnl`.) The recover option executes the commands in the specified model database journal file.

The model database journal file differs from the replay file in that it does not contain every operation performed during a session. The model database journal file contains only the commands that change the saved model database; for example, commands that create or edit a part, change the time incrementation of an analysis step, or modify the mesh. Operations that do not change the model database are not saved in the journal file; for example, sending an image to a printer, creating a viewport, rotating the model, or viewing results in the Visualization module.

As you continue to work on your model, the model database in memory will differ from the most recently saved model database. The model database journal file is updated only when you perform an explicit save of the model database using **File**->**Save** or **File**->**Save As**. If you copy the model database to a different location, you should also copy the associated model database journal file. Otherwise, you will not be able to recreate the model database.

Recreating an unsaved model database

When you start a new session and make changes to your model, Abaqus/CAE records those changes to a model database recovery file (`abaqus`*n*`.rec`). If you subsequently save the model database, Abaqus/CAE appends the commands in the recovery file to the journal file for that model database (*model_database_name*`.jnl`) and deletes the recovery file. If you make further changes to your model, Abaqus/CAE creates a new recovery file (*model_database_name*`.rec`) to record the changes since your last save. Upon your next save, the commands in the recovery file are appended to the journal file and the recovery file is deleted. The journal file contains all the commands necessary to rebuild the entire model database. For example, *Table 1* shows the changes that Abaqus/CAE makes to the model database, recovery, and journal files for a model named `engine`.

Table 1: Modeling changes and their effect on the model database, recovery, and journal files.

User action	Abaqus/CAE action	Files
Start Abaqus/CAE session	None	None
Make model changes	Record commands in recover file	`abaqus1.rec`
Save the model database	Create model database file Copy recover commands to journal file Delete recover file	`engine.cae` `engine.jnl`
Make more changes to the model	Record commands in recover file	`engine.rec` `engine.cae` (out of date) `engine.jnl` (out of date)
Save model database	Update model database file Append recover commands to journal file Delete recover file	`engine.cae` (updated) `engine.jnl` (updated)

If your Abaqus/CAE session exits unexpectedly—for example, because of a power loss to your computer—the recovery file will still be available to Abaqus/CAE for your next session. Abaqus/CAE first checks for the presence of a recovery file of the form `abaqus`*n*`.rec`; if such a file exists, it might be from a previous session that stopped unexpectedly, or it might be from another Abaqus/CAE session that you started in the same directory. Because Abaqus/CAE cannot tell the difference between these two cases and cannot determine automatically whether you want to implement the changes, Abaqus/CAE prompts you with three options: recover the changes and delete the recovery file, do not recover changes and delete the recovery file, or disregard the recovery file because its changes belong to another Abaqus/CAE session. When you recover changes, you can skip the last command in the recovery file if you think the last command you issued caused the termination of the session.

If a recovery file belongs to a model database (*model_database_name*`.rec`), Abaqus/CAE will not detect the recovery file until you attempt to open that model database. Upon your attempt to open the model database, Abaqus/CAE prompts you to recover or disregard the changes. If you recover the changes, Abaqus/CAE appends the changes in the database recovery file to the journal file and deletes the database recovery file; if you choose to disregard the changes, Abaqus/CAE deletes the recovery file and does not implement any of the model changes described in the file.

Creating and running your own scripts

Almost every operation that you perform during an Abaqus/CAE session can be duplicated by a script (*script_name*`.py`) containing a set of Abaqus Scripting Interface commands. Conversely, running a script from within Abaqus/CAE is equivalent to performing the corresponding operations using the menus, toolboxes, and dialog boxes that Abaqus/CAE provides.

You can create scripts that duplicate operations you perform routinely during a session; for example, you might write a script that defines the material properties of a commonly used material or one that produces a contour plot of a particular variable shown in a particular view orientation.

Abaqus/CAE commands are written in the Python scripting language, and you can use Python to enhance the scripts generated by Abaqus/CAE. Commands are stored as ASCII text in the replay, journal, and recovery files and in Abaqus/CAE scripts that you create. As a result, you can use a standard text editor to edit the contents of the files. For more information on commands, see the *Abaqus Scripting User's Guide*.

To run a script, select **File->Run Script** from the main menu bar, and select the script to run from the **Run Script** dialog box.

Note:

You should use the recover option from the Abaqus/CAE execution procedure to run a journal file and recreate a saved model database. (Type `abaqus cae recover=model_database_name.jnl`.) Selecting **File->Run Script** to run a journal file may result in an incomplete model database.

You can also create and run scripts using the Abaqus Python development environment (AbaqusPDE). The Abaqus Scripting Interface commands in the scripts must be run in the kernel workspace in the AbaqusPDE. For more information on the AbaqusPDE, see *The Abaqus Python Development Environment*.

Creating and running a macro

The **Macro Manager** allows you to record a sequence of Abaqus Scripting Interface commands in a macro file while you interact with Abaqus/CAE. Each command corresponds to an interaction with Abaqus/CAE, and replaying the macro reproduces the sequence of interactions. You can use a macro to automate tasks that you find yourself performing repeatedly, such as printing the current viewport or applying a predefined view. For more information on Abaqus Scripting Interface commands, see the *Abaqus Scripting User's Guide*.

Macros are stored in a file called `abaqusMacros.py`. Abaqus/CAE searches three directories for `abaqusMacros.py`, in the following order:

- The site directory of the Abaqus installation.
- Your home directory.
- The current working directory.

The `abaqusMacros.py` file can exist in more than one of these directories. The **Macro Manager** contains a list of the existing macros that Abaqus/CAE detected in all of the `abaqusMacros.py` files. If a macro uses the same name in more than one `abaqusMacros.py` file, Abaqus/CAE uses the last macro encountered.

To create, delete, or run a macro, select **File->Macro Manager** from the main menu bar. For more information, see *Managing macros*.

Customizing your Abaqus/CAE environment

You use the Abaqus environment file (`abaqus_v6.env`) to specify parameters that control Abaqus/Standard and Abaqus/Explicit. In addition, you can use the environment file to specify a set of commands that are executed when you start an Abaqus/CAE session. Examples of commands that configure how you want a job to run on a remote host computer are given in *Submitting a job remotely*.

Using the File menu

A variety of operations are available from the File menu.

Use the items under **File** on the main menu bar to do the following:

- Select **File->New Model Database->With Standard/Explicit Model** to create a new model database for an Abaqus/Standard or an Abaqus/Explicit analysis. You can also click  in the File toolbar. For more information, see *Creating a new model database*.
- Select **File->New Model Database->With Electromagnetic Model** to create a new model database for an electromagnetic analysis. For more information, see *Creating a new model database*.
- Select **File->Open** to open an existing model database or output database. You can also click  in the File toolbar. For more information, see *Opening a model database or an output database*.
- Select **File->Network ODB Connector** to create a connection with a remote host that you can use to read a remote output database. For more information, see *Creating a network ODB connector*.
- Select **File->Close ODB** to close an output database. For more information, see *Closing the current output database*.
- Select **File->Set Work Directory** to change the work directory. For more information, see *Setting the work directory*.
- Select **File->Save** to save the current model database. You can also click  in the File toolbar. For more information, see *Saving the current model database*.
- Select **File->Save As** to save the current model database to a new file with a different name. For more information, see *Saving the current model database to a new file with a different name*.
- Select **File->Compress MDB** to compress the current model database. For more information, see *Compressing the file size of the current model database*.
- Select **File->Save Display Options** to save your customized part, assembly, and Visualization module display settings. For more information, see *Understanding Abaqus/CAE GUI settings*, and *Saving your display options settings*.
- Select **File->Save Session Objects** to save session-specific object definitions such as view cuts, display groups, or paths to a file, model database, or output database. For more information, see *Managing session objects and session options*.
- Select **File->Load Session Objects** to load previously saved session-specific object definitions into the current session. For more information, see *Managing session objects and session options*.
- Select **File->Import->Sketch** to import a planar sketch. For more information, see *Importing sketches*.
- Select **File->Import->Part** to import a part. For more information, see *Importing parts*.
- Select **File->Import->Model** to import a model. For more information, see *Importing a model*.
- Select **File->Export->Sketch** to export the current sketch. For more information, see *Exporting a sketch to an ACIS-, IGES-, or STEP-format file*.
- Select **File->Export->Part** to export the current part. For more information, see *Exporting a part to an ACIS-, IGES-, STEP-, or VDA-format file*.
- Select **File->Export->Assembly** to export the part instances in the assembly. For more information, see *Exporting the assembly to an ACIS-format file*.
- Select **File->Export->VRML** to export the current viewport to a VRML-format file. For more information, see *Exporting viewport data to a VRML-format file*.
- Select **File->Export->3DXML** to export the current viewport to a 3D XML-format file. For more information, see *Exporting viewport data to a 3D XML-format file*.

- Select **File->Export->OBJ** to export the current viewport to an OBJ-format file. For more information, see *Exporting viewport data to an OBJ-format file*.
- Select **File->Run Script** to execute a file containing Abaqus Scripting Interface commands. For more information, see *Replaying an Abaqus/CAE session*, and *Creating and running your own scripts*.
- Select **File->Macro Manager** to store your actions in a macro file as a sequence of Abaqus Scripting Interface commands. You can also run a macro and rename an existing macro. For more information, see *Creating and running a macro*.
- Select **File->Print** to print all or selected viewports and annotations. You can also click  in the File toolbar. For more information, see *Printing viewports*.
- Select **File->Abaqus PDE** to open the Abaqus Python development environment. The AbaqusPDE is a separate application used to create, edit, test, and debug scripts. For more information, see *About the Abaqus Python development environment*.
- Select **File->Exit** to exit the Abaqus/CAE session. For more information, see *Exiting an Abaqus/CAE session*.

Additional information

- *Understanding the files generated by creating and analyzing a model*
- *Abaqus/CAE command files*

Managing model and output databases

This section describes how you use the main menu bar's **File** menu to manage model and output databases.

In this section:

- *Creating a new model database*
- *Opening a model database or an output database*
- *Upgrading a model database or an output database*
- *Creating a network ODB connector*
- *Customizing a network ODB connector*
- *Managing network ODB connectors*
- *Closing the current output database*
- *Setting the work directory*
- *Saving the current model database*
- *Saving the current model database without a license*
- *Saving the current model database to a new file with a different name*
- *Compressing the file size of the current model database*

Creating a new model database

You can create and store multiple model databases on your computer, but you can have only one model database open at any time.
Choose one of the following options to create a new model database:

- Click  in the File toolbar or select **File->New Model Database->With Standard/Explicit Model** to create a new model database for an Abaqus/Standard or an Abaqus/Explicit analysis.
- Select **File->New Model Database->With Electromagnetic Model** to create a new model database for an electromagnetic analysis.

If you have made any changes to the current model database, Abaqus/CAE asks if you want to save your changes before it closes the current model database and creates the new one. The new database then becomes the current database. To save the new model database, select **File->Save** from the main menu bar and enter the name of the database. After you save the model database, Abaqus/CAE displays its name in the title bar of the main window.

Additional information

- *Using file selection dialog boxes*
- *What is an Abaqus/CAE model database?*
- *Understanding the files generated by creating and analyzing a model*
- *Using the File menu*

Opening a model database or an output database

Select **File->Open** from the main menu bar to open either:

- A model database (file extension `.cae`)
- An output database (file extension `.odb`)

From the **Open Database** dialog box that appears, select the **File Filter** and the file to open and click **OK**.

You can open multiple output databases and display the combined contents of the output databases in an overlay plot in a single viewport by using the **Append to layers** option. For details about working with overlay plots, see *Overlaying multiple plots*.

By default, output database files are opened as read-only. You can choose to open an output database file with write privileges; you must do so if you want to copy any *X–Y* data objects to the output database (see *Copying a session X–Y data object to an output database file*, for more information). Output database files that reside on remote machines can be opened only as read-only; you cannot write to a remote output database file.

Output and model database files from previous releases of Abaqus must be upgraded to the current release when they are opened (for more information, see *Upgrading a model database or an output database*). When you open multiple output database files, all the files must be upgraded already to the current release; otherwise, Abaqus/CAE will print a warning in the message area, and the files requiring upgrade will not be opened.

If you are using an earlier release of Abaqus/CAE, you cannot open a model or output database file created from a later release.

1. From the main menu bar, select **File->Open**.

   Tip: You can also click in the File toolbar to open a model database or an output database.

   Abaqus/CAE displays the **Open Database** dialog box.

2. From the **File Filter** menu at the bottom of the **Open Database** dialog box, select one of the following:

Model Database (*.cae)

Abaqus/CAE lists all the files in the selected directory with the file extension `.cae`.

Output Database (*.odb*)

Abaqus/CAE lists all the files in the selected directory with the file extension `.odb`.

Model & Output Databases (*.cae, *.odb*)

Abaqus/CAE lists all the files in the selected directory with file extension `.cae` or `.odb`.

3. If you selected **Output Database (*.odb*)** in Step 2, use the following options to filter the list of files further or to change the file opening behavior:

Network connectors

If you previously created and started a network ODB connector, the **Directory** field includes a **Network connectors** item that allows you to access a remote directory and open a remote output database. For more information, see *Creating a network ODB connector*.

Read-only

By default, output database files are opened as read-only. To open an output database file with write privileges, toggle off **Read-only** near the bottom of the **Open Database** dialog box before clicking **OK**. You must open an output database file with write privileges if you want to copy *X–Y* data objects from your session to the file or permanently upgrade an old file to the current release of Abaqus/CAE. You can open a remote output database file only as read-only.

Append to layers

Toggle on **Append to layers** and select multiple files if you want to open more than one output database and display the combined contents in an overlay plot in a single viewport. You can use any of the following methods to select multiple output database files:

- Select files using **[Shift] + Click** or **[Ctrl] + Click**.
- Type a comma-separated list of file names in the **File Name** field, such as

  ```
  lug.odb,hinge.odb
  ```
- Type a list of file names surrounded by double quotes in the **File Name** field, such as

  ```
  "lug.odb" "hinge.odb"
  ```

Note:

If you open an output database file while the analysis that creates it is running but before output results are written, you may have to close the file and reopen it after the results are available.

4. Click **OK** to open the selected file or files.

   Abaqus/CAE saves the selected filter type for use as the default the next time you open a file and closes the **Open Database** dialog box.

   If you opened a model database, Abaqus/CAE displays its name in the title bar of the main window. All operations now refer to the new model database. If you have modified the current model database, Abaqus/CAE asks if you want to save it before opening the selected model database.

   If you opened one or more output databases, Abaqus/CAE starts the Visualization module in the current viewport and displays the model that is last, alphabetically, in the undeformed plot state. Any other selected output databases are opened but not displayed unless you toggled on **Append to layers**, in which case the selected output databases are all plotted in the same viewport.

Additional information

- *Using file selection dialog boxes*
- *What is an Abaqus/CAE model database?*
- *What is an Abaqus/CAE model?*
- *Using the File menu*
- *Upgrading a model database or an output database*

Upgrading a model database or an output database

Output and model database files from previous releases of Abaqus must be upgraded to the current release when they are opened.

To upgrade an output database permanently, you must either open the file with write permissions and convert it when prompted or use the **abaqus upgrade** utility (see *Output Database Upgrade Utility*). You can use the **abaqus upgrade** utility to upgrade a remote output database only from the system on which the database resides.

When a model database or an output database from a previous release is opened, Abaqus/CAE does one of the following:

- If Abaqus/CAE has permission to write to the original file (i.e., it is an output database file that you have chosen to open with write privileges or a model database file), you are prompted to convert the file to the current release. During the conversion Abaqus/CAE creates a backup of the original model or output database and the journal file associated with the model database; the converted database file and the new journal file are saved in the current directory (the directory from which you opened Abaqus/CAE) with the original file names. If the database was opened from a directory other than the current directory, that directory will still contain the original version of the file with the original file name.

  When the conversion is complete, Abaqus/CAE creates a log file called *file_name*`-upgrade.log` that indicates the result of the conversion. For upgrades of model database files, Abaqus/CAE also displays a dialog box that provides the name of the conversion log file and includes the **View the conversion log file** option. Toggle on this option, and click **OK** to display the conversion log file in an Abaqus/CAE dialog box from which you can browse the log file or search its contents for error messages.
- If you are opening a local output database file as read-only, Abaqus/CAE automatically creates a converted version of the output database that is saved to a temporary location. The converted output database file is saved to the directory defined by the `$TMPDIR` (Linux) or `TEMP` (Windows) environment variable on your system. This temporary version of the output database file is deleted when you exit Abaqus/CAE.
- If you are opening a remote output database file, Abaqus/CAE tries to create a converted version of the output database file that is saved to a temporary location. The converted output database file is saved to the `/tmp` directory on the remote system or to the directory defined by the `$TMPDIR` environment variable on the remote system. This temporary version of the output database file is deleted when you exit Abaqus/CAE.

When you upgrade an older model database, the upgrade process may place keywords that you added manually to a model in the wrong location in the upgraded input file. As a result, you may experience problems when you submit the model for analysis in the Job module. If that is the case, you should open the upgraded model, return to the **Keywords Editor**, and click **Discard All Edits** to delete all of the keywords that you added. You can then recreate the keywords in the correct location in the input file.

Additional information

- *Using file selection dialog boxes*
- *What is an Abaqus/CAE model database?*
- *What is an Abaqus/CAE model?*
- *Using the File menu*
- *Opening a model database or an output database*

Creating a network ODB connector

You can use a network ODB connector to access an output database on a remote computer. For example, you can submit an analysis to a high-performance Linux compute server and view the results on a local Windows workstation. You can create a network ODB connector from any platform—Windows or Linux. However, the server for the network ODB server must reside on a Linux platform. Abaqus/CAE maintains a secure connection to the network ODB connector by generating a key that is passed back and forth between the server and the client. For more information, see *How secure is the access to a network ODB connector?*.

Select **File->Network ODB Connector->Create** from the main menu bar to create a connector. After you create a network ODB connector, you must start it by selecting **File->Network ODB connector->Start->*Connector name*** from the main menu bar. The remote system must have Abaqus installed for Abaqus/CAE to establish the network connection. For more information, see *Managing network ODB connectors*.

In most cases you will use Abaqus/CAE to start the network ODB server on the remote system and to assign port numbers. Abaqus/CAE can start the server only if the user name on the remote host is the same as the user name on the local system. If you experience problems establishing communication or if the user names are different, you can start the server by running the **abaqus networkDBConnector** execution procedure on the remote system. For more information, see *Network Output Database File Connector*.

1. From the main menu bar, select **File->Network ODB Connector->Create**.
2. From the **Network ODB Connector** editor that appears, enter the name of the remote connector. When you subsequently open an output database, the **Open Database** dialog box displays the name of the remote connector. Abaqus/CAE also displays this name in the **Network ODB Connector Manager**.
3. From the **Basic** tabbed page of the **Network ODB Connector** editor, enter the following:

Host name

The name of the remote system in the form of a URL or an IP address; for example, `computeserver.mycompany.com`.

Directory

The directory to open on the remote system. The directory that you enter must contain the remote output database that you want to access, or it must include subdirectories that contain the remote output database.

4. In most cases you will be able to click **OK** to close the dialog box and to establish a remote connection using the default configuration options. However, if you have difficulty establishing communication with the remote system or if your site requires a particular configuration, you may need to customize the network ODB connector. For more information, see *Customizing a network ODB connector*.

Additional information

• *Accessing an output database on a remote computer*

Customizing a network ODB connector

If you have difficulty establishing communication with the remote system or if your site requires a particular configuration, you may need to customize the network ODB connector. Use the **Advanced** tabbed page of the **Edit Network ODB Connector** dialog box to customize a network ODB connector.

1. From the main menu bar, select **File->Network ODB Connector->Edit->*connector name***.
2. From the **Edit Network ODB Connector** dialog box that appears, click the **Advanced** tab.
3. From the **Advanced** tabbed page, choose how the server will be started.
   - Choose **Automatically start server** to indicate that Abaqus/CAE will start the network ODB server when you start the network ODB connector.
   - Choose **Use manually started server** to indicate that you have already started a network ODB server using the **abaqus networkDBConnector** execution procedure.
4. Select the shell that will be used by the local system to execute commands on the network ODB server. You must ensure that the shell command that you select is installed and found in the PATH environment variable on the local system.
   - Select **ssh** to use the secure shell command. The secure shell command uses identity authentication and encryption when communicating with the server and provides more security than the remote shell command. The ssh daemon service must be running on the remote machine.
   - Select **rsh** to use the remote shell command. The rsh daemon service must be running on the remote machine.

   Note: The secure shell command and the remote shell command must be configured so that they do not prompt the user for a password. For more information, see the Dassault Systèmes Knowledge Base at *http://support.3ds.com/knowledge-base/*.
5. If you chose **Automatically start server** to indicate that Abaqus/CAE will start the network ODB server, perform the following steps:
   a. Choose from the following to specify the port numbers:
      - Choose **Auto-assign port** to allow the host and remote systems to establish their own network communication port numbers.
      - Choose **Specify port** to force the host and remote systems to use a specified port number. In the **Port** field that appears, enter the desired port number. The port number must be a valid port number. You cannot use a port number that is reserved by the system or a port that is already in use.

   b. In the **Remote Abaqus execution procedure** field, enter the command to run Abaqus on the remote system. The default command is the command that you used to start the current session of Abaqus/CAE; however, your site may have a customized command for executing Abaqus.
   c. In the **Server timeout** field, enter the network ODB server timeout in minutes. The default value is one day (1440 minutes). The server exits if it does not receive any communication from the client during the time specified. Regardless of this setting, if you started the server using Abaqus/CAE, the server exits when you end your Abaqus/CAE session. You can also stop the server by selecting **File->Network ODB Connector->Stop->*server name*** from the main menu bar.
   d. Click **OK** to create the network ODB connector and to close the editor. You still need to start the network ODB connector to make it active and to open a remote output database; for more information, see *Managing network ODB connectors*.

6. If you chose **Use manually started server** to indicate that you already started the network ODB server from the command line, perform the following steps:
   a. Enter the **Port** number returned by the **abaqus networkDBConnector** execution procedure.
   b. Click **OK** to create the network ODB connector and to close the editor. You still need to start the network ODB connector to make it active and to open a remote output database; for more information, see *Managing network ODB connectors*.

      If you started the server manually from the command line, you can close it using the **stop** parameter of the **abaqus networkDBConnector** execution procedure, or you can wait for the server to timeout. The **abaqus networkDBConnector** execution procedure is described in *Network Output Database File Connector*.

Additional information

- *Accessing an output database on a remote computer*
- *Creating a network ODB connector*

Managing network ODB connectors

Select **File->Network ODB Connector->Manager** from the main menu bar to manage your network connectors. The manager also monitors the status of your network ODB connectors.

You can use the **Network ODB Connector Manager** to create a network ODB connector. For more information, see *Creating a network ODB connector*. You can also do the following:

- Edit a network ODB connector.
- Copy a network ODB connector to another connector with a different name.
- Rename a network ODB connector.
- Delete a network ODB connector.
- Start a network ODB connector. After you create a network ODB connector, you must start it to make it active.

  Note:

  You can also start a connector by selecting **Network connectors** from the **Directory** field in the **Open Database** dialog box. Abaqus/CAE displays a list of network connectors, and you can double-click a connector to start it. You display the **Open Database** dialog box by selecting **File->Open** from the main menu bar.

- Stop a network ODB connector that you previously started. You must stop the connector before you can edit, rename, or delete it.

Additional information

• *Accessing an output database on a remote computer*

Closing the current output database

Select **File->Close ODB** from the main menu bar to close an output database. Closing an output database releases computer resources, such as memory.

1. From the main menu bar, select **File->Close ODB**.

   The **Close Output Database** dialog box appears with a list of all the output databases that are open, the date they were last updated, and the viewports that reference each open output database.

2. Select the output database to close, and click **OK** to close the dialog box.

   Abaqus/CAE closes the selected output database and clears any viewports that were displaying data from that output database.

Additional information

- *Understanding the files generated by creating and analyzing a model*
- *Using the File menu*

Setting the work directory

The work directory is the directory into which Abaqus/CAE writes files that it generates when you submit a job for analysis, such as input files and output database files.

Select **File->Set Work Directory** from the main menu bar to change the work directory (including, on Windows, the drive). The Work Directories toolbar is updated to show the new setting. When you start an Abaqus/CAE session, the work directory is the directory from which you started Abaqus/CAE. Changing the work directory does not change the location where the replay file is saved, nor does it change the default directory for opening or saving files such as the model database file. However, Abaqus/CAE does use the new work directory to save any files that do not display a path when you save them. For example, the report file (`abaqus.rpt`) is written to the work directory.

When you use the file selection dialog boxes, you can click the work icon  to access the work directory. (The file selection dialog box displays the full path to the directory you are accessing.) For more information, see *Using file selection dialog boxes*.

Additional information

- *What is an Abaqus/CAE model database?*
- *Using the File menu*
- *Understanding the files generated by creating and analyzing a model*
- *Components of the toolbars*

Saving the current model database

Until you save the current model database for the first time, it exists only in memory.

Select **File->Save** from the main menu bar or click  in the File toolbar to save the current model database, if it is new, or to append changes made during the current session to a previously saved model database. After you save the model database, Abaqus/CAE displays its name in the title bar of the main window.

Before you save the current model database for the first time, it exists only in memory and has no name. When you save the current model database for the first time, Abaqus/CAE displays the **Save Model Database As** dialog box to allow you to enter a name; subsequent saves use this name and append changes made during the current session to the previously saved model database. If you omit the file extension, Abaqus/CAE appends `.cae` to the file name.

For information on saving the model database to a new file using a different name, see *Saving the current model database to a new file with a different name*. For more information on saving files, see *Using file selection dialog boxes*.

You should save the model database periodically. Abaqus/CAE never saves the model database unless you perform an explicit save operation; there is no timer-based automatic saving, for example. If you try to save a model database that has not been modified, no action is taken.

Abaqus/CAE asks you if you want to save a modified model database before you exit the session.

The **File->Save** command does not compress the model database even if you have deleted items from the model. To reduce the file size when you have deleted model contents, use the **File->Compress MDB** command or save the model database to a new file name (using the **File->Save As** command).

Additional information

- *What is an Abaqus/CAE model database?*
- *What is an Abaqus/CAE model?*
- *Using the File menu*
- *Using file selection dialog boxes*

Saving the current model database without a license

If your system loses contact with the license server or your license is otherwise lost during a session, you can save the model database in its current state. Abaqus/CAE displays a message dialog containing the following options:

- Try to reacquire a license or check to see if the server is available
- Save the model database
- Exit Abaqus without saving the model database

By default, Abaqus/CAE will attempt to reacquire a license or reconnect to the license server. To save the model database, select the second option and provide a file name; if you have already saved a model during the current session, Abaqus/CAE shows the last file name and path as the defaults to save the current model database. When you click **OK**, Abaqus/CAE saves the model.

Note:

If you are in a procedure, such as creating a sketch or editing a material, only the portions of the model completed prior to the start of the procedure can be saved.

If you choose to exit without saving the model, Abaqus/CAE will attempt to recover the model information the next time that you start a session. Once you have saved the model, the save option is removed from the dialog box—you can either continue trying to obtain a license or exit the session.

You should save the model database periodically. Abaqus/CAE never saves the model database unless you perform an explicit save operation; there is no timer-based automatic saving, for example. If you try to save a model database that has not been modified, no action is taken.

Additional information

- *What is an Abaqus/CAE model database?*
- *What is an Abaqus/CAE model?*
- *Using the File menu*
- *Using file selection dialog boxes*

Saving the current model database to a new file with a different name

Select **File->Save As** from the main menu bar to save the current model database to a new file with a different name. If you deleted items from your model during the current session, using **File->Save As** may decrease the size of your file (for more information about compressing files, see *Compressing the file size of the current model database*). From the **Save Model Database As** dialog box that appears, enter a new name for the model database and click **OK**. If you omit the file extension, Abaqus/CAE appends `.cae` to the file name. See *Saving the current model database*, for information on saving the model database using the same name.

Using **File->Save As** with the same file name will not decrease the size of your file.

Note:

You cannot save a model database using the name `abaqus`.

Additional information

- *Using file selection dialog boxes*
- *What is an Abaqus/CAE model database?*
- *What is an Abaqus/CAE model?*
- *Using the File menu*

Compressing the file size of the current model database

Select **File->Compress MDB** from the main menu bar to compress the current model database (MDB). Compressing the MDB attempts to reduce the file size. The change will be most noticeable if you have deleted multiple items from your model.

Abaqus/CAE uses the compression function if you select **File->Save As** to save a file with a new file name.

Managing models

This section describes how you manage models within the current model database.

For general information on managing objects, see *Managing objects* and *Managing objects using manager menus*.

In this section:

- *Manipulating models within a model database*
- *Opening an existing model*
- *Copying objects between models*
- *Specifying model attributes*

Manipulating models within a model database

A model database can contain many models. Although you can have only one model database open at any time, you can open more than one model at a time. The main window's title bar displays the name of the model database, and the title bar of each viewport displays the name of the model associated with the viewport. The current viewport is indicated by a dark gray title bar; the model associated with the current viewport is known as the current model. The name of the current model is also displayed in the **Model** list in the context bar.

To create a new model, select **Model->Create** from the main menu bar and enter the name of the model in the **Edit Model Attributes** dialog box that appears.

To open a model and associate it with the current viewport, select the desired model from the **Model** list in the context bar. The **Model** list contains all the models in the current model database.

To copy, rename, or delete models, select the **Copy Model**, **Rename**, or **Delete** items listed under the **Model** menu on the main menu bar. The **Copy Model**, **Rename**, and **Delete** items contain submenus listing all the models in the current model database. For general information on how to use these menus, see *Managing objects using manager menus*.

You can also create, copy, rename, and delete models using the **Model Manager**. To display the **Model Manager**, select **Model->Manager** from the main menu bar. The **Model Manager** dialog box contains functions identical to those listed under the **Model** menu but with a convenient browser that lists all the models available in the current model database. For general information on how to use managers, see *Managing objects*.

You can copy a model to a new model in a model database. In addition, you can copy objects such as sketches, parts, and materials between the models in a model database; for more information, see *Copying objects between models*. You can also copy a model from another Abaqus/CAE model database to a new model in the current model database; for more information, see *Importing a model from an Abaqus/CAE model database*.

Additional information

- *Managing models*
- *What is an Abaqus/CAE model?*
- *Using the File menu*
- *Copying objects between models*
- *Managing objects*

Opening an existing model

To open a model and associate it with the current viewport, select the desired model from the **Model** list in the context bar. The **Model** list contains all the models in the current model database.

Abaqus/CAE switches to the selected model and associates it with the current viewport (indicated by a red border). The new model appears in the list of models in the context bar.

You can have multiple models open at any one time; the title bar of a viewport indicates the model associated with the current viewport. You do not have to save the current model prior to opening an existing model because Abaqus/CAE stores all models in the model database.

Additional information

• *What is an Abaqus/CAE model?*

Copying objects between models

You can copy objects such as parts, instances, materials, discrete fields, and analytical fields between the models in a model database.
Select **Model->Copy Objects** from the main menu bar to copy objects between models in the current model database.

You can copy the following objects:

- Sketches
- Parts (part sets are also copied)
- Instances (part instances and model instances)
- Materials
- Sections (including connector sections)
- Profiles
- Amplitudes
- Interaction properties
- Discrete fields
- Analytical fields
- Constraints

When you select part instances to copy, the corresponding part is also selected by default; you can deselect the part if it already exists. You cannot copy other individual objects, such as the assembly, loads, or steps; however, you can achieve a similar effect by copying the entire model to a new model and editing the objects in the new model. For more information, see *Manipulating models within a model database*. Dependent objects are not copied automatically when you copy an object between models. For example, if you copy a section, the associated material is not copied along with the section; you must copy the material in a separate copy operation.

If you are copying a part and the assembly context of the model to which you are copying the object is displayed in the viewport, the assembly will be regenerated only if an instance of the part being copied exists in the assembly of the model to which you are copying the object.

If you are copying a model instance and the target model contains an instance with the same name, the instance in the target model is first deleted and a new instance is created by copying the model instance from the source model. Any features, such as sets and surfaces, associated with the deleted instance are invalidated.

1. From the main menu bar, select **Model->Copy Objects**.

   The **Copy Objects** dialog box appears.
2. From the dialog box, select the model to copy objects from.
3. Use the following techniques to specify the objects to copy from the selected model:

   - Click the arrow next to the desired object category. From the list of objects that appears, toggle the names of the objects of your choice. An object category is unavailable if it contains no objects.
   - Toggle the desired object category. This action selects or deselects all objects within that category.

   The check box next to an object category displays a black check mark on a white background when all objects within that category are selected. The check box displays a dark gray check mark on a light gray background if only some of the objects within that category are selected. You must select at least one object or object category to copy.
4. From the bottom of the **Copy Objects** dialog box, select the model to copy the selected objects to.
5. Click **OK** to copy the selected objects and to close the **Copy Objects** dialog box.

Abaqus/CAE copies the selected objects. If an object with the same name already exists in the model to which you are copying the object, Abaqus/CAE asks for confirmation that you want to overwrite the existing object. Click **Yes to All** to overwrite all existing objects with the same name as the objects you are copying.

Additional information

- *What is an Abaqus/CAE model?*
- *Manipulating models within a model database*

Specifying model attributes

You specify the attributes that describe characteristics of the model, such as name, model description, physical constants, and restart information.

You specify the following model attributes that describe characteristics of the model:

- Name.
- Model type.
- Description of the model.
- Whether parts and assemblies should be included when you write the model to an input file.
- Physical constants for the model.
- If desired, the restart information that will start the analysis using data from a previous analysis. For more information, see *Restarting an analysis* and *Restarting an Analysis*.
- Whether the global model that will drive the submodel boundary conditions or loads. You can also specify that the global model is a shell driving a solid submodel. For more information, see *Submodeling*.
- Whether constraints, connector section assignments, and surface-to-surface contact and self-contact interactions defined in the initial step will be copied to the current working model when you create model instances from this model. For more information, see *Working with model instances*.

1. From the main menu bar, display the **Edit Model Attributes** dialog box using one of the following methods:
   - To specify model attributes in a new model, select **Model->Create** from the main menu bar.
   - To specify model attributes in an existing model, select **Model->Edit Attributes->*model name*** from the main menu bar.
2. If you are creating a new model, select the model type:
   - Select **Standard & Explicit** (default) to create a model for an Abaqus/Standard or an Abaqus/Explicit analysis.
   - Select **Electromagnetic** to create a model for an electromagnetic analysis.

   You cannot change the model type in an existing model.
3. If desired, enter or revise a description for the model.
   a. Click  in the **Edit Model Attributes** dialog box.
   The model description editor appears.
   b. In the model description editor, type information that you want to record about the model.
   c. Click **OK** to store the description and to close the model description editor.

   The description that you enter is saved in the model database and is written above the header of the input file when you submit the model for analysis; the description is not written to the output database. For more information, see *Adding descriptions to your Abaqus/CAE model*.
4. If you want Abaqus/CAE to write input files without parts and assemblies, toggle on **Do not use parts and assemblies in input files**. For more information about this option, see *Writing input files without parts and assemblies*.
5. In the **Physical Constants** portion of the dialog box, do the following:
   - To specify surface emissivity and radiation conditions in heat transfer analyses, enter values for the absolute zero temperature and the Stefan-Boltzmann constant.

- To specify the universal gas constant, enter a value in the **Universal gas constant** field.
- To identity the type of incident wave loading for an incident wave interaction in acoustic analyses, toggle on **Specify acoustic wave formulation**, click the arrow to the right of the text field, and select the formulation.
  - Select **Scattered wave** to obtain the scattered wave field solution that will be produced by incident wave loading.
  - Select **Total wave** to obtain the total acoustic pressure wave solution.

6. If desired, click the **Restart** tab to specify restart information that will start the analysis using data from a previous analysis. Toggle on **Read data from job** and do the following:
   - Type the name of the job from which Abaqus/CAE will read the restart information.
   - Type the name of the step from which Abaqus/CAE will restart the analysis.
   - Choose the increment, interval, iteration, or cycle of the step from which Abaqus/CAE will restart the analysis.
7. If desired, click the **Submodel** tab and do the following:
   - Toggle on **Read data from job** and enter the name of the output database from which the global solution will be used to drive the submodel boundary conditions or loads. You can also enter the name of a results file, if an output database is not available.
   - Specify whether the submodel will be a solid that is driven by a global shell model.

   For more information, see *Creating a submodel*.
8. By default, constraints, connector section assignments, and surface-to-surface contact and self-contact interactions defined in the initial step (along with their contact interaction properties) will be copied to the current working model when you create model instances from this model. To change this behavior, click the **Model Instances** tab and toggle off the objects that you do not want copied.
9. Click **OK** to save your data and to close the dialog box.

Managing session objects and session options

This section describes how you save session objects and session options to a file and how you load these objects and options for use in subsequent sessions.

In this section:

- *Saving session objects and session options to a file*
- *Loading session objects and session options from a file*

Saving session objects and session options to a file

By default, many objects and options in Abaqus/CAE persist only for the current session. To retain these session objects or session options for use in a future Abaqus/CAE session, save them to the model database, to an output database, or to a settings file in XML format.

If you save settings to an output database, Abaqus/CAE loads those settings when you open that file; if you save to a model database or a settings file, you must load the settings from that file into your session to use them.

When you save session objects or options, you can include all the session-specific settings you specified in that session, or you can select settings from individual categories. For example, you can save all the display groups and path definitions in your session to a file while excluding all view cut definitions. The **Save Session Objects & Options** dialog box saves all the definitions in a particular category when you select the category; you cannot save individual display groups to a file while excluding others. If you want only a subset of display groups to be available for use in subsequent sessions, you must delete the other display groups from your session before saving the display groups to a file.

You must pay attention to object dependencies when you save session objects and options to a file. For example, a free body cut might refer to a previously defined display group, so it would make sense to save both display groups and free body cuts if you want to retain the free body cut in the future. Likewise, if you want to save the list of active view cuts and free body cuts to a file, you should also save the view cuts and free body cuts themselves.

Session objects are typically items that you define in a session, such as a display group or view cut; while session options are typically settings in a dialog box, such as the **Common Plot Options** dialog box. You can save the following session objects:

- display groups
- paths
- *X*–*Y* data objects
- free body definitions
- view cuts including cut-specific options (in the Visualization module only)
- the active status for free body cuts and view cuts
- the currently selected view and the 11 views specified on the Views toolbar
- spectrums

You can save the following session options:

- **ODB Display Options**
- **Result Options**
- **Common Plot Options**
- **Contour Plot Options**
- **Superimpose Plot Options**
- **Material Orientation Plot Options**
- **Ply Stack Plot Options**
- **Symbol Plot Options**
- **Free Body Plot Options**
- **View Cut Options** (common cut options from the **Free Body** and **Slicing** tabbed pages only)
- **Color Mapping**

You can save session objects and options to an output database only when it has been opened with write privileges. For more information, see *Opening a model database or an output database*.

1. Select **File->Save Session Objects** from the main menu bar.

    **Tip:** You can also click  from the File toolbar.

   The **Save Session Objects & Options** dialog box appears.

2. From the **Destination** options, select the type of file to which you want to save session objects and options and, if applicable, select the file:

   - Select **File** to save to a settings file in XML format, and specify the file name.
   - Select **MDB (.cae)** to save to the current model database.
   - Select **ODB** to save to an output database, and specify one of the output databases that are currently open in your session.

3. Specify the categories of session objects or session options that you want to save:

   - If you want to save all session objects or all session options, toggle on **Objects** or **Options**, respectively.
   - If you want to select categories of session objects or session options individually, expand the **Objects** or **Visualization Options** container, and toggle on the categories that you want to save.

4. Click **OK**. If you selected **MDB (.cae)** as the destination file, you must select **File->Save** or **File->Save As** to save the model database as well.

Additional information

- *What is an X–Y data object, and what is an X–Y plot?*
- *Creating or editing a free body cut*
- *Understanding how to create display groups*
- *Displaying a cut section and its resultant force and moment vectors*

Loading session objects and session options from a file

You can load session objects or session options from a file into your session. Session options or objects can be loaded from the current model database, an output database, or a settings file in XML format.

When you load session objects or options, you can load all the session-specific settings you specified in that file, or you can select settings from individual categories. For example, you can load all the display groups and path definitions in your session to a file while excluding all view cut definitions. The **Load Session Objects & Options** dialog box loads all the definitions in a particular category when you select the category; you cannot load individual display groups while excluding others. If you want only a subset of the display groups that are included in a file, you must load the display groups included in the file and delete the ones you do not want to use.

1. Select **File->Load Session Objects** from the main menu bar.

    **Tip:** You can also click  from the File toolbar.

   The **Load Session Objects & Options** dialog box appears.

2. From the **Source** options, do the following:

   - Select **File** to load from a settings file in XML format, and specify the file name.
   - Select **MDB (.cae)** to load from the current model database.
   - Select **ODB** to load from an output database, and specify one of the output databases that are currently open in your session.

3. Specify the categories of session objects or session options that you want to load:

   - If you want to load all session objects or all session options, toggle on **Objects** or **Visualization Options**, respectively.
   - If you want to select categories of session objects or session options individually, expand the **Objects** or **Visualization Options** container, and toggle on the categories that you want to load.

4. Click **OK**.

Additional information

- *What is an X–Y data object, and what is an X–Y plot?*
- *Creating or editing a free body cut*
- *Understanding how to create display groups*
- *Displaying a cut section and its resultant force and moment vectors*

Controlling the input file generated by Abaqus/CAE

This section describes techniques you can use to control the input file generated by Abaqus/CAE.

In this section:

- *Adding unsupported keywords to your Abaqus/CAE model*
- *Adding descriptions to your Abaqus/CAE model*
- *Resolving conflicts in the input file*
- *Writing input files without parts and assemblies*

Adding unsupported keywords to your Abaqus/CAE model

Abaqus/CAE uses your model definition to generate Abaqus/Standard or Abaqus/Explicit keywords and data that are placed in an input file when you submit the analysis job. Currently Abaqus/CAE may not support Abaqus/Standard or Abaqus/Explicit functionality that you might like to include in your model. If that is the case, you may be able to add the functionality using the **Keywords Editor**. Select **Model->Edit Keywords->*model _name*** from the main menu bar to start the **Keywords Editor**.

To use the **Keywords Editor**, you should be familiar with the syntax of Abaqus keywords and data. For example, the Step module does not allow you to provide boundary impedances or nonreflecting boundaries for acoustic and coupled acoustic-structural analysis. To provide boundary impedances or nonreflecting boundaries, you can use the **Keywords Editor** to add the **IMPEDANCE* keyword to the model.

When you submit the model for analysis in the Job module, Abaqus/CAE incorporates changes you made using the **Keywords Editor** in the input file that is submitted for analysis. Keywords that you add to your model using the **Keywords Editor** persist even after you modify or regenerate the model using Abaqus/CAE, because Abaqus/CAE stores the contents of the **Keywords Editor** along with the model definition in the model database. As a result, the contents of the input file may not be valid (for example, if you added keywords that refer to steps that you subsequently deleted), and the analysis may fail.

Warning:

If you used the **Keywords Editor** to edit the original model, Abaqus/CAE ignores those changes when you restart the analysis. For more information, see *Rules governing a restart analysis*.

Abaqus/CAE indents some of the keywords in the **Keywords Editor** to make the input file easier to read on the screen. The keywords that are indented can never appear on their own in the input file and must always be used in conjunction with another keyword. The indentation that you see in the **Keywords Editor** is not included in the input file that is generated by Abaqus/CAE.

The **Keywords Editor** does not allow you to edit the geometry of your model; you must use Abaqus/CAE to make geometry changes. Therefore, the **Keywords Editor** is available only after you have generated the mesh. If the input file generated by Abaqus/CAE is exceptionally long, the **Keywords Editor** displays the input file one buffer at a time. You can use the scroll bar to scroll through each buffer and the controls at the bottom of the editor to navigate to different buffers.

If you use the **Keywords Editor** to modify the input file and then use Abaqus/CAE to modify the model, Abaqus/CAE merges the changes into the input file. If a conflict arises during the merge, Abaqus/CAE issues a warning message.

It is recommended that you not edit keywords that are supported by Abaqus/CAE; for example, you should use the Property module, not the **Keywords Editor**, to change the properties of a material. This approach maintains consistency between directly supported aspects of a model and those added by the **Keywords Editor**. If you do edit a keyword using the **Keywords Editor** and then use Abaqus/CAE to make a change to your model that refers to the same keyword, a conflict will occur.

To minimize the length of the input file displayed in the **Keywords Editor**, Abaqus/CAE hides the data lines for keywords that require a large amount of data, notably **NODE*, **ELEMENT*, and **DISTRIBUTION*. If you modify the line immediately following such keywords in the **Keywords Editor**, conflicts occur when Abaqus/CAE merges and writes the input file.

For tips on resolving input file conflicts generated by the **Keywords Editor**, see *Resolving conflicts in the input file*.

You can review the keywords supported by Abaqus/CAE by selecting **Help->Keyword Browser** from the main menu bar.

1. From the main menu bar, select **Model->Edit Keywords->*model _name***.

   The **Keywords Editor** appears and displays the keywords associated with the model you select.

Note:

The keywords are available to be edited only after you have generated a mesh.

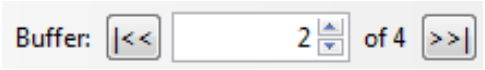
Note:

The contents are truncated if you include an asterisk (*) in an object name or description.

2. Each keyword in the input file is displayed in its own block. Buttons in the lower left corner of the **Keywords Editor** allow you to do the following:

Add After

Add an empty block of text below the selected block; text that you add to a new block appears in blue.



Remove

Remove the selected block of text that was added using the **Keywords Editor**. You cannot remove a block generated by Abaqus/CAE.

Discard Edits

Discard the changes you made to a block generated by Abaqus/CAE during the most recent use of the **Keywords Editor**.

Buffer *x* of *y* :

Display the buffer of the input file as specified in the box. Use the scroll bar to scroll within a buffer.

|<<

Display the first buffer of the input file.

>>|

Display the last buffer of the input file.

In addition, you can click any block and edit the text inside. Cyan text indicates a block generated by Abaqus/CAE that you edited.

3. From the buttons across the bottom of the **Keywords Editor**, click **OK** to include your changes and to close the editor. Click **Cancel** to close the editor and to disregard your changes. Click **Discard All Edits** to keep the editor open and to remove all of the changes that you made to the input file.

Additional information

- *What is an Abaqus/CAE model?*
- *Abaqus keyword browser table*

Adding descriptions to your Abaqus/CAE model

In Abaqus/CAE you can enter descriptions for the model and for the materials in your model in the **Edit Model Attributes** dialog box and the **Edit Material** dialog box, respectively. When you submit the job for analysis, Abaqus/CAE generates an input file and writes these descriptions to the input file using comment lines. The comment lines for the model description immediately precede the header of the input file, and the comment lines for the material descriptions immediately precede the material definitions.

For related information on using descriptions, see *Importing descriptions*.

Additional information

- *Specifying model attributes*
- *Creating or editing a material*

Resolving conflicts in the input file

If you edit a keyword using the **Keywords Editor** and then use Abaqus/CAE to make a change to your model that refers to the same keyword, Abaqus/CAE cannot determine which version of the keyword to incorporate in the input file and writes text to the input file signaling the problem. As a result, an error is generated when you submit the model for analysis. If you display the input file using the **Keywords Editor**, any keywords or data lines that conflict are indicated by a *Conflicts statement. In addition, the *Conflicts statement indicates whether the text was generated by Abaqus/CAE or by the **Keywords Editor**. You should use the **Keywords Editor** to remove any unwanted keywords or data lines. You should also remove all the *Conflicts statements.

Certain input file conflicts cannot be resolved using the **Keywords Editor**; for example, conflicts caused by modifications to the input file line immediately following hidden data lines (see *Adding unsupported keywords to your Abaqus/CAE model*). In these situations you can use the Job module to write the complete input file to a text file (see *Writing the input file only*, for details). You can modify this input file using a text editor, then manually submit the modified input file for analysis (see *Abaqus/Standard and Abaqus/Explicit Execution*). To perform the analysis in Abaqus/CAE, create a new job in the Job module using the modified input file as the job source (see *Creating a new analysis job*).

Writing input files without parts and assemblies

Abaqus/CAE uses your model definition to generate an Abaqus/Standard or Abaqus/Explicit input file when you submit the analysis job.
The Abaqus/CAE model contains parts and assemblies; and, by default, an input file generated by Abaqus/CAE contains parts and assemblies. Some Abaqus functionality is not supported in a model that contains parts and assemblies.

Abaqus/CAE attempts to preserve the node and element labels of the model when writing an input file without parts and assemblies. If there are no conflicts between any part or part instance labels, Abaqus/CAE maintains the labels in the model when it writes the nodes and elements to the input file. Conversely, if any conflicts arise between any part or part instance labels, such as two part instances with the same node and element labels, Abaqus/CAE displays a warning before it writes an input file with renumbered node and element labels.

If you want Abaqus/CAE to write input files without parts and assemblies, you can use one of the following methods to change the format of input files generated by Abaqus/CAE:

When you start an Abaqus/CAE session

To change the format of the input files generated by Abaqus/CAE, you can modify the **cae_no_parts_input_file** parameter in the Abaqus environment file (`abaqus_v6.env`) as follows:

```
cae_no_parts_input_file=ON
```

If you use this method, the input file format cannot be changed during the Abaqus/CAE session. For more information on defining environment file parameters, refer to the *Abaqus Configuration Guide*.

During an Abaqus/CAE session

There are two methods that you can use to change the format of the input files generated by Abaqus/CAE.

- Select **Model->Model Attributes->*model name*** for the model that you want to change, then toggle on **Do not use parts and assemblies in input files**.
- Enter the following Abaqus Scripting Interface command into the command line interface at the bottom of the Abaqus/CAE main window:

  ```
  mdb.models[modelName].setValues(noPartsInputFile=ON)
  ```

  Note:

  The command line interface is hidden by default, but it uses the same space that is occupied by the message area at the bottom of the main window. To access the command line interface, click  in the bottom left corner of the main window.

If you use either method, the changed input file format is a part of the model definition. When you exit the Abaqus/CAE session and return to the model database at a later time, the changed input file format is retained.

If you find yourself repeatedly changing the format of the input file generated by Abaqus/CAE, you can create and run a macro that contains the previous Abaqus Scripting Interface command. For more information on macros, see *Managing macros*.

Warning:

When Abaqus/CAE writes an input file without parts and assemblies, it tries to preserve the node and element labels generated in Abaqus/CAE. However, if you use the **Keywords Editor** to edit keywords in a model that uses the parts and assemblies input file format and then change the format of the input file generated by

Abaqus/CAE, conflicts may occur when the input file is written and the keywords are regenerated. For more information, see *Resolving conflicts in the input file*.

Additional information

- *The Abaqus/CAE main window*
- *Managing macros*

Managing macros

When you create a macro, Abaqus/CAE records a sequence of Abaqus Scripting Interface commands in a macro file while you interact with Abaqus/CAE. Each command corresponds to an interaction with Abaqus/CAE, and replaying the macro reproduces the sequence of interactions.
To manage macros containing a set of Abaqus Scripting Interface commands, select **File->Macro Manager** from the main menu bar.

Macros are stored in a file called `abaqusMacros.py`. Abaqus/CAE searches three directories for `abaqusMacros.py`, in the following order:

- The site directory of the Abaqus installation.
- Your home directory.
- The current working directory.

The `abaqusMacros.py` file can exist in more than one of these directories. The **Macro Manager** contains a list of the existing macros that Abaqus/CAE detected in all the `abaqusMacros.py` files. If a macro uses the same name in more than one `abaqusMacros.py` file, Abaqus/CAE uses the last macro encountered.

Your macro will run only in the same context in which it was recorded. For example, if you create a macro that copies a part named `gear1` to a new part named `gear2`, the macro will be executed in a new Abaqus/CAE session only if a part named `gear1` exists. When using a plug-in, you may be required to import additional Python modules only the first time you access the plug-in, and this initialization may not be recorded in the macro.

The Abaqus Scripting Interface commands are stored in ASCII text. You can edit `abaqusMacros.py` with a standard text editor; however, any errors that you introduce into the file will prevent the **Macro Manager** from displaying. For more information on commands, see the *Abaqus Scripting User's Guide*.

Tip: If you edit any of the `abaqusMacros.py` files using a text editor, you can click **Reload** from the buttons at the bottom of the **Macro Manager** to update the macro list without closing the manager.

Additional information

• *Creating and running a macro*
• *Abaqus Scripting User's Guide*

Create a macro

1. From the main menu bar, select **File->Macro Manager**.

   The **Macro Manager** dialog box appears.
2. From the buttons across the bottom of the **Macro Manager** dialog box, click **Create**.
3. Enter a name for the macro in the **Create Macro** dialog box that appears, and click **Continue**. You cannot overwrite an existing macro.

   Each of your interactions with Abaqus/CAE is stored as a command in the `abaqusMacros.py` file. A **Recording macro** dialog box appears to remind you the macro is recording. In addition, the **Create**, **Delete**, **Run**, and **Reload** buttons are not available in the **Macro Manager** while the macro is recording.
4. Click the **Stop recording** button to save the macro in `abaqusMacros.py`.

   Abaqus/CAE updates the macro list in the **Macro Manager**.

Delete a macro

1. From the main menu bar, select **File->Macro Manager**.

The **Macro Manager** dialog box appears.

2. Select the macro to delete. You can select more than one macro.
3. From the buttons across the bottom of the **Macro Manager** dialog box, click **Delete**.
4. From the dialog box that appears, click **OK** to confirm your action.

   Abaqus/CAE deletes the macro from `abaqusMacros.py` and updates the macro list in the **Macro Manager**. You cannot recover a deleted macro.

Run a macro

1. From the main menu bar, select **File->Macro Manager**.

   The **Macro Manager** dialog box appears.
2. Select the macro to run.
3. From the buttons across the bottom of the **Macro Manager** dialog box, click **Run**. You can run only one macro; the **Run** button is not available if you selected more than one macro.

   Abaqus/CAE runs the commands in the selected macro and displays a message in the message area when the macro execution completes.

Importing and exporting geometry data and models

This section describes the files that can be imported into and exported from Abaqus/CAE.

In this section:

- *Importing files into and exporting files from Abaqus/CAE*
- *Valid parts, precise parts, and tolerance*
- *Controlling the import process*
- *Understanding the contents of an IGES file*
- *What can you import from a model?*
- *A logical approach to successful import of IGES files*
- *Importing sketches and parts*
- *Importing a model*
- *Exporting geometry, model, and mesh data*

Importing files into and exporting files from Abaqus/CAE

Abaqus/CAE can import part and assembly geometries from a variety of external sources and CAD systems. The associative interfaces for Abaqus/CAE provide straightforward and powerful techniques for importing geometry. More traditional techniques are also available for importing and exporting geometry using standard CAD file formats. Understanding the capabilities of each format, as well as the limitations of representing the geometry of a part in a file, will help you select the import or export technique that is appropriate for your application.

In this section:

- *What kinds of files can be imported and exported from Abaqus/CAE?*
- *What can I do with the associative interfaces?*
- *What can I do with the Elysium plug-ins?*
- *Importing an assembly*
- *Know what you want as an end product*
- *Vendors interpret the standards differently*
- *How do solid modelers represent a solid?*

What kinds of files can be imported and exported from Abaqus/CAE?

Abaqus/CAE reads and writes geometry data stored in Abaqus file formats as well as non-Abaqus file formats.

Abaqus file formats

Abaqus/CAE reads and writes geometry data stored in the following Abaqus file formats:

Abaqus output database (*output_database_name*`.odb`)

An output database contains the data generated during an Abaqus/Standard or Abaqus/Explicit analysis. You can import parts from an output database in the form of meshes. A mesh part contains no feature information and is extracted from the output database as a collection of nodes, elements, surfaces, and sets. If the output database contains multiple part instances, you can select the part instances to import. Abaqus/CAE imports each part instance as a separate part. You can import either the undeformed or the deformed shape. If you import the deformed shape, you can specify the step and the frame from which to import.

To verify the quality of the mesh, you can display the part in the Mesh module and select **Mesh->Verify** from the main menu bar. In addition, you can use the Mesh module to change the element type assigned to the mesh and to edit the original mesh definition. For more information, see *Importing a part from an output database*, *What can I do with the Edit Mesh toolset?*, and *Assigning Abaqus element types*.

You can also import a model from an output database. The model that is imported will contain parts representing each of the undeformed part instances in the output database along with a mesh representation of the undeformed assembly. The model will also contain any sets, surfaces, materials, section definitions, and beam profiles that were defined in the output database. For more information, see *Importing a model from an output database*.

Abaqus/CAE model database (*model_database_name*`.cae`)

Abaqus/CAE can import a model into the current model database from a different Abaqus/CAE model database. For more information on importing model data from another model database, see *Importing a model from an Abaqus/CAE model database*.

Abaqus/Standard and Abaqus/Explicit input files

Abaqus/CAE generates an input file when you submit a job for analysis. You can import input files into Abaqus/CAE. Abaqus/CAE translates the keywords and data lines in the imported input file into a new model; however, a limited set of Abaqus/Standard and Abaqus/Explicit keywords is supported, as described in *Importing a model from an Abaqus input file*. For more information on creating and submitting jobs, see *Basic steps for analyzing a model*.

Abaqus substructure files (*substructure_name*`.sim`)

Abaqus/CAE can import a substructure definition from a SIM database as a new part definition. The `.sim` file you import must reside in the same directory as the supporting Abaqus files to which the SIM database refers; these supporting files might include data in the formats `.prt`, `.mdl`, or `.stt`. For step-by-step instructions, see *Importing a substructure into a model database as a part*.

Supported non-Abaqus file formats

Abaqus/CAE reads and writes geometry data stored in the following non-Abaqus file formats:

3D XML (*file_name*`.3dxml`)

3D XML is an XML-based format developed by Dassault Systèmes for encoding three-dimensional images and data. The format is open and extendable, allowing three-dimensional graphics to be easily shared and integrated into existing applications and processes. 3D XML files can be many times smaller than typical model database files. The 3D XML Player from Dassault Systèmes is required to view 3D XML files or to integrate them into business applications. You can also view 3D XML files in CATIA V5. This export capability cannot be used to transfer geometry or models to **3D**EXPERIENCE platform apps.

You can export viewport data from Abaqus/CAE in 3D XML or compressed 3D XML format. For more information, see *Exporting viewport data to a 3D XML-format file*. You cannot import 3D XML into Abaqus/CAE.

ACIS (*file_name*`.sat` or *file_name*`.asat`)

ACIS is a library of solid modeling functions, and most CAD products can generate ACIS-format parts. You can import ACIS-format parts, and you can export parts or the assembly in ACIS format. In addition, you can import and export sketches in ACIS format. For more information, see *Importing parts from an ACIS-format file*, *Importing sketches*, and *Exporting geometry, model, and mesh data*.

ANSYS input files (*file_name*`.cdb`)

ANSYS Mechanical and ANSYS Multiphysics software are computer-aided engineering products that allow you to perform finite element analysis and computational fluid dynamics. You can import models from files in ANSYS input file format into Abaqus/CAE. For more information, see *Importing a model from an ANSYS input file*, and *Importing a model*.

AutoCAD (*file_name*`.dxf`)

Two-dimensional profiles stored in AutoCAD (`.dxf`) files can be imported as stand-alone sketches. However, Abaqus/CAE supports only a limited number of AutoCAD entities, and you should use this format only if no other formats are available. For more information and details on the AutoCAD entities supported by Abaqus/CAE, see *Importing sketches*. Unsupported entities include:

- Polyline
- Spline
- Block
- Dimension
- Shape

CATIA V5 parts and assemblies (*file_name*`.CATPart` or `.CATProduct`)

With the optional CATIA V5 Associative Interface add-on feature for Abaqus/CAE, you can import CATIA V5-format parts and assemblies. For more information, see *Importing a part from a V5-format file*. You cannot export parts from Abaqus/CAE in CATIA V5 format.

CATIA V6 parts and assemblies (*file_name*`.CATPart` or `.CATProduct`)

You use the CATIA V6 Associative Interface to import CATIA V6-format parts and assemblies. The CATIA V6 parts and assemblies are first converted to CATIA V5 format, and Abaqus/CAE imports the resulting CATIA

V5`CATPart` or `CATProduct` files. For more information, see *Importing a part from a V5-format file*. You cannot export parts from Abaqus/CAE to CATIA V6.

Elysium assembly files (*file_name* `.eaf`)

Elysium assembly files are created by the associative interface applications, which are plug-ins for third-party CAD systems that allow you to transfer models from the CAD system to Abaqus/CAE using a technique called associative import (see *What can I do with the associative interfaces?*). The associative interface plug-ins save model information in the assembly file, and you can use the assembly file to associatively import the model from the third-party CAD system into Abaqus/CAE. For more information, see *Importing an assembly from an Elysium assembly file*. You cannot export assemblies from Abaqus/CAE in Elysium assembly file format.

IGES (*file_name* `.igs` or `.iges`)

The Initial Graphics Exchange Specification (IGES) is a neutral data format designed for graphics exchange between computer-aided design (CAD) systems.

You can import IGES-format parts, and you can export parts in IGES format. In addition, you can import and export sketches in IGES format. For more information, see *Importing a part from an IGES-format file*; *Importing sketches*; and *Exporting geometry, model, and mesh data*.

The IGES-format allows for many interpretations, and most of the parts that you import into Abaqus/CAE using IGES-format will need to be repaired before you can use them. Thus, it is recommended that you try to use another format, if possible.

Nastran input files (*file_name* `.bdf`, *file_name* `.dat`, *file_name* `.nas`, *file_name* `.nastran`, *file_name* `.blk`, or *file_name* `.bulk`)

You can import Nastran model data from a Nastran input file into Abaqus/CAE, and you can export data from an Abaqus/CAE model and job into Nastran bulk data file format. Imported and exported models include many common entities in the Nastran bulk data. For more information on supported entities for import of Nastran input files into Abaqus/CAE, see *Translating Nastran Bulk Data in Text Files to Partial Abaqus Input Files*. For more information on supported entities for export of Abaqus/CAE jobs and models to Nastran, see *Translating an Abaqus Input File to a Partial Nastran Bulk Data Text File*.

NX Elysium Neutral File (*file_name* `.enf_abq`)

Abaqus provides a translator plug-in for NX that will generate a geometry file using the Elysium Neutral File (`.enf`) format. You can use Elysium Neutral Files to import NX parts. In addition, you can use Elysium Neutral Files to import an entire NX assembly into the Abaqus/CAE assembly, or you can choose to import only selected part instances from the assembly. For more information, see *Importing a part from an Elysium Neutral file*, and *Importing an assembly from an Elysium Neutral file*. You cannot export parts or assemblies from Abaqus/CAE in Elysium Neutral File format.

OBJ (*file_name* `.obj`)

OBJ is an open file format that describes the geometry in terms of the position of the vertices, the edges between them, and the faces that comprise each polygon in the geometry. Data in OBJ format are saved as a text file.

You can export geometry data or mesh data from Abaqus/CAE in OBJ format. For more information, see *Exporting viewport data to an OBJ-format file*. You cannot import OBJ-format data into Abaqus/CAE.

Parasolid (*file_name*`.x_t`, *file_name*`.x_b`, *file_name*`.xmt_txt`, or *file_name*`.xmt_bin`)

Parasolid is a library of solid modeling functions developed by UGS. A variety of CAD products can generate Parasolid-format parts, such as NX, SOLIDWORKS, Solid Edge, FEMAP, and MSC.Patran. You can import Parasolid-format parts. You can also import an entire Parasolid assembly into the Abaqus/CAE assembly, or you can choose to import only selected part instances. For more information, see *Importing a part from a Parasolid-format file* and *Importing an assembly from a Parasolid-format file*. You cannot export parts or assemblies from Abaqus/CAE in Parasolid format.

Pro/ENGINEER Elysium Neutral File (*file_name*`.enf_abq`)

Abaqus provides a translator plug-in for Pro/ENGINEER that will generate a geometry file using the Elysium Neutral File (`.enf`) format. You can use Elysium Neutral Files to import Pro/ENGINEER parts. In addition, you can use Elysium Neutral Files to import an entire Pro/ENGINEER assembly into the Abaqus/CAE assembly, or you can choose to import only selected part instances from the assembly. For more information, see *Importing a part from an Elysium Neutral file* and *Importing an assembly from an Elysium Neutral file*. You cannot export parts or assemblies from Abaqus/CAE in Elysium Neutral File format.

SOLIDWORKS parts and assemblies (*file_name*`.sldprt` or *file_name*`.sldasm`)

You can import SOLIDWORKS native file formats for parts and assemblies. For more information, see *Importing a part from a SOLIDWORKS-format file*. You cannot export parts from Abaqus/CAE in SOLIDWORKS format.

STEP (*file_name*`.stp` or `.step`)

The STandard for the Exchange of Product model data (STEPISO 10303–1) is designed as a high-level replacement for IGES that attempts to overcome some of the shortcomings of IGES. The STEPAP203 standard is designed to provide a computer-interpretable representation of a mechanical product throughout its lifecycle, independent of any particular system.

You can import STEP-format parts, and you can export parts in STEP format. In addition, you can import and export sketches in STEP format. For more information, see *Importing a part from a STEP-format file* and *Exporting geometry, model, and mesh data*.

STEP-format parts are similar to IGES-format parts in that most of the parts that you import into Abaqus/CAE using STEP-format will need to be repaired before you can use them. Thus, it is recommended that you try to use another format, if possible.

VDA-FS (*file_name*`.vda`)

The Verband der Automobilindustrie Flächen Schnittstelle (VDA-FS) surface data format is a geometry standard developed by the German automotive industry. Both VDA-FS and IGES files contain a mathematical representation of the part in an ASCII format; however, the VDA-FS standard concentrates on geometry information. Additional information covered by the IGES standard, such as dimensions, text, and colors, is not stored in a VDA-FS file.

You can import VDA-FS-format parts, and you can export parts in VDA-FS format. For more information, see *Importing a part from a VDA-FS-format file* and *Exporting geometry, model, and mesh data*.

VDA-FS format parts are similar to IGES-format parts in that most of the parts that you import into Abaqus/CAE using VDA-FS format will need to be repaired before you can use them. Thus, it is recommended that you try to use another format, if possible.

VRML (*file_name* `.wrl`)

Virtual Reality Modeling Language (VRML) is the ISO standard for displaying three-dimensional images in a web browser or a stand-alone VRML client. It is an open, platform-independent, vector-based, three-dimensional modeling language that encodes computer-generated graphics to allow them to be shared easily across a network. VRML files use meters for all lengths and distances. VRML-format files can be many times smaller than typical model database files. A special plug-in viewer, such as Cortona or Cosmo, is required to view VRML files.

You can export viewport data from Abaqus/CAE in VRML format or compressed VRML format. For more information, see *Exporting viewport data to a VRML-format file*.

What can I do with the associative interfaces?

The associative interfaces are optional add-on products that simplify the process of transferring model data between CAD systems and Abaqus/CAE. The associative interfaces use the CAD Connection toolset to create a connection between Abaqus/CAE and a CAD system running an associative interface plug-in. Associative interface plug-ins are available for the following CAD systems:

- CATIA V6
- CATIA V5
- NX (Unigraphics)
- SOLIDWORKS
- Pro/ENGINEER

The associative interfaces allow for associative import of models from a CAD system to Abaqus/CAE. You can export an entire assembly from the CAD system into Abaqus/CAE with a single mouse click, and you can modify your model in the CAD system and use the connection to quickly update the model in Abaqus/CAE. Features that you created in Abaqus/CAE—such as loads, boundary conditions, sets, and surfaces—are updated when you import the modified model. In addition to modified parts, any changes that you make to the position of instances in the assembly will also be exported to Abaqus/CAE.

Associative import is useful when you are running the CAD system and Abaqus/CAE on the same computer and are iterating on the design of the model based on the results of the analysis. *Figure 1* shows the connection between SOLIDWORKS and Abaqus/CAE using associative import.

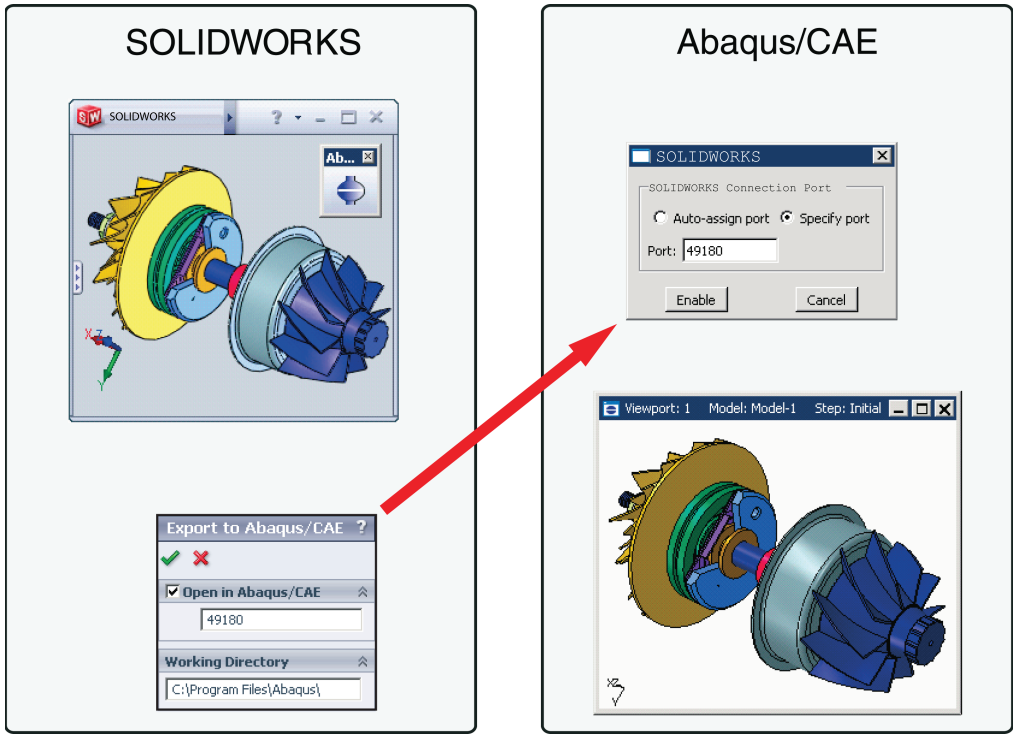


Figure 1: Associative import using the SOLIDWORKS Associative Interface.

You can modify the model with either the CAD system or Abaqus/CAE while you iterate on the design. If you import a model into Abaqus/CAE from the CAD system and then add features to the model in Abaqus/CAE, Abaqus/CAE regenerates these features in the model the next time you import it from the CAD system. Geometry modifications that you make in Abaqus/CAE (such as partitions, fillets, etc.) are also regenerated each time you import the model from

the CAD system. Abaqus/CAE may fail to regenerate features if the changes that you make using the CAD system significantly change the topology of the model. Geometry modifications made in Abaqus/CAE are not propagated to the original CAD model, although the Abaqus Associative Interface for Creo Parametric does provide a method for revising certain geometric entities in the original Pro/ENGINEER model from within Abaqus/CAE (see *Updating geometry parameters in an imported model*).

The associative interfaces also allow you to save assemblies in a CAD system to an assembly file format that can subsequently be imported to Abaqus/CAE at a later time. For example, the CATIA V5 Associative Interface saves your CATIA V5 Assembly (`.CATProduct`) in an assembly file (`.eaf`) format that you can manually import into Abaqus/CAE. Similarly, the CATIA V6 Associative Interface converts your CATIA V6 product to a CATIA V5 Assembly and then saves it in an assembly file format that you can manually import into Abaqus/CAE.

For more information about creating a connection between Abaqus/CAE and CAD systems, see *The CAD Connection toolset*. For information about the versions of the CAD software supported by the associative interfaces, see the Dassault Systèmes Knowledge Base at *http://support.3ds.com/knowledge-base/*.

What can I do with the Elysium plug-ins?

You can use a Neutral File-based translator from Elysium, Inc., to import parts into Abaqus/CAE that were created by CAD software that creates Parasolid-format files, such as SOLIDWORKS, NX, Solid Edge, FEMAP, and MSC.Patran.

You can also use the Elysium translator to import the entire assembly or only selected part instances from the assembly.

In addition, you can import a part, the assembly, or selected part instances from the assembly into Abaqus/CAE using the Elysium Neutral File format. Abaqus provides a translator plug-in from Elysium that will generate a geometry file using the Elysium Neutral File format. The plug-in is available for the following products:

- CATIA V5
- NX
- Pro/ENGINEER

For information about the versions of the CAD software supported by the Elysium translators, see the Dassault Systèmes Knowledge Base at *http://support.3ds.com/knowledge-base/*.

Importing an assembly

A file from a CAD system, such as CATIA, can contain a single part or an assembly of parts. Abaqus/CAE allows you to select **File->Import** from the main menu bar and choose either **Part** or **Assembly**. Both options allow you to import all of the parts in an assembly; however, the end result is slightly different.

Importing parts

If you choose to import parts from a file that contains an assembly of parts, you can import either all of the parts from the file or only a specified part. If you import all of the parts, Abaqus/CAE creates a group of parts that corresponds to each part instance in the original assembly. To recreate the original assembly, you must use the Assembly module to instance each imported part. However, the relationship between the parts and the part instances in the original assembly is lost during the import process. For example, if the original assembly contained a bolt that was instanced nine times, Abaqus/CAE creates nine identical parts. When you recreate the assembly in the Assembly module, Abaqus/CAE creates a part instance for each of the nine bolts. Although the relationship between the parts and part instances is lost, Abaqus/CAE does retain the position of the parts. As a result, when you instance each part, it appears in the correct position in the assembly.

Importing an assembly

If you choose to import an assembly, you can import the entire assembly or you can import only selected part instances. Abaqus/CAE appends your selection to the existing assembly and retains the original positioning of the instances. In addition, Abaqus/CAE creates parts that correspond to the imported part instances and maintains the relationship between the parts and their instances. For example, if a bolt is instanced nine times in the assembly, Abaqus/CAE imports nine instances of the bolt but creates only a single part.

Importing an assembly also offers the following advantages:

- In most cases Abaqus/CAE retains the names of the parts and the part instances from the original file.
- If the parts and part instances in the original file were colored by the third-party CAD system, Abaqus/CAE retains those colors during the import procedure. For information about modifying the color coding, see *Color coding geometry and mesh elements*.

Know what you want as an end product

Many of the problems associated with importing a complex solid part into Abaqus/CAE can be alleviated if you recognize what you want as an end product: a finite element mesh of the parts to be analyzed using Abaqus/Standard or Abaqus/Explicit.

A small feature in the imported part will result in a fine mesh in the area of the detail. The fine mesh will influence the mesh in adjacent regions and may dominate the time taken to perform the analysis. If you are not interested in analyzing the feature, you should use the CAD system to remove the detail from the part before you import the part into Abaqus/CAE. Removing small features may solve precision errors in the imported part. Examples of small features include:

- Fillets
- Chamfers
- Holes

Simplifying a solid part will increase your chances of successfully importing it into Abaqus/CAE. You must decide the level of detail that will produce meaningful results from the analysis.

Finally, you should consider the type of mesh required by the analysis. If you plan to mesh the part with triangular or tetrahedral elements or with quadrilateral elements generated by the advancing front algorithm, you can use the Virtual Topology toolset in the Mesh module to remove small details from the part before you generate the mesh. For more information, see *The Virtual Topology toolset*.

Vendors interpret the standards differently

Using an accepted industry standard, such as IGES and VDA-FS, to exchange geometric information between a CAD system and Abaqus/CAE is not a guarantee of success. When a CAD system exports a part, the system maps its proprietary representation of the part into an array of entities available from the standard. Similarly, when Abaqus/CAE imports the file, it converts the entities defined by the standard into its internal representation—ACIS.

ACIS recognizes only some of the entities defined in the IGES and VDA-FS standards and also expects a certain level of smoothness or continuity in the trimmed surfaces. Although the exporting CAD system is not aware of the requirements of Abaqus/CAE, setting the correct export options will increase your chance of success. For more information, see *How do solid modelers represent a solid?*, and *Understanding the contents of an IGES file*.

In addition, you may experience problems because CAD systems interpret the industry standards differently. In many cases there is more than one way to define a geometric entity, resulting in a particular “flavor” of the file format. In more extreme cases, vendors violate the standard, especially when creating trimmed surfaces.

How do solid modelers represent a solid?

Abaqus/CAE provides tools that allow you to import a sketch, a part, or an assembly into the current model. When you import a sketch or a planar part or assembly, the process is usually straightforward. However, when you import a solid, you may find that you have to perform some additional steps to obtain a satisfactory result. To understand what the steps accomplish and why you need to perform them, you need to understand how solids are represented by solid modelers.

As modeling systems have evolved during the last 30 years, the techniques used to represent a solid body have also evolved. Each new generation of modelers incorporates more knowledge about the construction of the body and relies less on the sheer volume of data points to describe a solid.

Wireframe

The original CAD systems used two-dimensional wireframes to replicate traditional mechanical drawings. Later versions introduced three-dimensionality in the form of isometric views and perspective views. In a wireframe a solid body is represented by a set of curves that define the edges of the body; however, the system has no information about the surfaces between the edges. A wireframe model defines an object by its edges and vertices; as a result the wireframe representation of a solid has limited use. For example, you cannot calculate the volume of the solid, and you cannot mesh the solid.

Trimmed surface

Later systems introduced the concept of trimmed surfaces, as shown in *Figure 1*.

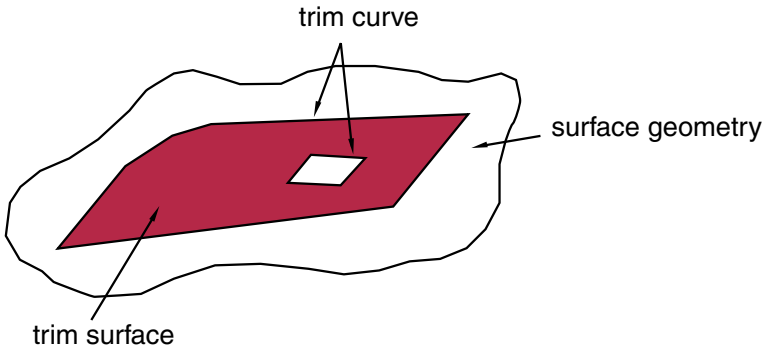

Figure 1: A trimmed surface.

A trimmed surface is defined by a combination of surface geometry and trim curves. The surface geometry is a general expression for the surface; the trim curves form a closed loop on the surface geometry and define the boundary of the surface. A surface can also have multiple internal trim curve surfaces. A solid is defined as a set of trimmed surfaces that form an enclosed volume.

For example, a cylinder can be defined from three trimmed surfaces as shown in *Figure 2*.

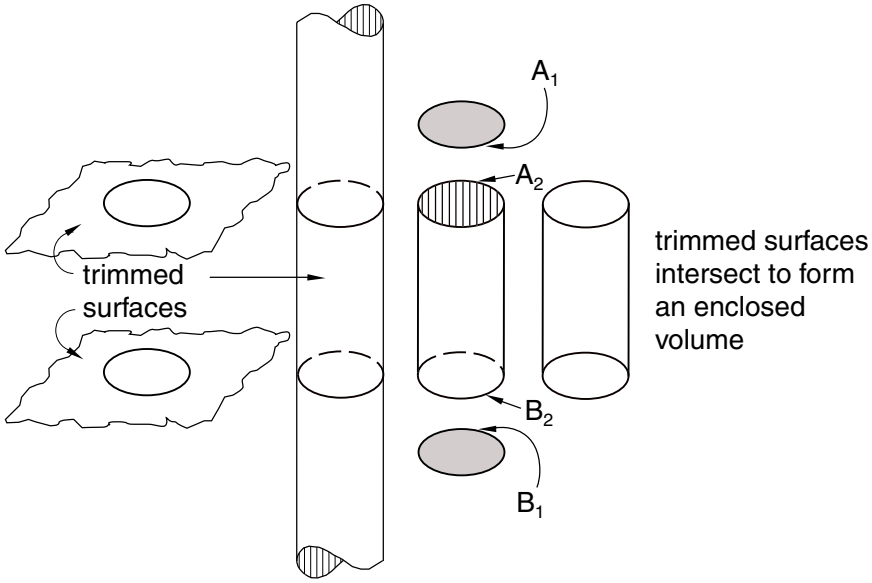

Figure 2: Three trimmed surfaces define a cylinder.

Each surface includes a set of edges that define the boundary of the surface. The flat trimmed surface at the top of the cylinder contains trim curve A_1. The flat trimmed surface at the base of the cylinder contains trim curve B_1. The cylindrical trimmed surface is bounded by two trim curves—A_2 and B_2. When two trimmed surfaces intersect, the definition of the resulting edge is duplicated by each surface. There is no information to indicate that a group of trimmed surfaces comprise a solid.

The edges of the solid are well defined when the intersecting surfaces are planar, cylindrical, or spherical. However, when more complex curves intersect, the resulting edge must be described by a polynomial expression that approximates the intersection of the two faces. The accuracy of the approximation depends on the order of the polynomial expression. If an edge does not lie on either surface, a gap is created and the solid is considered invalid. *Figure 3* illustrates a gap between trimmed surfaces.

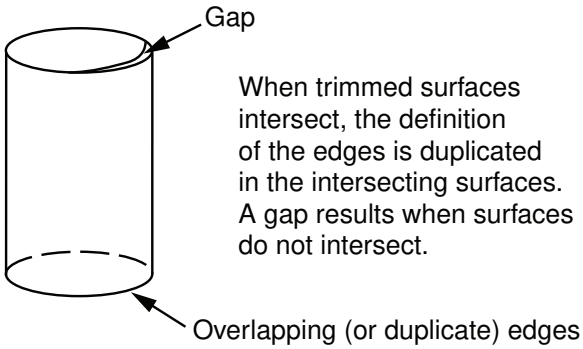

Figure 3: A gap between trimmed surfaces.

You can use the Geometry Edit toolset to stitch gaps. For more information, see *What is stitching?*.

Both the IGES and VDA-FS standards use trimmed surfaces. Most of the problems that can occur during import arise from the translation of a trimmed surface from the original file into a form recognized by Abaqus/CAE.

B-rep

More recently, solid modelers have introduced the concept of a "boundary representation," or "B-rep," to define a solid object. A B-rep solid is similar to a solid defined by a set of trimmed surfaces; however, a B-rep solid

includes additional information about the faces, edges, and vertices that are generated when the surfaces intersect to form the solid. Abaqus/CAE uses ACIS to store geometric entities, and ACIS uses the concept of B-reps. *Figure 4* illustrates the cylinder defined as a B-rep solid.

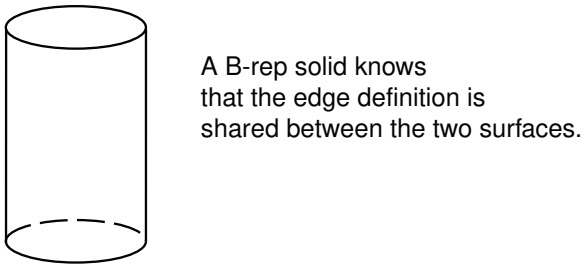

Figure 4: A B-rep solid.

Unlike a solid represented by only trimmed surfaces, a B-rep solid does not duplicate edges that are shared between two surfaces. In a B-rep solid one trimmed surface defines the shared edge and the second edge refers to that definition. For the B-rep solid to be recreated correctly, it must be possible to duplicate the trim curve defined by the first surface along the geometry of the second surface. In some cases ACIS will stitch adjacent edges to create the B-rep solid.

The IGES and STEP standards include the concept of B-reps, although IGES calls them Manifold Solid B-rep Objects or MSBOs. If you import an IGES or STEP file containing two or more trimmed surfaces that are close enough to be stitched together into a B-rep solid, Abaqus/CAE groups the surfaces together as a single solid entity. The VDA-FS standard does not include the concept of B-rep solids; VDA-FS uses only trimmed surfaces to define a solid.

Valid parts, precise parts, and tolerance

A part that you import into Abaqus/CAE must be valid if you wish to analyze the part with Abaqus/Standard or Abaqus/Explicit. The following sections describe valid and precise parts and how Abaqus/CAE uses imprecise modeling and tolerance to construct an imported part.

In this section:

- *What is a valid and precise part?*
- *How are precision and tolerance related?*
- *Working with invalid parts*

What is a valid and precise part?

When you import a solid part, Abaqus/CAE tries to create a closed solid part. Similarly, when you import a shell part, Abaqus/CAE tries to create a connected shell part. If the part is imported successfully, the part is considered valid and precise. However, if the precision of the original part is less than the precision used by Abaqus/CAE, the part may be imprecise or invalid. In most cases you can continue working with an imprecise part. You can also work with an invalid part if you repair it or choose to ignore the invalid status.

The terms “imprecise” and “invalid” are described in more detail below.

Imprecise

A valid part can be either precise or imprecise. If Abaqus/CAE must use a looser tolerance in some areas to recreate a closed volume from the imported part, the part is considered imprecise. You can complete most modeling operations with imprecise parts.

You should try to work with an imprecise part. If Abaqus/CAE cannot proceed, you can suppress the imprecise region or use the geometry edit tools to try and make the part precise. However, if the part contains many complex surfaces, the geometry edit tools may not be able to make the part precise and using the tools may be time consuming. If you cannot work with the imprecise part and you cannot make the part precise, you should return to the CAD application that generated the original file and increase the precision.

Invalid

If the errors are so large that Abaqus/CAE cannot recreate a closed volume from the imported part, the part is considered to be invalid. For example, large gaps between edges cause a part to be invalid. Similarly, points on edges that are far away from an underlying surface cause a part to be invalid.

If the part is invalid, you can use the Geometry Edit toolset to try to make it valid. If you cannot repair a part, you can indicate that you want to ignore the invalid part status and continue to use the part as if it were valid (for more information, see *Working with invalid parts*). However, operations on invalid geometry may fail, give inconsistent results, or cause instabilities in Abaqus/CAE. If you encounter problems with your model after ignoring the invalidity of a part, consider attempting to fix the geometry in the CAD application that generated the original file.

If you do not repair or ignore the status of an invalid part, the only way that you can use it in Abaqus/CAE is to apply a display body or a rigid body constraint to the part in the Interaction module. A display body is included in the model for display purposes only. If you apply a display body constraint, you do not have to mesh the instance and can continue to analyze your model. For more information, see *Display bodies*.

How are precision and tolerance related?

Precision and tolerance are important considerations for successfully importing a part into Abaqus/CAE. For trimmed surfaces the tolerance defines the maximum allowable deviation between an edge and the surface bounded by the edge. The accuracy of the polynomial defining an edge of a trimmed surface depends on the tolerance of the CAD system. Abaqus/CAE uses ACIS to represent a part or the assembly. ACIS uses a precision of 10^{-6} to define a geometric entity.

To successfully import a solid defined by trimmed surfaces or B-reps, the tolerance of the original file and the tolerance of Abaqus/CAE must match within an acceptable limit. If the tolerance of the original file is considerably looser than the tolerance of Abaqus/CAE, the import may fail because Abaqus/CAE cannot reconstruct the solid from the trimmed surfaces and B-rep information.

After you import a part into Abaqus/CAE, the healing process is designed to improve the part's accuracy. Abaqus/CAE tries to change neighboring entities so that their geometry matches exactly. Converting to a precise representation usually results in precise geometry. However, this can be a lengthy operation that increases the complexity of the imported part. As a result, subsequent processing and analysis of the part may be slower. Moreover, if the part contains many complex surfaces, converting to a precise representation is likely to fail. If possible, you should return to the CAD application that generated the original file and increase the precision.

You can use the Query toolset in the Part module to highlight regions of an imported part that have geometry precision and validity errors. An imprecise vertex can be thought of as a vertex surrounded by an imaginary sphere, where the diameter of the sphere is equal to the local precision. When you heal a part, ACIS assumes that any point inside the imaginary sphere is coincident with the vertex, as shown in *Figure 1*.

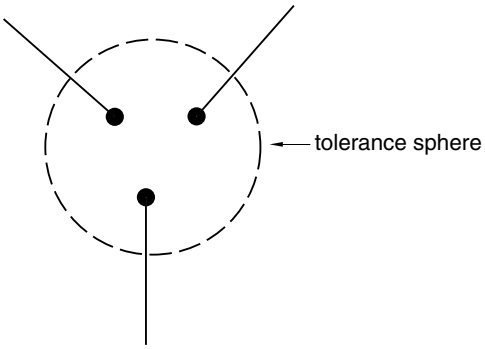

Figure 1: An imaginary sphere defines an imprecise vertex.

Similarly, an imprecise edge can be thought of as an edge surrounded by an imaginary tube, where the diameter of the tube is equal to the local precision. When you heal a part, ACIS assumes that any point inside the imaginary tube is lying on the edge, as shown in *Figure 2*.

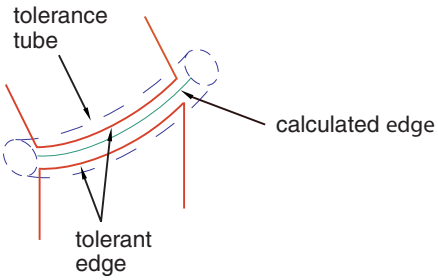

Figure 2: An imaginary tube defines an imprecise edge.

During the healing process ACIS also uses tolerance to determine if a trim curve is positioned on the underlying surface geometry, as shown in *Figure 3*.

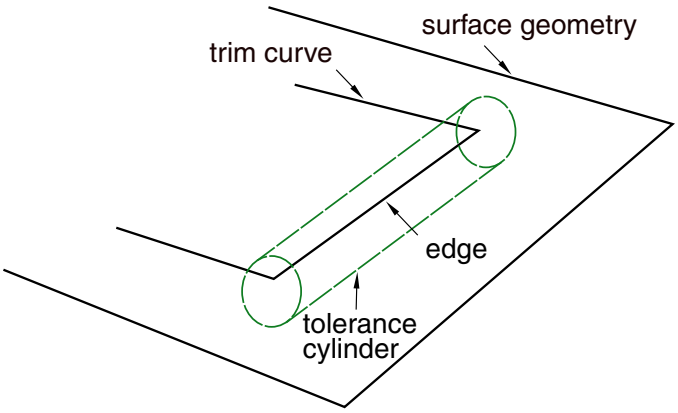

Figure 3: Tolerance determines if a trim curve lies on the underlying surface.

Working with invalid parts

If geometry errors prevent Abaqus/CAE from recreating a closed volume for a solid or shell part, the part is considered to be invalid. In most cases, parts are invalid because they were imported into Abaqus/CAE with errors. Parts may also change validity due to changes in the ACIS interpretation of the geometry between different releases of Abaqus/CAE. If you have invalid parts that are essential to an analysis and cannot be repaired, you can ignore the invalid part status. If a valid part becomes invalid during a database upgrade, you can ignore the invalid geometry without unlocking the part; this allows you to remesh the part if needed without regenerating it.

There are two methods that you can use to ignore the invalid status of a part:

- Select an invalid part in the **Part Manager**, and click **Ignore Invalidity**.
- Select an invalid part or an invalid independent part instance in the Model Tree, click mouse button 3, and select **Ignore Invalidity**.

When you choose to ignore the invalid status of a part or part instance, Abaqus/CAE displays a warning. The warning indicates that while ignoring the invalidity of the part allows you to perform all geometry and meshing functions, ignoring the invalidity may cause some part functions to fail or lead to other undesirable behavior. If you accept this warning, Abaqus/CAE changes the part status to **Invalid (ignored)**. The part status is displayed in the **Part Manager** and in the Model Tree. *Table 1* shows the icons and text used to indicate the status of invalid parts.

Table 1: Part status in the Model Tree and the Part Manager.

Model Tree symbol	Part Manager text	Meaning
	**Invalid**	An unlocked invalid part.
	**Invalid (ignored)**	An unlocked invalid part with the invalid status ignored.
	**Locked, Invalid**	A locked invalid part.
	**Locked, Invalid (ignored)**	A locked invalid part with the invalid status ignored.

Regardless of whether you are trying to repair the geometry or working with the invalid status ignored, Abaqus/CAE does not always recompute the validity of parts as you make changes. Recomputing the validity, especially for complex parts, can take a substantial amount of time. To recompute and update the validity of a part, select **Update Validity** in the **Part Manager** or in the menu that appears when you click mouse button 3 on an invalid part or part instance in the Model Tree. You can also use the **Geometry diagnostics** query to update validity. (For more information on geometry diagnostics, see *Using the geometry diagnostic tools*.)

Controlling the import process

When you import a part from a file generated by a third-party CAD system, Abaqus/CAE allows you to control how it interprets the contents of the file. This section describes the options that are available to you.

In this section:

- *Repairing a part during import*
- *What are the part attributes?*
- *Scaling a part during the import process*

Repairing a part during import

You can import a part and subsequently use the Geometry Edit toolset in the Part module to apply any repair operations that might be required to make the part usable by Abaqus/CAE; see *The Geometry Edit toolset* for more information. Alternatively, you can import a part and repair the part during the import process, as described in this section.

When you import a part, Abaqus/CAE scans the contents of the file and displays a dialog box with a **Name-Repair** tabbed page that allows you to control the following:

Name

The name of the part.

Repair Options

For most of the file formats supported, Abaqus/CAE automatically repairs the part during the import process. However, Abaqus/CAE provides the following additional options when you are importing an IGES- or a VDA-FS-format file:

- **Convert to analytical representation**
- **Stitch gaps**

In most cases, the default settings for these options provide the best results. For more information, see *Editing techniques*.

Part Filter

The following file formats can include several parts in a single file:

- ACIS
- Elysium Neutral File (CATIA V5 or Pro/ENGINEER)
- Parasolid
- STEP

Abaqus/CAE imports all of the parts in the file by default. If you import all the parts in the file, you can create individual Abaqus parts for each of them or you can combine them together into a single Abaqus part; in addition, if you combine these parts, Abaqus/CAE enables you to stitch these imported parts together using a user-specified stitching tolerance value. Alternatively, you can toggle on **Import part number** and enter the number of a single part to import from the file. Abaqus/CAE indicates if any of the parts have validity or precision problems.

In some cases when you import a part into Abaqus/CAE, the geometry of the part contains additional edges and vertices that serve no purpose. The additional geometry splits faces into additional faces and edges into additional edges, resulting in unnecessary complexity. The additional geometry will influence your mesh unduly, and you should use the Geometry Edit toolset to remove the redundant edges and vertices. You can also use virtual topology in the Mesh module to combine small faces and edges and to ignore unnecessary vertices and edges; for more information, see *The Virtual Topology toolset*.

What are the part attributes?

A part has the following attributes:

Modeling Space

When you import a part, Abaqus/CAE scans the file and tries to determine the modeling space of the part being imported as follows:

- If Abaqus/CAE determines the part is three-dimensional, it sets the modeling space to three-dimensional.
- If Abaqus/CAE determines the part is planar, you can choose whether the modeling space is two- or three-dimensional.
- If Abaqus/CAE determines the part is planar and that its geometry does not cross the *Y*-axis, you can choose whether the modeling space is axisymmetric, two-dimensional, or three-dimensional. If you choose axisymmetric, the *Y*-axis is assumed to be the axis of revolution, and you can add a twist degree of freedom.

For more information, see *Part modeling space*.

Type

Abaqus/CAE always assumes that the part type is deformable. Alternatively, you can select **Discrete rigid** to import a discrete rigid part or select **Eulerian** to import an Eulerian part. For more information, see *Part types*.

Although you cannot define an imported part to be an analytical rigid part, you can import the geometry of the analytical rigid part into a sketch. You can then create a new analytical rigid part and copy the imported sketch into the Sketcher toolset.

Scaling a part during the import process

When you import a part, you can choose to maintain the dimensions stored in the file, or you can change the scale of the part during the import process. You can do the following:

- Enter a scale factor that Abaqus/CAE will apply to all of the coordinates in the file. Any offset from the origin will be scaled accordingly.
- If you are importing a part from an ACIS file, you can read the scale factor, the rotation matrix, and the translation matrix from the file.

You can also change the scale of a part while copying it to a new part. For more information, see *Copying a part*.

Understanding the contents of an IGES file

The IGES neutral file format is an international standard that allows you to transfer geometric data between Abaqus/CAE and other CAD applications. You can use IGES-format files to import and export sketches and parts. This section describes the IGES format and the options that are available to you when importing and exporting IGES files.

For a detailed description of how to import and export IGES-format files, see *Importing a part from an IGES-format file*, and *Exporting geometry, model, and mesh data*.

In this section:

- *What are the IGES options in Abaqus/CAE?*
- *What is an IGES entity?*
- *What is in the IGES log file?*
- *Exporting to an IGES file*

What are the IGES options in Abaqus/CAE?

The IGES options allow you to control the following:

Trim Curve Preference

An IGES file can contain curves defined using real space, parameter space, or both. When you import a part from an IGES file into Abaqus/CAE, the surface and the trim curves are converted into an internal representation of the part. By default, Abaqus/CAE uses the information stored in the IGES file to decide how the trim curve is defined; alternatively, you can force Abaqus/CAE to always use either real space or parameter space.

- **As per IGES file**. This is the default option. When this option is selected, Abaqus/CAE uses either the **Always use parametric data** option or the **Always use 3D data** option to decide how the trim curve is defined. Information in the IGES file determines which of the two options is used.

- **Always use parametric data**. This option computes the trim curve parametrically using the surface on which the curve is lying. Each of the data points on the trim curve is located by a surface parameter (u, v). Abaqus/CAE evaluates the surface corresponding to the data point and generates three-dimensional coordinates for the point.

  If the underlying surface has too many sharp deflections that cannot be accurately defined parametrically, the trim curve may not lie on the surface when Abaqus/CAE tries to reconstruct the part. This produces a trimming error and may result in gaps between edges.

- **Always use 3D data**. This option computes the trim curve from the three-dimensional coordinates in space—the part's coordinate system—together with an indication that the trim curve lies on the parametric surface. Each of the data points has its own three-dimensional geometrical point; as a result the trim curve must be re-evaluated each time the surface is moved. The trim curve can move only along the surface. The **Always use 3D data** option should allow trim curves to stay with their underlying surface; however, this is not guaranteed. If you select the **Always use 3D data** option, the import will take longer to complete.

MSBO

A Manifold Solid B-rep Object (MSBO, entity type 186) is an IGES term for a B-rep solid. Like all B-rep solids, the MSBO entity indicates the overall topology of a solid entity by referencing all the trimmed surfaces that define the solid. Abaqus/CAE sets the MSBO option automatically after scanning an IGES-format file and finding the entity.

For an IGES file to contain an MSBO entity, the CAD package that created the file must include the MSBO in the export procedure. CATIA V5 allows for the MSBO entity; SOLIDWORKS does not.

Levels

CAD applications can store entities in an IGES-format file in a sequence of levels (also referred to as layers). For example, different levels can contain geometry, dimensions, text annotations, construction lines, notes, or a legend. When you import a part from an IGES-format file, Abaqus/CAE scans the file and the **Create Part from IGES File** dialog box displays a list of the levels that were found in the IGES file.

If a level contains something other than geometry, such as dimensions, Abaqus/CAE ignores the level during the import. However, if a level does contain geometry, you can delete the level from the list in the dialog box and Abaqus/CAE will not import the level. You must import at least one level. As a result, if the IGES file contains only one level, the **Level** field is not available. Abaqus/CAE ignores any levels that you enter that are not present in the IGES file.

If you encounter problems during the import, you may want to modify the default settings.

What is an IGES entity?

When you import an IGES-format file, Abaqus/CAE scans the contents of the file before displaying the **Create Part from IGES File** dialog box. You can then use buttons on the **IGES Options** tabbed page to view the following:

IGES Header

The IGES header information includes details about the application that wrote the IGES file. It also includes information about the author of the file and the date when the file was written, along with the scale, resolution, and units.

Entity List

An entity can be a geometric entity, such as a point, an arc, or a line. Alternatively, an entity can be separate from the geometry, such as a comment. IGES allocates a number to each entity; for example, a circular arc is entity number 100. The IGES entity list displays a list of each type of entity found in the file. The list includes the IGES entity number, a description of the entity, and the number found in the file.

For a complete list of the IGES entities that can be imported into Abaqus/CAE, see *IGES entities recognized by Abaqus/CAE when importing a part or a sketch*.

What is in the IGES log file?

When you import a part from an IGES file, Abaqus/CAE creates a file called `abaqus_read_iges.log` in the directory from which you started the session. The IGES log file contains information about the entities that were translated along with any problems that were encountered.

Abaqus/CAE overwrites the `abaqus_read_iges.log` file after each IGES import. The following information is written to the IGES log file:

- The global header information.
- A summary of the IGES entities found.
- IGES read options. The options displayed are the options used by the ACIS geometry engine in Abaqus/CAE during the import. You can control only the following options:
  - MSBO
  - Read trim curves
- A conversion log.
- Errors.

Exporting to an IGES file

CAD applications store data in IGES-format files using their own interpretation of the IGES standard. Abaqus/CAE is able to interpret IGES-format files generated by most applications. In addition, when you export a part or assembly to an IGES-format file, Abaqus/CAE allows you to specify the application that will be reading the file, and the data are written out in the appropriate tailored format or flavor. You can choose one of the following flavors:

- Standard
- MSBO
- AutoCAD
- SOLIDWORKS
- JAMA (Japanese Automotive Manufacturer's Association)

By default, Abaqus/CAE exports data to an IGES file using a standard flavor. Abaqus/CAE writes the geometry data to a single layer in the IGES file.

What can you import from a model?

You can import a model from an input file, an output database, or an Abaqus/CAE model database. You can import the complete model from an input file or model database; however, you can import only parts, section definitions, materials, and beam profiles from an output database.
The following sections describe how you can import a model.

For a detailed description of how to import a model, see *Importing a model*.

In this section:

- *Importing a model from an Abaqus/CAE model database*
- *Importing a model from an Abaqus input file*
- *Importing a model from an output database*
- *Importing a model from a Nastran input file*
- *Importing a model from an ANSYS input file*

Importing a model from an Abaqus/CAE model database

You can import a model into the current Abaqus/CAE model database from a different model database by selecting **File->Import->Model** from the main menu bar. Select a model database (`.cae`) file from the dialog box that appears, then select the model you want to import from the **Import Model from Model Database** dialog box. Model databases from previous releases of Abaqus must be upgraded to the current release before you can import their model data.

When you import a model from a model database, Abaqus/CAE creates a copy of that model that includes all model data in the original version. However, this import excludes the following data present in the original model database file but not directly related to the model:

- Job data
- Custom user data created using the Abaqus Scripting Interface

You can also prompt Abaqus/CAE to display the **Copy Objects** dialog box immediately after the model is imported. This dialog box enables you to copy individual objects such as parts, sketches, or materials between models in the current model database. For more information about copying objects, see *Copying objects between models*.

Models imported from different model databases are not linked to their original models; any changes to the original model that occur after the import are not propagated to the copy.

Importing a model from an Abaqus input file

You can use an Abaqus input file to import a model into Abaqus/CAE by selecting **File->Import->Model** from the main menu bar.
Abaqus keywords that are imported from the input file are incorporated into a new model; for example, if the Young's modulus was imported from the **ELASTIC* keyword, it will be available in the Property module. Keywords that are not supported are ignored during import. Model component labels that differ only in case are not imported into Abaqus/CAE consistently; therefore, you should not use case to distinguish between model components of the same type. The input file does not have to be complete; for example, it may not contain any history data. Because an input file is unable to store all of the data from an Abaqus/CAE model database, you should not use input files to archive model data.

The following functionality can be imported into a model from an Abaqus input file:

- Nodes and elements
- Surfaces, node and element sets, and contact node sets
- Adaptive mesh controls
- Material, section, and orientation definitions
- Model and material descriptions
- Interactions and interaction properties
- Discrete fasteners (previously defined in Abaqus/CAE)
- Loads and boundary conditions (in the global coordinate system)
- Amplitudes
- Procedures, output requests, and monitor variables

Note:

Importing models with a very large number of attributes, such as steps or predefined fields, (on the order of 8000 or more) may take a significant amount of time.

See *Keyword support from the input file reader* for a complete list of the keywords that are supported by the input file reader. Not all keyword data lines are supported for import; Abaqus/CAE issues warning messages when unsupported entries are encountered. You can use the Keywords Editor to include options that the input file reader does not support; for detailed instructions on using the Keywords Editor, see *Adding unsupported keywords to your Abaqus/CAE model*.

Importing parts

Parts are imported from an input file in the form of meshes; a mesh consists of node and element definitions along with the type of element assigned. The input file reader can import a mesh containing most of the commonly used element types. However, the input file reader cannot import a mesh containing the following element types:

- Tube support elements (ITS*)
- User-defined elements (U*)

The following element types can be imported, but their section properties are not yet supported:

- Distributing coupling elements (DCOUP*)
- Drag chain elements (DRAG*)
- Frame elements (FRAME*)
- Gap contact stress/displacement elements (GAPCYL, GAPSPHER, and GAPUNI)

- Interface elements (INTER*, ISL*, IRS*, ISP*, ITT*, and DINTER*)
- Joint elements (JOINT*)
- Line spring elements (LS*)

Pore pressure cohesive elements can be imported, but you cannot view them in the Abaqus/CAE model. However, you can view pore pressure cohesive elements in the Visualization module after an analysis is complete.

You can use the Mesh module to change the element type assigned to elements imported from an input file.

Importing sets and surfaces

The import capability creates sets based on any **ELSET* or **NSET* keywords, as well as any ELSET or NSET parameters on other supported keywords. If the input file was written in terms of an assembly of part instances, Abaqus/CAE preserves your intent when creating part and assembly sets. If a set was defined within a part (deformable or rigid), Abaqus/CAE creates a part set. When you instance the part in the Assembly module, you can refer to the part set; however, the assembly-related modules provide only read-only access to part sets. If a set was defined within the assembly, Abaqus/CAE creates an assembly set. For more information, see *How do part sets and assembly sets differ?*.

In contrast, if the input file was not written in terms of an assembly of part instances, Abaqus/CAE tries to minimize the number of sets created. In most cases, sets in the input file are imported as only assembly sets. However, if a section assignment refers to a set, Abaqus/CAE imports the set as only a part set.

Element-based surfaces can be imported; however, Abaqus/CAE imports a node-based surface as a set of nodes, not as a surface. As a result, an imported node-based surface appears in the Set manager and not in the Surface manager.

Importing descriptions

Model descriptions and material descriptions that appear as comment lines in input files are imported into Abaqus/CAE. The comment lines that immediately precede the header of the input file store the model description, which is available in the **Edit Model Attributes** dialog box upon import. The comment lines that immediately precede the material and material behavior definitions store the material descriptions, which are available in the **Edit Material** dialog box upon import.

The job description from the **Edit Job** dialog box appears as the data line for the header of the input file. If desired, you can modify this data line to include more details about the job; however, this data line is not imported into Abaqus/CAE.

Importing interactions, constraints, and fasteners

Abaqus/CAE imports reactivated contact pairs only if the contact pairs were deactivated in the first analysis step.

Abaqus/CAE imports multi-point constraints as MPC connector sections and wire features or as MPC constraints, depending on how the input file identifies the nodes involved.

A fully defined discrete fastener contains both an attachment line and a connector section assignment. In order to recreate these discrete fasteners as originally modeled in Abaqus/CAE upon import, Abaqus/CAE writes special comment lines to the input file when you submit a job for analysis. These special comment lines immediately precede the Abaqus keyword used to define the discrete fasteners, begin with `**@ABQCAE`, and are ignored by the Abaqus solvers.

Assembled fasteners and point-based (mesh-independent) fasteners cannot be imported from an input file.

Importing distributed loads

In certain cases element-based distributed loads defined in the input file using the **DLOAD* keyword are imported as surface-based distributed loads. For identical element-based distributed loads applied over a region, Abaqus/CAE combines the associated regions, creates internal surfaces, and creates surface-based distributed loads applied to the internal surfaces.

Analyzing a submodel

When you analyze a submodel using Abaqus/Standard or Abaqus/Explicit, you provide the name of the output database or results file containing the global solution in the Abaqus execution procedure; the file name does not appear in the input file. As a result, when you import an input file that analyzes a submodel, you must specify the name of the output database or results file containing the global solution that will drive the submodel. Select **Model->Edit Attributes->*Model Name*** and enter the name of the file containing the global solution on the **Submodel** tabbed page.

Importing a model from an output database

You can use an output database to import a model into Abaqus/CAE by selecting **File**->**Import**->**Model** from the main menu bar.

The following functionality can be imported into a model from an output database:

- Nodes and elements
- Surfaces, node and element sets, and contact node sets
- Materials and section definitions
- Beam profiles

Although sections are imported, the assignment of a section to the appropriate element set is not imported. Similarly, the assignment of a beam profile to the appropriate beam section is not imported. When you submit an input file for analysis, Abaqus does not write some material definitions to the output database. As a result, if you import the output database into Abaqus/CAE, these materials will be missing from the model. If this occurs, you can import the model from the input file instead of from the output database.

Abaqus/CAE imports a part from an output database by reading the nodes and elements that define each part instance in the assembly. If the input file that created the output database was structured using parts and assemblies, each part instance imported from the output database appears as a separate part in Abaqus/CAE. In addition, the assembly appears in Abaqus/CAE along with each part instance. As a result, the model imported into Abaqus/CAE contains a part and a part instance corresponding to each part instance in the output database.

The nodes and elements that define a part instance in an output database have been translated and rotated to their position in the assembly. The resulting part that is imported into Abaqus/CAE has the same name as the original part instance in the output database, and its orientation reflects the orientation of the part instance in the output database. As a result, the orientation of the imported part may be different from the orientation of the part in the input file that created the output database.

If the input file that created the output database was not structured using parts and assemblies, Abaqus/CAE writes the mesh definition to the output database as a single part and a single part instance. If the single part in the output database includes an analytical rigid surface, the part that Abaqus/CAE tries to import will contain an invalid combination of deformable parts and analytical rigid parts. As a result the output database cannot be imported.

Importing a model from a Nastran input file

You can use a Nastran input file to import a model into Abaqus/CAE by selecting **File->Import->Model** from the main menu bar. Abaqus/CAE imports many common entities in the Nastran bulk data into the model you create; for more information on supported entities, see *Translating Nastran Bulk Data in Text Files to Partial Abaqus Input Files*.

When you import a Nastran input file into Abaqus/CAE, you can control several aspects of the Nastran-to-Abaqus conversion. These options include:

- Mapping of elements from Nastran to Abaqus element types.
- Selecting a method for converting Nastran section or membrane data into Abaqus sections. You can create Abaqus sections corresponding to each Nastran PSHELL or PCOMP property ID, create sections for all homogeneous elements referencing the same material, or create a separate shell or membrane section for each combination of orientation, offset, and/or thickness in the Nastran input file.
- Using pre-integrated shell sections.
- Applying a scaling multiplier for all density, mass, and rotary inertia values created in the Abaqus/CAE model.
- Converting statements that use the Nastran libraries SOL 101, SOL 108, or SOL 111 into Abaqus perturbation steps with load cases.
- Coupling of beam element offsets by creating new nodes at the offset locations, changing the beam connectivity to the new nodes, and rigidly coupling the new and original nodes.

Importing a model from an ANSYS input file

You can use an ANSYS input file to import a model into Abaqus/CAE by selecting **File->Import->Model** from the main menu bar. Abaqus/CAE imports many common entities in the ANSYS input file into the model you create; for more information on supported entities, see *Translating ANSYS Input Files to Partial Abaqus Input Files*.

A logical approach to successful import of IGES files

The following list describes the steps that you should follow if you experience problems importing a part from an IGES file into Abaqus/CAE. The same approach can be applied to import other file types, but the import options will vary based on the file type.

Defeature the part

Before you export a part from a CAD system, you should know what type of part you want to analyze with Abaqus and what you expect from the analysis. For example, you may want to remove excessive detail that will influence the mesh and dominate the time taken to perform the analysis. For more information, see *Know what you want as an end product*.

Modify the import options in Abaqus/CAE

If you are importing a part from an IGES file, you can choose the following options:

- **Trim Curve Preference**
- **Scale**
- **MSBO**

You can also specify the levels in the IGES file from which to import. For more information on the effects of setting these options, see *What are the IGES options in Abaqus/CAE?*.

Try to repair the part

If Abaqus/CAE requires a precise part to proceed (for example, if you need to partition the part), you can use the Geometry Edit toolset in the Part module to edit the part. For more information, see *Editing techniques*.

Diagnose and locate problems

If you are not sure why a part is still unusable by Abaqus/CAE, you can try the following:

- Look at the **IGES Entity Filter** list in the **IGES Options** dialog box for unsupported entities.
- Grey or lighter unconnected lines on a face are silhouette lines indicating undulations in the surface that Abaqus/CAE introduced while attempting to make the surface more precise. You should manually delete the face or import the part again without using the **Convert to precise representation** automated repair option.
- Try to mesh the part. Faces that cannot be meshed by Abaqus/CAE are an indication of poor geometry.

Try to reimport the part

If the repair tools fail to produce a valid part, the file describing the part may be invalid or contain illegal statements. You should try to import the part back into the CAD system that created it. If the part cannot be imported, you should check the export settings and regenerate the file. Entities in the file that are not related to the part definition will cause the import to fail; for example, a border around the part or a title block. Ideally, you should not try to import a part into Abaqus/CAE until you know that it can be imported back into the CAD system that generated the part.

Importing sketches and parts

This section describes how you use the main menu bar's **File** menu to import sketches and parts.

In this section:

- *Importing sketches*
- *Importing parts*
- *Importing an assembly*
- *Importing parts from an ACIS-format file*
- *Importing a part from a V5-format file*
- *Importing a part from an Elysium Neutral file*
- *Importing a part from an IGES-format file*
- *IGES entities recognized by Abaqus/CAE when importing a part or a sketch*
- *Importing a part from a Parasolid-format file*
- *Importing a part from a STEP-format file*
- *Importing a part from a VDA-FS-format file*
- *Importing a part from a SOLIDWORKS-format file*
- *Importing a part from an output database*
- *Importing a substructure into a model database as a part*
- *Importing a part from an Abaqus input file*
- *Importing an assembly from an Elysium assembly file*
- *Importing an assembly from an Elysium Neutral file*
- *Importing an assembly from a Parasolid-format file*

Importing sketches

Select **File->Import->Sketch** from the main menu bar to import a sketch from either:

- An IGES-format file (`.igs` files)
- An AutoCAD-format file (`.dxf` files)
- An ACIS-format file (`.sat` files)
- A STEP-format file (`.stp` files)

If you are importing a sketch, the file must contain a two-dimensional planar profile that can be mapped directly to the sketch plane. If the file contains three-dimensional geometry, Abaqus/CAE does the following:

- If you are importing an AutoCAD file, Abaqus/CAE creates the sketch using the geometry in the *X*–*Y* plane only.
- If you are importing an IGES, ACIS, or STEP file, Abaqus/CAE displays an error message and cancels the import procedure.

You can import sketches from files that contain only simple geometry because Abaqus/CAE must be able to translate the geometry to a corresponding Sketcher entity, such as a line, circle, arc, or spline. If Abaqus/CAE finds geometry it cannot translate, it ignores that geometry. For a list of the IGES and AutoCAD entities supported by Abaqus/CAE, see *Imported sketches*.

1. From the main menu bar, select **File->Import->Sketch**.

   Abaqus/CAE displays the **Import Sketch** dialog box.

2. From the **File Filter** menu at the bottom of the **Import Sketch** dialog box, select one of the following:

   - **ACIS SAT (*.sat*)**
   - **IGES (*.igs*)**
   - **STEP (*.stp*)**
   - **AutoCAD DXF (*.dxf*)**

3. Select the file containing the sketch to import, and click **OK**.

   Abaqus/CAE converts the profile in the file to a sketch. The sketch now appears in the list of sketches in the model and can be retrieved when you enter the Sketch module. For information on how to use the imported sketch, see *Stand-alone sketches*.

Additional information

- *What is an Abaqus/CAE model?*
- *The Sketch module*
- *Using the File menu*

Importing parts

You can import a part from a file that uses an external format, from an output database, from a substructure, or from an Abaqus input file.

Select **File->Import->Part** from the main menu to import a part from either:

An external-format file

You can import geometry information from the following formats:

- ACIS
- Elysium Neutral file generated by Pro/ENGINEER, NX, CATIA V5, or CATIA V6
- CATIA V5
- IGES
- Parasolid
- STEP
- VDA-FS
- SOLIDWORKS

For information about the versions of the CAD software supported by Abaqus/CAE, see the Dassault Systèmes Knowledge Base at *http://support.3ds.com/knowledge-base/*.

You can import all of the parts in an assembly, or you can import only a specified part. Abaqus/CAE creates a separate part for each part that is imported. As a result, if a part is instanced many times in the assembly, Abaqus/CAE creates separate parts corresponding to each instance. Abaqus/CAE does not retain the names of the parts or any color coding.

An output database

You can import the part instances stored in an output database in the form of mesh parts. A mesh part contains no feature information and is extracted from the output database as a collection of nodes, elements, surfaces, and sets. You can import either the undeformed or the deformed shape. If you import the deformed shape, you can specify the step and the increment from which to import. For more information, see *Importing a part from an output database*.

A substructure

You can import a substructure into a model database as a new part definition. For more information, see *Importing a substructure into a model database as a part*.

An Abaqus input file

You can import parts defined in an Abaqus input file in the form of orphan mesh parts. For more information, see *Importing a part from an Abaqus input file*.

1. From the main menu, select **File->Import->Part**.

   The **Import Part** dialog box appears.

2. From the **File Filter** menu at the bottom of the **Import Part** dialog box, select one of the following:

   - **ACIS SAT (*.sat*)**; for more information, see *Importing parts from an ACIS-format file*.
   - **IGES (*.igs*, *.iges*)**; for more information, see *Importing a part from an IGES-format file*.

- **VDA (*.vda*)**; for more information, see *Importing a part from a VDA-FS-format file*.
- **STEP (*.stp*, *.step*)**; for more information, see *Importing a part from a STEP-format file*.
- **CATIA V5 (*.CATPart*, *.CATProduct*)**; for more information, see *Importing a part from a V5-format file*.
- **Parasolid (*.x_t*,*.x_b*, *.xmt*)**; for more information, see *Importing a part from a Parasolid-format file*.
- **ProE/NX/CATIA V5 Elysium Neutral (*.enf*)**; for more information, see *Importing a part from an Elysium Neutral file*.
- **Output Database (*.odb)**; for more information, see *Importing a part from an output database*.
- **Substructure (*.sim*)**; for more information, see *Importing a substructure into a model database as a part*.
- **Abaqus Input File (*.inp)**; for more information, see *Importing a part from an Abaqus input file*.
- **SOLIDWORKS (*.sldprt*, *.sldasm*)**; for more information, see *Importing a part from a SOLIDWORKS-format file*.

3. Abaqus/CAE lists all the files in the selected directory with the appropriate file extension. Select the file containing the part to import, and click **OK**.

   Abaqus/CAE enters the Part module and either displays a **Create** dialog box pertaining to your selection or creates the parts.

4. If applicable, select the desired repair options and part attributes and click **OK**. For more information, see *Controlling the import process* and *What are the part attributes?*.

Additional information

- *Editing techniques*
- *Using file selection dialog boxes*
- *What is an Abaqus/CAE model?*
- *Using the File menu*

Importing an assembly

Select **File->Import->Assembly** from the main menu bar to import an assembly from the following formats:

- Assembly file
- Elysium Neutral file generated by Pro/ENGINEER, CATIA V5, or CATIA V6
- Parasolid

For information about the versions of the CAD software supported by Abaqus/CAE, see the Dassault Systèmes Knowledge Base at *http://support.3ds.com/knowledge-base/*. Abaqus/CAE does not support subassemblies. As a result, assemblies and subassemblies in the imported file appear as a single assembly in Abaqus/CAE.

You can import the entire assembly, or you can import only selected part instances. Abaqus/CAE appends your selection to the existing assembly and retains the original positioning of the instances.

1. From the main menu bar, select **File->Import->Assembly**.

   The **Import Assembly** dialog box appears.

2. From the **File Filter** menu at the bottom of the **Import Assembly** dialog box, select one of the following:

   - **Assembly File (*.eaf*)**; for more information, see *Importing an assembly from an Elysium assembly file*.
   - **Parasolid (*.x_t*,*.x_b*, *.xmt*)**; for more information, see *Importing an assembly from a Parasolid-format file*.
   - **ProE/NX/CATIA V5 Elysium Neutral (*.enf*)**; for more information, see *Importing an assembly from an Elysium Neutral file*.

3. Abaqus/CAE lists all the files in the selected directory with the appropriate file extension. Select the file containing the assembly to import, and click **OK**.

   Abaqus/CAE enters the Assembly module and displays the **Import Assembly from *format* File** dialog box.

4. Do either of the following:

   - Click on the assembly name to import all of the part instances in the assembly.
   - Click on the arrow to the left of the assembly name to display all of the part instances in the assembly. Click on the names of the part instances that you want to import.

5. Click **OK** to import the assembly or selected part instances and to exit the **Import Assembly from *format* File** dialog box.

   Abaqus/CAE creates the part instances and the corresponding parts.

   Abaqus/CAE displays a message in the message area indicating if any of the part instances are invalid or imprecise. If necessary, use the Query toolset to locate areas of invalid and imprecise geometry. For more information, see *Using the Query toolset in the Part module*.

Additional information

- *Editing techniques*

- *Using the File menu*

Importing parts from an ACIS-format file

Many computer-aided modeling and drafting applications can read and write ACIS-format files; you can use these files to exchange geometry information between these applications and Abaqus/CAE. Select **File->Import->Part** from the main menu bar to import a part from an ACIS-format file. You can import multiple parts stored in an ACIS-format file. You can export parts and the assembly from Abaqus/CAE into an ACIS-format file.

You cannot import parts of mixed modeling space from an ACIS-format file; for example, solids and axisymmetric surfaces. In addition, you cannot import parts of mixed type; for example, deformable bodies and discrete rigid surfaces.

An imported ACIS part forms the base feature of a new part in Abaqus/CAE; you cannot modify this base feature directly, but you can add additional features to it, such as a solid extrusion or a blind cut.

1. From the main menu bar, select **File->Import->Part**.

   The **Import Part** dialog box appears.

2. From the **File Filter** menu at the bottom of the **Import Part** dialog box, select **ACIS SAT (*.sat*)**.

   Abaqus/CAE lists all the files in the selected directory with a `.sat*` file extension.

3. Select the ACIS file containing the part or parts to import, and click **OK**.

   The **Create Part from ACIS File** dialog box appears.

4. Click the **Name-Repair** tab to set the following:

Name

The name of the new part. For more information, see *Using basic dialog box components*.

Part Filter

An ACIS file can contain more than one part, and Abaqus/CAE imports all of the parts in the file by default. If you import all the parts in the ACIS file, you can create individual Abaqus parts for each of them or you can combine them together into a single Abaqus part.

In addition, if you combine these parts, Abaqus/CAE enables you to control the following aspects of the geometry combination:

- You can retain the intersecting boundaries between the imported parts, which enables you to eliminate invalid geometry.
- You can stitch these imported parts together using a user-specified stitching tolerance value.

If you want to import an individual part from the ACIS file, you can toggle on **Import part number** and enter the number of a single part to import from the file.

5. Click the **Part Attributes** tab to set the following:

   - The modeling space of the part being imported. When you import a part, Abaqus/CAE scans the file and tries to determine the modeling space.
   - The type of the part being imported. Abaqus/CAE always assumes that the part type is deformable. Alternatively, you can select **Discrete rigid** to import a discrete rigid part or select **Eulerian** to import an Eulerian part. For more information, see *Part types*.

   Again, in most cases you should accept the default settings; for more information, see *What are the part attributes?*.

6. Click the **Scale** tab to scale the part during the import process.

- Choose **No scale** to maintain the dimensions stored in the file.
- Choose **Use transform from file, including scale** to read the scale factor, the rotation matrix, and the translation matrix from the ACIS file.
- Choose **Multiply all lengths by**, and enter a scale factor. Abaqus/CAE applies the scale factor to all of the coordinates in the file. As a consequence, any offset from the origin will be scaled accordingly.

7. Click **OK** to import the ACIS part.

   Abaqus/CAE enters the Part module, the imported part replaces the contents of the current viewport, and the part appears in the model's list of parts in the context bar.

   When you import a single part, Abaqus/CAE displays a message in the message area indicating if the part contains any validity or precision problems. If you import multiple parts from a single ACIS file, you can use the **Part Manager** to check if any of the parts are invalid or imprecise. If necessary, use the Query toolset to locate areas of invalid and imprecise geometry. For more information, see *Using the Query toolset in the Part module*.

Additional information

- *Editing techniques*
- *Using file selection dialog boxes*
- *What is an Abaqus/CAE model?*
- *Using the File menu*

Importing a part from a V5-format file

Select **File->Import->Part** from the main menu bar to import a part from a V5-format file directly into Abaqus/CAE. You can import CATIA-format parts, but you cannot export a CATIA-format part. For information about the versions of CATIA V5 supported by Abaqus/CAE, see the Dassault Systèmes Knowledge Base at *http://support.3ds.com/knowledge-base/*.

Note:

You can directly import CATIA V5-format files only if you have a license for the optional add-on CATIA V5 Associative Interface. For more information, see *What can I do with the associative interfaces?*.

An imported CATIA part forms the base feature of a new part in Abaqus/CAE; you cannot modify this base feature directly, but you can add additional features to it, such as a solid extrusion or a blind cut.

1. From the main menu bar, select **File->Import->Part**.

   The **Import Part** dialog box appears.

2. From the **File Filter** menu at the bottom of the **Import Part** dialog box, select **CATIA V5 (*.CATPart*, *.CATProduct*)**.

   Abaqus/CAE lists all the files in the selected directory with acceptable file extensions.

3. Select the CATIA file containing the part to import, and click **OK**.

   Abaqus/CAE displays the **Create Part from CATIA File** dialog box.

4. Click the **Name-Repair** tab to set the following:

Name

The name of the new part. For more information, see *Using basic dialog box components*.

Repair Options

Abaqus/CAE automatically repairs a CATIA part during the import process.

Part Filter

A CATIA file can contain more than one part, and Abaqus/CAE imports all of the parts in the file by default. If you import all the parts in the CATIA file, you can create individual Abaqus parts for each of them or you can combine them together into a single Abaqus part; in addition, if you combine these parts, Abaqus/CAE enables you to stitch these imported parts together using a user-specified stitching tolerance value.

If you want to import an individual part from the CATIA file, you can toggle on **Import part number** and enter the number of a single part to import from the file.

5. Click the **Part Attributes** tab to set the following:

   - The modeling space of the part being imported. When you import a part, Abaqus/CAE scans the file and tries to determine the modeling space.
   - The type of the part being imported. Abaqus/CAE always assumes that the part type is deformable. Alternatively, you can select **Discrete rigid** to import a discrete rigid part or select **Eulerian** to import an Eulerian part. For more information, see *Part types*.

Again, in most cases you should accept the default settings; for more information, see *What are the part attributes?*.

6. Click the **Scale** tab to scale the part during the import process.

   - Choose **Multiply all lengths by**, and enter a scale factor. Abaqus/CAE applies the scale factor to all of the coordinates in the file. As a consequence, any offset from the origin will be scaled accordingly.

7. Click **OK** to import the part and to exit the **Create Part from CATIA File** dialog box.

   Abaqus/CAE scans the CATIA file and starts the repair process, depending on the options selected. If you want to cancel the import process, click **Stop** in the prompt area.

8. When you import a single part, Abaqus/CAE displays a message indicating if the part contains any validity or precision problems. If you import multiple parts from a single CATIA file, you can use the **Part Manager** to check if any of the parts are invalid or imprecise. If necessary, use the Query toolset to locate areas of invalid and imprecise geometry. For more information, see *Using the Query toolset in the Part module*.

Additional information

- *Editing techniques*
- *Using file selection dialog boxes*
- *What is an Abaqus/CAE model?*
- *Using the File menu*

Importing a part from an Elysium Neutral file

Select **File->Import->Part** from the main menu bar to import a part from an Elysium Neutral file. You can import an Elysium Neutral file that was generated by the following:

- NX using the Abaqus/CAE Associative Interface for NX.
- Pro/ENGINEER using the Abaqus Associative Interface for Creo Parametric.

For information about the versions of NX and Pro/ENGINEER supported by Abaqus/CAE, see the Dassault Systèmes Knowledge Base at *http://support.3ds.com/knowledge-base/*.

During the part import process, Abaqus/CAE automatically determines whether the selected file was generated by NX or Pro/ENGINEER and tailors the import process accordingly. An imported part from an Elysium Neutral file forms the base feature of a new part in Abaqus/CAE; you cannot modify this base feature directly, but you can add additional features to it, such as a solid extrusion or a blind cut.

1. From the main menu bar, select **File->Import->Part**.

   The **Import Part** dialog box appears.

2. From the **File Filter** menu at the bottom of the **Import Part** dialog box, select **ProE/NX Elysium Neutral (*.enf*)**.

   Abaqus/CAE lists all the files in the current directory with a `.enf*` file extension.

3. Select the Elysium Neutral file containing the part to import, and click **OK**.

   Abaqus/CAE displays the **Create Part from ENF File** dialog box.

4. Click the **Name-Repair** tab to set the following:

Name

The name of the new part. For more information, see *Using basic dialog box components*.

Repair Options

Abaqus/CAE automatically repairs an Elysium Neutral file part during the import process.

Part Filter

An Elysium Neutral file can contain more than one part, and Abaqus/CAE imports all of the parts in the file by default. If you import all the parts in the Elysium Neutral file, you can create individual Abaqus parts for each of them or you can combine them together into a single Abaqus part; in addition, if you combine these parts, Abaqus/CAE enables you to stitch these imported parts together using a user-specified stitching tolerance value.

Alternatively, you can toggle on **Import part number** and enter the number of a single part to import from the file.

5. Click the **Part Attributes** tab to set the following:

   - The modeling space of the part being imported. When you import a part, Abaqus/CAE scans the file and tries to determine the modeling space.
   - The type of the part being imported. Abaqus/CAE always assumes that the part type is deformable. Alternatively, you can select **Discrete rigid** to import a discrete rigid part or select **Eulerian** to import an Eulerian part. For more information, see *Part types*.

In most cases you should accept the default settings; for more information, see *What are the part attributes?*.

6. Click the **Scale** tab to scale the part during the import process.
   - Choose **Do not change units** to maintain the units and dimensions stored in the file.
   - Choose **Convert units to mm** to convert the units stored in the Elysium Neutral file to millimeters.
   - Choose **Multiply all lengths by**, and enter a scale factor. Abaqus/CAE applies the scale factor to all of the coordinates in the file. As a consequence, any offset from the origin will be scaled accordingly.
7. Click **OK** to import the part and to exit the **Create Part from ENF File** dialog box.

   Abaqus/CAE scans the Elysium Neutral file and starts the repair process, depending on the options selected. If you wish to cancel the import process, click **Stop** in the prompt area.
8. When you import a single part, Abaqus/CAE displays a message in the message area indicating if the part contains any validity or precision problems. If you import multiple parts from a single Elysium Neutral file, you can use the **Part Manager** to check if any of the parts are invalid or imprecise. If necessary, use the Query toolset to locate areas of invalid and imprecise geometry. For more information, see *Using the Query toolset in the Part module*.

Additional information

- *Using the File menu*

Importing a part from an IGES-format file

Many computer-aided modeling and drafting applications can read and write IGES-format files; you can use these files to exchange geometry information between these applications and Abaqus/CAE. Select **File->Import->Part** from the main menu bar to import a part from an IGES-format file. You can export sketches and parts from Abaqus/CAE into an IGES-format file, but you cannot export the assembly to an IGES-format file.

If the IGES-format file contains multiple parts, Abaqus/CAE imports them as a single part. An imported IGES part forms the base feature of a new part in Abaqus/CAE; you cannot modify this base feature directly, but you can add additional features to it, such as a solid extrusion or a blind cut.

1. From the main menu bar, select **File->Import->Part**.

   The **Import Part** dialog box appears.

2. From the **File Filter** menu at the bottom of the **Import Part** dialog box, select **IGES (*.igs*. *.iges*)**.

   Abaqus/CAE lists all the files in the current directory with a `.igs*` or `.iges*` file extension.

3. Select the IGES file containing the part to import, and click **OK**.

   Abaqus/CAE displays the **Create Part from IGES File** dialog box.

4. Click the **Name-Repair** tab to set the following:

   - The name of the new part.
   - The repair options that Abaqus/CAE will apply during the import.

   In most cases you should accept the default settings; for more information, see *Controlling the import process*.

5. Click the **Part Attributes** tab to set the following:

   - The modeling space of the part being imported. When you import a part, Abaqus/CAE scans the file and tries to determine the modeling space.
   - The type of the part being imported. Abaqus/CAE always assumes that the part type is deformable. Alternatively, you can select **Discrete rigid** to import a discrete rigid part or select **Eulerian** to import an Eulerian part. For more information, see *Part types*.

   Again, in most cases you should accept the default settings; for more information, see *What are the part attributes?*.

6. Click the **Scale** tab to scale the part during the import process.

   - Choose **No scale** to maintain the dimensions stored in the file.
   - Choose **Use transform from file, including scale** to read the scale factor, the rotation matrix, and the translation matrix from the IGES file.
   - Choose **Multiply all lengths by**, and enter a scale factor. Abaqus/CAE applies the scale factor to all of the coordinates in the file. As a consequence, any offset from the origin will be scaled accordingly.

7. Click the **IGES Options** tab to set the following:

   - How Abaqus/CAE converts surface and trim curves into an internal representation of the part.
   - Whether Abaqus/CAE recognizes a Manifold Solid B-rep Object (MSBO, entity type 186). In most cases Abaqus/CAE sets the MSBO option automatically after scanning an IGES-format file and finding the entity. However, if the IGES file is very large, you must set this option manually.

- The levels in the IGES file that Abaqus/CAE will try to import. For example, if the **Levels** field contains `0:2,4`, Abaqus/CAE will try to import levels 0, 1, 2, and 4. If a level contains something other than geometry, Abaqus/CAE will ignore the level during the import. You can remove levels from the list, but you cannot add levels. This field is not available if the IGES file contains only one level.

For more information, see *What are the IGES options in Abaqus/CAE?*, and *What is an IGES entity?*. You can also use the **IGES Options** dialog box to view the header information in the IGES file and to view a list of the entities found in the file. For more information, see *What is an IGES entity?*.

8. Click **OK** to import the IGES part and to close the **Create Part from IGES File** dialog box.

   Abaqus/CAE scans the IGES file and starts the repair process, depending on the options selected. If you wish to cancel the import process, click **Stop** in the prompt area.

9. When the part is imported, Abaqus/CAE displays a message indicating if the part contains any validity or precision problems. If necessary, use the Query toolset to locate areas of invalid and imprecise geometry. For more information, see *Using the Query toolset in the Part module*.

Additional information

- *What are the IGES options in Abaqus/CAE?*
- *Editing techniques*
- *Using the File menu*

IGES entities recognized by Abaqus/CAE when importing a part or a sketch

During the import process, Abaqus/CAE converts the entities stored in the IGES file to an internal representation recognized by Abaqus/CAE. The IGES file can contain entities that are not recognized by Abaqus/CAE; however, these entities are ignored during the conversion.

Table 1 lists the IGES entities that Abaqus/CAE recognizes.

Table 1: IGES entities recognized by Abaqus/CAE when importing a part or a sketch.

Entity	Form	IGES Entity Name
100	0	Circular arc
104	1	Conic arc: general
104	2	Conic arc: ellipse
104	3	Conic arc: parabola
106	11	Copious data: 2D path
106	12	Copious data: 3D path
106	63	Copious data: Closed 2D curve
108	1	Plane entity: bounded
110	0	Line
112	0	Parametric spline curve
114	0	Parametric spline surface
116	0	Point
118	1	Ruled surface
120	0	Surface of revolution
122	0	Tabulated cylinder
123	0	Direction
124	0	Transformation
126	0	Rational B-spline curve
128	0	Rational B-spline surface
130	0	Offset curve
140	0	Offset surface
141	0	Boundary entity
142	0	Curve on parametric surface
143	0	Bounded surface
144	0	Trimmed surface
186	0	MSBO
190	0	Plane surface
192	0	Right circular cylindrical surface
194	0	Right circular conical surface
196	0	Spherical surface

Entity	Form	IGES Entity Name
198	0	Toroidal surface
502	1	Vertex list
504	1	Edge list
508	1	Loop
510	1	Face
514	1	Shell

You cannot import composite curves (IGES entity ID 102) into Abaqus/CAE.

Additional information

- *Importing a part from an IGES-format file*
- *Understanding the contents of an IGES file*
- *Editing techniques*

Importing a part from a Parasolid-format file

Select **File->Import->Part** from the main menu bar to import a part from a Parasolid-format file. Parasolid is a library of solid modeling functions developed by Unigraphics Solutions and marketed by EDS. You can use a translator from Elysium, Inc., to import Parasolid-format parts directly into Abaqus/CAE. A variety of CAD products can generate Parasolid-format parts, such as Unigraphics, SOLIDWORKS, Solid Edge, FEMAP, and MSC.Patran. For information about the versions of the CAD software supported by the translators from Elysium, Inc., see the *https://www.3ds.com/products-services/simulia/products/abaqus/add-ons/geometry-translators/* page at *www.3ds.com/simulia*.

An imported Parasolid part forms the base feature of a new part in Abaqus/CAE; you cannot modify this base feature directly, but you can add additional features to it, such as a solid extrusion or a blind cut.

1. From the main menu bar, select **File->Import->Part**.

   The **Import Part** dialog box appears.

2. From the **File Filter** menu at the bottom of the **Import Part** dialog box, select **Parasolid (*.x_t*,*.x_b*, *.xmt*)**.

   Abaqus/CAE lists all the files in the current directory with a `.x_t*`, `.x_b*`, or `.xmt*` file extension.

3. Select the Parasolid file containing the part to import, and click **OK**.

   Abaqus/CAE displays the **Create Part from PARASOLID File** dialog box.

4. Click the **Name-Repair** tab to set the following:

Name

The name of the new part. For more information, see *Using basic dialog box components*.

Repair Options

Abaqus/CAE automatically repairs a Parasolid part during the import process.

Part Filter

A Parasolid file can contain more than one part, and Abaqus/CAE imports all of the parts in the file by default. If you import all the parts in the Parasolid file, you can create individual Abaqus parts for each of them or you can combine them together into a single Abaqus part; in addition, if you combine these parts, Abaqus/CAE enables you to stitch these imported parts together using a user-specified stitching tolerance value.

If you want to import an individual part from the Parasolid file, you can toggle on **Import part number** and enter the number of a single part to import from the file.

5. Click the **Part Attributes** tab to set the following:

   - The modeling space of the part being imported. When you import a part, Abaqus/CAE scans the file and tries to determine the modeling space.
   - The type of the part being imported. Abaqus/CAE always assumes that the part type is deformable. Alternatively, you can select **Discrete rigid** to import a discrete rigid part or select **Eulerian** to import an Eulerian part. For more information, see *Part types*.

   In most cases you should accept the default settings; for more information, see *What are the part attributes?*.

6. Click the **Scale** tab to scale the part during the import process.

- Choose **Multiply all lengths by**, and enter a scale factor. Abaqus/CAE applies the scale factor to all of the coordinates in the file. As a consequence, any offset from the origin will be scaled accordingly.

7. Click **OK** to import the Parasolid part and to close the **Create Part from PARASOLID File** dialog box.

   Abaqus/CAE scans the Parasolid file and repairs the part during the import process. If you wish to cancel the import process, click **Stop** in the prompt area.

8. When you import a single part, Abaqus/CAE displays a message indicating if the part contains any validity or precision problems. If you import multiple parts from a single Parasolid file, you can use the **Part Manager** to check if any of the parts are invalid or imprecise. If necessary, use the Query toolset to locate areas of invalid and imprecise geometry. For more information, see *Using the Query toolset in the Part module*.

- *What is an Abaqus/CAE model?*
- *Using the File menu*

Importing a part from a STEP-format file

Select **File->Import->Part** from the main menu bar to import a part from a STEP-format file. You can export sketches and parts from Abaqus/CAE into a STEP-format file, but you cannot export the assembly to a STEP-format file.

1. From the main menu bar, select **File->Import->Part**.

   The **Import Part** dialog box appears.

2. From the **File Filter** menu at the bottom of the **Import Part** dialog box, select STEP **(*.stp, *.step)**.

   Abaqus/CAE lists all the files in the selected directory with a `.stp` or `.step` file extension.

3. Select the STEP file containing the part to import, and click **OK**.

   Abaqus/CAE displays the **Create Part from STEP File** dialog box.

4. Click the **Name-Repair** tab to set the following:

Name

When you import a part or parts into Abaqus/CAE, you can use the part names specified in the STEP-format file or you can provide a name for the imported part or parts. If you import multiple parts and provide a part name, Abaqus/CAE uses your name and appends a number to it; for example, if you specify the part name `ImportedPart` and create three individual parts, the newly imported Abaqus/CAE parts will be named `ImportedPart-1`, `ImportedPart-2`, and `ImportedPart-3`.

Part Filter

A STEP file can contain more than one part, and Abaqus/CAE imports all of the parts in the file by default. If you import all the parts in the STEP file, you can create individual Abaqus parts for each of them or you can combine them together into a single Abaqus part; in addition, if you combine these parts, Abaqus/CAE enables you to stitch these imported parts together using a user-specified stitching tolerance value.

If you want to import an individual part from the STEP file, you can toggle on **Import part number** and enter the number of a single part to import from the file.

5. Click the **Part Attributes** tab to set the following:

   - The modeling space of the part being imported. When you import a part, Abaqus/CAE scans the file and tries to determine the modeling space.
   - The type of the part being imported. Abaqus/CAE always assumes that the part type is deformable. Alternatively, you can select **Discrete rigid** to import a discrete rigid part or select **Eulerian** to import an Eulerian part. For more information, see *Part types*.

   Again, in most cases you should accept the default settings; for more information, see *What are the part attributes?*.

6. Click the **Scale** tab to scale the part during the import process.

   - Choose **No scale** to maintain the dimensions stored in the file.
   - Choose **Use transform from file, including scale** to read the scale factor, the rotation matrix, and the translation matrix from the STEP file.
   - Choose **Multiply all lengths by**, and enter a scale factor. Abaqus/CAE applies the scale factor to all of the coordinates in the file. As a consequence, any offset from the origin will be scaled accordingly.

7. Click **OK** to import the STEP part and to close the **Create Part from STEP File** dialog box.

   Abaqus/CAE scans the STEP file and starts the repair process, depending on the options selected. If you wish to cancel the import process, click **Stop** in the prompt area.

   When you import a single part, Abaqus/CAE displays a message indicating if the part contains any validity or precision problems. If you import multiple parts from a single STEP file, you can use the **Part Manager** to check if any of the parts are invalid or imprecise. If necessary, use the Query toolset to locate areas of invalid and imprecise geometry. For more information, see *Using the Query toolset in the Part module*.

Importing a part from a VDA-FS-format file

Many computer-aided modeling and drafting applications can read and write VDA-FS-format files; you can use these files to exchange geometry information between these applications and Abaqus/CAE. Select **File->Import->Part** from the main menu bar to import a part from a VDA-FS-format file. You can export parts from Abaqus/CAE into a VDA-FS-format file, but you cannot export the assembly to a VDA-FS-format file.

If the VDA-FS-format file contains multiple parts, Abaqus/CAE imports them as a single part. An imported VDA-FS part forms the base feature of a new part in Abaqus/CAE; you cannot modify this base feature directly, but you can add additional features to it, such as a solid extrusion or a blind cut.

1. From the main menu bar, select **File->Import->Part**.

   The **Import Part** dialog box appears.

2. From the **File Filter** menu at the bottom of the **Import Part** dialog box, select **VDA-FS (*.vda*)**.

   Abaqus/CAE lists all the files in the selected directory with a `.vda*` file extension.

3. Select the VDA-FS file containing the part to import, and click **OK**.

   Abaqus/CAE displays the **Create Part from VDA File** dialog box.

4. Click the **Name-Repair** tab to set the following:

   - The name of the new part.
   - The repair options that Abaqus/CAE will apply during the import.

   For more information, see *Controlling the import process*.

5. Click the **Part Attributes** tab to set the following:

   - The modeling space of the part being imported. When you import a part, Abaqus/CAE scans the file and tries to determine the modeling space.
   - The type of the part being imported. Abaqus/CAE always assumes that the part type is deformable. Alternatively, you can select **Discrete rigid** to import a discrete rigid part or select **Eulerian** to import an Eulerian part. For more information, see *Part types*.

   In most cases you should accept the default settings; for more information, see *What are the part attributes?*.

6. Click the **Scale** tab to scale the part during the import process.

   - Choose **No scale** to maintain the dimensions stored in the file.
   - Choose **Use transform from file, including scale** to read the scale factor, the rotation matrix, and the translation matrix from the VDA-FS file.
   - Choose **Multiply all lengths by**, and enter a scale factor. Abaqus/CAE applies the scale factor to all of the coordinates in the file. As a consequence, any offset from the origin will be scaled accordingly.

7. Click **OK** to import the VDA-FS part and to close the **Create Part from VDA File** dialog box.

   Abaqus/CAE scans the VDA-FS file and starts the repair process, depending on the options selected. If you wish to cancel the import process, click **Stop** in the prompt area.

When the part is imported, Abaqus/CAE displays a message indicating if the part contains any validity or precision problems. If necessary, use the Query toolset to locate areas of invalid and imprecise geometry. For more information, see *Using the Query toolset in the Part module*.

Importing a part from a SOLIDWORKS-format file

Select **File->Import->Part** from the main menu to import a part from a SOLIDWORKS-format file.

1. From the main menu, select **File->Import->Part**.

   The **Import Part** dialog box appears.

2. From the **File Filter** menu at the bottom of the **Import Part** dialog box, select **SOLIDWORKS (*.sldprt*, *.sldasm*)**.

   Abaqus/CAE lists all the files in the selected directory with a `.sldprt` or `.sldasm` file extension.

3. Select the SOLIDWORKS file containing the part to import, and click **OK**.

   Abaqus/CAE displays the **Create Part from SOLIDWORKS File** dialog box.

4. Click the **Name-Repair** tab to set the following:

Name

When you import a part or parts into Abaqus/CAE, you can use the part names specified in the SOLIDWORKS-format file or you can provide a name for the imported part or parts. If you import multiple parts and provide a part name, Abaqus/CAE uses your name and appends a number to it; for example, if you specify the part name `ImportedPart` and create three individual parts, the newly imported Abaqus/CAE parts will be named `ImportedPart-1`, `ImportedPart-2`, and `ImportedPart-3`.

Part Filter

A SOLIDWORKS file can contain more than one part, and Abaqus/CAE imports all of the parts in the file by default. If you import all the parts in the SOLIDWORKS file, you can create individual Abaqus parts for each of them or you can combine them together into a single Abaqus part; in addition, if you combine these parts, Abaqus/CAE enables you to stitch these imported parts together using a user-specified stitching tolerance value.

If you want to import an individual part from the SOLIDWORKS file, you can toggle on **Import part number** and enter the number of a single part to import from the file.

5. Click the **Part Attributes** tab to set the following:

   - The modeling space of the part being imported. When you import a part, Abaqus/CAE scans the file and tries to determine the modeling space.
   - The type of the part being imported. Abaqus/CAE always assumes that the part type is deformable. Alternatively, you can select **Discrete rigid** to import a discrete rigid part or select **Eulerian** to import an Eulerian part. For more information, see *Part types*.

   Again, in most cases you should accept the default settings; for more information, see *What are the part attributes?*.

6. Click the **Scale** tab to scale the part during the import process.

   - Choose **No scale** to maintain the dimensions stored in the file.
   - Choose **Use transform from file, including scale** to read the scale factor, the rotation matrix, and the translation matrix from the SOLIDWORKS file.
   - Choose **Multiply all lengths by**, and enter a scale factor. Abaqus/CAE applies the scale factor to all of the coordinates in the file. As a consequence, any offset from the origin will be scaled accordingly.

7. Click **OK** to import the SOLIDWORKS part and to close the **Create Part from SOLIDWORKS File** dialog box.

   Abaqus/CAE scans the SOLIDWORKS file and starts the repair process, depending on the options selected. If you wish to cancel the import process, click **Stop** in the prompt area.

   When you import a single part, Abaqus/CAE displays a message indicating if the part contains any validity or precision problems. If you import multiple parts from a single SOLIDWORKS file, you can use the **Part Manager** to check if any of the parts are invalid or imprecise. If necessary, use the Query toolset to locate areas of invalid and imprecise geometry. For more information, see *Using the Query toolset in the Part module*.

Additional information

- *Editing techniques*
- *Using file selection dialog boxes*
- *What is an Abaqus/CAE model?*
- *Using the File menu*

Importing a part from an output database

Select **File->Import->Part** from the main menu bar to import part instances stored in an output database in the form of mesh parts. If the output database contains multiple part instances, you can select the part instances to import. Abaqus/CAE imports each part instance as a separate part. You can import either the undeformed or the deformed shape. If you import the deformed shape, you can specify the step and the frame from which to import.

To verify the quality of the mesh, you can display the part in the Mesh module and select **Mesh->Verify** from the main menu bar. In addition, you can use the Mesh module to change the element type assigned to the mesh and to edit the original mesh definition. For more information, see *What can I do with the Edit Mesh toolset?*, and *Assigning Abaqus element types*.

1. From the main menu bar, select **File->Import->Part**.

   The **Import Part** dialog box appears.

2. From the **File Filter** menu at the bottom of the **Import Part** dialog box, select **Output Database (*.odb)**.

   Abaqus/CAE lists all the files in the selected directory with an `.odb` file extension.

3. Select the output database containing the part to import, and click **OK**.

   The **Create Part from Output Database** dialog box appears. The dialog box lists each part instance in the output database along with its type (deformable body or discrete rigid surface).

4. From the dialog box, select the instances to import.
5. If you selected only a single part instance, Abaqus/CAE uses the name of the instance to name the resulting part, although you can change the name if desired. In contrast, if you selected more than one part instance to import, Abaqus/CAE uses the name of each instance to name each part and you cannot change their names.

   Abaqus/CAE determines the modeling space (three-dimensional, two-dimensional, or axisymmetric) of the part instances. You cannot change the modeling space or the type.

6. By default, Abaqus/CAE imports the undeformed configuration of the parts. To import the deformed parts, click **Import deformed configuration**. Select the step and frame containing the deformed shape from the available steps and frames in the output database.

   When importing deformed parts, the deformations are read from the field output variable U, if available; otherwise, the deformations are read from the field output variable UT.

7. Click **OK** to import the orphan mesh from the output database and to close the dialog box.
8. If the name that you entered is the same as the name of an existing part in the model, Abaqus/CAE asks if you want to overwrite the existing part or replace the mesh.

   If you choose to replace the mesh, Abaqus/CAE replaces the nodes and elements of the existing part with the nodes and elements of the imported orphan mesh. Sets and section assignments that referred to the original part are maintained. However, because the sets and section assignments refer to node and element numbers, the mesh of the imported part should be similar to the mesh of the original part. For example, you could replace the undeformed mesh with the deformed mesh.

   Abaqus/CAE enters the Part module, the imported part replaces the contents of the current viewport, and the part appears in the model's list of parts in the context bar.

Additional information

- *Using file selection dialog boxes*
- *Using the File menu*
- *Editing techniques*

Importing a substructure into a model database as a part

Select **File->Import->Part** from the main menu bar to import a substructure definition in a `.sim` file in the form of a new part definition. The `.sim` file you import must reside in the same directory as the supporting Abaqus files to which the SIM database refers; these supporting files might include data in the formats `.prt`, `.mdl`, or `.stt`. In addition, the release of the `.sim` file you import must be consistent with the release of Abaqus/CAE that you are using.

Substructure import also requires an output database (`.odb`) file for mesh display.

1. From the main menu bar, select **File->Import->Part**.

   The **Import Part** dialog box appears.
2. From the **File Filter** menu at the bottom of the **Import Part** dialog box, select **Substructure (*.sim*)**.

   Abaqus/CAE lists all the files in the selected directory with a `.sim*` file extension.
3. Select the SIM database containing the substructure to import, and click **OK**.

   The **Create Substructure Part** dialog box appears, displaying the substructure's name and its unique identifier (which begins with the letter Z).
4. If desired, customize the **Part name** for the substructure you are importing.
5. In the **Use mesh from ODB file** field, specify the name of the output database file containing the mesh that you want to associate with this substructure definition.
6. Click **OK**.

   Abaqus/CAE imports the substructure into your model as a new part definition.

Additional information

- *Using file selection dialog boxes*
- *Using the File menu*
- *Editing techniques*

Importing a part from an Abaqus input file

You can import parts defined in an Abaqus input file in the form of orphan mesh parts.
Select **File->Import->Part** from the main menu bar to import parts defined in an Abaqus input file.

If the input file contains multiple parts, Abaqus/CAE imports each part as a separate orphan mesh part. Only the orphan mesh part information is imported; properties that are assigned to the parts, such as sections and materials, are not imported.

1. From the main menu bar, select **File->Import->Part**.

   The **Import Part** dialog box appears.

2. From the **File Filter** menu at the bottom of the **Import Part** dialog box, select **Abaqus Input File (*.inp)**.

   Abaqus/CAE lists all the files in the selected directory with an `.inp` file extension.

3. Select the input file containing the parts to import, and click **OK**.

   Abaqus/CAE enters the Part module and imports the parts. The parts appear in the Model Tree and in the model's list of parts in the context bar.

Additional information

- *Using file selection dialog boxes*
- *Using the File menu*

Importing an assembly from an Elysium assembly file

Select **File->Import->Assembly** from the main menu bar to import an assembly from an Elysium assembly file. Elysium assembly files are created by all of the associative interfaces for Abaqus/CAE (see *What can I do with the associative interfaces?*).

The geometry files for the individual parts in the assembly must be located in the same directory as the assembly file. The Elysium assembly file always has the file extension `.eaf`; however, the file type of the part geometry files depends on which associative interface was used to write the model:

CATIA V6 Associative Interface

CATIA V5 part files (`.CATPart`). (The CATIA V6 parts and assemblies are converted to CATIA V5 format before they are exported.)

CATIA V5 Associative Interface

CATIA V5 part files (`.CATPart`)

SOLIDWORKS Associative Interface

ACIS files (`.sat`)

Abaqus Associative Interface for Creo Parametric

Pro/ENGINEER Elysium Neutral files (`.enf_abq`)

Abaqus/CAE Associative Interface for NX

NX Elysium Neutral files (`.enf_abq`)

The following procedure is necessary only when performing a manual associative import of a model assembly. For complete details about creating assembly files and various methods for importing models using the associative interfaces, refer to the user guides for each associative interface. The user guides are available from the Dassault Systèmes Knowledge Base at *http://support.3ds.com/knowledge-base/*.

1. From the main menu bar, select **File->Import->Assembly**.

   The **Import Assembly** dialog box appears.

2. From the **File Filter** menu at the bottom of the **Import Assembly** dialog box, select **Assembly File (*.eaf*)**.

   Abaqus/CAE lists the files in the selected directory with a `.eaf` file extension.

3. Select the file containing the assembly to import, and click **OK**.

   Abaqus/CAE displays the **Import Assembly from EAF File** dialog box.

4. Do either of the following:

   - Click on the assembly name to import all of the part instances in the assembly.
   - Click on the arrow to the left of the assembly name to display all of the part instances in the assembly. Click on the names of the part instances that you want to import.

5. Click **OK** to import the assembly or selected part instances and to exit the **Import Assembly from EAF File** dialog box.

Abaqus/CAE displays a message indicating if any of the part files were not found or if any part instances are invalid or imprecise. If necessary, use the Query toolset to locate areas of invalid and imprecise geometry. For more information, see *Using the Query toolset in the Part module*.

Importing an assembly from an Elysium Neutral file

Select **File->Import->Assembly** from the main menu bar to import an assembly from an Elysium Neutral file. You can import an Elysium Neutral file that was generated by the following:

- CATIA V6 using the CATIA V6 Associative Interface.
- NX using the Abaqus Associative Interface for Creo Parametric.
- Pro/ENGINEER using the Abaqus Associative Interface for Creo Parametric.

For details about the versions of CATIA V6, NX, and Pro/ENGINEER supported by Abaqus/CAE, see the Dassault Systèmes Knowledge Base at *http://support.3ds.com/knowledge-base/*.

1. From the main menu bar, select **File->Import->Assembly**.

   The **Import Assembly** dialog box appears.

2. From the **File Filter** menu at the bottom of the **Import Assembly** dialog box, select **ProE/NX Elysium Neutral (*.enf*)**.

   Abaqus/CAE lists all the files in the current directory with the appropriate file extension.

3. Select the file containing the assembly to import, and click **OK**.

   Abaqus/CAE displays the **Import Assembly from ENF File** dialog box.

4. Do either of the following:

   - Click on the assembly name to import all of the part instances in the assembly.
   - Click on the arrow to the left of the assembly name to display all of the part instances in the assembly. Click on the names of the part instances that you want to import.

5. Click **OK** to import the assembly or selected part instances and to exit the **Import Assembly from ENF File** dialog box.

   Abaqus/CAE displays a message indicating if any of the part instances are invalid or imprecise. If necessary, use the Query toolset to locate areas of invalid and imprecise geometry. For more information, see *Using the Query toolset in the Part module*.

- *Using the File menu*

Importing an assembly from a Parasolid-format file

Select **File->Import->Assembly** from the main menu bar to import an assembly from a Parasolid-format file. Parasolid is a library of solid modeling functions developed by Unigraphics Solutions and marketed by EDS. You can use a translator from Elysium, Inc., to import Parasolid-format assemblies directly into Abaqus/CAE. A variety of CAD products can generate Parasolid-format parts, such as Unigraphics, SOLIDWORKS, Solid Edge, FEMAP, and MSC.Patran. For information about the versions of the CAD software supported by the translators from Elysium, Inc., see the *https://www.3ds.com/products-services/simulia/products/abaqus/add-ons/geometry-translators/* page at *www.3ds.com/simulia*.

1. From the main menu bar, select **File->Import->Assembly**.

   The **Import Assembly** dialog box appears.

2. From the **File Filter** menu at the bottom of the **Import Assembly** dialog box, select **Parasolid (*.x_t*,*.x_b*, *.xmt*)**.

   Abaqus/CAE lists all the files in the current directory with a `.x_t*`, `x_b*`, and `.xmt*` file extension.

3. Select the Parasolid file containing the assembly to import, and click **OK**.

   Abaqus/CAE displays the **Import Assembly from PARASOLID File** dialog box.

4. Do either of the following:

   - Click on the assembly name to import all of the part instances in the assembly.
   - Click on the arrow to the left of the assembly name to display all of the part instances in the assembly. Click on the names of the part instances that you want to import.

5. Click **OK** to import the assembly or selected part instances and to exit the **Import Assembly from PARASOLID File** dialog box.

   Abaqus/CAE displays a message indicating if any of the part instances are invalid or imprecise. If necessary, use the Query toolset to locate areas of invalid and imprecise geometry. For more information, see *Using the Query toolset in the Part module*.

Additional information

- *Editing techniques*
- *Using file selection dialog boxes*
- *What is an Abaqus/CAE model?*
- *Using the File menu*

Importing a model

Select **File->Import->Model** from the main menu bar to import a model. You can import a model from the following:

Abaqus/CAE model database (*.cae)

Abaqus/CAE creates a copy of the model that you select in the current model database. Data other than model data, such as analysis jobs or custom user data that were created using the Abaqus Scripting Interface, are not copied to the current model database.

Abaqus input file (*.inp, *.pes)

Options and parameters in the input file are translated into objects recognized by the import capability, and Abaqus/CAE creates a new model. For a detailed list of the keywords supported by the import model capability, see *Keyword support from the input file reader*.

Most of the commonly used element types can be assigned to orphan elements. However, some element types cannot be imported from an input file. For a description of the input file reader and a full list of unsupported elements, see *Importing a model from an Abaqus input file*.

The input file reader is not able to import models with a very large number (roughly 8000 or more) of steps.

Abaqus output database (*.odb)

Abaqus/CAE imports the nodes and elements defined in the output database along with the materials, sets, surfaces, section definitions, and beam profiles and creates a new model.

Nastran input file (*.bdf, *.dat, *.nas, *.nastran, *.blk, *.bulk)

Abaqus/CAE imports entities in the Nastran input file as a new model in the current model database. The Nastran-to-Abaqus conversion enables you to select the Abaqus elements to which you map Nastran elements, select a method for converting Nastran section data into Abaqus sections, use pre-integrated shell sections, scale mass/inertia values, convert Nastran subcases to Abaqus load cases in a linear perturbation step, and couple beam element offsets.

ANSYS input file (*.cdb)

Abaqus/CAE imports entities in the ANSYS input file as a new model in the current model database. The ANSYS-to-Abaqus conversion converts selected ANSYS entities to their equivalent entities in Abaqus and notes in a log file the entities that could not be translated.

1. From the main menu bar, select **File->Import->Model**.

   The **Import Model** dialog box appears.

2. Select the type of file from which to import the model.

   - Select **Abaqus/CAE Database** (file extension `.cae`) to import a model from an Abaqus/CAE database. For more information, see *Importing a model from an Abaqus/CAE model database*.
   - Select **Abaqus Input File** (file extensions `.inp` and `.pes`) to import a model from an Abaqus input file. Abaqus/CAE imports the input file and creates a model using information from the supported options. Unsupported options and parameters are ignored. For more information, see *Importing a model from an Abaqus input file*.

- Select **Abaqus Output Database** (file extension `.odb`) to import a model from an output database. Abaqus/CAE imports the output database and creates a new model. For more information, see *Importing a model from an output database*.
- Select **Nastran Input File** (file extensions `.bdf`, `.dat`, `.nas`, `.nastran`, `.blk`, and `.bulk`) to import a model from a Nastran input file. Abaqus/CAE imports the Nastran data and creates a new model. For more information, see *Importing a model from a Nastran input file*.
- Select **Ansys Input File** (file extension `.cdb`) to import a model from an ANSYS input file. Abaqus/CAE imports the ANSYS data and creates a new Abaqus model. For more information, see *Importing a model from an ANSYS input file*.

Abaqus/CAE filters the list of available files based on your file type selection.

3. Select the file from which you want to import data, and click **OK**. For more information on specifying the file to open, see *Using file selection dialog boxes*.
4. If you are importing a model from a model database file, the **Import Model from Model Database** dialog box appears. Complete the following additional steps:
   a. Select the model that you want to copy from the selected model database.
   b. If desired, rename the model as you import it into the current model database. By default, the copied model retains its original name.
   c. If you want to copy objects between models immediately after you import the model, toggle on **After export, show "Model->Copy Objects" dialog**.
   d. Click **OK** to close the **Import Model from Model Database** dialog box.

      Abaqus/CAE imports the selected model into the current model database and, if you selected **After export, show "Model->Copy Objects" dialog**, Abaqus/CAE opens the **Copy Objects** dialog box. You can use this dialog box to select individual objects to copy between models in the current model database. For more information about selecting items in this dialog box, see *Copying objects between models*.

5. If you are importing a model from an Abaqus input file or an output database file, Abaqus/CAE completes the import process by performing the following steps:
   - Creating the new model
   - Naming the model with the same name as the original input file or output database file
   - Making the imported model the current model
   - Displaying the imported model in the model list in the context bar

6. If you are importing a model from a Nastran input file, the **Import Nastran Input File** dialog box appears. Complete the following additional steps:
   a. If desired, rename the model as you import it into Abaqus/CAE. By default, the imported model inherits the name of the Nastran input file.
   b. From the **Element Type Mapping** options, choose the Abaqus element types to which you want to map the Nastran element types **CBAR**, **CQUAD4**, **CHEXA(8)**, and **CTETRA(10)**. For each Nastran element type, click , then select the Abaqus element type by toggling element controls from the dialog box that appears.
   c. From the **Section consolidation** options, select the method you want to use to convert section or membrane data in the Nastran input file:
      - Select **Preserve section IDs** to create an Abaqus section corresponding to each Nastran PSHELL or PCOMP property ID and to create Abaqus discrete fields for shell or membrane thickness and material orientation data in Nastran.

- Select **Group by material ID** to create a single Abaqus section for all elements referencing the same material and to create Abaqus discrete fields for shell thickness and material orientation data in Nastran.
- Select **None** to create a separate shell or membrane section for each combination of orientation, offset, and/or thickness.

d. Toggle on **Use pre-integrated shell sections** to provide the section property data before the analysis. If this option is not selected, Abaqus calculates (integrates) the cross-sectional behavior from section integration points during the analysis.

e. Toggle on **Apply mass/inertia scaling from PARAM, WTMASS** to use the value on the Nastran data line `PARAM, WTMASS, value` as a multiplier for all density, mass, and rotary inertia values created in the Abaqus model.

f. Toggle on **Convert subcases to load cases in a linear perturbation step** to translate Nastran data lines that use the Nastran libraries SOL 101, SOL 108, or SOL 111 into Abaqus perturbation steps with load cases.

g. Toggle on **Couple beam element offsets** to translate beam element offsets in the Nastran data by creating new nodes at the offset locations, changing the beam connectivity to the new nodes, and rigidly coupling the new and original nodes. If this option is not selected, Abaqus translates beam element offsets to the centroid and shear center for the beam general section definition.

h. If you want to retain the Abaqus input file created during the translation process, toggle on **Keep generated Abaqus input file**.

i. Click **OK** to close the **Import Nastran Input File** dialog box.

Abaqus/CAE translates the Nastran data according to your specifications and imports the model into the current model database. If any errors arise during translation, you can display the translation log file in the **Import Nastran Log** dialog box, which enables you to browse the log file and search its contents for error messages.

Additional information

- *Using the File menu*
- *Importing a model from a Nastran input file*
- *Importing a model from an ANSYS input file*

Exporting geometry, model, and mesh data

This section describes how you can export sketches, parts, the assembly, or the model.

In this section:

- *Exporting a sketch to an ACIS-, IGES-, or STEP-format file*
- *Exporting a part to an ACIS-, IGES-, STEP-, or VDA-format file*
- *Exporting the assembly to an ACIS-format file*
- *Exporting viewport data to a VRML-format file*
- *Exporting viewport data to a 3D XML-format file*
- *Exporting viewport data to an OBJ-format file*
- *Exporting model data to Nastran bulk data file format*

Exporting a sketch to an ACIS-, IGES-, or STEP-format file

Select **File->Export->Sketch** from the main menu bar to export the current sketch to an ACIS, IGES, or STEP file. Many computer-aided modeling and drafting applications can read and write ACIS, IGES, and STEP files; therefore, you can transfer sketches between Abaqus/CAE and these applications.

After you save a sketch in the Sketcher, you can export the sketch at any time during an Abaqus/CAE session

1. From the main menu bar, select **File->Export->Sketch**.

   The **Export Sketch** dialog box appears.
2. From the **File Filter** menu at the bottom of the **Export Sketch** dialog box, select one of the following:

   - **ACIS SAT (*.sat)**
   - **IGES (*.igs)**
   - **STEP (*.stp)**

   Abaqus/CAE lists all the files in the selected directory with the appropriate file extension.
3. Select the file to which you want to export the sketch, or type the name of a new file in the **File Name** text field.
4. From the **Export Sketch** dialog box, click **OK**.

   Abaqus/CAE closes the dialog box and displays the **Select Sketch** dialog box with a list of all the saved sketches.
5. From the **Select Sketch** dialog box, select the sketch to export and click **OK**.
6. If you are exporting a sketch to an IGES file, Abaqus/CAE displays the **IGES Flavors** dialog box. Do the following:

   a. Choose one of the following flavors with which to write the IGES file:

      - **Standard**
      - **AutoCAD**
      - **Solid Works**
      - **JAMA**

   b. Click **OK**.

   Abaqus/CAE tailors the internal representation of the IGES file to match the format expected by the selected application. By default, Abaqus/CAE exports a sketch in a **Standard** format. Abaqus/CAE writes all of the geometry data to a single layer in the IGES file. The IGES file contains geometry data only, Abaqus/CAE does not export construction lines and dimensions from the sketch.

Additional information

- *Using file selection dialog boxes*
- *What is an Abaqus/CAE model?*
- *Using the File menu*
- *What kinds of files can be imported and exported from Abaqus/CAE?*

Exporting a part to an ACIS-, IGES-, STEP-, or VDA-format file

Select **File->Export->Part** from the main menu bar to export the current part to a file using one of the following formats:

- **ACIS SAT (*.sat)**
- **IGES (*.igs)**
- **STEP (*.stp)**
- **VDA (*.vda)**

Before you export a part, you must display the part that you want to export in the current viewport. You can export only the geometry of a part; orphan elements, if they exist, are not included in the exported part.

1. In the current viewport, display the part that you wish to export.
2. From the main menu bar, select **File->Export->Part**.

   The **Export Part** dialog box appears.
3. From the **File Filter** menu at the bottom of the **Export Part** dialog box, select the file format.

   Abaqus/CAE lists all the files in the selected directory with the appropriate file extension.
4. Select the file to which you want to export the part, or type the name of a new file in the **File Name** text field, and click **OK**.
5. If you are exporting a part to an IGES file, Abaqus/CAE displays the **IGES Flavors** dialog box. Do the following:

   a. Choose one of the following flavors with which to write the IGES file:

      - **Standard**
      - **AutoCAD**
      - **Solid Works**
      - **JAMA**

   b. Click **OK**.

   Abaqus/CAE tailors the internal representation of the IGES file to match the format expected by the selected application. By default, Abaqus/CAE exports a part in a **Standard** format. Abaqus/CAE writes all of the geometry data to a single layer in the IGES file.

Additional information

- *Using file selection dialog boxes*
- *What is an Abaqus/CAE model?*
- *Using the File menu*
- *What kinds of files can be imported and exported from Abaqus/CAE?*

Exporting the assembly to an ACIS-format file

Select **File->Export->Assembly** from the main menu bar to export the assembly to an ACIS-format file.
You can export the assembly to the ACIS part (SAT) format or to the ACIS assembly (ASAT) format.

Many computer-aided modeling and drafting applications can read and write ACIS files; therefore, you can transfer parts between Abaqus/CAE and these applications. You can export the assembly at any time during an Abaqus/CAE session. You can export the geometry of parts; orphan elements, if they exist, are not included in the exported parts. You can export the complete assembly to a single file and maintain the part and model instances. The assembly is exported with all applied transformations. Assembly-level constraints (such as the parallel face or coaxial position constraint) are not exported.

When you export the assembly to the ACIS part (SAT) format, Abaqus/CAE exports a copy of each part transformed to its position in the assembly. This file is a flat part file with no assembly structure. If you subsequently import the SAT file, Abaqus/CAE creates a part corresponding to each ACIS part in the SAT file for later use when you instance the part in the Assembly module. When you create instances of the imported ACIS parts, Abaqus/CAE uses the position information to recreate the original assembly. You cannot import the assembly directly.

When you export the assembly to the ACIS assembly (ASAT) format, Abaqus/CAE exports "true" assembly part instance information; no duplication of part information, separate position information, and model instance support. The import of assemblies in an ACIS assembly (ASAT) format is not supported.

1. From the main menu bar, select **File->Export->Assembly**.

   The **Export to ACIS File** dialog box appears.

2. From the **File Filter** menu at the bottom of the **Export to ACIS File** dialog box, select the file format.

   Abaqus/CAE lists all the files in the selected directory with the appropriate file extension.

3. Select the file to which you want to export the assembly, or enter the name of a new file in the **File Name** text field.
4. Click **OK** to export the assembly and to close the **Export to ACIS File** dialog box.

Additional information

- *Using file selection dialog boxes*
- *What is an Abaqus/CAE model?*
- *Using the File menu*
- *What kinds of files can be imported and exported from Abaqus/CAE?*

Exporting viewport data to a VRML-format file

Select **File->Export->VRML** from the main menu bar to export the model in the current viewport to a VRML-format file. VRML-format files can be used to display three-dimensional images in a web browser or a stand-alone VRML client. VRML files use meters for all lengths and distances. A special plug-in viewer, such as Cortona or Cosmo, is required to view VRML files.

You can export your model at any time during an Abaqus/CAE session to a standard VRML file or to a compressed VRML file. A compressed VRML file will generally be significantly smaller than the corresponding standard VRML file, but the compression ratio depends on the contents of the model.

VRML files are stored in an ASCII format that can be viewed in a standard text editor. Compressed VRML files must be uncompressed to convert them to ASCII format.

Animations and two-dimensional images such as sketches or layers will not be exported. (For information on exporting animations, see *Saving an animation file*.) In addition, view orientation or coordinate system triads and viewport arrow annotations will not be exported. Text fonts in the viewport image may appear smaller in the VRML file; you can increase the font size in the viewport to ensure that the text will be legible in the VRML file (see *Customizing fonts*, for more information).

When you export an image of a shell or membrane with face labels displayed, the face labels will appear in the VRML file only with respect to the view in which the image was displayed in Abaqus/CAE. If you rotate the image or otherwise change the view in a VRML viewer, the face labels shown may not be appropriate for the displayed faces. For example, if you export an image of a shell model with the positive (`SPOS`) face showing, the `SPOS` label will appear in a VRML viewer even if you rotate the model to show the negative face.

1. From the main menu bar, select **File->Export->VRML**.

   The **Export to VRML File** dialog box appears.
2. From the **File Filter** menu at the bottom of the dialog box, select one of the following:

   ### VRML (*.wrl)

   Abaqus/CAE lists all the files in the selected directory with the file extension `.wrl`.

   ### Compressed VRML (*.wrz)

   Abaqus/CAE lists all the files in the selected directory with the file extension `.wrz`.
3. Select the file to which you want to export the image, or type the name of a new file in the **File Name** text field.
4. Click **OK** to export the image and to close the **Export to VRML File** dialog box.

Additional information

- *Using file selection dialog boxes*
- *Using the File menu*
- *What kinds of files can be imported and exported from Abaqus/CAE?*

Exporting viewport data to a 3D XML-format file

Select **File->Export->3DXML** from the main menu bar to export the model in the current viewport to a 3D XML-format file. 3D XML files can be used to integrate three-dimensional images into common business applications, such as e-mail messages, web pages, word processing documents, and presentations. The 3D XML Player (available from Dassault Systèmes at no cost) can be used as a stand-alone 3D XML client, and it is required to view 3D XML files in other applications. You can also view 3D XML files in CATIA V5 without the 3D XML Player. This export capability cannot be used to transfer geometry or models to **3D**EXPERIENCE platformapps.

You can export your model at any time during an Abaqus/CAE session to a standard 3D XML file.

3D XML files are stored in an XML format based on the universal standard XML language.

To view certain line-based features (such as element edges, orientation triads, and datum planes) in an exported 3D XML file, set the view mode in the 3D XML Player to **Shading with Edges**. One- and two-dimensional features—including beam or truss elements, wireframe plots, reference points, sketches, and layers—and coordinate system triads are not exported. In addition, text is not exported; therefore, annotations, plot legends, and labels do not appear in the 3D XML file.

For visualization purposes, the 3D XML Player models a "floor" in the *X*–*Y* plane, and the default isometric view orients the *Z*-axis in the up direction. In Abaqus/CAE the default isometric view orients the *Y*-axis in the up direction. Models that appear upright in the default Abaqus/CAE view, therefore, normally appear to lie sideways on the floor in the default 3D XML Player view. To avoid this problem, Abaqus automatically rotates the model 90° about the *X*-axis and 90° about the *Z*-axis in the exported 3D XML file. These rotations make the default views of the model equivalent in Abaqus/CAE and the 3D XML Player.

The 3D XML format displays still images only. For information on exporting animations, see *Saving an animation file*.

Note:

Some 3D XML viewers do not support texture mapping in the 3D XML files. Therefore, when exporting a contour plot, you may need to switch to the tessellated rendering method to visualize colors in some 3D XML viewers; select **Tessellated** as the **Contour Method** in the **Contour Plot Options** dialog box, as described in *Choosing the contour method*.

1. From the main menu bar, select **File->Export->3DXML**.

   The **Export to 3DXML File** dialog box appears.
2. From the **File Filter** menu at the bottom of the dialog box, select **3DXML (*.3dxml)**.

   Abaqus/CAE lists all the files in the selected directory with the file extension `.3dxml`.
3. Select the file to which you want to export the image, or type the name of a new file in the **File Name** text field.
4. Click **OK** to export the image and to close the **Export to 3DXML File** dialog box.

Additional information

- *Using file selection dialog boxes*
- *Using the File menu*
- *What kinds of files can be imported and exported from Abaqus/CAE?*

Exporting viewport data to an OBJ-format file

Select **File->Export->OBJ** from the main menu bar to export the model in the current viewport to an OBJ-format file. When you export data from the Visualization module, Abaqus/CAE exports only mesh data to the OBJ-format file. If you export data from any other module, Abaqus/CAE exports mesh data if the mesh is displayed in the current viewport; otherwise, Abaqus/CAE exports geometry data.

Export from the Visualization module is sensitive to the current step and frame. If you display an undeformed plot in the viewport, Abaqus/CAE exports undeformed data to the OBJ-format file; if you display a deformed plot, Abaqus/CAE exports deformed data for the current step and frame to the OBJ-format file.

Abaqus/CAE performs the following conversions to geometry and mesh data during the export process:

- Solid elements in the model database are converted to shell elements in the OBJ-format file.
- Quadrilateral elements in the model database are converted to triangular elements in the OBJ-format file.
- Second-order elements in the model database are converted to first-order elements in the OBJ-format file.

  If your model is meshed with a large number of second-order elements, the export process can create a large OBJ file as Abaqus/CAE splits the second-order elements into the resulting first-order elements.

The quality of the geometry or mesh data you export and the resulting file size both depend on the curve refinement settings. For more information on changing curve refinement quality, see *Controlling curve refinement*.

1. If you are exporting data from the Visualization module, select the plot state for which you want to export data. For export of data from a deformed plot state, select the step and frame for which you want to export data. For more information on selecting the current step and frame, see *Selecting the results step and frame*.
2. From the main menu bar, select **File->Export->OBJ**.

   The **Export to OBJ File** dialog box appears.
3. From the **File Filter** menu at the bottom of the dialog box, select **OBJ (*.obj)**.

   Abaqus/CAE lists all the files in the selected directory with the file extension `.obj`.
4. Select the file to which you want to export the geometry and mesh data, or type the name of a new file in the **File Name** text field.
5. Click **OK** to export the data and to close the **Export to OBJ File** dialog box.

Additional information

- *Using file selection dialog boxes*

Exporting model data to Nastran bulk data file format

Select **Job->Export->Nastran Input File->*jobname*** from the main menu bar in the Job module to export the model data and job data associated with an Abaqus job to Nastran bulk data file (`.bdf`) format.

Tip: You can also initiate this export from the Model Tree. Expand the **Jobs** container, click mouse button 3 on the job, and select **Export->Nastran Input File**.

The Nastran bulk data file you create includes selected data from the Abaqus model and job; see *Translating an Abaqus Input File to a Partial Nastran Bulk Data Text File*, for more information about the supported Abaqus keywords and the Nastran entities to which they map. The bulk data file includes selected history data in the Abaqus model, but it does not include parts and assemblies, which are not supported in Nastran.

Additional information

Creating and analyzing a model using the Abaqus/CAE modules

This part describes how to use the modules in Abaqus/CAE to define a model's geometry and other physical properties and then submit the model for analysis.

In this section:

The Part module

Parts are the building blocks of an Abaqus/CAE model. You use the Part module to create each part, and you use the Assembly module to assemble instances of the parts.

The tutorial in *Using Additional Techniques to Create and Analyze a Model in Abaqus/CAE* contains examples of how you create, modify, and manipulate parts. This chapter explains how you use the tools within the Part module to work with parts.

Understanding the role of the Part module

There are several ways to create a part in Abaqus/CAE:

- Create the part using the tools available in the Part module.
- Import the part from a file containing geometry stored in a third-party format.
- Import the part mesh from an output database.
- Import a meshed part from an Abaqus input file.
- Merge or cut part instances in the Assembly module.
- Create a meshed part in the Mesh module.

A part created using the Part module tools is called a native part and has a feature-based representation. A feature captures your design intent and contains geometry information as well as a set of rules that govern the behavior of the geometry. For example, a circular through cut is a feature, and Abaqus/CAE stores the diameter of the cut along with the information that it should pass all the way through the part. If you increase the size of the part, Abaqus/CAE recognizes that the depth of the cut should increase so that it continues to pass through the part.

You use the Part module to create, edit, and manage the parts in the current model. Abaqus/CAE stores each part in the form of an ordered list of features. The parameters that define each feature—extruded depth, hole diameter, sweep path, etc.—combine to define the geometry of the part.

The Part module allows you to do the following:

- Create deformable, discrete rigid, analytical rigid, or Eulerian parts. The part tools also allow you to edit and manipulate the existing parts defined in the current model.
- Create the features—solids, shells, wires, cuts, and rounds—that define the geometry of the part.
- Use the Feature Manipulation toolset to edit, delete, suppress, resume, and regenerate a part's features.
- Assign the reference point to a rigid part.
- Use the Sketcher to create, edit, and manage the two-dimensional sketches that form the profile of a part's features. These profiles can be extruded, revolved, or swept to create part geometry; or they can be used directly to form a planar or axisymmetric part.
- Use the Set toolset, the Partition toolset, and the Datum toolset. These toolsets operate on the part in the current viewport and allow you to create sets, partitions, and datum geometry, respectively.

Entering and exiting the Part module

You can enter the Part module at any time during an Abaqus/CAE session by clicking **Part** in the **Module** list located in the context bar. The **Part**, **Shape**, **Feature**, and **Tools** menus appear on the main menu bar, and the title bar of the current viewport displays the name of the current part, if one exists.

To exit the Part module, select any other module from the **Module** list. You need not take any specific action to save your parts before exiting the module; they are saved automatically when you save the entire model by selecting **File**->**Save** or **File**->**Save As** from the main menu bar.

What is feature-based modeling?

This section describes the feature-based modeling approach that Abaqus/CAE uses to define a part.

In this section:

- *The relationship between parts and features*
- *The base feature*
- *Simplifying a part's feature list*
- *What is a part instance?*

The relationship between parts and features

A part created in Abaqus/CAE has a feature-based representation. A feature is a meaningful piece of the design and provides the engineer with a convenient and natural way to build and modify a part. Parts created in Abaqus/CAE are constructed from an ordered list of features and the parameters that define the geometry of each feature. You select from the following shape features to build a part in the Part module:

- Solids
- Shells
- Wires
- Cuts
- Blends

Using the tools in the Part module, you create and edit all the features necessary to describe each of the parts in your model. Abaqus/CAE stores each feature and uses this information to define the entire part, to regenerate the part if you modify it, and to generate an instance of the part in the Assembly module. For more information on how parts are related to part instances, see *What is a part instance?*.

The following sequence illustrates how the three-dimensional part in *Figure 1* would be constructed using features available in Abaqus/CAE:

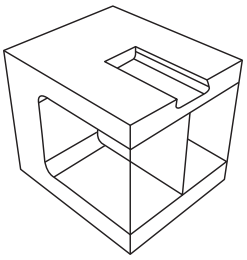

Figure 1: Part constructed using solid, shell, wire, cut, and blend features.

1. The first feature you create while building a part is called the base feature; you construct the remainder of the part by adding more features that either modify or add detail to the base feature. In this example the base feature is a U-shaped part; the user sketched a two-dimensional profile and extruded it to form the base feature, as shown in *Figure 2*.

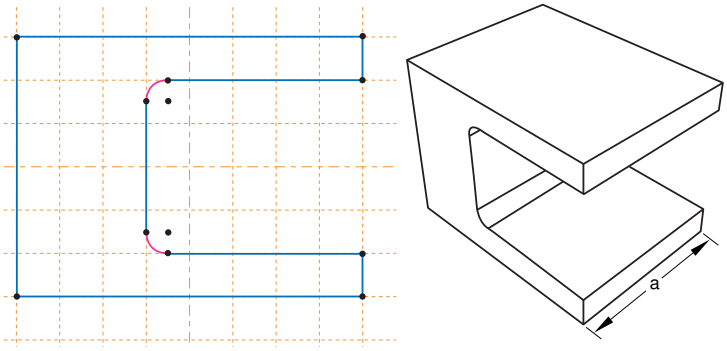

Figure 2: The base feature.

The sketch and the extrusion depth (a) are the modifiable parameters that define the base feature. You can revisit the base feature and change its size or shape by using the Feature Manipulation toolset to modify either the section sketch or the extrusion distance. If desired, you can delete the base feature and sketch a new shape.

2. A stiffening web is added as a shell feature. The user sketched a line on one of the internal faces and extruded the sketch to the opposite face, as shown in *Figure 3*. The sketch is the only modifiable parameter that defines the shell feature.

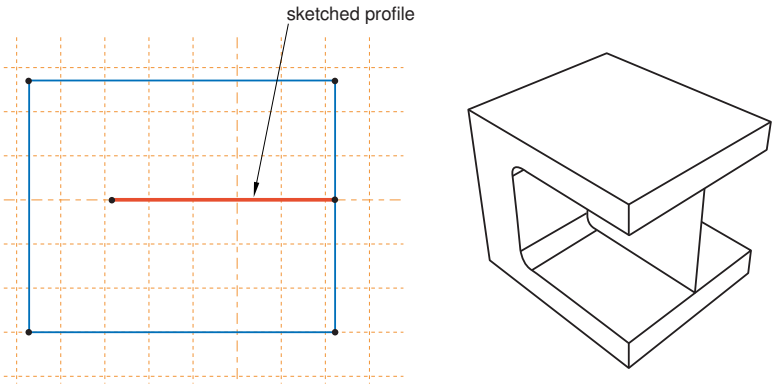

Figure 3: A shell feature.

3. Rods are added to the corners as wire features. The wire was created by connecting two points that the user selected, as shown in *Figure 4*. Wires created in this way have no modifiable parameters; they must be deleted and recreated if you need to change them.

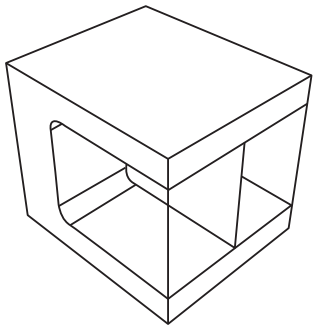

Figure 4: Wire features.

4. A blind cut is cut into the top of the clamp. The user sketched a two-dimensional profile, and the profile was extruded into the clamp through a specified distance, as shown in *Figure 5*. The sketch and the depth of the slot are the modifiable parameters that define the blind cut feature.

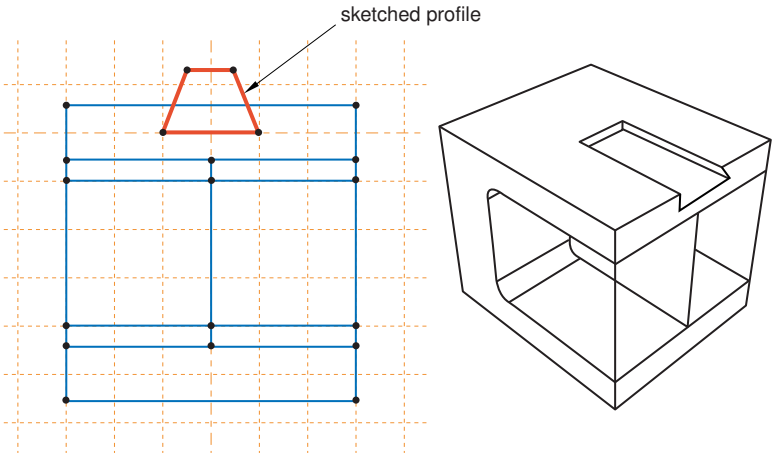

Figure 5: A cut feature.

5. The edges of the cut are rounded. The user selected the edges to round and provided the radius of the round, as shown in *Figure 6*. The radius is the modifiable parameter that defines the round feature.

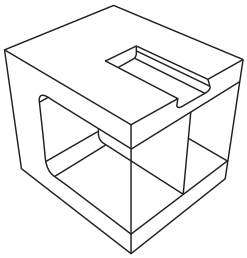

Figure 6: Round features.

If the geometry of a new feature depends on an existing feature, Abaqus/CAE creates a parent-child relationship between the features. The new feature is the child, and the feature it depends on is the parent. For example, in the part described above the round feature is a child of the cut feature. If you change the position or size of the cut, the edges remain rounded. Similarly, if you delete the cut, Abaqus/CAE also deletes the rounds.

If you modify a parent feature, the modification might invalidate children of the parent feature. For example, in the part described above if you were to increase the depth of the cut so that it became a through cut, you would lose the fillets along its edges; that is, the fillets would fail to regenerate after the modification. Abaqus/CAE offers you the following two choices:

- Keep the changes to the parent feature but suppress the features that failed to regenerate. Children of the suppressed features will also be suppressed.
- Exit the modification of the parent feature and return to the state of the last successful regeneration.

Additional information

- *What is feature-based modeling?*
- *Modifying and manipulating features*

The base feature

The first feature you create while building a part is called the base feature; you construct the remainder of the part by adding more features that either modify or add detail to the base feature. This process of building an Abaqus/CAE native part using the tools in the Part module follows a sequence of operations analogous to building a part in a machine shop. For example, you start with a piece of billet stock (the base feature) and then you do the following:

- Attach additional pieces to the billet (apply a solid extrusion, a revolved shell, or a sketched wire).
- Cut away the billet (apply an extruded cut, a revolved cut, or a circular hole; or round or chamfer an edge).

When you create a new part, you must describe the base feature. You do this by specifying two properties of the base feature: its shape and type. The shape indicates the basic topology of the feature; that is, whether it is a solid, shell, wire, or point. The type indicates which of the following methods will be used to generate the base feature:

Planar

You sketch the feature on a two-dimensional sketch plane.

Extrusion

You sketch the feature profile and then extrude it through a specified distance.

Revolution

You sketch the feature profile and then revolve it by a specified angle about an axis.

Sweep

You sketch two shapes: a sweep path and a sweep profile. The profile is then swept along the path to create the feature.

Coordinates

You enter the coordinates of a single point in the prompt area.

Before you create a part and choose the shape and the type of the base feature, you should know the sequence you will use to construct the desired part. Choosing the correct type and shape of the base feature is important.

Table 1 shows the base features that you can select based on the part's modeling space and type.

Table 1: Choosing the base feature.

	Modeling Space	
Part Type	**Three-dimensional**	**Two-dimensional or Axisymmetric**
Deformable	Any	Planar shell, planar wire, or point
Discrete rigid	Any (you must convert a 3D solid discrete rigid part to a shell before you instance it)	Planar wire or point
Analytical rigid	Extruded or revolved shell	Planar wire
Eulerian	Extruded, revolved, or swept solid	Not applicable
Fluid	Extruded, revolved, or swept solid	Not applicable
Electromagnetic	Extruded, revolved, or swept solid	Planar shell

A part imported from a file containing third-party format geometry consists of a single feature that you import into Abaqus/CAE as the base feature of a new part. You cannot modify this base feature, but you can add additional features to it. Similarly, a mesh part is created in the Mesh module or imported from an output database as the base feature of a new part. You can use the mesh editing tools to add and delete nodes and elements from a mesh, or you can use the tools in the Part module to add geometric features to the mesh.

Additional information

- *How is a part defined in Abaqus/CAE?*
- *Using the Create Part dialog box*
- *Adding a solid feature*
- *Adding a shell feature*
- *Adding a wire feature*

Simplifying a part's feature list

When you copy a part to a new part, you can reduce all the feature and parameter information to a simple definition. If you reduce the feature list, Abaqus/CAE will regenerate the part faster if you subsequently modify it; however, you will no longer be able to modify any parameters of the part. You copy a part by selecting **Part->Copy->*part name*** from the main menu bar.

Simplifying a part's feature list is especially useful if you have spent a lot of time creating a part and have iterated many times over the design. For example, if you created a slot and redimensioned the slot before arriving at the final design, the original part contains features that define each variation of the slot. If you copy the part and simplify the feature list, the new part will contain only one feature that defines the final version of the slot.

What is a part instance?

A part instance can be thought of as a representation of the original part. You create a part in the Part module and define its properties in the Property module. However, when you assemble the model using the Assembly module, you work only with instances of the part, not the part itself. The Interaction and Load modules also operate on the assembly and, therefore, on part instances. In contrast, the Mesh module enables you to operate on either the assembly or one or more of its component parts.

You create part instances in the Assembly module. You then position those instances relative to each other in a global coordinate system to form the assembly. You can create and position multiple instances of a single part. In addition, you can assemble instances of deformable, analytical rigid, and discrete rigid parts when you are solving contact problems. For more information on the types of parts you can create in Abaqus/CAE, see *Part types*.

The following example illustrates the relationship between parts and part instances. A pump housing is composed of three parts: the housing cover, a gasket, and a mounting bolt. In the Part module you create each of the three parts shown in *Figure 1*:

- One housing cover
- One gasket
- One bolt

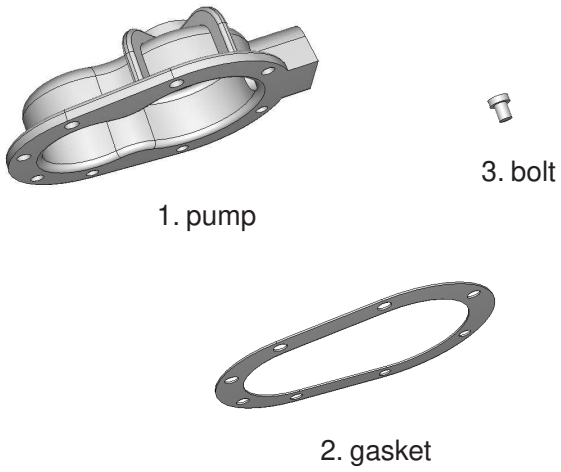

Figure 1: The original parts.

In the Assembly module you assemble instances of each part:

- One instance of the body
- One instance of the gasket
- Eight instances of the bolt

You then position the instances relative to a common coordinate system, thereby creating the model of the pump housing, as shown in *Figure 2*.

Figure 2: The model is assembled from instances of the parts.

Now, suppose you want to change the length of the bolts. You return to the Part module and modify the length of the bolt by editing the original part. When you return to the Assembly module, Abaqus/CAE recognizes that the part was modified and automatically regenerates the eight instances of the bolt to reflect the change in the length.

You cannot modify the geometry of a part instance directly; you can modify the part itself only within the Part module. When you modify a part, Abaqus/CAE automatically regenerates all instances of the modified part in the assembly. Part instances are discussed in more detail in the context of the Assembly module in *Working with part instances*.

How is a part defined in Abaqus/CAE?

This section describes the parts you can create in the Part module—deformable, rigid, and Eulerian—and the electromagnetic parts available in electromagnetic models.

In this section:

- *Part modeling space*
- *Part types*
- *Part size*

Part modeling space

When you create a new part, you must specify the modeling space in which the part will reside. You can assign the following three types of modeling space:

Three-dimensional

Abaqus/CAE embeds the part in the *X*, *Y*, *Z* coordinate system. A three-dimensional part can contain any combination of solid, shell, wire, cut, round, and chamfer features. You model a three-dimensional part using three-dimensional solid, shell, beam, truss, or membrane elements.

Two-dimensional planar

Abaqus/CAE embeds the part in the *X*–*Y* plane. A two-dimensional planar part can contain a combination of only planar shell and wire features, and all cut features are defined as planar through cuts. You model a two-dimensional planar part using two-dimensional solid continuum elements, as well as truss or beam elements.

Axisymmetric

Abaqus/CAE embeds the part in the *X*–*Y* plane with the *Y*-axis indicating the axis of revolution. An axisymmetric part can contain a combination of only planar shell and wire features, and all cut features are defined as planar through cuts. You model an axisymmetric part using axisymmetric solid continuum elements or axisymmetric shell elements.

Modeling space refers to the space in which the part is embedded rather than to the topology of the part itself. Thus, you can create a three-dimensional part using a topologically two-dimensional shell feature or a one-dimensional wire feature. You can change the modeling space of a part after you have created it by clicking mouse button 3 on the part in the Model Tree and selecting **Edit** from the menu that appears.

Abaqus/CAE uses the following methods to determine the modeling space of an imported part:

- When you import a part from a file containing geometry stored in a third-party format, you can specify the part's modeling space, provided that Abaqus/CAE does not determine it must be three-dimensional.
- When you import a mesh from an output database, Abaqus/CAE determines the modeling space of the new part from the information stored in the output database.
- When you import a mesh from an input file, Abaqus/CAE determines the modeling space of the new part from the element type.
- When you create a mesh part in the Mesh module, the modeling space of the mesh part is the same as the modeling space of the original part.

Detailed instructions on how to specify modeling space when creating and importing a part can be found in *Choosing the modeling space of a new part*, and *Importing sketches and parts*.

Additional information

• *How is a part defined in Abaqus/CAE?*

Part types

When you create a new part or import a part from a file containing geometry stored in a third-party format, you must choose the part's type.
The possible types for Abaqus/Standard and Abaqus/Explicit are:

Deformable

Any arbitrarily shaped axisymmetric, two-dimensional, or three-dimensional part that you can create or import can be specified as a deformable part. A deformable part represents a part that can deform under load; the load can be mechanical, thermal, or electrical. By default, Abaqus/CAE creates parts that are deformable.

Discrete rigid

A discrete rigid part is similar to a deformable part in that it can be any arbitrary shape. However, a discrete rigid part is assumed to be rigid and is used in contact analyses to model bodies that cannot deform.

Analytical rigid

An analytical rigid part is similar to a discrete rigid part in that it is used to represent a rigid surface in a contact analysis. However, the shape of an analytical rigid part is not arbitrary and must be formed from a set of sketched lines, arcs, and parabolas.

Eulerian

Eulerian parts are used to define a domain in which material can flow for an Eulerian analysis. Eulerian parts do not deform during an analysis; instead, the material within the part deforms under load and can flow across the rigid element boundaries. For more information about Eulerian analyses, see *Eulerian analyses*.

Electromagnetic

The electromagnetic part type is used only in an electromagnetic model. For more information, see *Eddy Current Analysis*.

You can assemble deformable bodies, discrete rigid parts, analytical rigid parts, Eulerian parts, and electromagnetic parts in the Assembly module. If allowed, you can change the type of a part after you have created it by clicking mouse button 3 on the part in the Model Tree and selecting **Edit** from the menu that appears.

Abaqus/CAE uses the following methods to determine the type of an imported part:

- When you import a part from a file containing geometry stored in a third-party format, you can specify the part's type to be either deformable, discrete rigid, or Eulerian.
- When you import a mesh from an output database, Abaqus/CAE determines the type of the new part from the information stored in the output database.
- When you import a mesh from an input file, Abaqus/CAE determines the type of the new part from the element type.
- When you create a mesh part in the Mesh module, the type of the mesh part is the same as the type of the original part.

Additional information

- *How is a part defined in Abaqus/CAE?*
- *Modeling rigid bodies and display bodies*

Part size

When you create a new part, you must choose the part's approximate size. The size that you enter is used by Abaqus/CAE to calculate the size of the Sketcher sheet and the spacing of its grid. You should set the approximate size of the part to match the largest dimension of the finished part. If you find subsequently that the part exceeds the size of the Sketcher sheet, use the Sketch customization options to increase the sheet size. You cannot change a part's approximate size after you have created it. However, you can copy the part to a new part and scale the part during the copy operation. For more information, see *Copying a part*.

Abaqus/CAE uses a geometry engine to model parts and features. The recommended approximate size limits are between 0.001 (10^{-3}) and 10000 (10^{4}) units. This size range should prevent your model from exceeding the limits of the geometry engine. For example, the minimum size supported by the geometry engine is 10^{-6}, so maintaining geometry on the order of 10^{-3} will normally allow node and element dimensions to remain above the minimum size. Parts that exceed the recommended limits may exhibit geometric defects. If you find that you need to specify an approximate size that is outside the suggested range, you should consider adopting a different set of units.

Additional information

- *Setting the approximate size of the new part*
- *Copying a part*

Copying a part

Select **Part->Copy->*part name*** from the main menu bar to copy a part to a new part.

You can create an identical copy of the original part, or you can do the following during the copy operation:

Compress features

Abaqus/CAE reduces all the feature and parameter information to a simple definition of the part. As a result, Abaqus/CAE will regenerate the part faster if you subsequently modify it; however, you will no longer be able to modify any parameters of the part. For more information, see *Simplifying a part's feature list*.

Scale part by

Abaqus/CAE scales the new part by the scale factor that you enter. If you choose to scale a part, Abaqus/CAE also compresses its features. You can use scaling to correct imported parts. If the scale of the imported part is incorrect, you can copy the part to a new part and scale it to the correct dimensions in the process. In some cases you can produce a valid part by scaling the part down, repairing the part, and then scaling the part back to its original dimensions. You can also scale an imported part during the import process. For more information, see *Importing sketches and parts*.

Mirror part about plane

Abaqus/CAE mirrors the part about the selected plane (*X*–*Y*, *Y*–*Z*, or *X*–*Z*). If you select the **Mirror part about plane** option, Abaqus/CAE selects the **Compress features** option.

To mirror a part about a plane other than one of the principal planes and without compressing the features, use **Shape->Transform->Mirror**. For more information, see *Mirroring a part*.

Separate disconnected regions into parts

In some cases when you import an IGES- or VDA-FS-format part and select the **Stitch edges** repair option, Abaqus/CAE imports separate parts as a single part. If you toggle on the **Separate disconnected regions into parts** option and copy the imported part to a new part, Abaqus/CAE will separate disconnected regions into separate parts. For more information, see *Controlling the import process*.

You can copy a mesh part and separate it into disconnected parts based on nodal connectivity. Abaqus/CAE assumes that all connected nodes belong to a single part and does not take element type into consideration. However, Abaqus/CAE ignores connectivity between axisymmetric solid elements with nonlinear, asymmetric deformation (CAXA) and some line elements (connectors, springs, dashpots, gap, and joint).

You can copy parts containing both geometry and orphan mesh features. You can use the **Compress features**, **Scale part by**, **Mirror part about plane**, and **Separate disconnected regions into parts** options on any part.

However, note the following:

1. When you compress or mirror a geometry part during the copy operation, reference points, attachment points, sets, surfaces, point parts, and datums are not copied .
2. When you compress an orphan mesh part during the copy operation, reference points, attachment points, sets, surfaces, point parts, and datums are copied.
3. When you mirror an orphan mesh part during the copy operation, reference points, attachment points, point parts, and datums are not copied. Only sets and surfaces are copied and mirrored.

What are orphan nodes and elements?

Orphan nodes and elements are components of a finite element mesh that exist without any associated geometry. In effect, the mesh information has been orphaned from its parent geometry. Orphan nodes and elements can be created in several ways; they can be:

- Imported from an output database (for more information, see *Importing a part from an output database*)
- Imported from an Abaqus input file (for more information, see *Importing a model*)
- Created as a mesh part (for more information, see *Creating a mesh part*)
- Created in a bottom-up meshing procedure (for more information, see *Bottom-up meshing*)
- Created by certain mesh editing operations, such as create element and offset (for more information, see *Using the mesh editing tools*)
- Created by deleting the associativity with their parent geometry (for more information, see *Deleting mesh-geometry associativity*)

The first three methods above create an orphan mesh feature as the base feature of a new part. The remaining methods are part of the Edit Mesh toolset; these methods edit the existing mesh and, therefore, do not exist as features of the part. For more information, see *The Edit Mesh toolset*.

You can select the face of an orphan element as the sketch plane to add geometric features. In addition, in the Mesh module you can change the element type assigned to orphan elements, and you can verify and edit the mesh.

Modeling rigid bodies and display bodies

This section describes rigid bodies and display bodies.

In this section:

- *Rigid parts*
- *Sketching the profile of an analytical rigid part*
- *What is the difference between a rigid part and a rigid body constraint?*
- *What is a display body?*

Rigid parts

When your model contains parts that contact each other, you can specify that one or more of the parts is rigid. A rigid part represents a part that is so much stiffer than the rest of the model that its deformation can be considered negligible.

In contrast to a part that you define as rigid, a part that you define as deformable can deform during contact with either a rigid part or another deformable part. For example, a model of a metal stamping process might use a deformable part to model the blank and rigid parts to model the mold and die, as shown in *Figure 1*.

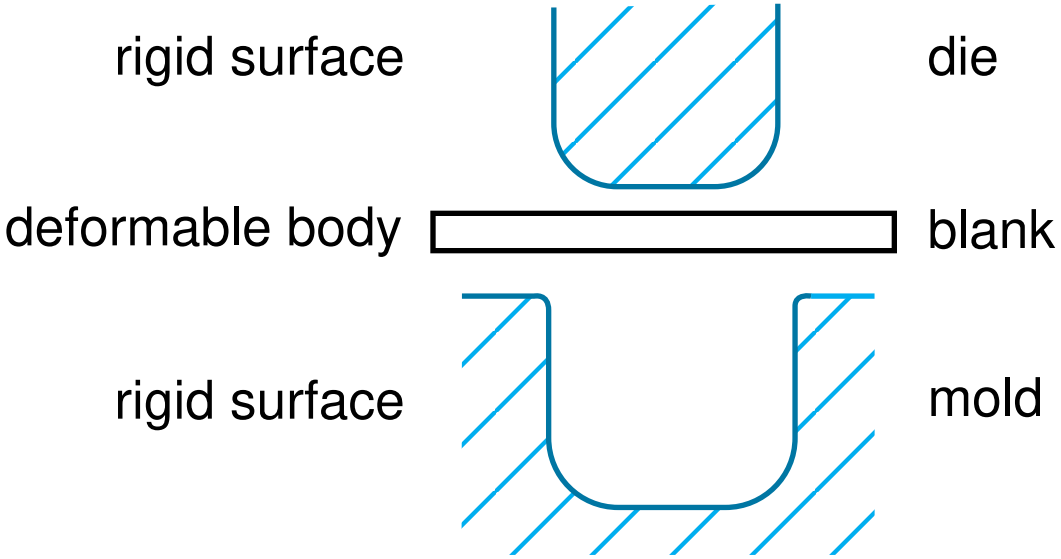

Figure 1: Rigid and deformable parts.

In this example the mold is constrained to have no motion, and the die moves through a prescribed path during the stamping process. You control the motion of rigid parts by selecting a rigid body reference point and constraining or prescribing its motion. For more information, see *The reference point*.

Computational efficiency is the principal advantage of rigid parts over deformable parts. During the analysis element-level calculations are not performed for rigid parts. Although some computational effort is required to update the motion of the rigid body and to assemble concentrated and distributed loads, the motion of the rigid body is determined completely by the reference point. To change the type of a part from deformable to rigid and vice versa, you can click mouse button 3 on the part in the Model Tree and select **Edit** from the menu that appears. For more information, see *What is the difference between a rigid part and a rigid body constraint?* and *Display bodies*.

You can choose between two kinds of rigid parts:

Discrete rigid parts

A part that you declared to be a discrete rigid part can be any arbitrary three-dimensional, two-dimensional, or axisymmetric shape. Therefore, you can use all the Part module feature tools—solids, shells, wires, cuts, and blends—to create a discrete rigid part. However, only discrete rigid parts containing shells and wires can be meshed with rigid elements in the Mesh module. If you try to create an instance of a solid discrete rigid part in the Assembly module, Abaqus/CAE displays an error message; you must return to the Part module and convert the faces of the solid to shells.

Analytical rigid parts

An analytical rigid part is similar to a discrete rigid part in that it is used to represent a rigid part in a contact analysis. If possible, you should use an analytical rigid part when describing a rigid part because it is

computationally less expensive than a discrete rigid part. The shape of an analytical rigid part is not arbitrary, and the profile must be smooth. You can use only the following methods to create an analytical rigid part:

- You can sketch the two-dimensional profile of the part and revolve the profile around an axis of symmetry to form a three-dimensional revolved analytical rigid part, as shown in *Figure 2*.

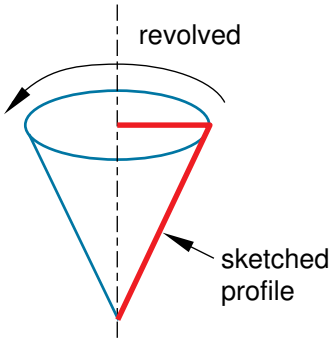

Figure 2: A revolved analytical rigid part.

- You can sketch the two-dimensional profile of the part and extrude the profile infinitely to form a three-dimensional extruded analytical rigid part. Although Abaqus/CAE considers that the extrusion extends to infinity, the Part module displays a three-dimensional extruded analytical rigid part with a depth that you specify, as shown in *Figure 3*.

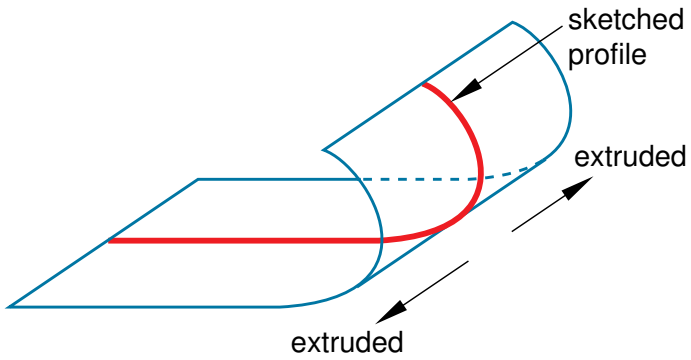

Figure 3: An extruded analytical rigid part.

- You can sketch the profile of a planar two-dimensional analytical rigid part, as shown in *Figure 4*.

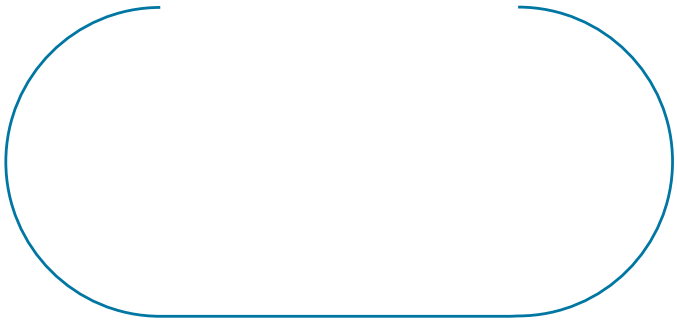

Figure 4: A planar analytical rigid part.

- You can sketch the profile of an axisymmetric two-dimensional analytical rigid part, as shown in *Figure 5*.

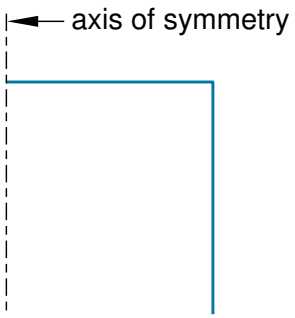

Figure 5: An axisymmetric analytical rigid part.

You can import a part from a file containing geometry stored in a third-party format and define it to be either a deformable or a discrete rigid part; however, you cannot define an imported part to be an analytical rigid part. As an alternative, you can import the geometry of the analytical rigid part into a sketch. You can then create a new analytical rigid part and copy the imported sketch into the Sketcher toolset.

A rigid part in Abaqus/CAE is equivalent to a rigid surface in an Abaqus/Standard or Abaqus/Explicit analysis. For more information, see the following:

- *Analytical Rigid Surface Definition*
- *Rigid Body Definition*
- *Rigid Elements*
- *About Contact Interactions*

Additional information

- *The reference point*
- *Part types*
- *How is a part defined in Abaqus/CAE?*
- *Sketching simple objects*

Sketching the profile of an analytical rigid part

Several tools are available in the Sketcher to help you construct each portion of the rigid part profile:

Lines

You use the Sketcher's **Line** tool to sketch straight lines.

Arcs and fillets

You use the Sketcher's **Arc** and **Fillet** tools to sketch circular arcs or to fillet two lines. Any resulting arcs must subtend an angle less than 180°; if you want to construct an arc subtending an angle greater than 180°, you should create two adjacent arcs. Abaqus/CAE displays an error message if you create an arc subtending an angle greater than 180° while sketching the profile of an analytical rigid surface.

Splines

You use the Sketcher's **Spline** tool to sketch parabolic splines. You create a parabolic spline by defining a three-point spline, where the three points are the start of the spline, a point anywhere along the spline, and the end of the spline. Only splines composed of exactly three points generate the profiles required by the analytical rigid part definition; consequently, Abaqus/CAE displays an error message if you create a spline using more than three points while sketching the profile of an analytical rigid part.

You can construct an analytical rigid part from any combination of lines, arcs, and parabolic splines; however, the resulting profile must be a single connected (but not necessarily closed) curve. In addition, the curve must be smooth to obtain a converged solution with Abaqus/Standard or Abaqus/Explicit. You may want to apply a sequence of small lines, arcs, or parabolic splines to eliminate any surface discontinuities (Abaqus/CAE does not have an equivalent to the FILLET RADIUS parameter on the Abaqus/Standard and Abaqus/Explicit **SURFACE* option). For more information on creating parabolic splines and maintaining tangency, see *Sketching splines*. For more information on the rules governing analytical rigid surfaces, see *Analytical Rigid Surface Definition*.

A sketch of an analytical rigid part that includes a line, an arc, and a fillet is illustrated in *Figure 1*.

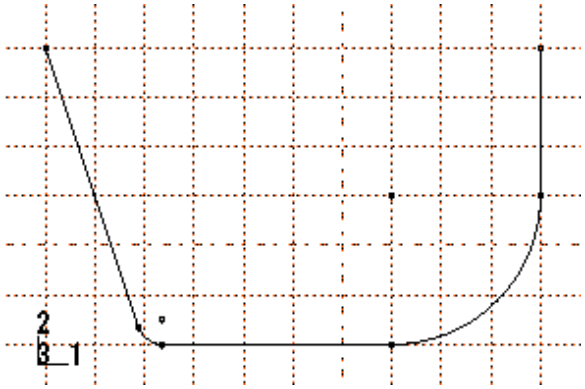

Figure 1: A sketch of an analytical rigid part.

An analytical rigid part is defined completely by the two-dimensional profile of the base feature that you create with the Sketcher; consequently, the Part module tools cannot be used to add features when you return to the Part module from the Sketcher. You can modify the part only by editing the original sketch.

After you create an analytical rigid surface, you must assign a rigid body reference point to it. You control the motion of the analytical rigid surface by constraining or prescribing the motion of the reference point. For more information, see *The reference point*.

Additional information

• *Sketching simple objects*

What is the difference between a rigid part and a rigid body constraint?

You can create a rigid part in the Part module by creating a part and declaring its type to be discrete or analytical rigid. You can create a reference point and assign it to the rigid body reference point. Motion or constraints that you apply to the reference point are then applied to the entire rigid part.

Similarly, you can create a rigid body constraint in the Interaction module. Rigid body constraints allow you to constrain the motion of regions of the assembly to the motion of a reference point. The relative positions of the regions that are part of the rigid body remain constant throughout the analysis. In addition, you can select regions from a part instance and use a rigid body constraint to specify an isothermal rigid body for a fully coupled thermal-stress analysis. For detailed instructions on defining rigid body constraints and assigning a rigid body reference point, see *Defining rigid body constraints*.

You do not have to create a reference point for a part, even if the part type is discrete or analytical rigid. However, if you do not create a reference point for a rigid part, every instance of the part in the assembly must be included in a rigid body constraint.

Rigid parts are associated with parts; rigid body constraints are associated with regions of the assembly. For example, if you define a part to be rigid, every instance of the part in the assembly is rigid. In contrast, if you define a part to be deformable, you can use rigid body constraints to make only some of the instances rigid. If you do not create a reference point in the Part module, you cannot create a rigid body reference point by associating an instance of the rigid part with a reference point created in the Assembly module. However, you can associate the instance with a rigid body constraint and a reference point created in the Assembly module.

If you define a part to be rigid, you can use the Model Tree to change the part type to be deformable. To check that your basic model is correct, you might run a quick analysis with a part defined as rigid and then change the type to deformable. Similarly, if you define a part to be deformable and apply a rigid body constraint to an instance of the part in the assembly, you can easily remove the constraint at a later time. You can run your quick analysis with a rigid body constraint applied to the part instance and then remove the constraint and run a full analysis with the part instance acting as a deformable body. The two approaches are very similar.

What is a display body?

A display body is a part instance that will be used for display only. You do not have to mesh the part, and the part is not included in the analysis; however, when you view the results of the analysis, the Visualization module displays the part along with the rest of your model. If Abaqus/CAE reports that an imported part is invalid, you can still include the part in your model as a display body. For more information, see *What is a valid and precise part?*.

You create a display body by applying a display body constraint in the Interaction module. You can apply a display body constraint to both deformable and rigid parts, and you can apply a display body constraint to parts containing both geometry and orphan elements. You can constrain the part instance to be fixed in space, or you can constrain it to follow selected points. For more information, see *Understanding constraints*. For an example of a model that uses display body constraints, see *Display bodies*.

The reference point and point parts

This section describes how you can create a reference point that is associated with a part and how you can create a part containing just a single point that is also the reference point.

In this section:

- *The reference point*
- *Point parts*

The reference point

You can use the Reference Point toolset to create a reference point that is associated with a part by selecting **Tools->Reference Point** from the main menu bar. A part can include only one reference point, and Abaqus/CAE labels it **RP**. Abaqus/CAE asks you if you want to delete the original point if you try to create a second point. A reference point on a part appears on all instances of the part in the assembly. The assembly can include more than one reference point, and Abaqus/CAE labels them **RP-1**, **RP-2**, **RP-3**, etc. For more information about the reference point, see *The Reference Point toolset*.

Abaqus/CAE displays the reference point at the desired location along with its label. You can change the reference point label by selecting **Rename** from the Model Tree. If desired, you can turn off the display of the reference point symbol and the reference point label; for more information, see *Controlling reference point display*.

If the part is a discrete or analytical rigid part, you use the reference point to indicate the rigid body reference point. When you create the assembly, the reference point appears on each instance of the part. You use the Interaction module to apply constraints to the reference point or the Load module to define the motion of the reference point using loads or boundary conditions. Motion or constraints that you apply to the reference point are then applied to the entire rigid part.

Point parts

When you create a part, you can choose the shape of its base feature to be a solid, a shell, a wire, or a point. If you select a point, you must specify the coordinates of the point and Abaqus/CAE creates a part for which the base feature is a point at that location. In addition, the point is the reference point for the part. The modeling space of a point part can be three-dimensional, two-dimensional, or axisymmetric. The type of a point part can be either deformable or rigid.

You can continue to add features to a point part, such as datums and wires. More typically, you will use a point part to simplify your model by replacing a rigid part with a point part that has mass and inertia. You can add mass to a rigid point part; see *Inertia*. In addition, you can attach a display body to the point and use the display body to represent the original rigid part; see *Display bodies*. Finally, you can constrain the point part to your model by modeling a connector such as JOIN or REVOLUTE; see *Connectors*.

What types of features can you create?

After you select the type and shape of the part and sketch the two-dimensional profile of its base feature, you add additional features or modify existing features to create the finished part.

In this section:

- *Solid features*
- *Shell features*
- *Wire features*
- *Cut features*
- *Blend features*

Solid features

To create a solid feature, select **Shape->Solid** from the main menu bar or select one of the solid tools in the Part module toolbox. Once you have sketched the initial profile, you perform one of the following operations to create the feature:

- To create an extruded solid feature, you extrude the profile through a specified distance (*d*), as shown in *Figure 1*.

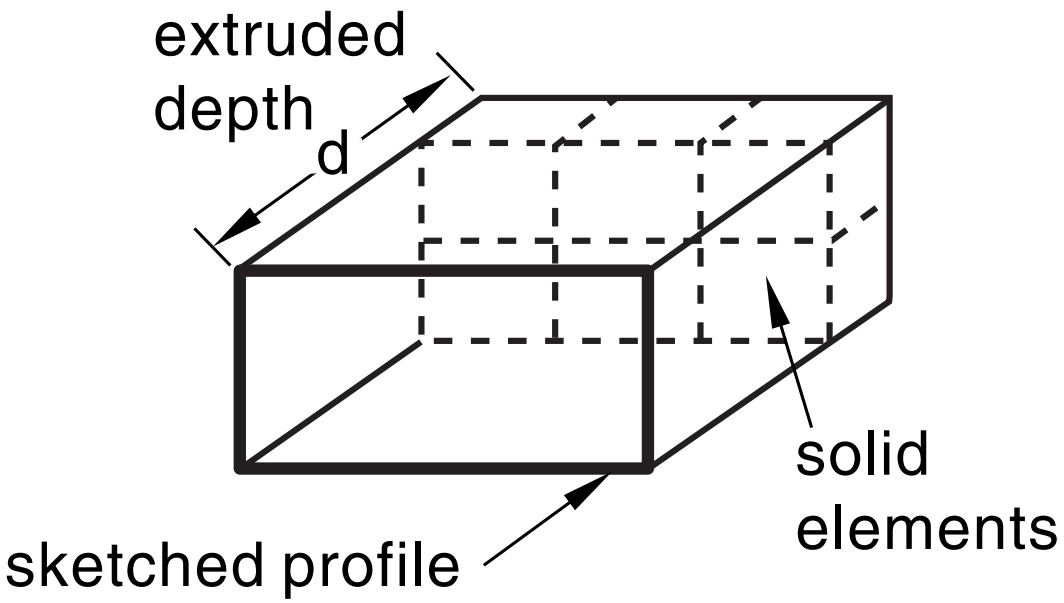

Figure 1: An extruded solid feature.

In addition, you can apply either draft or twist to the extrusion, as shown in *Figure 2*.

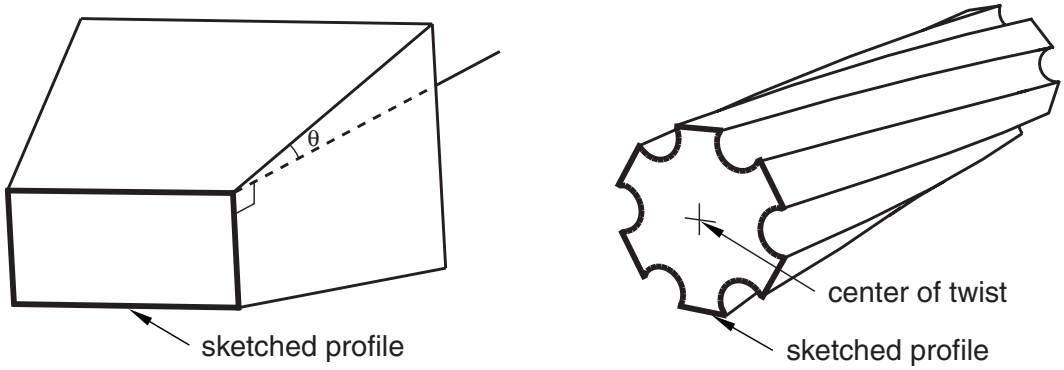

Figure 2: An extruded solid feature with draft and one with twist.

You define the draft angle for an extrusion with draft or the center of twist and the pitch (the extrusion distance in which a 360° twist occurs) for an extrusion with twist. Select **Shape->Solid->Extrude** from the main menu bar to create this type of feature.

- To create a solid loft feature, you transition the shape from the initial loft section to an end section of a different shape or orientation. Abaqus/CAE determines the shape between the start and end sections using tangency constraints, intermediate sections, and a path curve. A simple loft (with only two loft sections, no tangency constraints, and a straight path) is shown in *Figure 3*. Select **Shape->Solid->Loft** from the main menu bar to create this type of feature.

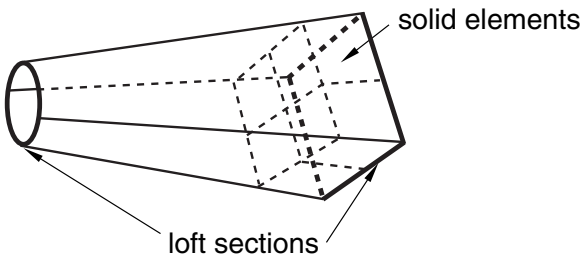

Figure 3: A solid loft feature.

- To create a revolved solid feature, you revolve the profile through a specified angle (α). A construction line serves as the axis of revolution, as shown in *Figure 4*.

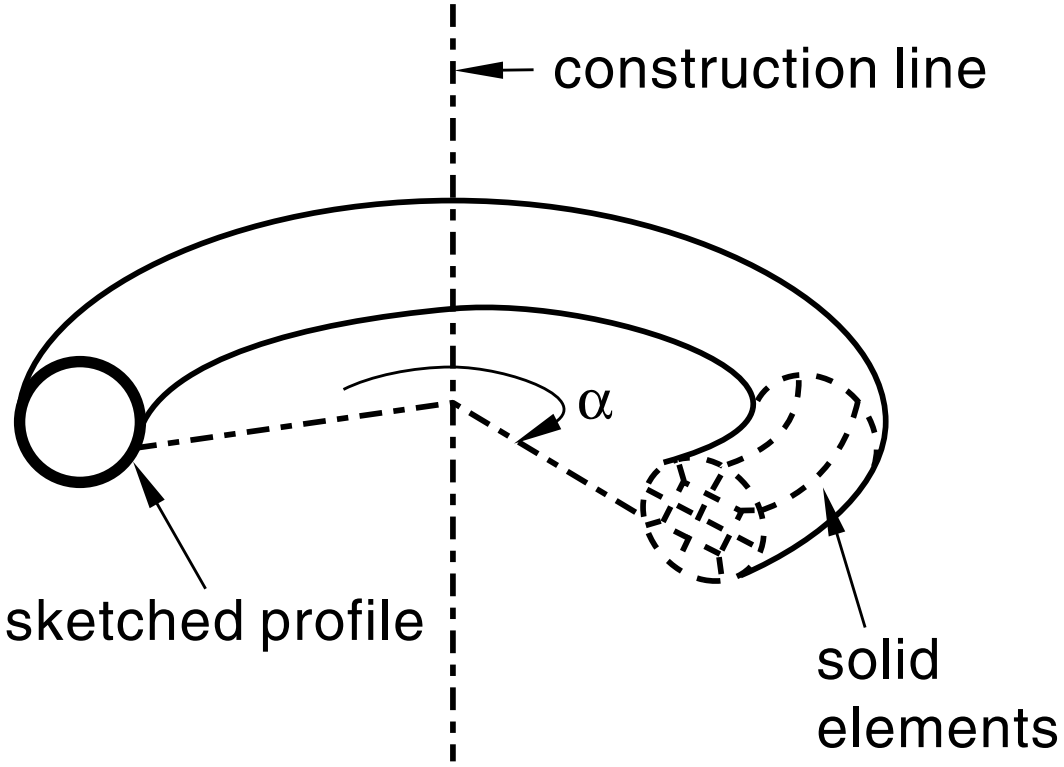

Figure 4: A revolved solid feature.

In addition, you can enter a pitch value (p) to translate the profile along the axis of revolution as it is revolved; *Figure 5* shows a solid revolved 360° with pitch. Select **Shape->Solid->Revolve** from the main menu bar to create this type of feature.

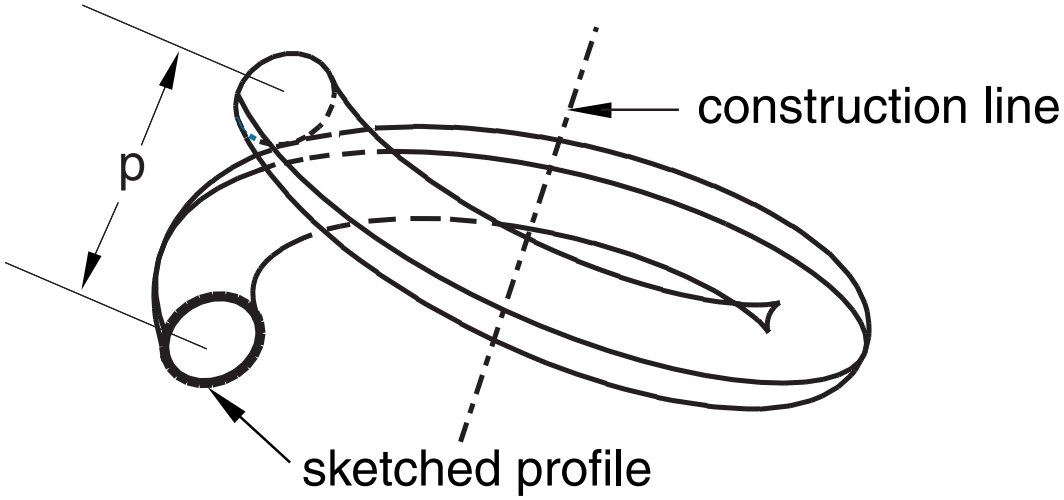

Figure 5: A 360° revolved solid feature with pitch (*p*).

- To create a swept solid feature, you sweep the profile along a specified path, as shown in *Figure 6*. Select **Shape->Solid->Sweep** from the main menu bar to create this type of feature. For more information, see *Defining the sweep path and the sweep profile*.

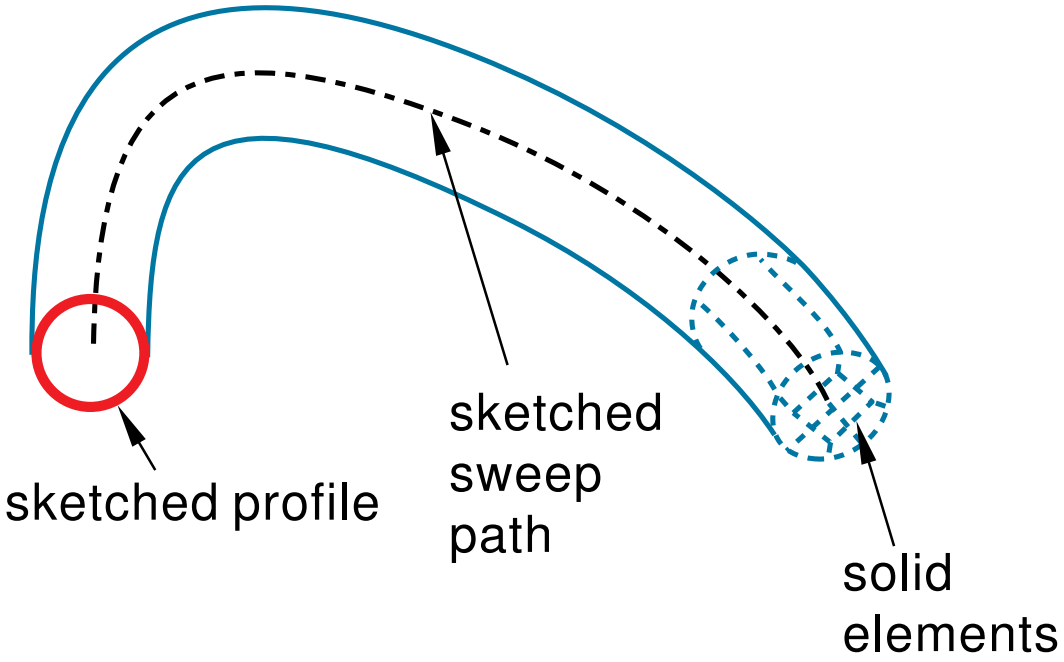

Figure 6: A swept solid feature.

You can use any of the solid tools to add a solid feature to a deformable or discrete part that you created in three-dimensional modeling space. You cannot add a solid feature to a two-dimensional or axisymmetric part.

Figure 1, *Figure 3*, *Figure 4*, and *Figure 6* illustrate how each feature might later be meshed. You can mesh a solid feature using any of the three-dimensional, solid continuum elements available in Abaqus/Standard or Abaqus/Explicit.

Additional information

- *Adding a solid feature*
- *What is feature-based modeling?*
- *Meshing complex solids with hexahedral elements*

Shell features

A shell feature is an idealization of a solid in which thickness is considered small compared to the width and depth. To create a shell feature, select **Shape->Shell** from the main menu bar or select one of the shell tools in the Part module toolbox. You create a shell feature by using the shell tools to do one of the following:

- To create an extruded shell feature, you sketch a profile and extrude it through a specified distance (*d*), as shown in *Figure 1*.

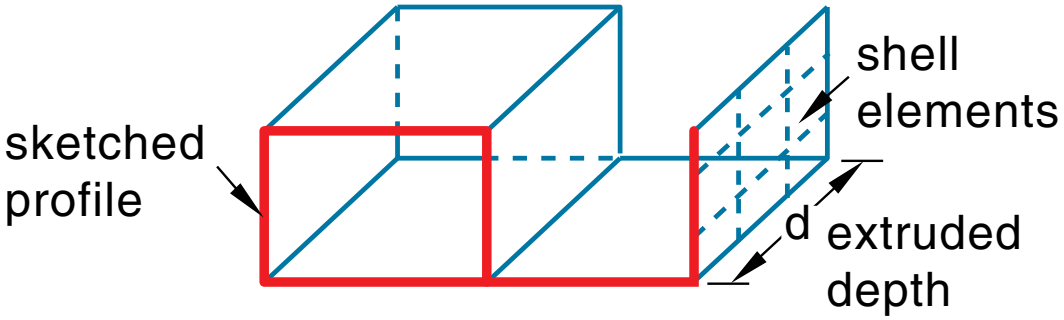

Figure 1: An extruded shell feature.

In addition, you can apply either draft or twist to the extrusion, as shown in *Figure 2*.

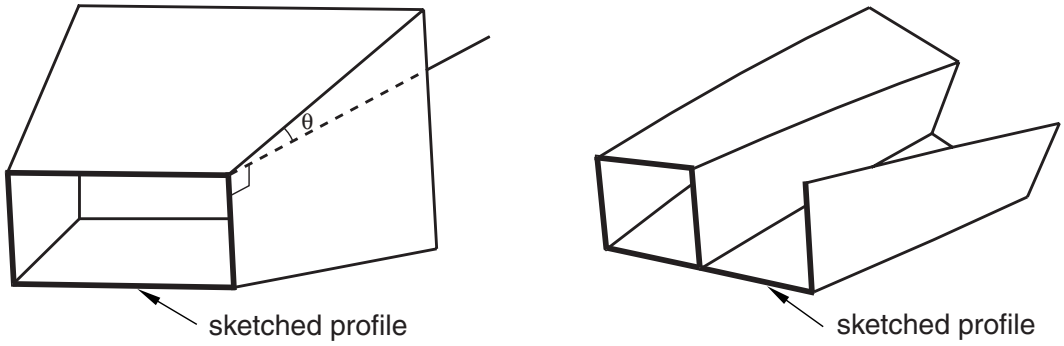

Figure 2: An extruded shell feature with draft and one with twist.

You define the draft angle for an extrusion with draft or the center of twist and the pitch (the extrusion distance in which a 360° twist occurs) for an extrusion with twist. Select **Shape->Shell->Extrude** from the main menu bar to create this type of feature.

- To create a shell loft feature, you transition the shape from the initial loft section to an end section of a different shape or orientation. Abaqus/CAE determines the shape between the start and end sections using tangency constraints, intermediate sections, and a path curve. A simple loft (with only two loft sections, no tangency constraints, and a straight path) is shown in *Figure 3*. Select **Shape->Shell->Loft** from the main menu bar to create this type of feature.

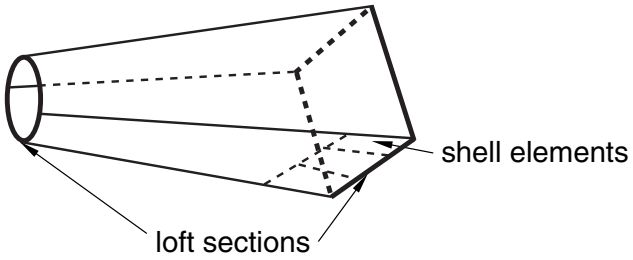

Figure 3: A shell loft feature.

- To create a revolved shell feature, you sketch a profile and revolve it through a specified angle ( ). A construction line serves as the axis of revolution, as shown in *Figure 4*.

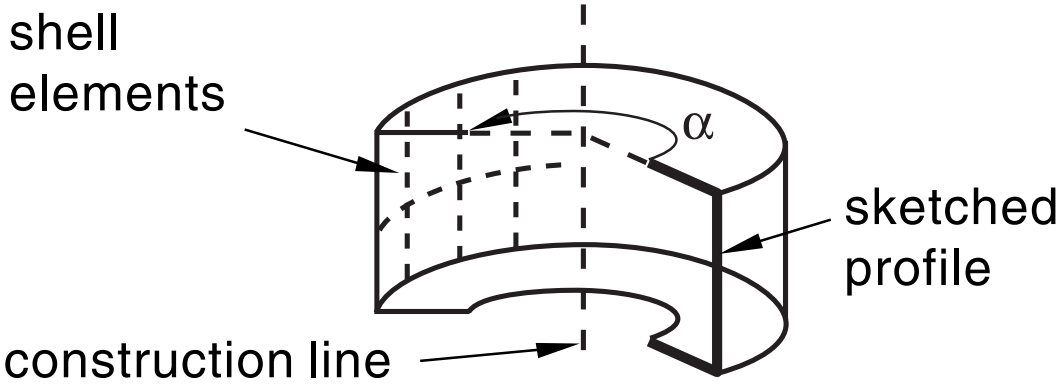

Figure 4: A revolved shell feature.

In addition, you can enter a pitch value to translate the profile along the axis of revolution as it is revolved; *Figure 5* shows a revolved shell with pitch.

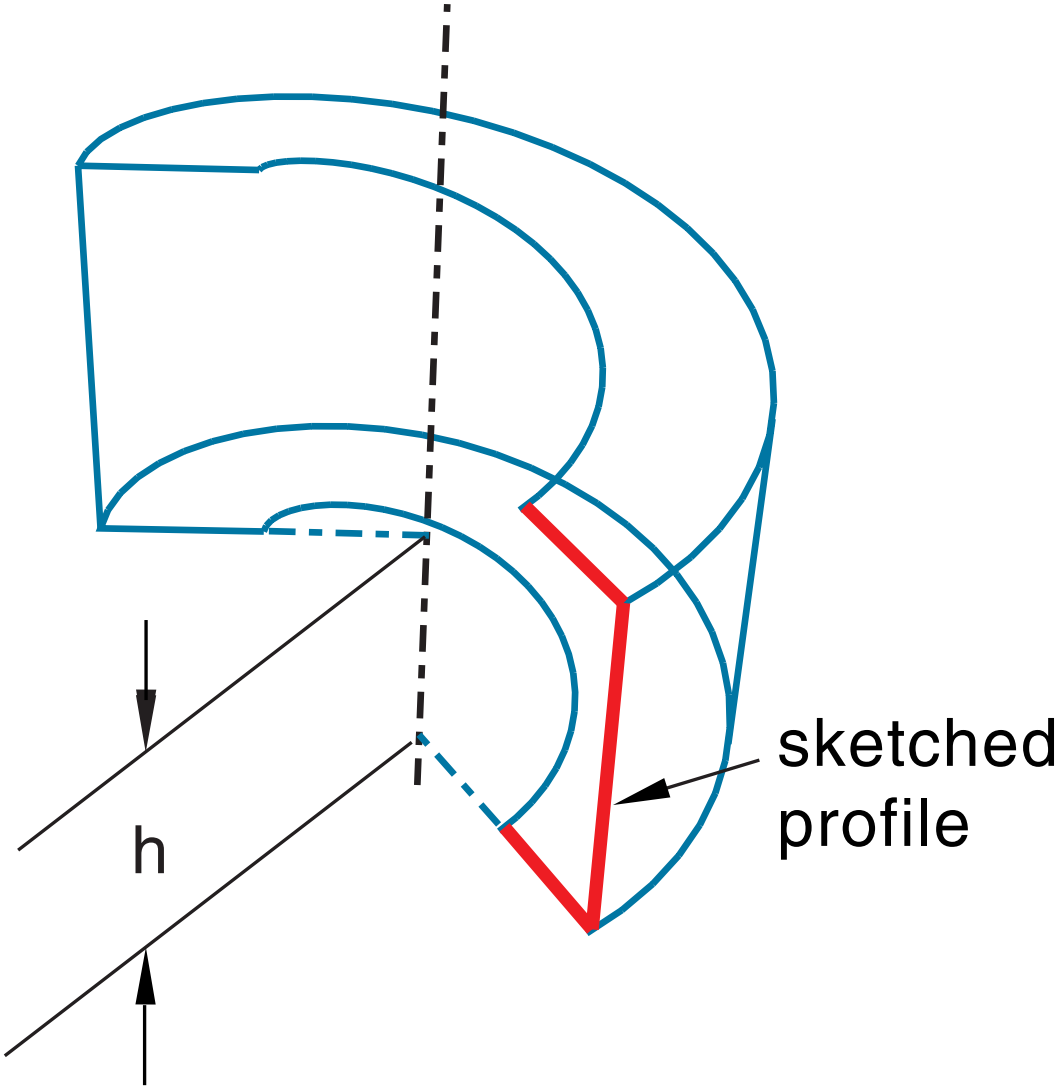

Figure 5: A revolved shell feature with pitch.

The dimension *h* represents the translation of the sketched profile due to pitch; *h* would be equal to the pitch if the part was revolved a full 360°. Select **Shape**->**Shell**->**Revolve** from the main menu bar to create this type of feature.

- To create a swept shell feature, you sketch a profile and sweep it along a specified path, as shown in *Figure 6*.

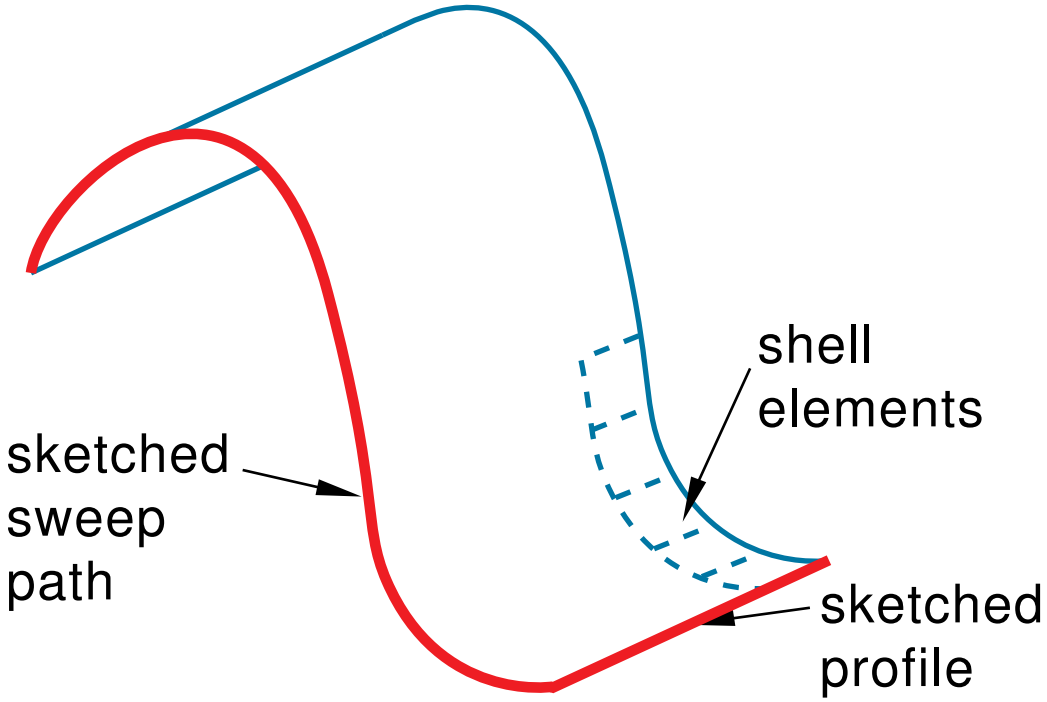

Figure 6: A swept shell feature.

Select **Shape->Shell->Sweep** from the main menu bar to create this type of feature. For more information, see *Defining the sweep path and the sweep profile*.

- To create a planar shell feature, you sketch the outline of the shell on a selected planar face or datum plane, as shown in *Figure 7*.

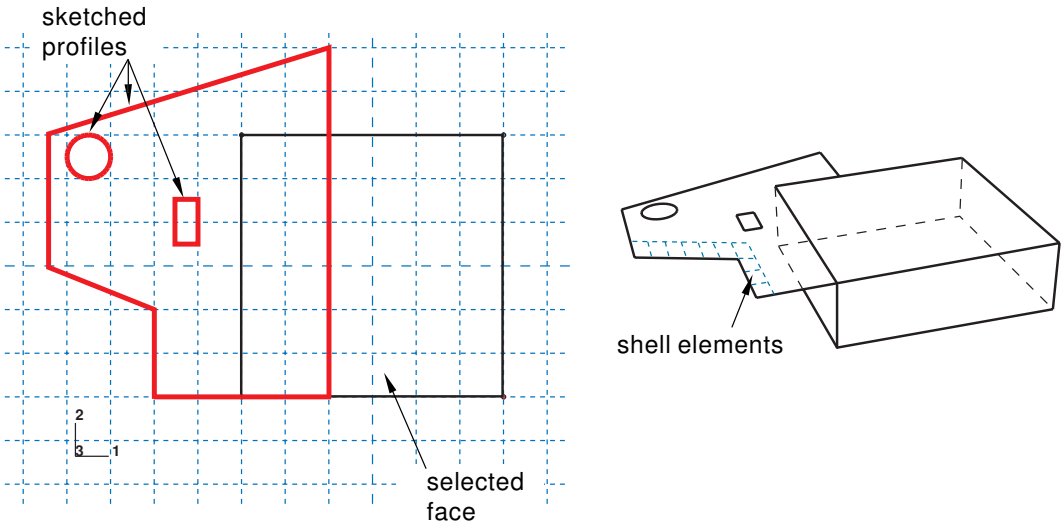

Figure 7: A sketched shell feature.

When you sketch on a planar face (for example, the side of a cube), the shell feature is created only where it extends beyond the face; a shell feature cannot overlap a face. A sketch on a planar face of a cube and the resulting shell feature are shown in *Figure 7*. In this example the shell feature is a fin extending beyond the selected face of the cube. Select **Shape->Shell->Planar** from the main menu bar to create this type of feature.

- To create a shell-from-solid feature, you convert the faces of a solid feature to shell features; in effect, hollow out a solid. A shell-from-solid feature is shown in *Figure 8*. Select **Shape->Shell->From Solid** from the main menu bar to create this type of feature.

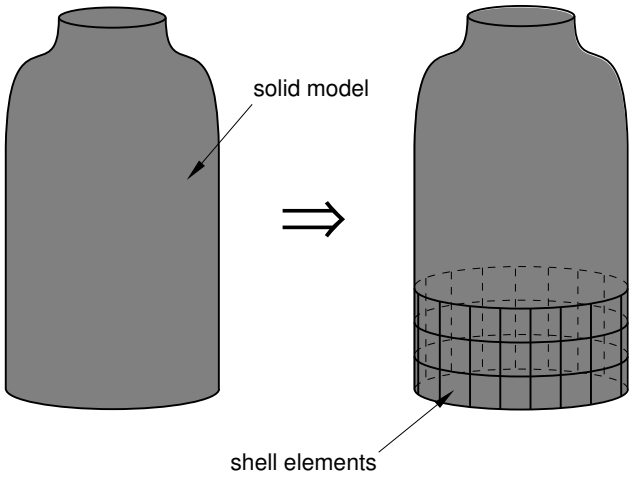

Figure 8: A shell-from-solid feature.

You can use any of the shell tools to add a shell feature to a part that you created in three-dimensional modeling space; however, when you are working on parts created in two-dimensional or axisymmetric modeling space, you can use only the planar shell tool to add a shell feature. You use the Property module to create a section prescribing the desired thickness and to assign the section to the shell feature. For more information, see *Defining sections*, and *Which properties can I assign to a part?*.

Many of the figures illustrate how the shell features might later be meshed. You can mesh a shell feature using:

- Two-dimensional or axisymmetric continuum elements (limited to planar shell features)
- Three-dimensional shell elements
- Membrane elements

Additional information

- *Adding a shell feature*
- *What is feature-based modeling?*

Wire features

A wire is depicted as a line in Abaqus/CAE and is used to idealize a solid in which both its thickness and depth are considered small compared to its length. To create a wire feature, select **Shape->Wire** from the main menu bar or select one of the wire tools in the Part module toolbox. You create a wire feature in the Part module using the wire tools to do one of the following:

- Sketch a wire on a selected planar face or datum plane to create a sketched wire feature, as shown in *Figure 1*. Select **Shape->Wire->Sketch** from the main menu bar to create this type of feature.

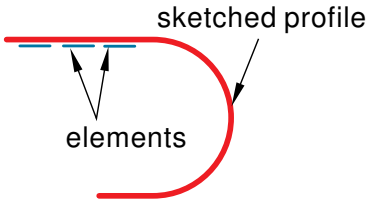

Figure 1: A sketched wire feature.

When you sketch on a planar face (for example, the side of a cube), the wire feature is created only where it extends beyond the face.

- Connect two or more points with straight lines, as shown in *Figure 2*, or with a spline curve, as shown in *Figure 3*. Select **Shape->Wire->Point to Point** from the main menu bar to create this type of feature. Select **Polyline** or **Spline** for the **Geometry Type** to create straight lines or a spline curve, respectively. You can choose to imprint the wire on the existing part by creating edges, merge the wire with the existing part, or create the wire separate from the existing part. The rectangular solid feature in *Figure 3* is shown for reference. The image on the left shows the full length of the spline wire using the **Imprint wire** or **Separate wire** options, while the image on the right shows a spline wire connecting the same set of points using the **Merge wire** option. You can create geometry sets that include the wires and vertices defined in the wire feature.

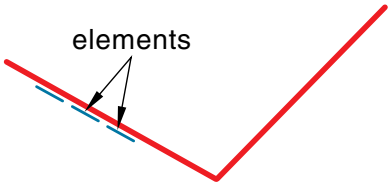

Figure 2: A wire feature connecting three points.

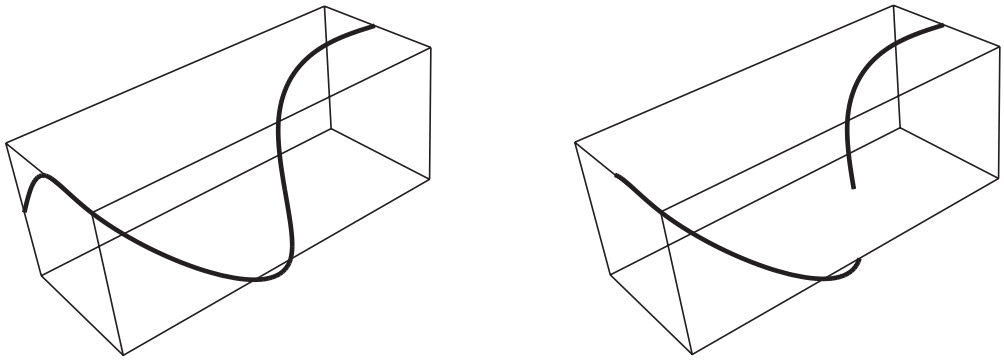

Figure 3: A wire feature connecting several points of a solid feature.

You can use the wire tools to add a wire feature to any deformable or discrete rigid part. You cannot add a wire feature to an analytical rigid part; you can only modify the original sketch that defined that part.

You use the Property module to create a section that prescribes the desired cross-sectional geometry and to assign that section to the wire feature. (For more information, see *Defining sections*, and *Which properties can I assign to a part?*.) You can model a wire feature using any of the beam, truss, or axisymmetric shell elements available in Abaqus/Standard or Abaqus/Explicit.

Note:

Although you can create a mesh of beam elements, the current release of Abaqus/CAE allows you to assign only the following sections to a wire:

- Beam section
- Truss section

Additional information

- *Adding a wire feature*
- *What is feature-based modeling?*

Cut features

A cut is a feature that removes material from a part. A cut can be a circular hole, or it can be any arbitrary shape. The sketched profile of any cut must be closed. In many cases the entire profile will affect the shape of the cut feature, even if it does not initially contact the surface being cut. To create a cut feature, select **Shape->Cut** from the main menu bar or select one of the cut tools in the Part module toolbox.

Note:

Most of the figures do not show a closed cut profile where it intersects with the part surface. These lines have been removed to show the shape of the cut feature.

Once you have sketched the initial profile, you perform one of the following operations to create a cut feature:

- To create an extruded cut, you extrude the profile through a specified distance (*d*), as shown in *Figure 1*.

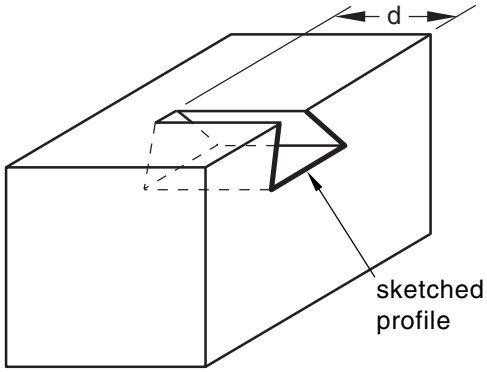

Figure 1: An extruded cut feature.

In addition, you can apply either draft or twist to the extruded cut, as shown in *Figure 2*. You define the draft angle for an extruded cut with draft or the center of twist and the pitch (the extrusion distance in which a 360° twist occurs) for an extruded cut with twist. Select **Shape->Cut->Extrude** from the main menu bar to create this type of feature.

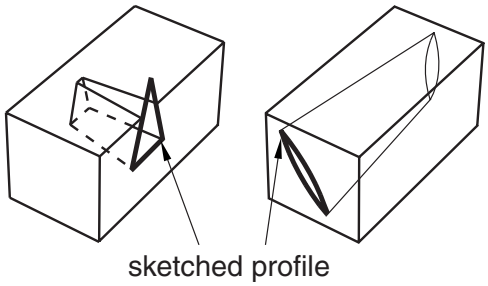

Figure 2: Extruded cut features with draft and twist.

- To create a cut loft feature, you transition the shape from the initial loft section to an end section of a different shape or orientation, as shown in *Figure 3*. Abaqus/CAE determines the shape between the start and end sections using tangency constraints, intermediate sections, and path curves. Select **Shape->Cut->Loft** from the main menu bar to create this type of feature.

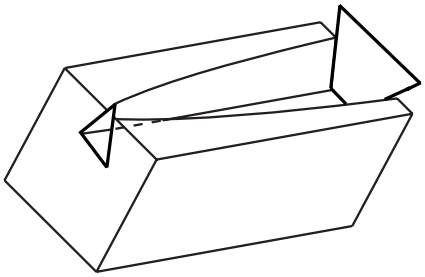

Figure 3: A cut loft feature.

- To create a revolved cut, you revolve the profile through a specified angle ( ). A construction line serves as the axis of revolution. In addition, you can enter a pitch value to translate the profile along the axis of revolution as it is revolved and to create part details such as screw threads. *Figure 4* shows a revolved cut and a revolved cut with pitch. Select **Shape->Cut->Revolve** from the main menu bar to create this type of feature.

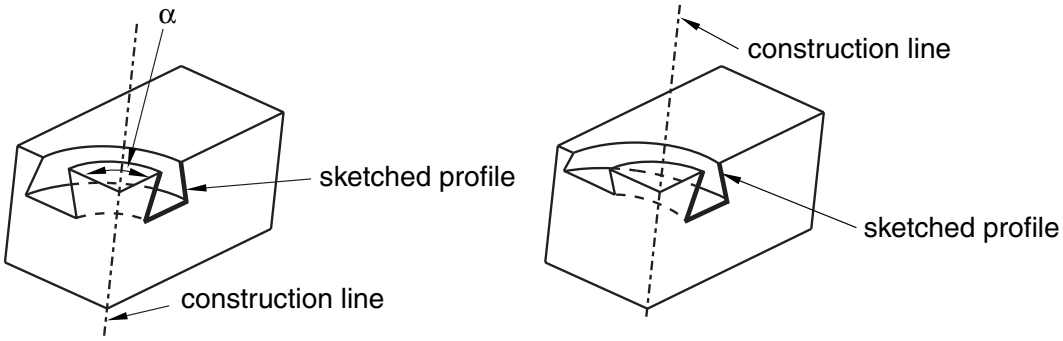

Figure 4: A revolved cut and a revolved cut with pitch.

- To create a swept cut, you sweep the profile along a specified path, as shown in *Figure 5*. Select **Shape->Cut->Sweep** from the main menu bar to create this type of feature. For more information, see *Defining the sweep path and the sweep profile*.

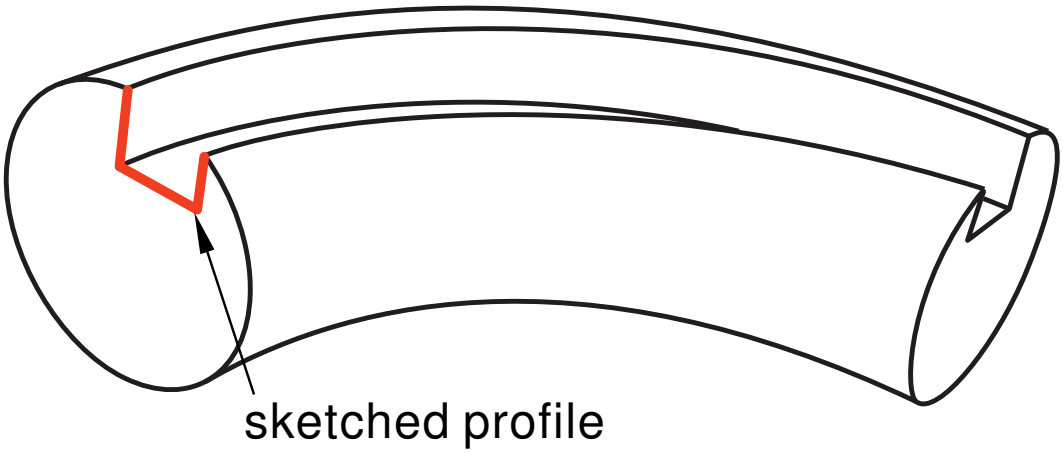

Figure 5: A swept cut feature.

- To create a circular hole, you enter the diameter of a hole and the distance of its center from two selected edges, as shown in *Figure 6*. Select **Shape->Cut->Circular Hole** from the main menu bar to create this type of feature.

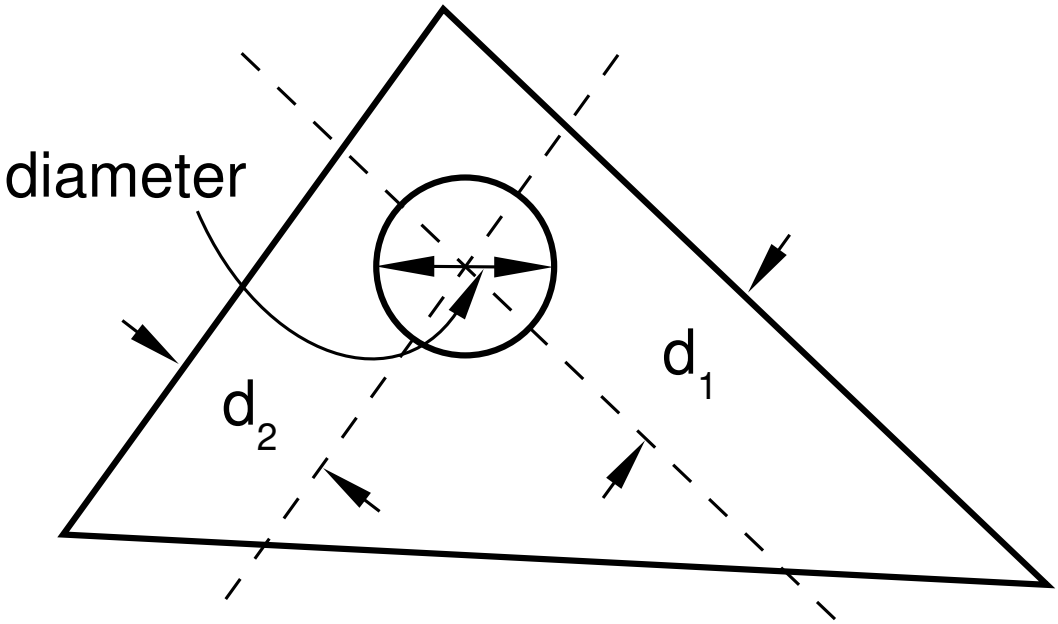

Figure 6: A circular hole feature.

When you are sketching the profile of an extruded, revolved, or swept cut, you can sketch multiple profiles in a single sketch. Abaqus/CAE extrudes each of the profiles when you exit the Sketcher and creates a cut corresponding to each profile as shown in *Figure 7*.

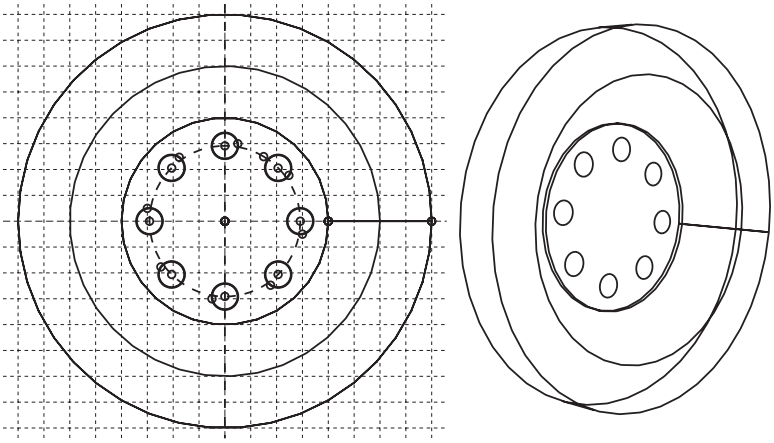

Figure 7: Multiple profiles extruded from a single sketch.

The sequence of cuts is stored as a single feature, and you can edit it only as a single feature. For example, if you change the extrusion depth, the depth will change for all the cuts in the feature.

You can use the cut tools to add a cut feature to any deformable or discrete rigid part. You cannot add a cut feature to an analytical rigid part; you can only modify the original sketch that defined that part.

Additional information

- *Adding a wire feature*
- *What is feature-based modeling?*

Blend features

A blend feature smooths an edge of a three-dimensional solid part. To create a blend feature, select **Shape->Blend** from the main menu bar or select one of the blend tools in the Part module toolbox. You create a blend feature in the Part module using the blend tools to do one of the following:

- Smooth an edge with a circular blend of a specified radius, as shown in *Figure 1*. Select **Shape->Blend->Round/Fillet** from the main menu bar to create this type of feature.

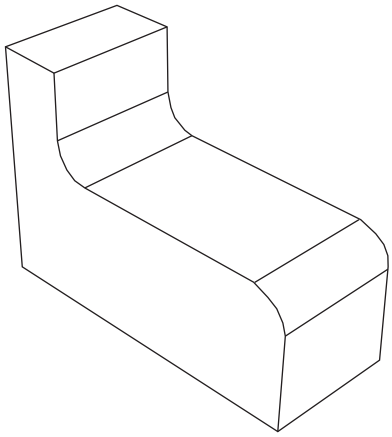

Figure 1: A round/fillet blend feature.

- Bevel an edge with a chamfered blend of a specified length, as shown in *Figure 2*. Select **Shape->Blend->Chamfer** from the main menu bar to create this type of feature.

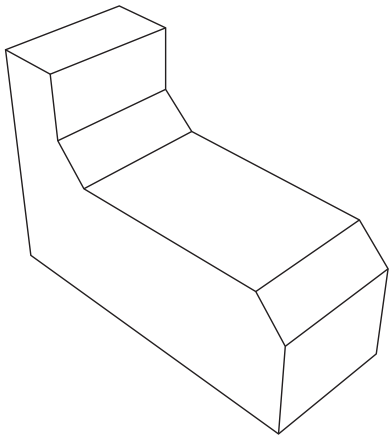

Figure 2: A chamfer blend feature.

You can use the blend tools to blend edges of a deformable or discrete rigid part that you created in three-dimensional modeling space. You cannot add a blend feature to a two-dimensional or axisymmetric part; however, you can blend its corners by editing the sketch of the part.

- *Adding a wire feature*
- *What is feature-based modeling?*

Using feature-based modeling effectively

You can devise a more efficient approach to creating a part if you understand how Abaqus/CAE uses feature-based modeling and how the rules that define a feature are applied. The following techniques will help you create robust parts that can be modified easily:

Plan a strategy

Feature-based modeling provides flexibility, but it can also add overhead to your model. For example, you can suppress an extrusion using the suppress tool in the Feature Manipulation toolset. Alternatively, you could effectively suppress the extrusion by removing it with a cut feature. Although you could restore the extrusion subsequently by removing the cut feature, the resulting part contains additional feature-based information that can slow down regeneration. Regeneration speed can be improved by using the geometry cache to save parts in different states, but the cache uses system memory that may be needed for other operations (for more information, see *Tuning feature regeneration*). In addition, dependencies may cause feature regeneration to fail if you add more detail to the part; and, because the extrusion is no longer visible, the cause of the failure to regenerate may be hard to determine.

Before you decide how to create a part, you should always consider if you will ever need to modify the part in the future. If you decide that you might need to modify the part, you should consider the techniques that you will use to create the features that define the part. The simplest techniques may not provide the flexibility you need for modifying the features. You may find it cumbersome to edit or suppress individual items of geometry, such as an extrusion, a fillet, or a hole.

Alternatively, if you know that you will never change the final design, you may not need the flexibility provided by feature-based modeling and can use the simplest and most convenient techniques to define the part.

In general, you should try to finish creating your parts in the Part module before you start creating part instances and positioning them in the assembly. You should try to finish creating all your parts before you apply attributes to the assembly, such as sets, loads, and boundary conditions. If you apply attributes to the assembly and then return to the Part module to modify the original part, Abaqus/CAE may not be able to determine where the attribute should be applied. For example, if you apply a pressure load to a face and then return to the Part module to partition the face into two regions, Abaqus/CAE will apply the pressure to only one of the regions.

Use reference geometry

When you are adding a feature to a part, you should always use underlying reference geometry to define the new feature's location relative to existing features. While sketching a feature, you may be able to select reference geometry directly; for example, if you are sketching a circle, you may be able to select a vertex from the reference geometry to define its center. Alternatively, you may have to add a dimension between reference geometry and the new feature. If you do not use reference geometry to position the sketch of a new feature and you subsequently modify the part, the resulting changes to the feature can be unpredictable.

Use dimensions

Dimensions add clarity to the sketches that define features and document your design intent for future reference. Dimensions also add constraints to your sketches. You can modify dimensions in the Sketcher, and the part and assembly will regenerate accordingly.

Pay attention to the order in which you create features

A new feature of a part is aware of existing features. In addition, if the new feature depends on an existing feature for positioning information, Abaqus/CAE creates a parent-child relationship between the features. Parent-child relationships and the order in which you created features play an important role in feature regeneration.

A modeling scheme that is carefully ordered and follows the sequence below is less likely to run into unnecessary or ill-conditioned modeling problems:

1. Create the basic geometry of a part using extrusions, revolutions, cuts, and sweeps.
2. Add extruded, revolved, swept, and planar features.
3. Add round or fillet features.
4. Add partitions only when the rest of the geometry is complete.

Allow for some overlap

If possible, you should allow for overlap between an existing feature and a feature that fills a hole or cuts a hole. Allowing for overlap makes your part robust, and the features are more likely to regenerate successfully. For example, when you cut a slot, extend its sketched profile above the surface you are cutting, as shown in *Figure 1*.

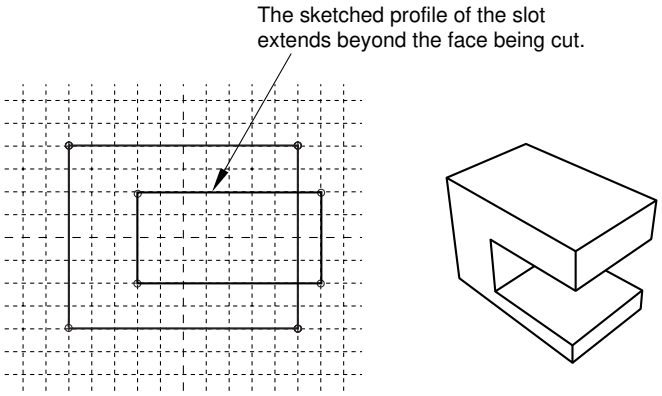

Figure 1: The sketched profile of a slot should extend beyond any surfaces that are cut.

Create solids where possible

Solid features are more robust than shell features. You may find it hard to position a group of shell features and match up the edges precisely. In contrast, sections of a solid can overlap and tolerance becomes less critical. Another advantage of using a solid is that you can use round and chamfer features to define the geometry. If you are modeling a shell, you should try to create solid features and convert the solids to shells when you have finished defining the shape. In addition, if you subsequently want to add additional shell features to a shell part, where the shell part was generated from a solid, you should do the following:

1. Delete the last solid-to-shell feature to convert the model back to a solid.
2. Add your new solid features.
3. Create a new solid-to-shell feature to convert the model back to a shell.

Additional information

- *What is feature-based modeling?*
- *Modifying and manipulating features*
- *Capturing your design and analysis intent*

Capturing your design and analysis intent

If used carefully, the feature-based modeling approach used by Abaqus/CAE allows you to capture both your design and analysis intent.

Design intent is the capability to make changes based on design considerations. For example, when you add a cut feature, you can select either a through cut or a blind cut. If the cut feature represents a bolt hole, you know that the hole must always pass completely through the part. As a consequence, you should select a through cut, and Abaqus/CAE recognizes that the hole remains through even when you change the thickness of the part.

Analysis intent is the capability to make changes based on analysis considerations. Although Abaqus/CAE allows you to create parts with complex, detailed geometry, your final goal is usually a finite element analysis of a meshed representation of the part. Excessive detail, such as fillets and small holes, can lead to regions with a very fine mesh that will, in turn, dominate the time taken by Abaqus/Standard or Abaqus/Explicit to reach a solution. The amount of detail you provide when you create a part in the Part module should be a reflection of your goals. Alternatively, you can create a part with detailed features but suppress them prior to meshing the assembly. For example, if a model takes several hours to analyze, you may wish to simplify it by suppressing features; you could then submit an analysis that runs faster and checks your basic modeling assumptions. If the simplified model behaves as expected, you can unsuppress the features and resubmit a full analysis.

For an example of different feature-based design approaches based on design and analysis intent, consider the cover plate shown in *Figure 1*.

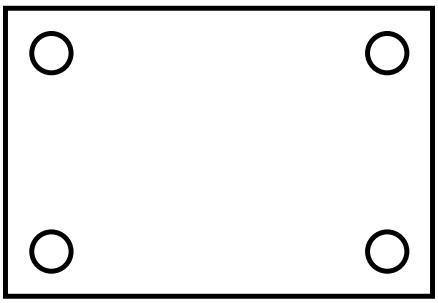

Figure 1: A model of a cover plate.

You could create the three-dimensional shell that models the plate in several ways:

1. Sketch a base feature that includes the four holes.
2. Sketch a rectangular base feature, and add four separate cut features.
3. Sketch a rectangular base feature, and add a single cut feature that cuts all four holes.

Either of the three approaches would generate the same part, but your design intent and your analysis intent govern the best approach. For example:

- Do you want to create and analyze plates of varying sizes with different sized holes for different applications? If the diameter of all four holes is always identical, you should create all four holes as a single cut feature. However, if the diameter of individual holes might differ, you should create four separate cut features.
- Do you want to suppress features before you finalize your design? For example, you could perform a series of analyses with the holes suppressed to determine the desired plate thickness. You could then unsuppress the holes and analyze the finished model. In addition, suppressing features may simplify the mesh that Abaqus/CAE generates, or suppressing features may make the assembly sweep meshable.

  If you want to suppress all four holes in the example of the rectangular cover plate, you should create all four holes as a single cut feature. However, if you want to suppress individual holes, you should create four separate cut

features. If the analysis is straightforward and you do not need to analyze a simplified model, you should sketch a base feature that includes the four holes.

What is part and assembly locking?

Part and assembly locking is an Abaqus/CAE function that prevents any changes to the features of a part or to the features of the assembly. You can lock parts or the assembly to prevent accidental changes, such as when sharing a model with other Abaqus users or when working on a model that contains many similar parts. You must unlock a part or the assembly if you plan on modifying it.

Note:

Part and assembly locking is not a security feature; any user can unlock and modify parts and assemblies that were locked by another user.

You can click mouse button 3 on a part or on the assembly in the Model Tree and use the menu that appears to lock and unlock the feature. A padlock before the feature name in the Model Tree indicates that a part or the assembly has been locked by the user or by a database upgrade. For more information, see *Using the Model Tree to manage features*.

Alternatively, you can use the **Part Manager** to lock or unlock any part in a model. If the part is unlocked, the **Status** field is empty in the **Part Manager**. If the part is locked, the **Status** field indicates one of two conditions:

Locked (Database upgrade)

Abaqus/CAE locked the part automatically while upgrading the model from a previous release of Abaqus.

Locked

A user locked the part using the Model Tree or the **Part Manager**.

Abaqus/CAE automatically locks the assembly and all the parts in a model when it upgrades a database from an older release of Abaqus. Locking the assembly and the parts allows Abaqus/CAE to complete the upgrade faster than if the assembly and all the parts were also regenerated. If you unlock a part that was locked by a database upgrade, Abaqus/CAE regenerates that part. Similarly, if you unlock an assembly that was locked by a database upgrade, Abaqus/CAE regenerates the assembly.

Warning:

If a part is locked due to a database upgrade, you should unlock the part prior to making any changes to set or property definitions. If you unlock the part after making modifications, your changes can become invalid when Abaqus/CAE regenerates the part.

If you unlock a part that you locked with the Model Tree or the **Part Manager**, Abaqus/CAE does not regenerate the part because it could not be modified while it was locked. Similarly, Abaqus/CAE does not regenerate the assembly when you unlock it after locking it with the Model Tree. If a part that you unlock fails to regenerate, both the locked version and the unlocked version are retained. You can recreate missing features on the unlocked version of the part and use it to replace the locked part throughout the model.

You can instance a locked part and use it in the assembly. In addition, you can add or delete set or property definitions to a locked part or to a locked assembly. However, you must unlock a part or the assembly before you can add features to it or edit existing features.

What are extruding, revolving, and sweeping?

The following sections describe the techniques you can use to extrude, revolve, and sweep a two-dimensional sketch to create a three-dimensional part or feature.

In this section:

- *Defining the extrusion distance*
- *Controlling the direction of an extruded feature*
- *Including twist in an extrusion*
- *Including draft in an extrusion*
- *Defining the axis of revolution for axisymmetric parts and for revolved features*
- *Controlling the direction of a revolved feature*
- *Controlling the cross-section of a revolved feature with pitch*
- *Defining the sweep path and the sweep profile*

Defining the extrusion distance

You can sketch a two-dimensional profile and extrude it to create the following:

- A three-dimensional extruded solid feature.
- A three-dimensional extruded shell feature.
- A three-dimensional extruded cut feature.

Abaqus/CAE provides the following methods for defining the extrusion distance:

Blind

Specify the distance over which Abaqus/CAE extrudes the sketch. The sketch and the distance define the feature and can be edited using the Feature Manipulation toolset. You can use this method when creating extruded solid, shell, and cut features. *Figure 1* illustrates a blind extruded cut in a solid part.

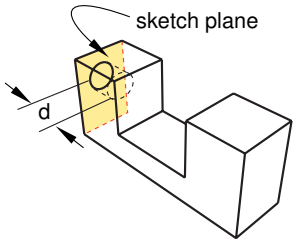

Figure 1: A blind extruded cut.

Up to Face

Select a single face to which Abaqus/CAE extrudes the sketch. The selected face does not have to be parallel to the sketch plane. The selected face can be a nonplanar face; however, it must completely contain the extruded section. If you select this method to define the extrusion distance, only the sketch can be modified using the Feature Manipulation toolset; if you wish to extrude to a different face, you must create a new extruded cut feature. You can use this method when creating extruded solid, shell, and cut features. *Figure 2* illustrates a sketch extruded to a nonplanar face.

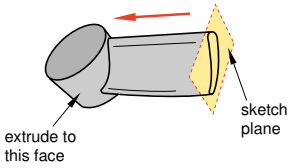

Figure 2: A solid feature extruded up to a nonplanar face.

Through All

This method is available only for extruded cut features. Abaqus/CAE extrudes the sketch defining the profile of the cut completely though the part. If you select this method to define the extrusion distance, only the sketch can be modified using the Feature Manipulation toolset. *Figure 3* illustrates a through all cut in a solid part.

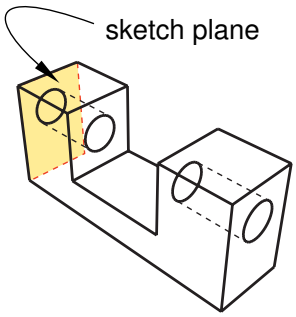

Figure 3: A through all extruded cut.

Controlling the direction of an extruded feature

When you add an extruded feature to a three-dimensional part, Abaqus/CAE chooses a default direction of extrusion from the sketched profile based on the type of feature you are creating. By default, a solid or shell feature is extruded outward such that material is added to the existing base feature. Conversely, a cut feature is extruded inward such that material is removed from the existing base feature.

You can control the direction of an extruded feature as follows:

Choosing the direction while adding an extruded feature

When you complete the sketch to add an extruded feature to an existing part, Abaqus/CAE displays the new sketched profile on the original part. The sketched profile includes an arrow that indicates the extrusion direction. Abaqus/CAE also displays the **Edit Extrusion** dialog box.

You can control the direction of extrusion by clicking  in the **Edit Extrusion** dialog box. The arrow in the viewport changes direction to show the new extrusion direction.

Editing the direction of an existing extruded feature

When you select an extruded feature to edit, Abaqus/CAE highlights the selected feature in the viewport and the **Edit Feature** dialog box appears.

You can reverse the direction of extrusion by toggling **Flip extrude direction** in the **Edit Feature** dialog box. Abaqus/CAE does not display an arrow that indicates the direction of extrusion; however, you can click **Apply** to view your changes. When the direction is acceptable, click **OK** to end the editing process.

You cannot change the direction of extrusion when you are creating a new part because the part would be identical regardless of the direction.

Additional information

- *Adding an extruded solid feature*
- *Adding an extruded shell feature*
- *Creating an extruded cut*

Including twist in an extrusion

You can choose to include twist during the creation of an extrusion. Twist can be used to create twisted cables, helical gears, and other complex shapes that can be formed by passing a constant cross-section through a sequence of parallel planes. Twist modifies an extrusion by rotating the sketched profile about an axis parallel to the direction of extrusion. The center of twist is an isolated point in the sketched profile; it is the point at which the axis used to twist the extrusion passes through the sketch plane. The pitch defines the extrusion distance in which the profile would be twisted by 360°. You can modify the extrusion profile, extrusion direction, center of twist, and pitch using the Feature Manipulation toolset.

You can add twist during the creation of extruded solid, shell, and cut features. *Figure 1* illustrates a twisted extrusion.

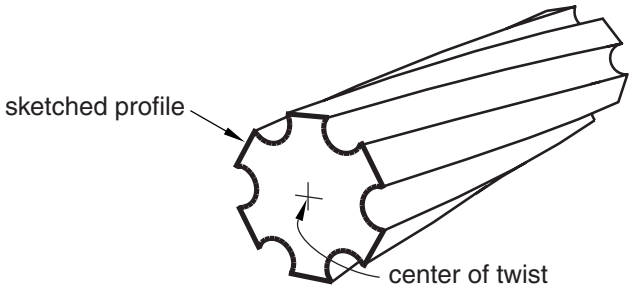

Figure 1: A solid feature extruded with twist.

If you want to create complex shapes in which the sketched profile is revolved rather than extruded, such as screw threads or coil springs, you can include pitch in a revolved solid, shell, or cut feature. See *What types of features can you create?*, for basic information about all the available feature types and *Defining the axis of revolution for axisymmetric parts and for revolved features*, for more information about revolved features.

Additional information

- *Adding an extruded solid feature*
- *Adding a revolved solid feature*
- *Adding an extruded shell feature*
- *Adding a revolved shell feature*
- *Creating an extruded cut*
- *Creating a revolved cut*
- *Meshing complex solids with hexahedral elements*

Including draft in an extrusion

You can choose to create an extrusion with draft. Draft can be used to accurately represent the small angle often applied to ease the removal of cast or molded parts from the tooling. Draft in an extrusion can also be used to create tapered parts.

In a straight extrusion the draft angle is 0°, so all extruded surfaces are perpendicular to the original profile. Draft modifies an extrusion by adjusting the angle between the extruded surfaces and the original sketch plane. Abaqus/CAE reverses the application of draft angle from internal to external features. If external loops in a sketched profile are expanding, internal ones are contracting; this behavior is expected for draft and is required for part removal from tooling (all surfaces taper in the same direction).

You can modify draft, along with the extrusion profile and direction, using the Feature Manipulation toolset. You can add draft during the creation of extruded solid, shell, and cut features. *Figure 1* illustrates an extruded cut with draft in a solid part.

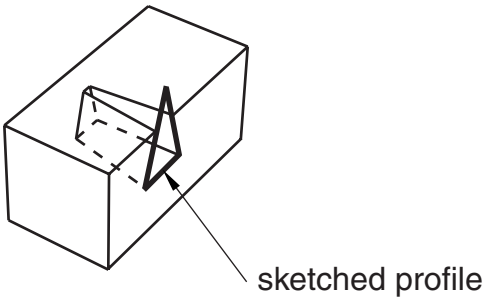

Figure 1: A cut feature extruded with draft.

Note:

The complete sketched profile for the cut in *Figure 1* is a triangle, as shown. If the profile were a trapezoid whose top edge coincided with the edge of the block, the cut would look very different. As the profile was extruded, the application of draft made it smaller. The top face of a trapezoid profile would immediately fall below the surface of the block instead of extending through the top surface.

Abaqus/CAE cannot mesh an extruded solid that includes draft with hexahedral elements unless you partition the solid into structured regions.

Defining the axis of revolution for axisymmetric parts and for revolved features

When you create an axisymmetric part and when you add a revolved feature to a part, the sketch of the profile must include a construction line that defines the axis of rotation. The following rules apply to the sketch and to the construction line:

Creating an axisymmetric part

You can create axisymmetric parts that are defined by either a shell or a wire along with an axis of symmetry by selecting **Part->Create** from the main menu bar. Abaqus/CAE allows you to include a twist degree of freedom in your model when you create an axisymmetric part.

When you sketch the part's base feature, Abaqus/CAE displays a vertical construction line on the *Y*-axis of the sketch representing the axis of symmetry. You must sketch only to the right of the line. Your sketch can touch this line but cannot cross it.

You can add only shell and wire features to an axisymmetric base feature. Abaqus/CAE displays the original sketch and construction line when you add a feature, and the same rules apply—you cannot delete this construction line, and you must sketch only to the right of it.

Creating revolved features

You can create three-dimensional parts with a revolved solid or a revolved shell base feature by selecting **Part->Create** from the main menu bar. Similarly, you can add revolved solids, shells, and cuts to three-dimensional solids and shells by selecting **Shape->Solid->Revolve**, **Shape->Shell->Revolve**, or **Shape->Cut->Revolve** from the main menu bar.

The sketch of a revolved feature must contain a construction line representing the axis of revolution. When you create a new revolved part, Abaqus/CAE creates a vertical construction line through the origin of the Sketcher grid. If desired, you can delete this construction line and redraw it at a new angle and position. In contrast, when you add a revolved feature to an existing part, you must sketch the construction line representing the axis of revolution. You can sketch to the right or to the left of the construction line. Your sketch can touch this line but cannot cross it. If the completed sketch contains more than one construction line, Abaqus/CAE prompts you to select the line that will represent the axis of revolution.

When you are sketching the construction line that represents the axis of revolution, you can position the construction line by selecting a datum axis from the underlying part if one exists. You cannot select the datum axis directly; you must select a point from either end of the datum axis. You can use the datum axis to create concentric features.

When you exit the Sketcher, Abaqus/CAE opens a dialog box to complete the definition of the revolved feature. You enter the angle through which the profile will be revolved and the direction of revolution, and you can choose whether to translate the profile along the axis of revolution by including pitch. You can also specify the direction of translation. The pitch value is the distance through which the profile would be translated during a rotation of 360°. Pitch allows the creation of parts such as coil springs and part details such as screw threads.

If you want to create complex shapes in which the sketched profile is extruded rather than revolved, such as twisted cables or helical gears, you can include twist in an extruded solid, shell, or cut feature. See *What types of features can you create?*, for basic information about all the available feature types and *Defining the extrusion distance*, for more information about extruded features.

Additional information

- *Adding an extruded solid feature*
- *Adding a revolved solid feature*
- *Adding an extruded shell feature*

- *Adding a revolved shell feature*
- *Creating an extruded cut*
- *Creating a revolved cut*

Controlling the direction of a revolved feature

When you create a part with a revolved base feature or add a revolved feature to a three-dimensional part, you can control the direction of revolution. If you include pitch in a revolved feature, you can also control the direction of translation. The descriptions that follow provide the details of controlling both the direction of revolution and, if applicable, the direction of translation for any revolved feature that you create in Abaqus/CAE:

Choosing the direction while creating a revolved feature

When you complete the sketch to create a revolved feature, Abaqus/CAE displays the sketched profile including an arrow that indicates the direction of revolution. If you are creating a part with a revolved base feature, the axis of revolution is also displayed. In addition, Abaqus/CAE displays the **Edit Revolution** dialog box.

If desired, rotate the view until you can discern the arrow direction that indicates the direction of revolution.

You can reverse the direction of revolution by clicking  for **Revolve direction** in the dialog box. The arrow in the viewport changes direction to show the new direction of revolution.

If you select **Include translation** for the revolved feature, a second arrow appears in the viewport to indicate the direction of translation along the axis of revolution. Click  for **Pitch direction** in the dialog box to reverse the direction of translation. Similar to the change for the direction of revolution, the corresponding arrow in the viewport changes direction to show the new translation direction.

Editing the direction of an existing revolved part or feature

When you select a revolved feature to edit, Abaqus/CAE highlights the selected feature in the viewport and the **Edit Feature** dialog box appears.

To reverse the direction of revolution, toggle **Flip revolve direction** in the **Edit Feature** dialog box. Click **Apply** to view your changes.

If the revolved feature you are editing includes pitch, you can edit the direction of translation. Toggle **Flip pitch direction** to reverse the direction of translation. Click **Apply** to view your changes.

Click **OK** to accept the changes.

Additional information

- *Adding a revolved solid feature*
- *Adding a revolved shell feature*
- *Creating a revolved cut*
- *Meshing complex solids with hexahedral elements*

Controlling the cross-section of a revolved feature with pitch

When you create a revolved feature without pitch, the sketched profile is swept about a circular path described by the radius between the axis of revolution and the sketch. The cross-section of the revolved feature is the sketch; the cross-section is both parallel to the axis of revolution and normal to the circular path at all times.

When you include pitch in a revolved feature, the path of the sketch becomes helical instead of circular. You can choose to keep the sketch parallel to the axis of revolution, or you can choose to rotate the sketch normal to the helical path.

To make your sketched profile normal to the helical path of the revolved feature with pitch, toggle on **Sweep sketch normal to path** in the **Edit Revolution** dialog box. When Abaqus/CAE creates the revolved feature, it rotates the sketched profile such that it is normal to the path of revolution at the starting point. The profile remains normal to the path throughout feature creation. Regardless of the pitch value, the cross-section will match the sketched profile. Using this option, you can create coil springs or other features where the cross-section to the path is your sketched profile.

If you do not choose **Sweep sketch normal to path**, the sketched profile remains parallel to the axis of revolution and the cross-section of the revolved feature will vary from the profile. The difference between the profile and the cross-section will increase as you increase the value of pitch. For example, if there is no pitch, a circular sketched profile creates a circular cross-section. If you increase the pitch, the cross-section will become increasingly elliptical. You can create screw threads or other features where the cross-section parallel to the axis of revolution is your sketched profile.

To change the cross-section behavior after the feature is created, you can toggle **Move sketch normal to path** in the **Edit Feature** dialog box.

Additional information

- *Adding a revolved solid feature*
- *Adding a revolved shell feature*
- *Creating a revolved cut*
- *Meshing complex solids with hexahedral elements*

Defining the sweep path and the sweep profile

To create a swept feature, select **Shape->Solid->Sweep**, **Shape->Shell->Sweep**, or **Shape->Cut->Sweep** from the main menu bar or select the equivalent tool from the Part module toolbox. Abaqus/CAE displays the **Create Solid Sweep**, **Create Shell Sweep**, or **Create Cut Sweep** dialog box.

Sweeping is a two-part operation: first you define the sweep path, and then you define the sweep profile. The profile is swept along the length of the path to form a three-dimensional solid, shell, or cut feature. The sweep path can be any continuous path you can create with the Sketcher or any series of connected edges or wires in your part. The latter option allows you to define a three-dimensional sweep path, such as a point-to-point spline wire; the sketch method provides greater flexibility but supports only two-dimensional paths. *Figure 1* shows an example of a sweep path and a sweep profile.

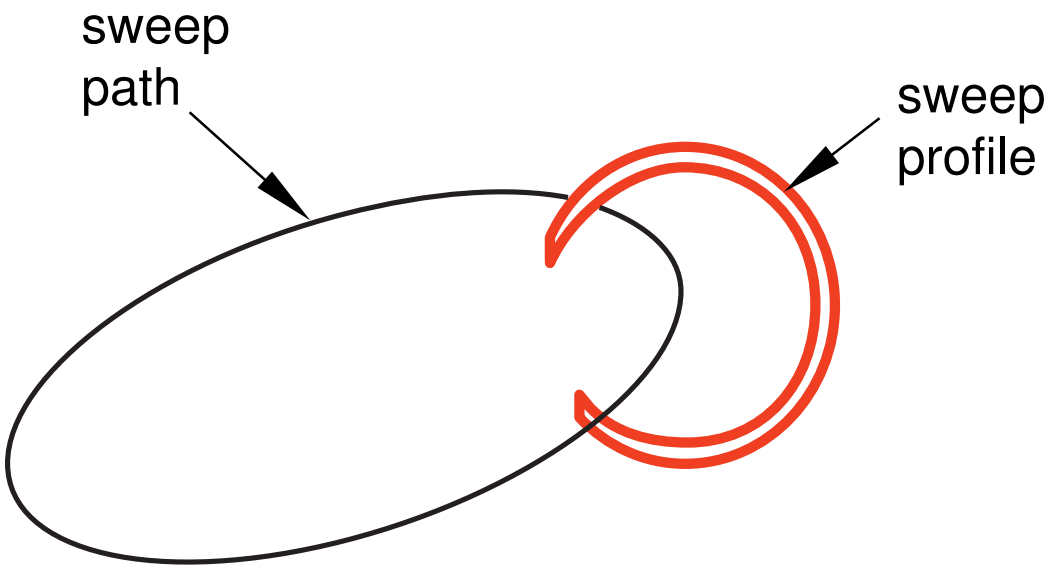

Figure 1: An example of a sweep path and profile.

The feature created by sweeping the sweep profile along the above path is shown in *Figure 2*.

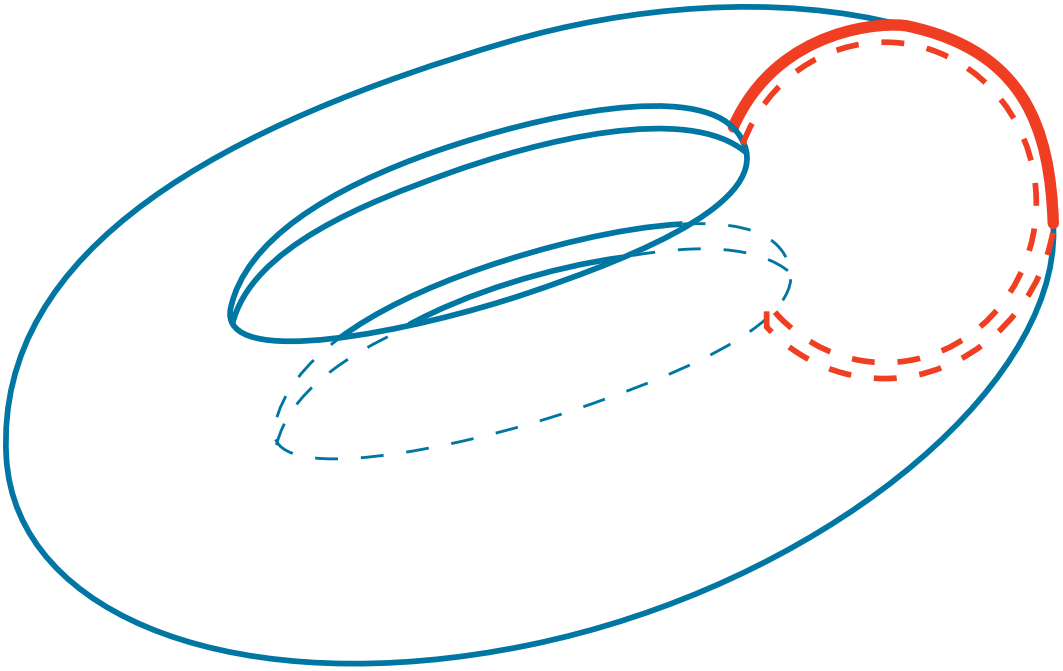

Figure 2: The resulting swept feature.

The sweep profile can be defined either in the Sketcher or by selecting components in the geometry. For solid or cut swept features you can select one of the faces in your part to use as the sweep profile; for shell swept features you can select one or more edges in your part to use as the sweep profile.

If you define your sweep path or sweep profile using the Sketcher, you can modify that feature using the Feature Manipulation toolset. The sweep tools are available only when you are working on a deformable or discrete part that you created in a three-dimensional modeling space.

You can define a swept solid, swept shell, or swept cut feature whose sweep profile is offset from the sweep path. In this case Abaqus/CAE moves the sweep path to a parallel location that passes through the sweep profile and creates the swept feature at that location.

You can control whether the orientation of the sweep profile changes as it travels along the sweep path. Applying a draft to a sweep feature works best when the sweep path is linear. If you toggle on **Keep profile normal constant**, Abaqus/CAE does not change the sweep profile orientation and the profile at the beginning of the sweep path will be parallel to the profile at the end of the sweep path. If you toggle off this option, Abaqus/CAE adjusts the orientation of the sweep profile so that the angle between the sweep path and the profile normal remains constant as the profile travels down the sweep path. The draft option and **Keep profile normal constant** option are mutually exclusive; Abaqus/CAE toggles off one of these options if you select the other.

The sweep profile must be closed when you are creating a swept solid or cut feature. However, unlike the sweep profile, the sweep path can be open or closed regardless of whether you are creating a swept solid, shell, or cut feature. If the sweep path is closed, the two ends of the path must meet tangentially. For example, the closed sweep paths labeled “Bad” in *Figure 3* are not allowed because the ends of the path meet at an angle.

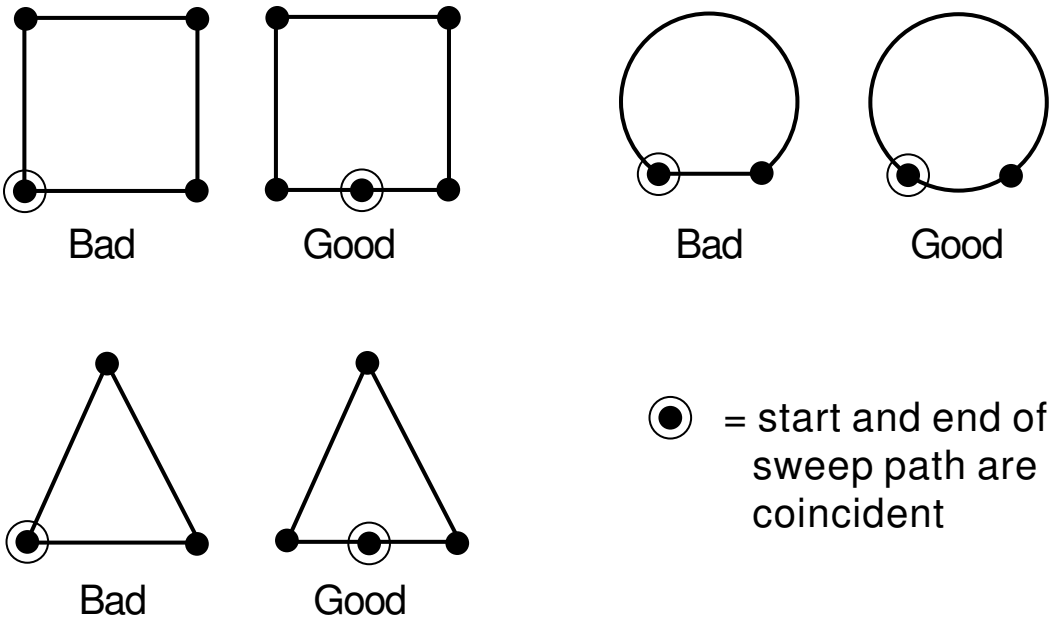

Figure 3: Valid and invalid sweep paths.

As you define your sweep feature, you can apply a twist or draft. For more information about these tools, see *What types of features can you create?*. You can also toggle on **Keep internal boundaries** to maintain any faces or edges that are generated between the swept solid feature and the existing part. The internal boundaries can create regions that can be structured or swept meshed without having to resort to partitioning.

Additional information

- *What is feature-based modeling?*
- *Adding a point-to-point wire feature*

What is lofting?

Lofting is a method that allows you to create complex three-dimensional features that cannot be created by extruding, revolving, or sweeping.
For example, you can use lofts to model an exhaust manifold that would be difficult to create by other means due to varying cross-sections. You can create solid, shell, or cut loft features in Abaqus/CAE. A loft feature transforms from a starting section shape and orientation to an ending shape and orientation. You first create sections that define the shape of the loft as it passes through an area in space. Then Abaqus/CAE can create the path between sections automatically, or you can define one or more continuous paths connecting one point on each loft section to a corresponding point on the next section. You can also choose from several tangency options to control the shape of the loft as it leaves the starting section or as it approaches the ending section. This section describes the options available for defining the loft sections, loft paths, and loft tangencies prior to creating a loft feature and explains self-intersection.

In this section:

- *Defining the loft sections*
- *Defining a loft path*
- *Defining loft tangency*
- *Self-intersection checks*

Defining the loft sections

Loft sections represent the shape that the loft feature will have at a particular point along a loft path. At least two sections are required to create a loft feature. You can create additional sections to control the shape of the loft between the starting and ending sections. In a solid or cut loft, each loft section must be a closed loop with no branches. In a shell loft, the loft sections can either all be open or all be closed. You can define planar or nonplanar loft sections to create a loft feature. Once the loft is created, the number of sections and their order within the loft cannot be changed.

You create loft sections by picking from existing edges on the part in the current viewport. Any edges can be selected; for example:

- Edges that define extruded, revolved, or swept features.
- Edges that define planar wire or shell features.
- Spline wire features.

You can use individual edges from several features to define a single section. However, planar wires sketched on datum planes are one of the simplest means you can use to define the loft sections. Using the simplest means to define your loft sections will give you more control and will result in a more robust loft feature.

You cannot modify loft sections directly. Once you create the loft feature, you can use the Feature Manipulation toolset to edit features that created the edges used in the loft sections. Moving a vertex or edge that is used in a loft section will change the shape of the section and the shape of the corresponding loft feature.

Defining a loft path

Each loft feature that you create requires at least one loft path. When you have defined the loft sections, you can choose to modify the loft path or paths. The paths of a loft feature connect a point on the starting section to a point on the ending section. If more than two loft sections are defined, each path also passes through a point on each intermediate section. You can define a loft path using the options on the **Transition** tabbed page of the **Edit Loft** dialog box.

When you create a loft feature, you can choose from the following methods to define a loft path:

Specify tangencies

Specify tangencies is the default loft path definition. If you select **Specify tangencies**, Abaqus/CAE creates a single smooth path that passes through the center of each loft section, as shown in *Figure 1*. You can apply tangency conditions that modify the shape of the loft near the starting and ending loft sections. For more information on loft tangency, see *Defining loft tangency*.

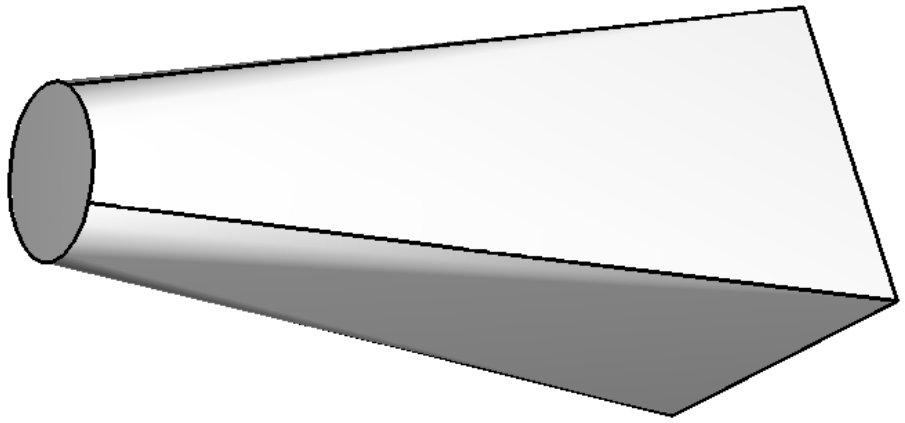

Figure 1: A loft feature with a path defined by Abaqus/CAE.

Select path

If you choose **Select path**, you can select from existing edges to define a loft path. This method also allows you to define multiple loft paths. The loft feature is created by following the loft paths as they connect one loft section to the next, as shown in *Figure 2*. A loft feature with a single selected path behaves similarly to a swept feature except that the cross-section of the loft is constantly changing to match the position and shape of the next loft section along the path.

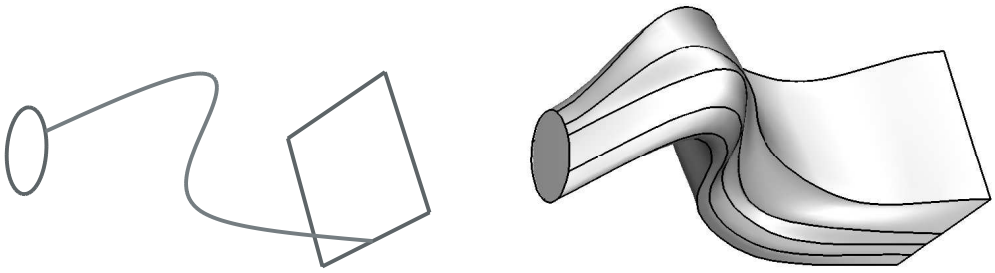

Figure 2: A loft feature with a single user-defined path.

You must pick from existing line segments in the viewport to create paths connecting all of the loft sections. Each path must be a smooth curve, and it must connect the sections in the same order that they will be connected when the loft is created. You can use the  tool to create spline wires that define the three-dimensional paths. For more information, see *Adding a point-to-point wire feature*.

Once the loft feature is created, you cannot edit the paths directly, regardless of which path definition you chose. However, if you used **Select path**, you can edit the points that created each spline wire by using the Feature Manipulation toolset to edit the features that created the wire vertices.

Defining loft tangency

If you accept the default **Specify tangencies** method for a loft, you can choose from several loft tangency options. Loft tangency affects the angle at which the loft faces leave the first loft section and approach the last section. The effect of tangency settings is transient, diminishing in proportion to the distance from the start or end section. The shape of the loft feature between any intermediate sections is unaffected by the loft tangency.

You can set all of the loft tangency options except **None** independently for the starting and ending section. For example, you can set the start tangency to **Normal** and the end tangency to **Radial**. You can choose from the following options to define the loft tangency:

None

None is the default setting, and it is the only tangency setting that can be used with nonplanar sections. If you choose **None**, you must use it for both the start and the end tangency. **None** applies no conditions to the shape or direction of the loft. The edges of the loft feature will make a linear approach from the starting section to the second section and from the next-to-last section to the last section as shown in *Figure 1*.

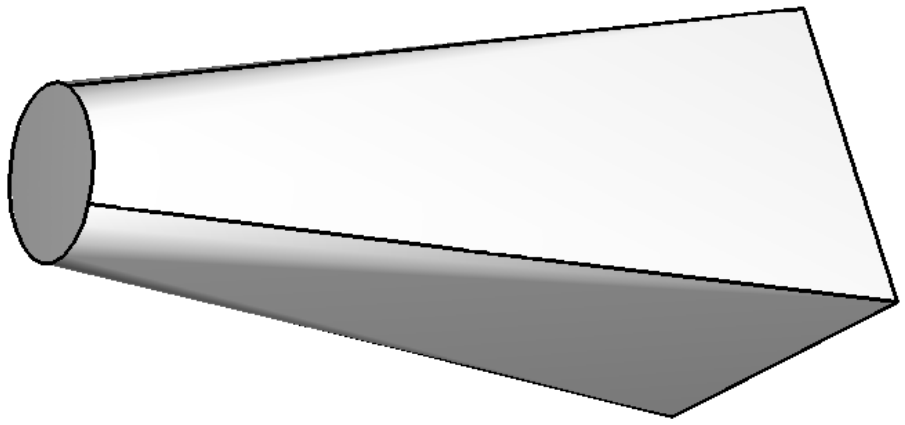

Figure 1: A loft feature with no tangency.

Normal

The **Normal** setting forces the faces created by the lofted edges to be at 90° to the first loft section as they are initially lofted toward the second section. Similarly, this setting forces the faces to be at 90° as they approach the last section of the loft feature. If you set **Start Tangency** to **Normal**, the initial part of the lofted feature will be similar to a straight extrusion as shown in *Figure 2*.

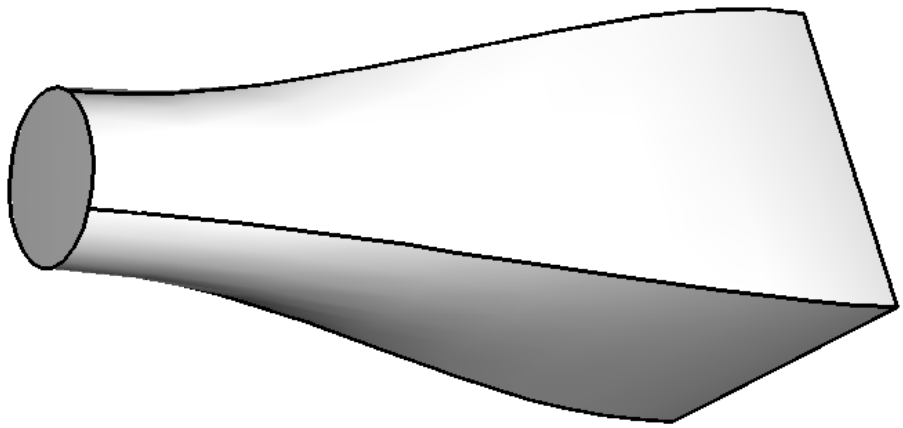

Figure 2: A loft feature with normal tangency at both ends.

Radial

The **Radial** setting forces the faces created by the lofted edges to be at 0° to the first loft section as they are initially lofted toward the second section. Similarly, this setting forces the faces to be at 0° as they approach the last section of the loft feature. Thus, the faces initially radiate outward from the starting loft section or inward toward the ending loft section. If you set **Start Tangency** to **Radial**, the initial part of the lofted feature will be similar to an extrusion with a draft angle approaching 90° as shown in *Figure 3*.

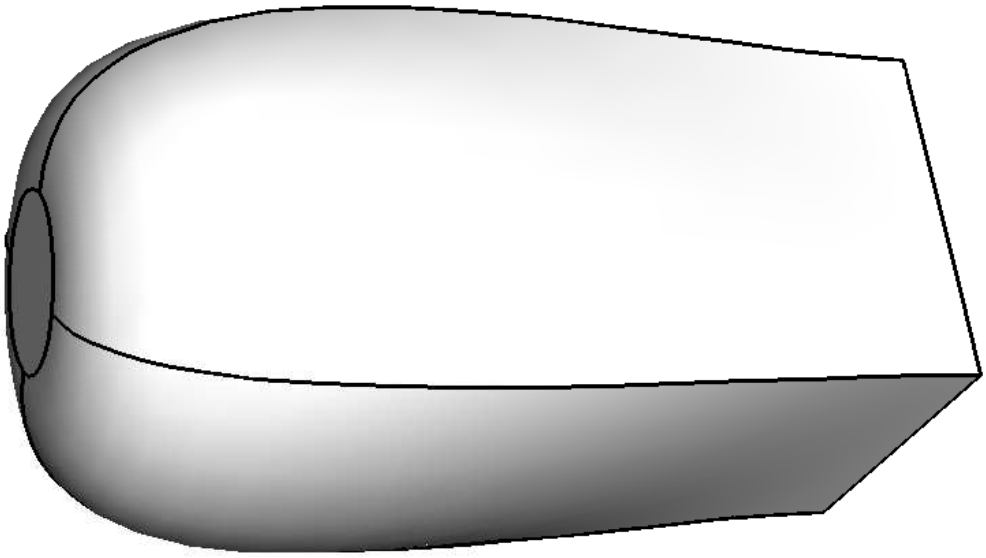

Figure 3: A loft feature with radial tangency at the left end and normal tangency at the right end.

Warning:

If you attempt to create a loft feature with only two loft sections and a dissimilar number of vertices, setting both **Start Tangency** and **End Tangency** to **Radial** may cause the loft feature to fail.

Specify

The **Specify** setting allows you to control both the **Angle** applied to the lofted edges and the **Magnitude %** that represents a relative distance through which the angle will affect the loft. If you set **Start Tangency** to **Specify**, the initial part of the lofted feature will be similar to an extrusion with a draft angle of **Angle** degrees as shown in *Figure 4*.

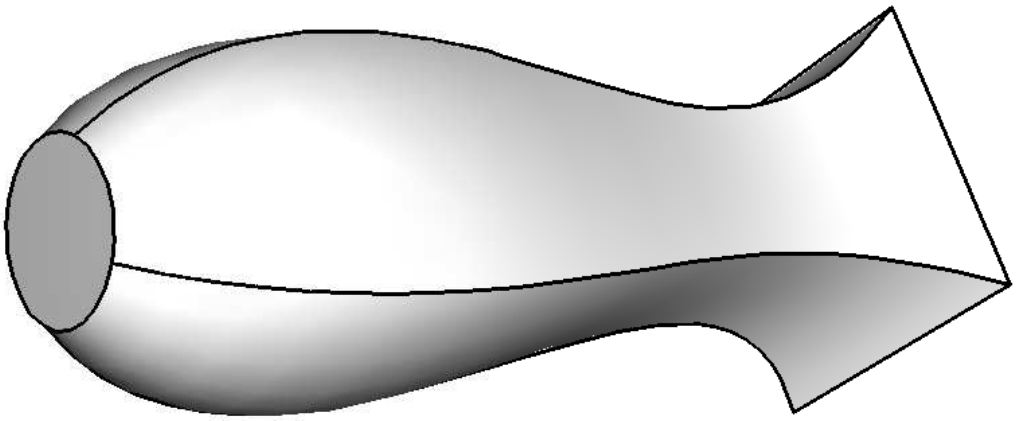

Figure 4: A loft feature with specified tangency at both ends.

Figure 4 shows a **Start Tangency** angle of 45° (left) and an **End Tangency** angle of 135° (right), both applied with magnitudes of 25%. For reference, a **Normal** tangency setting corresponds to specifying an angle of 90° and a magnitude of 25% and a **Radial** tangency setting corresponds to specifying an angle of 0° and a magnitude of 25%.

The angle of the loft faces at any point depends on the **Angle** and **Magnitude %** settings, the distance between consecutive loft sections, and the severity of change between the loft sections. Depending on these conditions, the requirement to make a smooth transition from one loft section to the next may override some loft tangency effects. If you require greater control over the shape of the loft, use the **Select path** method to define paths that the loft feature will follow exactly.

Self-intersection checks

Due to the complexity of features that you can create by lofting, a set of tests is available to ensure that the geometry will be valid for analysis. You can define loft sections and paths such that the loft feature would intersect itself. A loft feature with self-intersections would be impractical as a manufactured part and would also be difficult or impossible to mesh and analyze.

When you toggle on **Perform self-intersection checks** in the **Feature Options** dialog box, Abaqus/CAE tests for self-intersection while it is creating the loft feature. If any faces of the loft intersect other faces, Abaqus/CAE displays an error message stating that there are invalid intersections and does not create the loft feature. The time required to complete the tests varies with the complexity of the loft you are attempting to create. For example, if the shape of your loft varies greatly from section to section or if you have defined a complex loft path, the tests will significantly increase the time required to create the loft feature. If you choose not to include the tests, Abaqus/CAE will create the loft feature regardless of whether the geometry is valid.

Using the Sketcher in conjunction with the Part module

Sketches are two-dimensional profiles that form the geometry of the features defining an Abaqus/CAE native part. You use the Sketcher to create these sketches; in the Part module you use them directly to define a planar part or a beam, or you extrude, sweep, or revolve them to form a three-dimensional or axisymmetric part. Whenever you need to create the base feature of a new part, add a feature to a part, or modify an existing feature, the Part module automatically enters the Sketcher and you operate on the sketch that forms the two-dimensional profile of the feature. When you have finished sketching, Abaqus/CAE automatically returns you to the Part module.

If you are adding a feature or modifying an existing feature, you must choose the plane on which to sketch. For a detailed description of how Abaqus/CAE determines the orientation of the part relative to the sketch plane, see *How Abaqus/CAE orients your sketch*.

Additional information

• *The Sketch module*

Understanding toolsets in the Part module

The Part module provides a set of toolsets that allow you to add and modify the features that define a part. This section describes how these toolsets are used within the Part module.

For more detailed information about each toolset, refer to:

- *The Datum toolset*
- *The Edit Mesh toolset*
- *The Feature Manipulation toolset*
- *The Filter toolset*
- *The Partition toolset*
- *The Query toolset*
- *The Reference Point toolset*
- *The Geometry Edit toolset*
- *The Set and Surface toolsets*

The Display Group toolset is discussed in *Using display groups to display subsets of your model*.

In this section:

- *Using the Datum toolset in the Part module*
- *Using the Feature Manipulation toolset in the Part module*
- *Using the Partition toolset in the Part module*
- *Using the Query toolset in the Part module*
- *Using the Reference Point toolset in the Part module*
- *Using the Geometry Edit toolset in the Part module*
- *Using the Set toolset in the Part module*

Using the Datum toolset in the Part module

A datum can be thought of as reference geometry or a construction aid that helps you create a feature when the part does not contain the necessary geometry; you create datum geometry using the Datum toolset. A datum is a feature of a part and is regenerated along with the rest of the part. Furthermore, datum geometry is visible unless you toggle it off by selecting **View->Part Display Options->Datum** from the main menu bar. A datum created in the Part module appears with each instance of the part in the Assembly module or any other assembly-based module.

Datum points are projected onto the Sketch plane in the Sketcher, and the projected point can be selected. However, you cannot refer to datum axes or planes in the Sketcher. Examples of how you might use datum planes and axes in the Part module are given below.

Datum plane

You can sketch directly on datum planes, and any features you sketch on a datum plane will be projected onto the part. Projecting a sketch from a datum plane is useful if the part does not already contain a convenient sketch plane.

For example, suppose you want to cut a hole straight through the three-dimensional triangular part shown in *Figure 1* parallel to the *X*-axis.

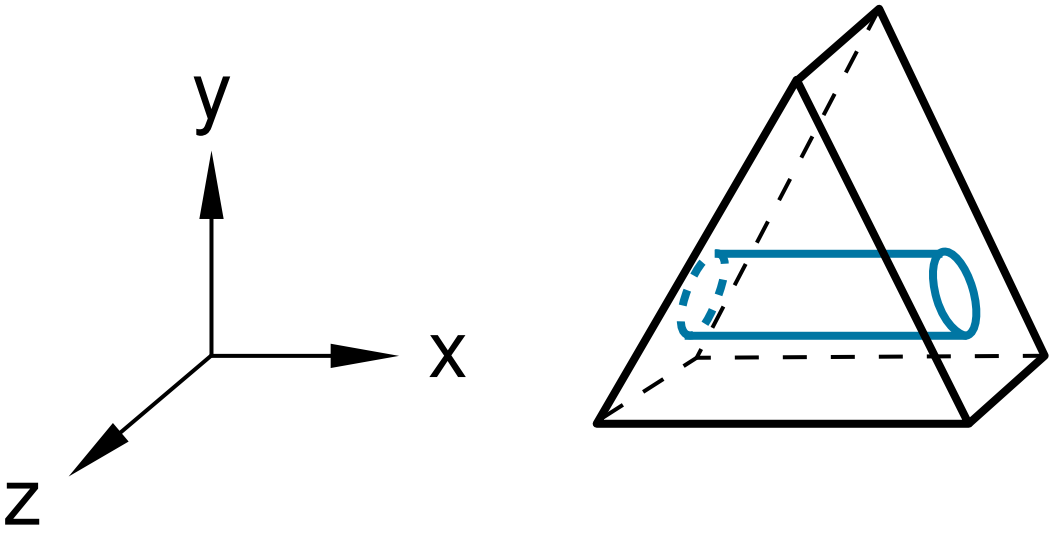

Figure 1: The desired cut feature.

The part does not already have a face that is suitable for sketching the profile of the hole; sketching the profile directly on a face results in a hole normal to the face, as shown in *Figure 2*.

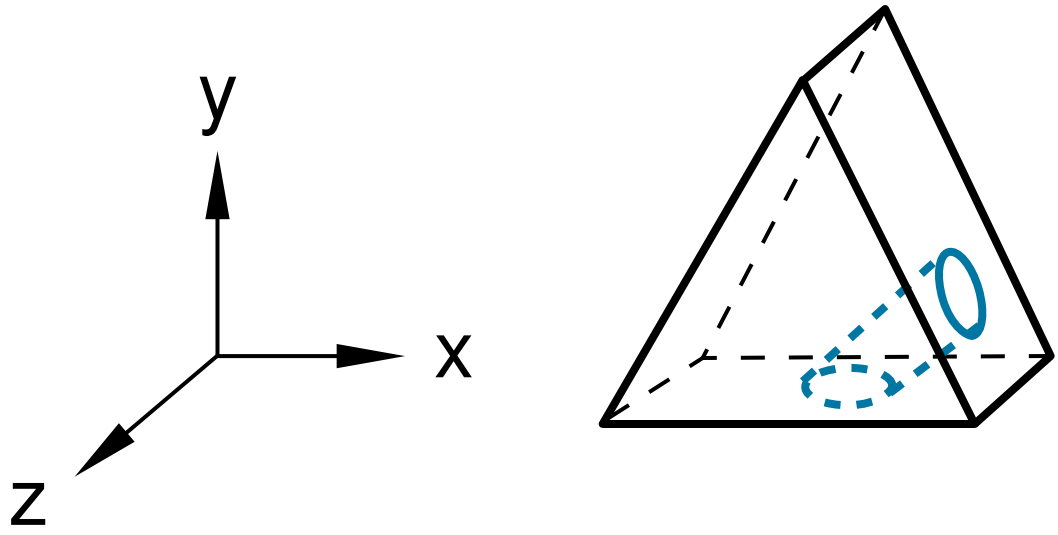

Figure 2: A cut normal to the face.

To cut the desired hole, first use the Datum toolset to create a datum plane on the *Y–Z* principal plane, as shown in *Figure 3*.

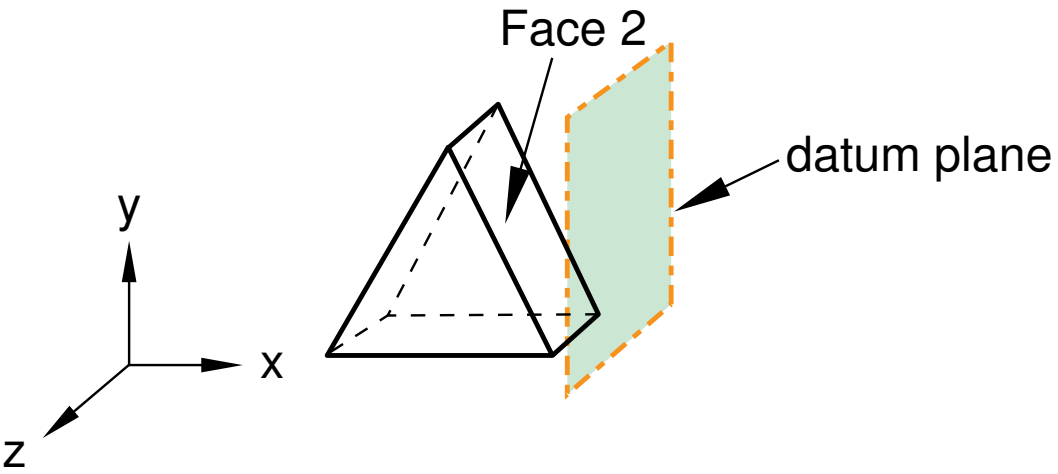

Figure 3: A datum plane.

Second, sketch the profile of the cut on the new datum plane, as shown in *Figure 4*.

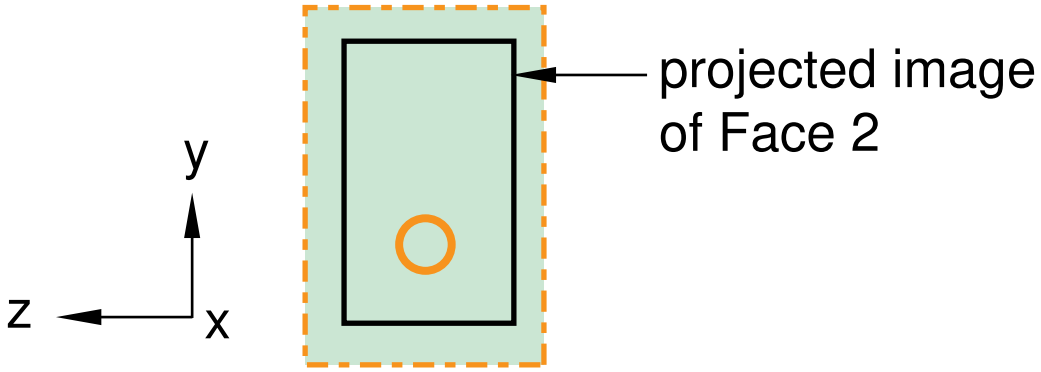

Figure 4: A sketch on the datum plane.

When you exit the Sketcher, Abaqus/CAE cuts the sketched hole through the part, perpendicular to the datum plane and parallel to the *X*-axis. This cut is illustrated in *Figure 5*.

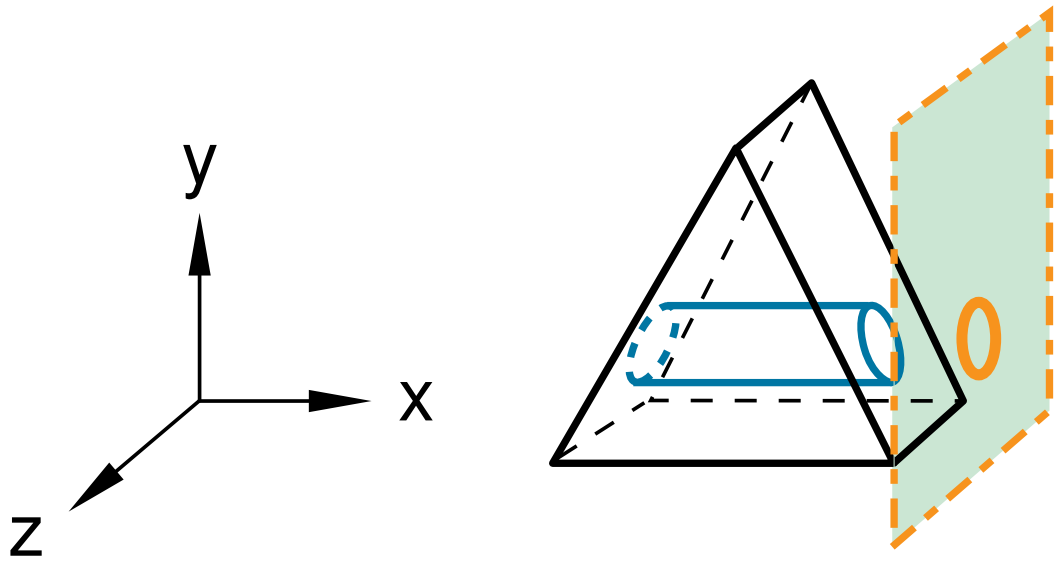

Figure 5: The desired cut.

Datum axis

You can use the Datum toolset to create a datum axis. You can then select the datum axis to control the orientation of the part on the Sketcher grid when adding or modifying a feature to a three-dimensional solid. Creating a datum axis is useful when the part does not already contain the necessary axis.

For example, suppose you want to cut a slot through the part as shown in *Figure 6*.

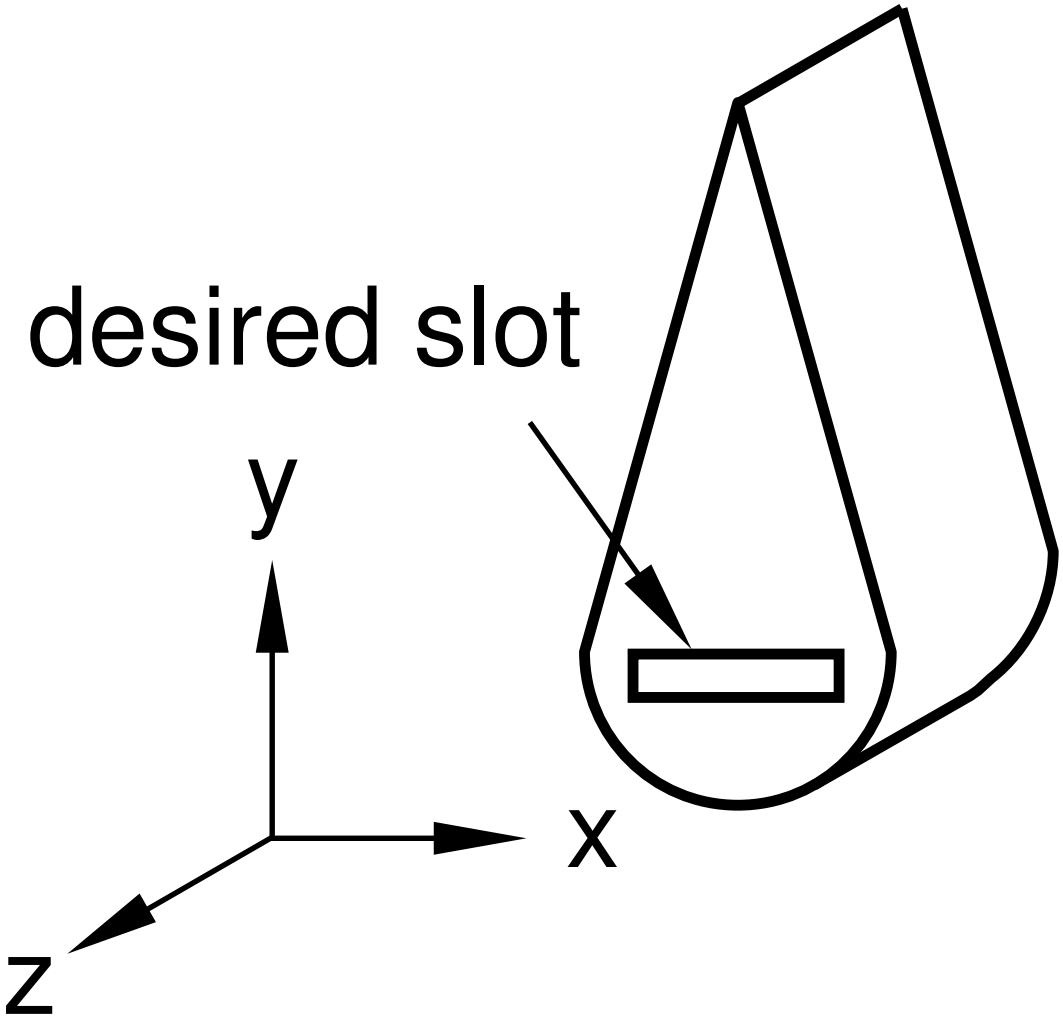

Figure 6: The desired slot.

Sketching the slot is difficult because selecting either of the two straight edges of the part as the sketch's vertical axis causes the sketch gridlines to align with the line you select, not with the *X*- or *Y*-axis. To make it easier to create the slot with the desired orientation, first use the Datum toolset to create a datum axis along the *Y*-axis, as shown in *Figure 7*.

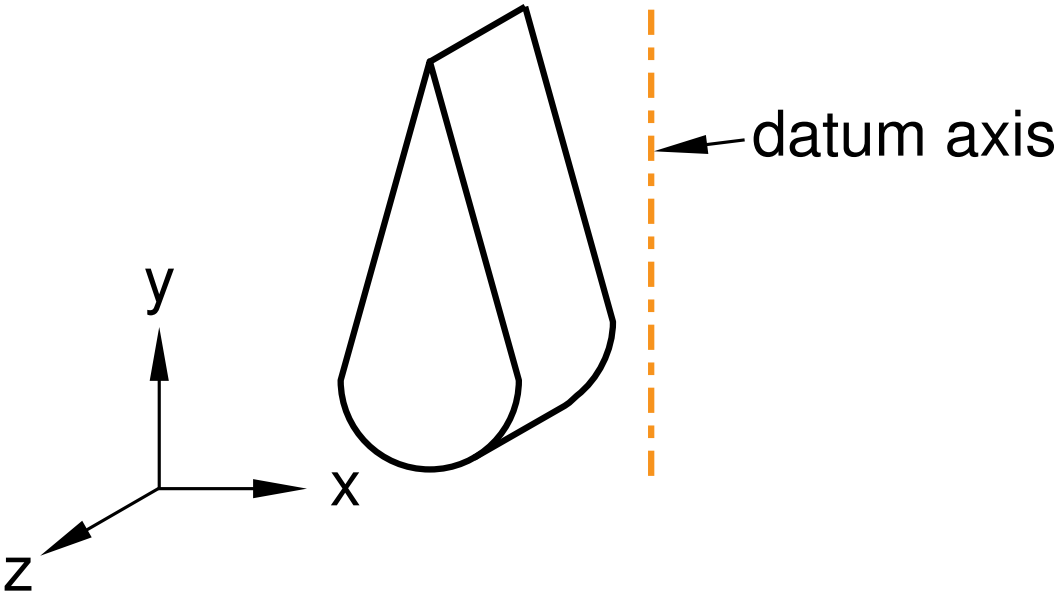

Figure 7: The datum axis.

When you select the datum axis to appear vertical and on the right, the Sketcher starts, and its grid is aligned with the part's *X*- and *Y*-axes, as shown in *Figure 8*.

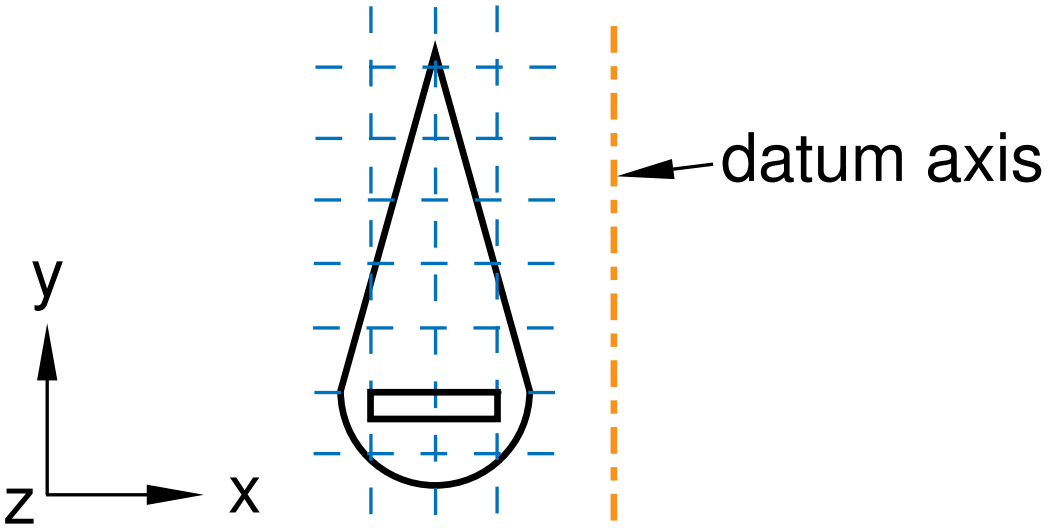

Figure 8: The resulting sketch orientation.

Additional information

- *Understanding toolsets in the Part module*
- *The Datum toolset*

Using the Feature Manipulation toolset in the Part module

The following are considered to be features of a part:

- Geometric features, such as extruded solids, revolved shells, sketched wires, and rounded edges
- Repair operations
- Partitions
- Datum geometry

When the Feature Manipulation toolset asks you to select a feature, you can select it from the viewport. Alternatively, you can select the feature from the Model Tree.

If you click mouse button 3 on a feature in the Model Tree, the menu that appears allows you to do the following:

Edit

When you edit a feature, Abaqus/CAE displays the feature editor. You can either modify the feature's parameters directly or, if applicable, you can modify the sketch that forms the two-dimensional profile or sweep path of a feature.

Regenerate

When you modify features in a complex part, it may be convenient to postpone regeneration until you make all your changes, since regeneration can be time consuming. Select **Feature->Regenerate** when you are ready to regenerate the part.

Rename

Rename a part.

Suppress

Suppressing a feature temporarily removes it from the definition of the part. A suppressed feature is invisible, cannot be meshed, and is not included in the analysis of the model. You cannot suppress the base feature, and suppressing a parent feature will suppress all of its child features.

Resume

Resuming a feature restores a suppressed feature to the part; resuming a parent feature restores all of its child features. You can choose to resume all features, the set of features most recently suppressed, or a selected feature.

Delete

Deleting a feature removes it from the part. You cannot resume a deleted feature.

Query

When you query a part, Abaqus/CAE displays information in the message area and writes the same information to the replay file (*abaqus*`.rpy`) in the form of comments.

Options

The **Feature Options** dialog box allows you to tune the regeneration performance of the current model.

Additional information

- *Understanding toolsets in the Part module*
- *The Feature Manipulation toolset*

Using the Partition toolset in the Part module

Within the Part module, you can use the Partition toolset to partition a part into additional regions. After you partition a part, you can use the Property module to assign different sections to the resulting regions; for example, you might use partitions to delineate regions of the part that are comprised of different materials.

The partitions you create are features associated with the part, so that each instance of that part in the assembly will contain all the partitions created in the Part module. You can use the regions when working with the assembly in other modules; for example, you can apply a load over a region in the Load module. If you do not want to associate the partitions with every instance of the part, create an independent instance in the Assembly module and partition the independent instance. For more information, see *Partitioning the assembly*.

If you have created the assembly and applied attributes to it, such as loads, boundary conditions, and sets, you should be careful if you subsequently decide to return to the Part module and partition one of the original parts. The region to which the attribute is assigned may change unexpectedly if the region is affected by the partition. In general, you should try to finish creating your parts in the Part module before you start creating part instances and applying sets, loads, and meshes to the assembly. If you do return to the Part module to create a partition, you should at least check that the regions in the assembly to which attributes are assigned are still valid.

Additional information

- *Understanding toolsets in the Part module*
- *The Partition toolset*

Using the Query toolset in the Part module

You can use the Query toolset to request either general information or module-specific information.

For a discussion of the information displayed by general queries, see *Obtaining general information about the model*.

Select **Tools->Query** from the main menu bar, or click the  tool in the Query toolset to start the Query toolset.

The following queries are specific to the Part module:

Part attributes

Abaqus/CAE displays the part name, modeling space, and type in the message area along with the shape (solid, shell, wire, or point) and the number of entities (cells, faces, edges, and vertices).

Regeneration warnings

If any sets or surfaces in the selected part cannot be regenerated because their underlying geometry has been modified or deleted, Abaqus/CAE displays the set or surface name, the original number of faces, and the number of faces found during the query.

Substructure statistics

Abaqus/CAE displays the following information about the selected substructure part: the number of retained nodes, eigenmodes, and substructure loads in the part; the availability of the recovery matrix, gravity load vectors, reduced mass matrix, reduced structural damping matrix, and reduced viscous damping matrix in the substructure; and mass properties of the substructure.

Additional information

- *Understanding toolsets in the Part module*
- *The Query toolset*

Using the Reference Point toolset in the Part module

From the main menu bar, select **Tools->Reference Point** to create a reference point on a part. A part can include only one reference point. For more information, see *The reference point and point parts*, and *The Reference Point toolset*.

Abaqus/CAE displays the reference point at the desired location and labels it **RP**. You can change the reference point label by clicking mouse button 3 on the feature in the Model Tree and selecting **Rename** from the menu that appears. If desired, you can turn off the display of the reference point symbol and the reference point label; for more information, see *Controlling reference point display*.

Using the Geometry Edit toolset in the Part module

You use the Geometry Edit toolset to repair regions of a part that contain invalid or imprecise geometry. For more information, see *Editing techniques*. You can use the Query toolset to locate regions that need repairing. For more information, see *The Query toolset*.

Additional information

- *Understanding toolsets in the Part module*
- *The Geometry Edit toolset*

Using the Set toolset in the Part module

Sets created by selecting geometry from a part are called part sets, and you use the Set toolset to create and manage part sets. You can use part sets in the Part module to select regions that should be repaired by the Geometry Edit toolset. In addition, in the Property module you can assign sections to regions specified by part sets. When Abaqus/CAE prompts you to select a region, you can either select the region from the part in the current viewport, or you can select a named part set.

Only part sets are visible in the **Set Manager** in the Part module. When you instance a part in the Assembly module, Abaqus creates part instance sets that refer to any part sets that you previously created. For more information, see *Understanding sets and surfaces*, and *Using sets and surfaces in the Assembly module*.

Additional information

- *Understanding toolsets in the Part module*
- *The Set and Surface toolsets*

Using the Part module toolbox

You can access all the Part module tools through either the main menu bar or the Part module toolbox. *Figure 1* shows the hidden icons for all the part tools in the Part module toolbox.

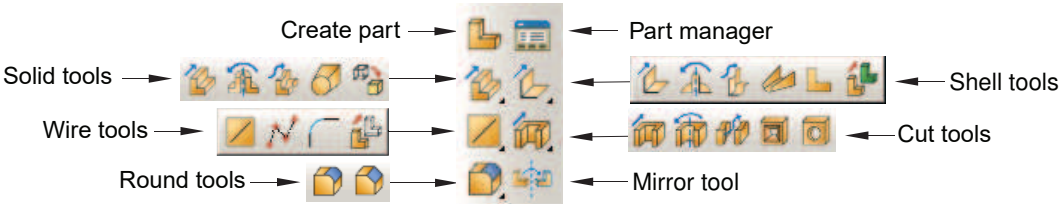

Figure 1: The Part module toolbox.

For information on using each of the Part module tools, refer to the following sections:

- *Managing parts*
- *Using the Create Part dialog box*
- *Adding a feature to a part*
- *Adding a solid feature*
- *Adding a shell feature*
- *Adding a wire feature*
- *Adding a cut feature*
- *Blending edges*

Managing parts

This section describes how you manage the parts in your model while working in the Part module.

In this section:

- *Managing parts*
- *Creating a new part*
- *Copying a part*

Managing parts

To create, copy, rename, and delete parts, use one of the following:

- The **Create**, **Copy**, **Rename**, and **Delete** items listed under the **Part** menu on the main menu bar.

  The **Copy**, **Rename**, and **Delete** items contain submenus listing all the parts in the current model.
- The **Part Manager** dialog box. The **Part Manager** dialog box contains functions similar to those listed under the **Part** menu on the main menu bar, but with a convenient browser that lists the names of all the parts available within the current model along with their modeling space (three-dimensional, two-dimensional, or axisymmetric), type (deformable, discrete rigid, analytical rigid, or Eulerian), and status (locked, invalid, or invalid (ignored)).

  To display the **Part Manager** dialog box, select **Part->Manager** from the main menu bar.

To lock or unlock parts for editing in the current model database, use the **Lock** and **Unlock** buttons in the **Part Manager** dialog box. The **Status** field indicates **Locked** parts . For more information on part locking, see *What is part and assembly locking?*.

To update the validity or to ignore the invalidity of parts, use the **Update Validity** and **Ignore Invalidity** buttons in the **Part Manager** dialog box. The **Status** field indicates **Invalid** or **Invalid (ignored)** parts. For more information on part validity, see *Working with invalid parts*.

To retrieve a part from the model database and display it in the current viewport, select the part from the **Part** list located in the context bar. The **Part** list contains all the parts in the current model.

Additional information

- *Managing parts*
- *Managing objects*

Creating a new part

Select **Part->Create** from the main menu bar to create a new part in the current viewport.

A model can contain multiple parts; each part exists in a local coordinate system, and you use the Assembly module to create instances of the parts and position those instances relative to each other in a global coordinate system. When you create a part, you name the part and select its type, modeling space, base feature, and approximate size; you then sketch the profile of the part's base feature. The part name should not be the same as the model name.

1. From the main menu bar, select **Part->Create**.

   The **Create Part** dialog box appears. For more information, see *Using the Create Part dialog box*.

   Tip: You can also create a part using the  tool in the Part module toolbox. For a diagram of the tools in the Part module toolbox, see *Using the Part module toolbox*.

2. Type a name for the part. For information on naming Abaqus/CAE objects, see *Using basic dialog box components*. You can rename a part after you create it.
3. Choose the new part's modeling space, type, base feature, and approximate size. For more information, see *How is a part defined in Abaqus/CAE?*.

   Note:

   To change a part's modeling space or type you must use the Model Tree to edit the part. For more information, see *How is a part defined in Abaqus/CAE?*.

4. Click **Continue** to close the **Create Part** dialog box.

   The Sketcher starts, and the **Sketch** grid appears in the current viewport.

   If you are creating a three-dimensional revolved solid or shell, Abaqus/CAE displays a vertical construction line on the *Y*-axis of the sketch that serves as the axis of revolution. You can sketch on either side of this construction line, but the sketch must not cross the construction line.

   If you are creating an axisymmetric part, Abaqus/CAE displays a vertical construction line on the left side of the sketch that serves as the axis of revolution. You must sketch to the right of this construction line.

5. Use the Sketcher to sketch the two-dimensional profile of the base feature. For more information, see *The Sketch module*."

   If you are constructing a swept part, you must first sketch the sweep path and exit the Sketcher. The **Sketch** will then restart automatically, and you can sketch the profile to be swept.

6. When you have finished sketching the base feature, click mouse button 2 to exit the current **Sketch** tool.
7. In the prompt area, click **Done** to exit the Sketcher. If the base feature is a three-dimensional solid or shell extrusion, the **Edit Base Extrusion** dialog box appears. You must use the **Depth** field to enter the distance through which to extrude the profile. You can also select **Twist** or **Draft** to modify the form of extrusion that Abaqus/CAE will create. If the base feature is a three-dimensional revolved solid or shell, you must enter the angle through which to rotate the profile.

   Abaqus/CAE exits the Sketcher and displays the new part in the current viewport.

8. If necessary, use the Part module tools to add additional features to the base feature. For more information, see *What is feature-based modeling?*.

Additional information

- *Managing parts*
- *How is a part defined in Abaqus/CAE?*
- *Including draft in an extrusion*
- *Including twist in an extrusion*
- *The Sketch module*
- *Importing and exporting geometry data and models*
- *Using the Part module toolbox*
- *What is feature-based modeling?*
- *Using basic dialog box components*

Copying a part

Select **Part->Copy->*part name*** from the main menu bar to copy a part to a new part. You can copy parts containing both geometry and orphan elements. The compress, scale, and mirror functions operate on both geometry and meshes. The separate disconnected regions function also works with parts containing both geometry and orphan elements; however, only geometry regions are copied to become new parts since regions do not exist for orphan elements.

1. From the main menu bar, select **Part->Copy->*part name***.

   Abaqus/CAE displays the **Part Copy** dialog box.

2. From the dialog box, enter the name of the new part.
3. You can create an identical copy of the original part, or you can select from the following **Copy options**:

   - **Compress features**
   - **Scale part by**
   - **Mirror part about**
   - **Separate disconnected regions into parts**

   For more information on the **Copy options**, see *Copying a part*.

4. Click **OK**.

   Abaqus/CAE closes the **Part Copy** dialog box and copies the selected part to a new part. The new part becomes the current part. You can return to the original part by selecting the part from the **Part** list on the context bar. For more information, see *The context bar*.

Additional information

• *Simplifying a part's feature list*

Using the Create Part dialog box

This section describes the options in the **Create Part** dialog box.

In this section:

- *Using the Create Part dialog box to define the properties of a part*
- *Choosing the modeling space of a new part*
- *Choosing the type of a new part*
- *Choosing the base feature of a new part*
- *Setting the approximate size of the new part*

Using the Create Part dialog box to define the properties of a part

When you create a part, you first use the **Create Part** dialog box to define the properties of the part, and then you use the **Sketch** to sketch the two-dimensional profile of the base feature.

You use the **Create Part** dialog box to define the following:

Name

Use the **Name** text field at the top of the **Create Part** dialog box to name the part you are creating. To rename a part, select **Part->Rename** from the main menu bar. The part name should not be the same as the model name. For more information on valid names, see *Using basic dialog box components*.

After you create a part, Abaqus/CAE displays the name of the new part in title bar of the current viewport.

Modeling Space

Use the **Modeling Space** radio buttons to choose the modeling space of the new part. You can define a part to be either three-dimensional, two-dimensional (planar), or axisymmetric in an Abaqus/Standard or Abaqus/Explicit model.

If you create an axisymmetric deformable part, you can toggle on **Include twist** in the **Create Part** dialog box to include a twist degree of freedom in your model. You can change the modeling space of a part after you have created it by clicking mouse button 3 on the part in the Model Tree and selecting **Edit** from the menu that appears. For more information, see *Choosing the modeling space of a new part*.

Type

In an Abaqus/Standard or Abaqus/Explicit model, use the **Type** radio buttons to choose the type of the new part. You can define a part to be either deformable, discrete rigid, analytical rigid, or Eulerian. If allowed, you can change the type of a part after you have created it by clicking mouse button 3 on the part in the Model Tree and selecting **Edit** from the menu that appears. For more information, see *Choosing the type of a new part*.

Base Feature

Use the **Base Feature** field to define the shape and the type of the new part's base feature. The shape and the type options that Abaqus/CAE displays depend on the part's modeling space and type. You cannot change the type of a part's base feature after you create it. For more information, see *Choosing the base feature of a new part*.

Approximate size

Use the approximate size text field to enter the size of the part. The size that you enter is used by Abaqus/CAE to calculate the size of the Sketcher sheet and the spacing of its grid. For more information, see *Setting the approximate size of the new part*. After you create the part and start sketching its profile, you can use the **Sketch** customization options to increase the sheet size. To display the Sketcher customization options click the  tool at the bottom of the Sketcher toolbox.

Additional information

- *How is a part defined in Abaqus/CAE?*
- *Creating a new part*
- *Using the Create Part dialog box*

Choosing the modeling space of a new part

Use the **Modeling Space** radio buttons at the top of the **Create Part** dialog box to choose the modeling space of the part you are creating.
Abaqus/CAE carries a part's modeling space through the modeling process; for example, modeling space determines which tools are available in the Part module and which elements are available in the Mesh module. You can change the modeling space of a part after you have created it by clicking mouse button 3 on the part in the Model Tree and selecting **Edit** from the menu that appears.

Modeling space refers to the space the part can inhabit, rather than to the part itself. Thus, you can create a part in three-dimensional modeling space but construct it using topologically two-dimensional shell or wire features. In an Abaqus/Standard or Abaqus/Explicit model, the new part's modeling space can be set to any of the following:

Three-dimensional

Abaqus/CAE positions the part in three-dimensional space.

Two-dimensional planar

Abaqus/CAE positions the part in planar, two-dimensional space.

Axisymmetric

Abaqus/CAE positions the part in axisymmetric two-dimensional space. If you create an axisymmetric deformable part, Abaqus/CAE allows you to include a twist degree of freedom in your model.

1. From the top of the **Create Part** dialog box, choose the desired **Modeling Space** radio button.
2. When you have finished choosing options, click **Continue** to close the **Create Part** dialog box.
   The Sketcher starts, and you sketch the profile of the new part's base feature.

Additional information

- *Part modeling space*
- *Defining the axis of revolution for axisymmetric parts and for revolved features*
- *How is a part defined in Abaqus/CAE?*
- *Creating a new part*

Choosing the type of a new part

Use the **Type** radio buttons in the **Create Part** dialog box to choose the type of the part you are creating in an Abaqus/Standard or Abaqus/Explicit model.

Abaqus/CAE carries a part's type through the modeling process; for example, you cannot assign section and material properties to a rigid part, you cannot mesh an analytical rigid part, and you can assign Eulerian sections and material assignment fields only to Eulerian parts. If allowed, you can change the type of a part after you have created it by clicking mouse button 3 on the part in the Model Tree and selecting **Edit** from the menu that appears.

In an Abaqus/Standard or Abaqus/Explicit model a new part's type can be set to one of the following:

Deformable

Any arbitrarily shaped axisymmetric, two-dimensional, or three-dimensional part that you can create or import can be specified as a deformable part. A deformable part represents a part that can deform under load; the load can be mechanical, thermal, or electrical. By default, Abaqus/CAE creates parts that are deformable.

Discrete rigid

A discrete rigid part is similar to a deformable part in that it can be any arbitrary shape. However, a discrete rigid part is assumed to be rigid and is used in contact analyses to model bodies that cannot deform.

Analytical rigid

An analytical rigid part is similar to a discrete rigid part in that it is used to represent a rigid surface in a contact analysis. However, the shape of an analytical rigid part is not arbitrary and must be formed from a set of sketched lines, arcs, and parabolas.

Eulerian

Eulerian parts are used to define a domain in which material can flow for an Eulerian analysis. Eulerian parts do not deform during an analysis; instead, the material within the part deforms under load and can flow across the rigid element boundaries. For more information about Eulerian analyses, see *Eulerian analyses*.

After you create either a discrete rigid part or an analytical rigid part, you must also do the following:

- Assign the rigid body reference point. You apply constraints or prescribe motion to the rigid body reference point in the Load module, and the same constraints or motion are applied to the entire rigid part. For more information, see *The reference point*.
- If the part is a discrete rigid part or an analytical rigid part, you must use the Surface toolset in the Assembly module to choose which side of the part represents the outer surface. For more information, see *The Set and Surface toolsets*.

1. From the middle of the **Create Part** dialog box, choose the desired **Type** radio button.
2. When you have finished choosing options, click **Continue** to close the **Create Part** dialog box.

   The Sketcher starts, and you sketch the profile of the new part's base feature.

- *The Set and Surface toolsets*

Choosing the base feature of a new part

Use the radio buttons and the list within the **Base Feature** field at the bottom of the **Create Part** dialog box to select the base feature of the part you are creating. The choices depend on both the part's modeling space and the part's type; for example, an axisymmetric deformable body can have only a planar shell, planar wire, or point base feature. For detailed information about the different shapes and types of base features that you can create, see *The base feature*.

Your choice of the base feature's type is important because you cannot change the type after you create the part. You can modify the base feature, but you should be aware that any features you subsequently add to the part will be linked to the base feature. Consequently, if you modify the base feature, these dependent (or child) features may move or fail to regenerate.

1. From the bottom of the **Create Part** dialog box, choose the desired base feature shape (**Solid**, **Shell**, **Wire**, or **Point**). The available choices depend on the modeling space and the type of the part you are creating.
2. If you are creating a three-dimensional deformable or discrete rigid part, you must also choose its **Type** (**Extrusion**, **Revolution**, **Sweep**, **Planar**, or **Coordinates**).
3. When you have finished choosing options, click **Continue** to close the **Create Part** dialog box.

   The Sketcher starts, and you sketch the profile of the new part's base feature.

Additional information

- *The Feature Manipulation toolset*

Setting the approximate size of the new part

Use the **Approximate size** text field at the bottom of the **Create Part** dialog box to set the approximate size of the new part. The size that you enter is used by Abaqus/CAE to calculate the size of the Sketcher sheet and the spacing of its grid. The approximate part size must be between 10000 (10^4) and 0.001 (10^{-3}) units. Abaqus/CAE does not use specific units, but the units must be consistent throughout the model.

When you exit the **Create Part** dialog box, Abaqus/CAE enters the Sketcher, and you sketch the profile of the base feature. The Sketcher displays a square sheet with an overlaying grid and adjusts the dimensions of the sheet to approximate the size of the part. As a result, the dimensions of the sketch will have the same order of magnitude as the part you are creating.

If you subsequently edit the part, Abaqus/CAE still determines the size of the Sketcher sheet from the same dimensions that it used when you created the base feature. Consequently, you should set the approximate size of the part to match the largest dimension of the finished part. If you find subsequently that the part exceeds the size of the Sketcher sheet, use the **Sketch** customization options to increase the sheet size.

1. Type the approximate size of the new part in the **Approximate size** text field at the bottom of the **Create Part** dialog box.
2. When you have finished choosing options, click **Continue** to close the **Create Part** dialog box.

   The Sketcher starts with a sheet size and grid spacing based on the approximate size of the new part, and you sketch the profile of the new part's base feature.

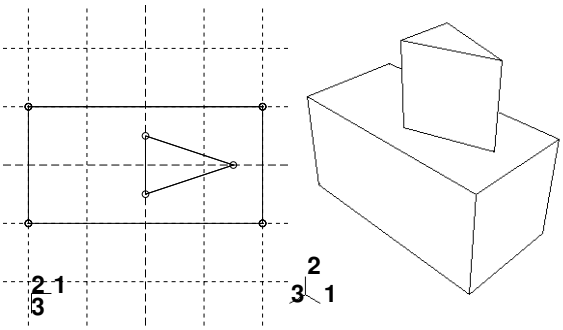
Adding a feature to a part

Use the **Shape** menu to add a feature to the current part. You can do the following:

- Use the **Solid** tools to add a solid feature to a to a three-dimensional solid part. For more information, see *Adding a solid feature*.
- Use the **Shell** tools to add a shell feature to a part. For more information, see *Adding a shell feature*.
- Use the **Wire** tools to add a wire feature to a part. For more information, see *Adding a wire feature*.
- Use the **Cut** tools to add a cut feature to a part. For more information, see *Adding a cut feature*.
- Use the **Blend** tools to add a blend feature to a three-dimensional solid part. For more information, see *Blending edges*.
- Use the **Transform** tool to mirror a part about a selected plane. For more information, see *Mirroring a part*.

Adding a solid feature

This section describes the Part module tools used to add a solid feature to the three-dimensional solid part in the current viewport.



In this section:

- *Adding an extruded solid feature*
- *Adding a revolved solid feature*
- *Adding a swept solid feature*
- *Adding a solid loft feature*
- *Creating a solid feature from a shell*

Adding an extruded solid feature

Select **Shape->Solid->Extrude** from the main menu bar to add an extruded solid feature to the part in the current viewport. You can add an extruded solid feature only to three-dimensional parts.

You add an extruded solid feature by sketching a two-dimensional cross-section and defining the distance over which to extrude it. A sketch and the resulting extruded solid feature are illustrated in the following figure:

You can also define the distance over which to extrude by selecting a single face to extrude to. Abaqus/CAE extrudes the sketch until it meets the selected face.

In addition, you can select a center point and specify a pitch that Abaqus/CAE uses to twist the cross-section as it is extruded. Alternatively, Abaqus/CAE can expand or contract the cross-section along a specified draft angle as the cross-section is extruded. For more information, see *Including twist in an extrusion*, and *Including draft in an extrusion*.

1. From the main menu bar, select **Shape->Solid->Extrude**.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also add an extruded solid feature using the tool, located with the solid tools in the Part module toolbox. For a diagram of the tools in the Part module toolbox, see *Using the Part module toolbox*.

2. If desired, specify the method you want to use to select an origin for your sketch of the extruded solid feature. Select one of the following options from the **Sketch Origin** field in the prompt area:

   - Select **Auto-Calculate** to place the sketch origin automatically.
   - Select **Specify** to define a custom sketch origin.
   - Select **Session Default** to use the custom origin you specified earlier in the session.

3. Select the planar face from which the solid will be extruded. If no suitable face exists, you can select a datum plane or an orphan element face.

   Tip: If you are unable to select the desired planar face, you can use the **Selection** toolbar to change the selection behavior. For more information, see *Using the selection options*.

   The selected face is highlighted in the viewport.

4. If you selected **Specify** as the **Sketch Origin** method, specify the origin location by clicking a point in the viewport or by entering the three-dimensional coordinates of the origin in the prompt area. You can also set this custom origin as the default origin for all sketches in your session by toggling on **Set as session default**.

5. Select an edge and the orientation of the edge on the Sketcher grid. The edge must not be perpendicular to the selected face. By default, the selected edge will appear vertical and on the right side of the Sketcher grid. To choose a different orientation for the edge, click the arrow on the right side of the dialog box and choose an orientation from the list that appears.

   Tip: If there is no straight edge with the desired orientation, you can create a datum axis. You can then select the datum axis to control the orientation of the part on the Sketcher grid.

   Abaqus/CAE highlights the selected edge, enters the Sketcher, and rotates the part until the selected face aligns with the plane of the Sketcher grid and the selected edge aligns with the grid in the desired orientation.

   If you are unsure of the part's orientation relative to the Sketcher grid, use the view manipulation tools from the View Manipulation toolbar to view its position. Use the reset view tool  to return to the original view.

6. Use the Sketcher to sketch the two-dimensional profile of the extrusion. In the prompt area, click **Done** to exit the Sketcher and to open the **Edit Extrusion** dialog box.

   Abaqus/CAE displays the part view that was active prior to entering the Sketcher. The part includes your sketched profile and an arrow indicating the extrusion direction.

7. Click  in the **Edit Extrusion** dialog box to reverse the extrusion direction, if necessary.

   If the arrow direction is difficult to see, use the rotate tool to rotate the part.

8. Select one of the following end conditions:

   - Select **Blind** and enter a value in the **Depth** field to specify the distance through which Abaqus/CAE will extrude the sketched profile.
   - Select **Up to Face** to specify that Abaqus/CAE will extrude the profile up to a selected face.

9. If desired, do one of the following:

   - Toggle on **Include twist**, and enter the pitch. The pitch is the extrusion distance in which a 360° twist would occur. The sketched extrusion profile must include an isolated point that indicates the center of twist.
   - Toggle on **Include draft**, and enter the draft angle (greater than −90° and less than 90°). A positive draft angle indicates that external faces of the profile expand and internal faces contract.

10. Toggle on **Keep internal boundaries** to maintain any faces or edges that are generated between the extruded solid feature and the existing part. The internal boundaries may create regions that can be structured or swept meshed without having to resort to partitioning.
11. Click **OK** to extrude the profile.

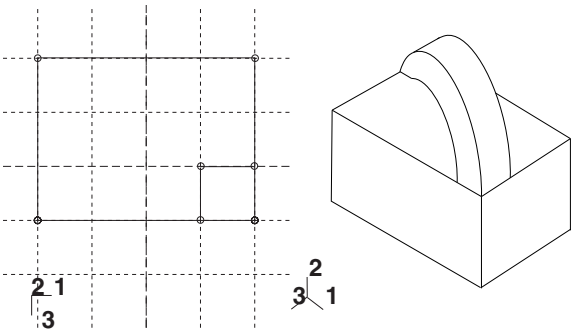
    If you selected the twist option and your sketch includes a single isolated point, Abaqus/CAE uses that point as the center of twist. If your sketch does not include an isolated point, Abaqus/CAE returns to the Sketcher for you to create one. If your sketch contains more than one isolated point, Abaqus/CAE returns to the Sketcher and prompts you to select an isolated point as the center of twist.

12. If you selected **Up to Face**, Abaqus/CAE prompts you to select the face to which to extrude the profile. Select a face to meet the following requirements:

    - the selected face does not have to be parallel to the sketch plane,
    - it can be a nonplanar face,
    - it must completely contain the extruded selection, and

- it cannot be a datum plane.

Abaqus/CAE creates the extruded solid feature.



Additional information

- *What are extruding, revolving, and sweeping?*
- *Meshing complex solids with hexahedral elements*
- *What is feature-based modeling?*

Adding a revolved solid feature

Select **Shape->Solid->Revolve** from the main menu bar to add a revolved solid feature to the part in the current viewport. You can add a revolved solid feature only to three-dimensional parts.

You add a revolved solid feature by sketching a two-dimensional cross-section and a construction line on a selected face. The construction line serves as an axis of revolution, and Abaqus/CAE creates the solid feature by rotating the cross-section about the axis using a specified angle of revolution. In addition, you can specify a pitch and a direction along the axis of revolution that Abaqus/CAE uses to translate the sketch along the axis of revolution as it revolves the profile. A sketch and the resulting feature, revolved through an angle of 180° with pitch, are illustrated in the following figure:

1. From the main menu bar, select **Shape->Solid->Revolve**.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also add a revolved solid feature using the tool, located with the solid tools in the Part module toolbox. For a diagram of the tools in the Part module toolbox, see *Using the Part module toolbox*.

2. If desired, specify the method you want to use to select an origin for your sketch of the revolved solid feature. Select one of the following options from the **Sketch Origin** field in the prompt area:

   - Select **Auto-Calculate** to place the sketch origin automatically.
   - Select **Specify** to define a custom sketch origin.
   - Select **Session Default** to use the custom origin you specified earlier in the session.

3. Select the planar face from which the solid will be revolved. If no suitable face exists, you can select a datum plane or an orphan element face.

   Tip: If you are unable to select the desired planar face, you can use the **Selection** toolbar to change the selection behavior. For more information, see *Using the selection options*.

   The selected face is highlighted in the viewport.

4. If you selected **Specify** as the **Sketch Origin** method, specify the origin location by clicking a point in the viewport or by entering the three-dimensional coordinates of the origin in the prompt area. You can also set this custom origin as the default origin for all sketches in your session by toggling on **Set as session default**.

5. Select an edge and the orientation of the edge on the Sketcher grid. The edge must not be perpendicular to the selected face. By default, the selected edge will appear vertical and on the right side of the Sketcher grid. To choose a different orientation for the edge, click the arrow on the right side of the dialog box and choose an orientation from the list that appears.

   Tip: If there is no straight edge with the desired orientation, you can create a datum axis. You can then select the datum axis to control the orientation of the part on the Sketcher grid.

   Abaqus/CAE highlights the selected edge, enters the Sketcher, and rotates the part until the selected face aligns with the plane of the Sketcher grid and the selected edge aligns with the grid in the desired orientation.

   If you are unsure of the part's orientation relative to the Sketcher grid, use the view manipulation tools from the View Manipulation toolbar to view its position. Use the reset view tool to return to the original view.

6. Use the horizontal, vertical, angle, or oblique construction line tools to sketch the axis of rotation. You can position the construction line by selecting a datum axis from the underlying part. You cannot select the datum axis directly; you must select a point from either end of the datum axis.
7. Use the Sketcher to sketch the two-dimensional profile of the revolved feature; the sketch must not cross the axis of revolution.
8. In the prompt area, click **Done** to indicate you have finished sketching the profile and the axis. If the sketch contains more than one construction line, Abaqus/CAE prompts you to select the construction line that will serve as the axis of rotation.

   Abaqus/CAE displays the part view that was active prior to entering the Sketcher. The part includes your sketched profile and an arrow indicating the direction of revolution. The **Edit Revolution** dialog box appears.

9. In the **Edit Revolution** dialog box, enter the desired angle of revolution or accept the default value.
10. Click next to **Revolve direction** to change the arrow direction and the associated direction of revolution.
11. If desired, toggle on **Include translation** and enter a positive value for the pitch. The pitch value is the distance through which the profile is translated along the axis of revolution during a rotation of 360°.

    An arrow appears to show the axis of revolution and to indicate the direction of sketch translation along the axis. Click next to **Pitch direction** in the **Edit Revolution** dialog box to reverse the arrow, if necessary.

12. If desired, toggle on **Sweep sketch normal to path** to rotate the sketched profile normal to the path of revolution. This option is available only when **Include translation** is toggle on.

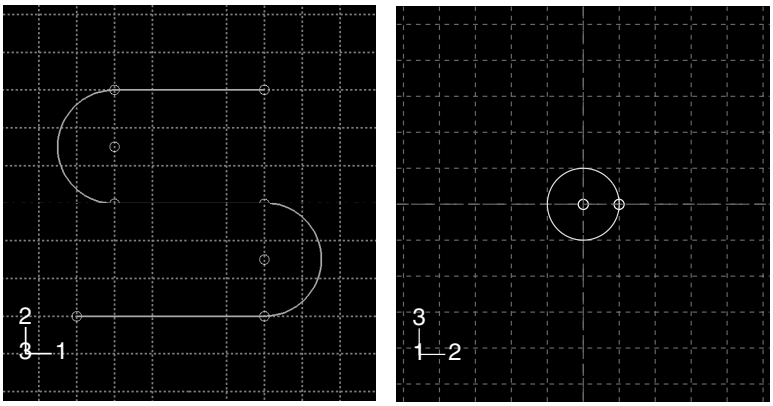
    The initial profile of the feature will be rotated from the sketch plane to create the feature.

13. Toggle on **Keep internal boundaries** to maintain any faces or edges that are generated between the revolved solid feature and the existing part. The internal boundaries may create regions that can be structured or swept meshed without having to resort to partitioning.
14. Click **OK** to accept the indicated direction and to create the revolved solid feature.

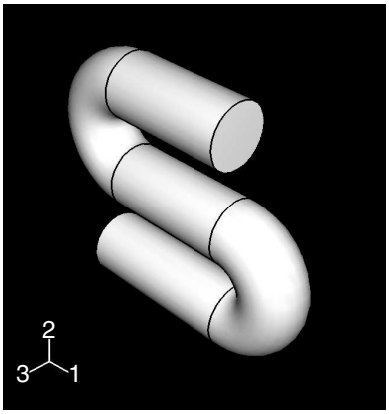
Abaqus/CAE creates the revolved feature using your selected parameters.

Additional information

- *Creating construction geometry*
- *Adding a solid feature*
- *Defining the axis of revolution for axisymmetric parts and for revolved features*
- *Controlling the cross-section of a revolved feature with pitch*
- *Meshing complex solids with hexahedral elements*
- *What is feature-based modeling?*



Adding a swept solid feature



Select **Shape**->**Solid**->**Sweep** from the main menu bar to add a swept solid feature to the part in the current viewport. You can add a swept solid feature only to three-dimensional parts.

You add a swept solid feature by first defining a sweep path, then defining a sweep profile. There are different methods available for defining each component:

- You can define a sweep path either by sketching the path on a selected face or by selecting a series of edges or wires that you want the sweep path to follow. The sketch method provides greater flexibility but supports only two-dimensional paths. The edge/wire method enables you to define a three-dimensional sweep path along a feature such as a spline wire or a set of edges in a three-dimensional part.
- You can define a sweep profile either by sketching a sweep profile using the Sketcher or by selecting one of the faces in your model as the profile. The sweep profile is initially perpendicular to the path; you can keep this orientation constant along the entire sweep path, or you can keep the sweep profile perpendicular to the sweep path as it is swept along its length.

The sweep path, the sweep profile, and the resulting solid feature are illustrated in the following figures:

The sketch or set of edges specifying the sweep path and the sketch or face specifying the sweep profile define the swept solid feature; both the sweep path and the sweep profile can be modified using the Feature Manipulation toolset if you define them using the Sketcher. You can also create a swept solid whose sweep profile is offset from the sweep path. In this case Abaqus/CAE moves the sweep path to a parallel location that passes through the sweep profile and creates the swept solid at that location.

As you define your sweep feature, you can apply a twist or draft to it. For more information about these tools, see *What types of features can you create?*. You can toggle on **Keep profile normal constant** to maintain the same orientation for the sweep profile as it travels along the sweep path; if this option is toggled off, the sweep profile orientation changes with the normal to the sweep path. In addition, you can toggle on **Keep internal boundaries** in the Feature Manipulation toolset to maintain any faces or edges that are generated between the swept solid feature and the existing part. The internal boundaries may create regions that can be structured or swept meshed without having to resort to partitioning.

1. From the main menu bar, select **Shape->Solid->Sweep**.

   Tip: You can also add a swept solid feature using the tool, located with the solid tools in the Part module toolbox. For a diagram of the tools in the Part module toolbox, see *Using the Part module toolbox*.

   The **Create Solid Sweep** dialog box appears.

2. If you want to sketch the sweep path, do the following:

   a. From the **Path** options, select **Sketch** and click .

      Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   b. If desired, specify the method you want to use to select an origin for your sketch of the swept solid feature. Select one of the following options from the **Sketch Origin** field in the prompt area:

      - Select **Auto-Calculate** to place the sketch origin automatically.
      - Select **Specify** to define a custom sketch origin.
      - Select **Session Default** to use the custom origin you specified earlier in the session.

   c. Select the planar face on which to sketch the sweep path. If no suitable face exists, you can select a datum plane.

      Tip: If you are unable to select the desired planar face, you can use the **Selection** toolbar to change the selection behavior. For more information, see *Using the selection options*.

   d. If you selected **Specify** as the **Sketch Origin** method, specify the origin location by clicking a point in the viewport or by entering the three-dimensional coordinates of the origin in the prompt area. You can also set this custom origin as the default origin for all sketches in your session by toggling on **Set as session default**.

   e. Select an edge and the orientation of the edge on the Sketcher grid. The edge must not be perpendicular to the selected face. By default, the selected edge will appear vertical and on the right side of the Sketcher grid. To choose a different orientation for the edge, click the arrow on the right side of the dialog box and choose an orientation from the list that appears.

      Tip: If there is no straight edge with the desired orientation, you can create a datum axis. You can then select the datum axis to control the orientation of the part on the Sketcher grid.

      Abaqus/CAE highlights the selected edge, enters the Sketcher, and rotates the part so that the selected face aligns with the plane of the Sketcher grid and the selected edge aligns with the grid in the desired orientation.

      If you are unsure of the part's orientation relative to the Sketcher grid, use the view manipulation tools from the View Manipulation toolbar to view its position. Use the reset view tool to return to the original view.

f. Sketch the sweep path. The sweep path must meet the following guidelines:

- The path can be closed, but the ends must meet smoothly; for example, the ends should not meet at a corner. For examples of valid sweep paths, see *Defining the sweep path and the sweep profile*.
- The path must be continuous; for example, it must not branch.
- The resulting solid cannot intersect with itself.

In the prompt area, click **Done** to indicate you have finished sketching the sweep path.

Abaqus/CAE exits the Sketcher and restores the original view of the part. A highlighted line indicates the sweep path and its direction. Abaqus/CAE also reopens the **Create Solid Sweep** dialog box and adds the word **(Defined)** next to the **Sketch** label in the **Path** options to indicate that the sweep path has been defined in the Sketcher.

3. If you want to specify the sweep path as a series of edges or wires, do the following:

a. From the **Path** options, select **Edges** and click .

Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

b. If desired, specify in the prompt area whether you want to select the edges in your sweep path **individually** or **by edge angle**. For more information about selecting objects, see *Using the angle and feature edge method to select multiple objects*.

c. Select the edges you want to include in the sweep path.

Abaqus/CAE shows the sweep path on your part and indicates the sweep direction.

d. In the prompt area, click **Yes** to confirm the sweep path direction or click **Flip** to reverse the sweep path direction.

Abaqus/CAE reopens the **Create Solid Sweep** dialog box and adds the word **(Defined)** next to the **Edges** label in the **Path** options to indicate that the sweep path has been defined using a series of edges.

4. If you want to sketch the sweep profile, do the following:

a. From the **Profile** options, select **Sketch** and click .

Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

b. Sketch the sweep profile. The sweep profile must meet the following guidelines:

- The profile must be closed.
- The resulting solid cannot intersect with itself.

You can sketch the profile anywhere on the Sketcher grid; Abaqus/CAE sweeps the profile along a path parallel to the sweep path. In the prompt area, click **Done** to indicate you have finished sketching the sweep profile.

Abaqus/CAE exits the Sketcher and restores the original view of the part.

c. Select an edge and the orientation of the edge on the Sketcher grid. The selected edge must not be parallel to the sweep path direction. By default, the selected edge will appear vertical and on the right side of the Sketcher grid. To choose a different orientation for the edge, click the arrow on the right side of the dialog box and choose an orientation from the list that appears.

Abaqus/CAE highlights the selected edge, enters the Sketcher again, and rotates the part so that the Sketcher grid lies on a plane normal to the beginning of the sweep path with the sweep path direction pointing out of the screen. In addition, the selected edge aligns with the grid in the desired orientation. The intersection of two dashed lines indicates the origin of the sweep path. Abaqus/CAE also reopens the **Create Solid Sweep** dialog box and adds the word **(Defined)** next to the **Sketch** label in the **Profile** options to indicate that the sweep profile has been defined in the Sketcher.

5. If you want to select a face as the sweep profile, do the following:

   a. From the **Profile** options, select **Face** and click .

      Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   b. Select a face from the viewport.

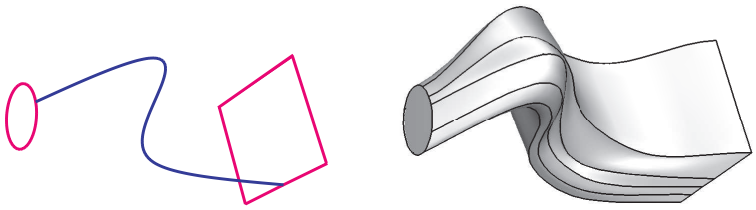
      Abaqus/CAE highlights the selected face and displays the **Create Solid Sweep** dialog box.

   Abaqus/CAE reopens the **Create Solid Sweep** dialog box and adds the word **(Defined)** next to the **Faces** label in the **Profile** options to indicate that the sweep profile has been defined using a face.

6. If desired, do any of the following:

   - Toggle on **Include twist**, and enter the pitch. The pitch is the extrusion distance in which a 360° twist would occur. The sketched extrusion profile must include an isolated point that indicates the center of twist.
   - Toggle on **Include draft**, and enter the draft angle (greater than −90° and less than 90°). A positive draft angle indicates that external faces of the profile expand and internal faces contract. You cannot apply a draft if the **Keep profile normal constant** option is selected.
   - Toggle on **Keep profile normal constant** to maintain the same profile orientation along the entire sweep path. If this option is toggled off, Abaqus/CAE adjusts the profile orientation so the angle between the sweep profile and the normal to the sweep path is always constant. You cannot toggle on this option if the **Include draft** option is selected.
   - Toggle on **Keep internal boundaries** to maintain any faces or edges that are generated between the swept solid feature and the existing part. The internal boundaries can create regions that can be structured or swept meshed without having to resort to partitioning.

7. Click **OK** to create the new swept solid.



Additional information

- *Adding a solid feature*
- *Defining the sweep path and the sweep profile*
- *The Sketch module*
- *What is feature-based modeling?*

Adding a solid loft feature

Select **Shape->Solid->Loft** from the main menu bar to add a solid loft feature to the part in the current viewport. You can add a solid loft feature only to three-dimensional parts.

You add a solid loft feature by creating two or more sections from selected edges and by defining one or more loft paths. Loft sections, a loft path, and the resulting solid loft feature are illustrated in the following figure:

You can allow Abaqus/CAE to define a single loft path using a smooth path to connect the center of each loft section. If you allow Abaqus/CAE to define the path, you can apply tangency methods to the start and end sections of the loft. The curve and tangencies define the path of the loft feature between sections. Alternatively, you can define one or more loft paths by selecting curves that connect a point on each loft section to a point on the next loft section. Each loft path must provide a continuous line connecting each consecutive loft section. If a loft path is not smooth (if there is more than one tangent to any point along the path), Abaqus/CAE will display an error message when you try to create the loft. For more information about loft sections, loft paths, and loft tangencies, see *What is lofting?*.

Note:

You do not use the Sketcher while adding a loft feature. As a result, all of the edges that define the loft sections and the loft paths must exist in the part geometry before you create the loft. To create a loft path or to create a nonplanar loft section, you can use the tool, located with the wire tools in the Part module toolbox, to create a spline wire (see *Adding a point-to-point wire feature*, for more information).

1. From the main menu bar, select **Shape->Solid->Loft**.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also add a solid loft feature using the tool, located with the solid tools in the Part module toolbox. For a diagram of the tools in the Part module toolbox, see *Using the Part module toolbox*.

   The **Edit Loft** dialog box appears.

2. Create the loft sections by selecting edges from the part in the viewport. See *Creating loft sections*, for detailed instructions on creating loft sections.
3. Toggle on **Keep internal boundaries** to maintain any faces or edges that are generated between the lofted solid feature and the existing part. The internal boundaries may create regions that can be structured or swept meshed without having to resort to partitioning.
4. When you have finished creating the loft sections, click on the **Transition** tab in the **Edit Loft** dialog box.
5. Do one of the following:

- Click **Select path** to create the loft path (or paths) by selecting edges from the part in the viewport.
- Click **Specify tangencies** to create the loft path (or paths) by using loft tangencies.

See *Creating a loft path*, for detailed instructions on creating a loft path.

6. Click the **Preview** button in the **Edit Loft** dialog box.

   Abaqus/CAE displays a wireframe representation of the loft that would be created with your current settings.

7. If desired, you can add or remove loft sections, change the loft path definition method, or edit the loft tangency options to change the shape of the loft feature. Click **Preview** to see the effect of your changes in the viewport.
8. If desired, you can have Abaqus/CAE test for self-intersection as it creates the loft feature. This test prevents creating a feature that would be difficult or impossible to mesh and analyze, but it becomes computationally expensive as the complexity of the loft feature increases. For more information, see *Self-intersection checks*. To use self-intersection checks, select **Feature->Options** to open the **Feature Options** dialog box, and toggle on **Perform self-intersection checks**.
9. Click **Done** to create the loft and to close the **Edit Loft** dialog box.

   If you choose to test for self-intersection and the test fails, the **Edit Loft** dialog box will reappear so that you can make changes. Otherwise, the solid loft feature is created in the viewport.

Additional information

- *Adding a solid feature*
- *What is feature-based modeling?*

Creating a solid feature from a shell

Select **Shape->Solid->From Shell** from the main menu bar to create a solid feature from a three-dimensional shell part by selecting the faces that will form a closed part. Abaqus/CAE adds the solid material to change the region defined by the selected faces from a shell to a solid.

1. From the main menu bar, select **Shape->Solid->From Shell**.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also create a solid feature from a shell by clicking the  tool, located with the solid tools in the Part module toolbox. For a diagram of the tools in the Part module toolbox, see *Using the Part module toolbox*.

2. Select faces from the shell that should be converted to a solid, and click mouse button 2 to indicate you have finished selecting faces.

   If you selected more than one face, Abaqus/CAE chooses the direction in which to add the solid material and changes the regions with the selected faces from a shell to a solid.

3. If you selected a single face, Abaqus/CAE highlights the face and displays an arrow indicating the direction in which material will be added to create the solid. If desired, click **Flip** to reverse the direction of the arrow.
4. Click mouse button 2 to confirm the direction of the arrow.

   Abaqus/CAE fills the shell in the direction indicated and creates a solid region.

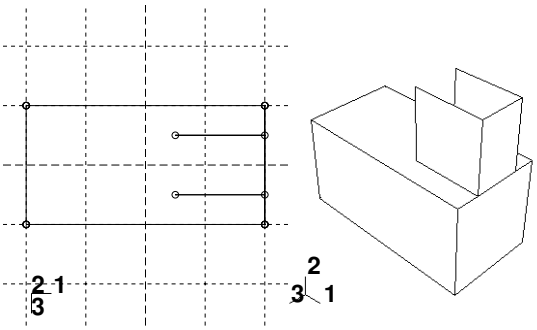
5. Click **Done** to create the solid part.

Additional information

- *Adding a solid feature*
- *What is feature-based modeling?*

Adding a shell feature

This section describes the tools used to add a shell feature to the part in the current viewport.



In this section:

- *Adding an extruded shell feature*
- *Adding a revolved shell feature*
- *Adding a swept shell feature*
- *Adding a shell loft feature*
- *Adding a planar shell feature*
- *Adding a shell-from-solid feature*

Adding an extruded shell feature

Select **Shape->Shell->Extrude** from the main menu bar to add an extruded shell feature to the part in the current viewport. You can add an extruded shell feature only to three-dimensional parts.

You add an extruded shell feature by sketching on a selected face and extending the profile a specified distance in a direction normal to the face. A sketch and the resulting extruded shell feature are illustrated in the following figure:

You can also define the distance over which to extrude by selecting a single face to extrude to. Abaqus/CAE extrudes the sketch until it meets the selected face.

In addition, you can select a center point and specify a pitch that Abaqus/CAE uses to twist the cross-section as it is extruded. Alternatively, Abaqus/CAE can expand or contract the cross-section along a specified draft angle as the cross-section is extruded. For more information, see *Including twist in an extrusion*, and *Including draft in an extrusion*.

1. From the main menu bar, select **Shape->Shell->Extrude**.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also add an extruded shell feature using the tool, located with the shell tools in the Part module toolbox. For a diagram of the tools in the Part module toolbox, see *Using the Part module toolbox*.

2. If desired, specify the method you want to use to select an origin for your sketch of the extruded shell feature. Select one of the following options from the **Sketch Origin** field in the prompt area:

   - Select **Auto-Calculate** to place the sketch origin automatically.
   - Select **Specify** to define a custom sketch origin.
   - Select **Session Default** to use the custom origin you specified earlier in the session.

3. Select the planar face from which the shell will be extruded. If no suitable face exists, you can select a datum plane or an orphan element face.

   Tip: If you are unable to select the desired planar face, you can use the **Selection** toolbar to change the selection behavior. For more information, see *Using the selection options*.

   The selected face is highlighted in the viewport.

4. If you selected **Specify** as the **Sketch Origin** method, specify the origin location by clicking a point in the viewport or by entering the three-dimensional coordinates of the origin in the prompt area. You

can also set this custom origin as the default origin for all sketches in your session by toggling on **Set as session default**.

5. Select an edge and the orientation of the edge on the Sketcher grid. The edge must not be perpendicular to the selected face. By default, the selected edge will appear vertical and on the right side of the Sketcher grid. To choose a different orientation for the edge, click the arrow on the right side of the dialog box and choose an orientation from the list that appears.

   Tip: If the edge of the selected face is curved or does not provide the desired orientation, you can create a datum axis. You can then select the datum axis to control the orientation of the part on the Sketcher grid.

   Abaqus/CAE highlights the selected edge, enters the Sketcher, and rotates the part until the selected face aligns with the plane of the Sketcher grid and the selected edge aligns with the grid in the desired orientation.

   If you are unsure of the part's orientation relative to the Sketcher grid, use the view manipulation tools from the View Manipulation toolbar to view its position. Use the reset view tool to return to the original view.

6. Use the Sketcher to sketch the profile of the line to be extruded. In the prompt area, click **Done** to exit the Sketcher and to open the **Edit Extrusion** dialog box.

   Abaqus/CAE displays the part view that was active prior to entering the Sketcher. The part includes your sketched profile and an arrow indicating the extrusion direction.

7. Click in the **Edit Extrusion** dialog box to reverse the extrusion direction, if necessary.

   If the arrow direction is difficult to see, use the rotate tool to rotate the part.

8. Select one of the following end conditions:

   - Select **Blind** and enter a value in the **Depth** field to specify the distance through which Abaqus/CAE will extrude the sketched profile.
   - Select **Up to Face** to specify that Abaqus/CAE will extrude the profile up to a selected face.

9. If desired, do one of the following:

   - Toggle on **Include twist**, and enter the pitch. The pitch is the extrusion distance in which a 360° twist would occur. The sketched extrusion profile must include an isolated point that indicates the center of twist.
   - Toggle on **Include draft**, and enter the draft angle (greater than –90° and less than 90°). A positive draft angle indicates that external faces of the profile expand and internal faces contract.

     Note:

     When you use draft with a shell feature, discontinuous profiles cannot be used. A discontinuous profile is a profile that is connected but cannot be traced in one continuous motion. If you specify draft on a discontinuous profile, Abaqus/CAE applies the draft angle to each face individually and the extruded edges are not joined.

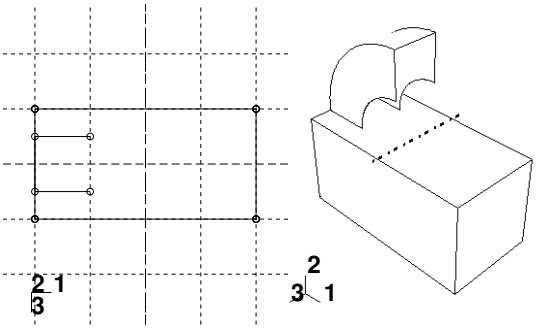
10. Toggle on **Keep internal boundaries** to maintain any faces or edges that are generated between the extruded shell feature and the existing part. The internal boundaries may create regions that can be structured or swept meshed without having to resort to partitioning.
11. Click **OK** to extrude the profile.

If you selected the twist option and your sketch includes a single isolated point, Abaqus/CAE uses that point as the center of twist. If your sketch does not include an isolated point, Abaqus/CAE returns to the Sketcher for you to create one. If your sketch contains more than one isolated point, Abaqus/CAE returns to the Sketcher and prompts you to select an isolated point as the center of twist.

12. If you selected **Up to Face**, Abaqus/CAE prompts you to select the face to which to extrude the profile. Select a face to meet the following requirements:

    - the selected face does not have to be parallel to the sketch plane,
    - it can be a nonplanar face,
    - it must completely contain the extruded selection, and
    - it cannot be a datum plane.

    Abaqus/CAE creates the extruded shell feature.



Additional information

- *The Datum toolset*
- *Adding a shell feature*
- *The Sketch module*
- *What is feature-based modeling?*

Adding a revolved shell feature

Select **Shape->Shell->Revolve** from the main menu bar to add a revolved shell feature to the part in the current viewport. You can add a revolved shell feature only to three–dimensional parts.

You add a revolved shell feature by sketching a profile and a construction line on a selected face. The construction line serves as an axis of revolution, and Abaqus/CAE creates the shell feature by rotating the profile about the axis using a specified angle of revolution. A sketch and the resulting feature, rotated about the axis of revolution through an angle of 90°, are illustrated in the following figure:

In addition, you can specify a pitch and a direction along the axis of revolution that Abaqus/CAE uses to translate the sketch along the axis of revolution as it revolves the profile.

1. From the main menu bar, select **Shape->Shell->Revolve**.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also add a revolved shell feature using the tool, located with the shell tools in the Part module toolbox. For a diagram of the tools in the Part module toolbox, see *Using the Part module toolbox*.

2. If desired, specify the method you want to use to select an origin for your sketch of the revolved shell feature. Select one of the following options from the **Sketch Origin** field in the prompt area:

   - Select **Auto-Calculate** to place the sketch origin automatically.
   - Select **Specify** to define a custom sketch origin.
   - Select **Session Default** to use the custom origin you specified earlier in the session.

3. Select the planar face from which the shell will be revolved. If no suitable face exists, you can select a datum plane or an orphan element face.

   Tip: If you are unable to select the desired planar face, you can use the **Selection** toolbar to change the selection behavior. For more information, see *Using the selection options*.

   The selected face is highlighted in the viewport.

4. If you selected **Specify** as the **Sketch Origin** method, specify the origin location by clicking a point in the viewport or by entering the three-dimensional coordinates of the origin in the prompt area. You can also set this custom origin as the default origin for all sketches in your session by toggling on **Set as session default**.

5. Select an edge and the orientation of the edge on the Sketcher grid. The edge must not be perpendicular to the selected face. By default, the selected edge will appear vertical and on the right side of the Sketcher grid. To choose a different orientation for the edge, click the arrow on the right side of the dialog box and choose an orientation from the list that appears.

   Tip: If the edge of the selected face is curved or does not provide the desired orientation, you can create a datum axis. You can then select the datum axis to control the orientation of the part on the Sketcher grid.

   Abaqus/CAE highlights the selected edge, enters the Sketcher, and rotates the part until the selected face aligns with the plane of the Sketcher grid and the selected edge aligns with the grid in the desired orientation.

   If you are unsure of the part's orientation relative to the Sketcher grid, use the view manipulation tools from the View Manipulation toolbar to view its position. Use the reset view tool to return to the original view.

6. Use the horizontal, vertical, angle, or oblique construction line tools to sketch the axis of rotation. You can position the construction line by selecting a datum axis from the underlying part. You cannot select the datum axis directly; you must select a point from either end of the datum axis.
7. Use the Sketcher to sketch the two-dimensional profile of the revolved feature; the sketch must not cross the axis of revolution.
8. In the prompt area, click **Done** to indicate you have finished sketching the profile and the axis. If the sketch contains more than one construction line, Abaqus/CAE prompts you to select the construction line that will serve as the axis of rotation.

   Abaqus/CAE displays the part view that was active prior to entering the Sketcher. The part includes your sketched profile and an arrow indicating the direction of revolution. The **Edit Revolution** dialog box appears.
9. In the **Edit Revolution** dialog box, enter the desired angle of revolution or accept the default value.
10. Click next to **Revolve direction** to change the arrow direction and the associated direction of revolution.
11. If desired, toggle on **Include translation**, and enter a positive value for pitch. The pitch value is the distance through which the profile is translated along the axis of revolution during a rotation of 360°.

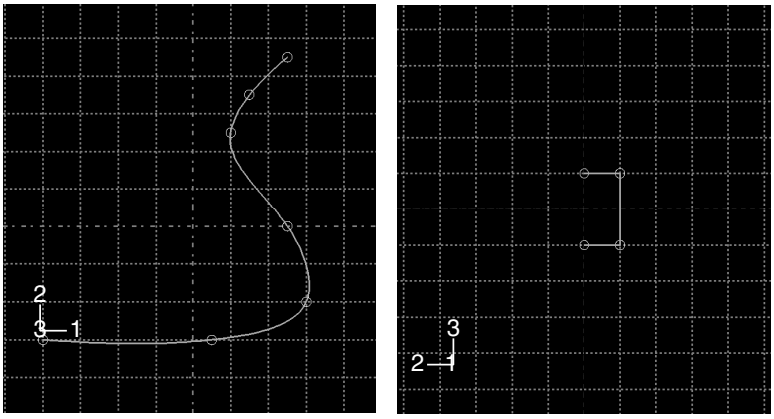
    An arrow appears to show the axis of revolution and to indicate the direction of sketch translation along the axis. Click next to **Pitch direction** in the **Edit Revolution** dialog box to reverse the arrow, if necessary.
12. If desired, toggle on **Sweep sketch normal to path** to rotate the sketched profile normal to the path of revolution. This option is available only when **Include translation** is used.

    The initial profile of the feature will be rotated from the sketch plane to create the feature.
13. Toggle on **Keep internal boundaries** to maintain any faces or edges that are generated between the revolved shell feature and the existing part. The internal boundaries may create regions that can be structured or swept meshed without having to resort to partitioning.
14. Click **OK** to accept the indicated direction and to create the revolved shell feature.

Abaqus/CAE creates the revolved feature using your selected parameters.

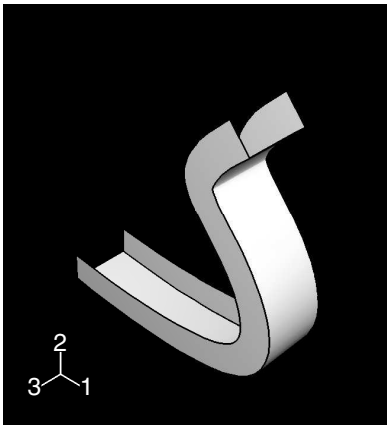
Additional information

- *Creating construction geometry*
- *Adding a shell feature*
- *Defining the axis of revolution for axisymmetric parts and for revolved features*
- *Controlling the cross-section of a revolved feature with pitch*
- *The Sketch module*
- *What is feature-based modeling?*



Adding a swept shell feature

Select **Shape**->**Shell**->**Sweep** from the main menu bar to add a swept shell feature to the part in the current viewport. You can add a swept shell feature only to three-dimensional parts.



You add a swept shell feature by first defining a sweep path, then defining a sweep profile. There are different methods available for defining each component:

- You can define a sweep path either by sketching the path on a selected face or by selecting a series of edges or wires that you want the sweep path to follow. The sketch method provides greater flexibility but supports only two-dimensional paths. The edge/wire method enables you to define a three-dimensional sweep path along a feature such as a spline wire or a set of edges in a three-dimensional part.
- You can define a sweep profile either by sketching a sweep profile using the Sketcher or by selecting one of the faces in your model as the profile. The sweep profile is initially perpendicular to the path; you can keep this orientation constant along the entire sweep path, or you can keep the sweep profile perpendicular to the sweep path as it is swept along its length.

The sweep path (a spline) and the sweep profile are shown in the following figure:

The resulting swept shell feature is shown in the following figure:

The sketch or set of edges defining the sweep path and the sketch, edge, or edges defining the sweep profile combine to define the swept shell feature; both the sweep path and the sweep profile can be modified using the Feature Manipulation toolset if you define them using the Sketcher. You can define a swept shell whose sweep profile is offset

from the sweep path. In this case Abaqus/CAE moves the sweep path to a parallel location that passes through the sweep profile and creates the swept shell feature at that location.

As you define your sweep feature, you can apply a twist or draft to it. For more information about these tools, see *What types of features can you create?*. You can toggle on **Keep profile normal constant** to maintain the same orientation for the sweep profile as it travels along the sweep path; if this option is toggled off, the sweep profile orientation changes with the normal to the sweep path. In addition, you can toggle on **Keep internal boundaries** in the Feature Manipulation toolset to maintain any faces or edges that are generated between the swept shell feature and the existing part. The internal boundaries can create regions that can be structured or swept meshed without having to resort to partitioning.

1. From the main menu bar, select **Shape->Shell->Sweep**.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also add a swept shell feature using the tool, located with the shell tools in the Part module toolbox. For a diagram of the tools in the Part module toolbox, see *Using the Part module toolbox*.

2. If you want to sketch the sweep path, do the following:

   a. From the **Path** options, select **Sketch** and click .

      Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   b. If desired, specify the method you want to use to select an origin for your sketch of the swept solid feature. Select one of the following options from the **Sketch Origin** field in the prompt area:

      - Select **Auto-Calculate** to place the sketch origin automatically.
      - Select **Specify** to define a custom sketch origin.
      - Select **Session Default** to use the custom origin you specified earlier in the session.

   c. Select the planar face on which to sketch the sweep path. If no suitable face exists, you can select a datum plane.

      Tip: If you are unable to select the desired planar face, you can use the **Selection** toolbar to change the selection behavior. For more information, see *Using the selection options*.

   d. If you selected **Specify** as the **Sketch Origin** method, specify the origin location by clicking a point in the viewport or by entering the three-dimensional coordinates of the origin in the prompt area. You can also set this custom origin as the default origin for all sketches in your session by toggling on **Set as session default**.

   e. Select an edge and the orientation of the edge on the Sketcher grid. The edge must not be perpendicular to the selected face. By default, the selected edge will appear vertical and on the right side of the Sketcher grid. To choose a different orientation for the edge, click the arrow on the right side of the dialog box and choose an orientation from the list that appears.

      Tip: If there is no straight edge with the desired orientation, you can create a datum axis. You can then select the datum axis to control the orientation of the part on the Sketcher grid.

      Abaqus/CAE highlights the selected edge, enters the Sketcher, and rotates the part so that the selected face aligns with the plane of the Sketcher grid and the selected edge aligns with the grid in the desired orientation.

If you are unsure of the part's orientation relative to the Sketcher grid, use the view manipulation tools from the View Manipulation toolbar to view its position. Use the reset view tool  to return to the original view.

f. Sketch the sweep path. The sweep path must meet the following guidelines:

- The path can be closed, but the ends must meet smoothly; for example, the ends should not meet at a corner. For examples of valid sweep paths, see *Defining the sweep path and the sweep profile*.
- The path must be continuous; for example, it must not branch.
- The resulting solid cannot intersect with itself.

In the prompt area, click **Done** to indicate you have finished sketching the sweep path.

Abaqus/CAE exits the Sketcher and restores the original view of the part. A highlighted line indicates the sweep path and its direction. Abaqus/CAE also reopens the **Create Shell Sweep** dialog box and adds the word **(Defined)** next to the **Sketch** label in the **Path** options to indicate that the sweep path has been defined in the Sketcher.

3. If you want to specify the sweep path as a series of edges or wires, do the following:

a. From the **Path** options, select **Edges** and click .

Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

b. If desired, specify in the prompt area whether you want to select the edges in your sweep path **individually** or **by edge angle**. For more information about selecting objects, see *Using the angle and feature edge method to select multiple objects*.

c. Select the edges you want to include in the sweep path.

Abaqus/CAE shows the sweep path on your part and indicates the sweep direction.

d. In the prompt area, click **Yes** to confirm the sweep path direction or click **Flip** to reverse the sweep path direction.

Abaqus/CAE reopens the **Create Shell Sweep** dialog box and adds the word **(Defined)** next to the **Edges** label in the **Path** options to indicate that the sweep path has been defined using a series of edges.

4. If you want to sketch the sweep profile, do the following:

a. From the **Profile** options, select **Sketch** and click .

Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

b. Sketch the sweep profile. The sweep profile must meet the following guidelines:

- The profile must be closed.
- The resulting solid cannot intersect with itself.

You can sketch the profile anywhere on the Sketcher grid; Abaqus/CAE sweeps the profile along a path parallel to the sweep path. In the prompt area, click **Done** to indicate you have finished sketching the sweep profile.

Abaqus/CAE exits the Sketcher and restores the original view of the part.

c. Select an edge and the orientation of the edge on the Sketcher grid. The selected edge must not be parallel to the sweep path direction. By default, the selected edge will appear vertical and on the right side of the Sketcher grid. To choose a different orientation for the edge, click the arrow on the right side of the dialog box and choose an orientation from the list that appears.

Abaqus/CAE highlights the selected edge, enters the Sketcher again, and rotates the part so that the Sketcher grid lies on a plane normal to the beginning of the sweep path with the sweep path direction pointing out of the screen. In addition, the selected edge aligns with the grid in the desired orientation. The intersection of two dashed lines indicates the origin of the sweep path. Abaqus/CAE also reopens the **Create Shell Sweep** dialog box and adds the word **(Defined)** next to the **Sketch** label in the **Profile** options to indicate that the sweep profile has been defined in the Sketcher.

5. If you want to select one or more edges as the sweep profile, do the following:

   a. From the **Profile** options, select **Edges** and click .

      Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   b. Select one or more edges from the viewport.

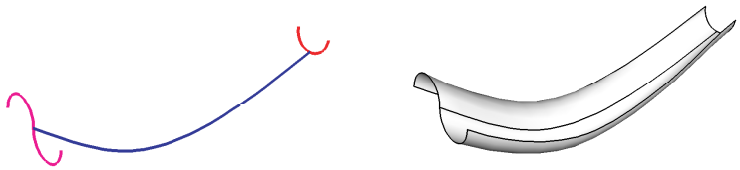
      Abaqus/CAE highlights the selected face and displays the **Create Shell Sweep** dialog box.

   Abaqus/CAE reopens the **Create Shell Sweep** dialog box and adds the word **(Defined)** next to the **Edges** label in the **Profile** options to indicate that the sweep profile has been defined using one or more edges.

6. If desired, do one of the following:

   - Toggle on **Include twist**, and enter the pitch. The pitch is the extrusion distance in which a 360° twist would occur. The sketched extrusion profile must include an isolated point that indicates the center of twist.
   - Toggle on **Include draft**, and enter the draft angle (greater than −90° and less than 90°). A positive draft angle indicates that external faces of the profile expand and internal faces contract. You cannot apply a draft if the **Keep profile normal constant** option is selected.
   - Toggle on **Keep profile normal constant** to maintain the same profile orientation along the entire sweep path. If this option is toggled off, Abaqus/CAE adjusts the profile orientation so that the angle between the sweep profile and the normal to the sweep path is always constant. You cannot toggle on this option if the **Include draft** option is selected.
   - Toggle on **Keep internal boundaries** to maintain any faces or edges that are generated between the swept solid feature and the existing part. The internal boundaries can create regions that can be structured or swept meshed without having to resort to partitioning.

7. Click **OK** to create the new swept shell.



Additional information

- *Defining the sweep path and the sweep profile*
- *The Sketch module*
- *What is feature-based modeling?*

Adding a shell loft feature

Select **Shape->Shell->Loft** from the main menu bar to add a shell loft feature to the part in the current viewport. You can add a shell loft feature only to three-dimensional parts.

You add a shell loft feature by creating two or more sections from selected edges and by defining one or more loft paths. Loft sections, a loft path, and the resulting shell loft feature are illustrated in the following figure:

You can allow Abaqus/CAE to define a single loft path using a smooth path to connect the center of each loft section. If you allow Abaqus/CAE to define the path, you can apply tangency methods to the start and end sections of the loft. The curve and tangencies define the path of the loft feature between sections. Alternatively, you can define one or more loft paths by selecting curves that connect a point on each loft section to a point on the next loft section. Each loft path must provide a continuous line connecting each consecutive loft section. If a loft path is not smooth (if there is more than one tangent to any point along the path), Abaqus/CAE will display an error message when you try to create the loft. For more information about loft sections, loft paths, and loft tangencies, see *What is lofting?*.

Note:

You do not use the Sketcher while adding a loft feature. As a result, all of the edges that define the loft sections and the loft paths must exist in the part geometry before you create the loft. To create a loft path or to create a nonplanar loft section, you can use the tool, located with the wire tools in the Part module toolbox, to create a spline wire (see *Adding a point-to-point wire feature*, for more information).

1. From the main menu bar, select **Shape->Shell->Loft**.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also add a shell loft feature using the tool, located with the shell tools in the Part module toolbox. For a diagram of the tools in the Part module toolbox, see *Using the Part module toolbox*.

   The **Edit Loft** dialog box appears.

2. Create the loft sections by selecting edges from the part in the viewport. See *Creating loft sections*, for detailed instructions on creating loft sections.

   Toggle on **Keep internal boundaries** to maintain any faces or edges that are generated between the lofted shell feature and the existing part. The internal boundaries may create regions that can be structured or swept meshed without having to resort to partitioning.

3. When you have finished creating the loft sections, click on the **Transition** tab in the **Edit Loft** dialog box.
4. Do one of the following:

- Click **Select path** to create the loft path (or paths) by selecting edges from the part in the viewport.
- Click **Specify tangencies** to create the loft path (or paths) by using loft tangencies.

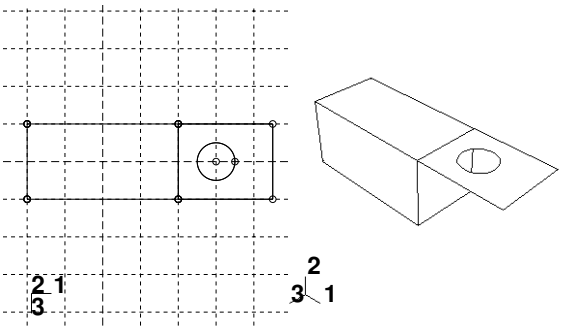
See *Creating a loft path*, for detailed instructions on creating a loft path.

5. Click **Preview**.

   Abaqus/CAE displays a wireframe representation of the loft that would be created with your current settings.

6. If desired, you can add or remove loft sections, change the loft path definition method, or edit the loft tangency options to change the shape of the loft feature. Click **Preview** to see the effect of your changes in the viewport.
7. If desired, you can have Abaqus/CAE test for self-intersection as it creates the loft feature. This test prevents creating a feature that would be difficult or impossible to mesh and analyze, but it becomes computationally expensive as the complexity of the loft feature increases. For more information, see *Self-intersection checks*. To use self-intersection checks, select **Feature->Options** to open the **Feature Options** dialog box, and toggle on **Perform self-intersection checks**.
8. Click **Done** to create the loft and to close the **Edit Loft** dialog box.

   If you choose to test for self-intersection and the test fails, the **Edit Loft** dialog box will reappear so that you can make changes. Otherwise, the shell loft feature is created in the viewport.



Additional information

- *Adding a shell feature*
- *What is feature-based modeling?*

Adding a planar shell feature

Select **Shape->Shell->Planar** from the main menu bar to add a planar shell feature to the part in the current viewport. The planar shell tool is always available, regardless of the modeling space of the part in the current viewport.

You add a planar shell feature by sketching the feature on a selected face. A sketch and the resulting planar shell feature are illustrated in the following figure:

The sketch defines a planar shell feature and can be modified using the Feature Manipulation toolset.

1. From the main menu bar, select **Shape->Shell->Planar**.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also add a planar shell feature using the tool, located with the shell tools in the Part module toolbox. For a diagram of the tools in the Part module toolbox, see *Using the Part module toolbox*.

2. If desired, specify the method you want to use to select an origin for your sketch of the planar shell feature. Select one of the following options from the **Sketch Origin** field in the prompt area:

   - Select **Auto-Calculate** to place the sketch origin automatically.
   - Select **Specify** to define a custom sketch origin.
   - Select **Session Default** to use the custom origin you specified earlier in the session.

3. If the modeling space of the part is two-dimensional or axisymmetric, Abaqus/CAE enters the Sketcher and aligns the *X*- and *Y*-axes of the part and the sketch.

   If the modeling space of the part is three-dimensional, do the following:

   a. Select the planar face on which the shell will be positioned. If no suitable face exists, you can select a datum plane.

   Tip: If you are unable to select the desired planar face, you can use the **Selection** toolbar to change the selection behavior. For more information, see *Using the selection options*.

   b. If you selected **Specify** as the **Sketch Origin** method, specify the origin location by clicking a point in the viewport or by entering the three-dimensional coordinates of the origin in the prompt area. You can also set this custom origin as the default origin for all sketches in your session by toggling on **Set as session default**.

   c. Select an edge and the orientation of the edge on the Sketcher grid. The edge must not be perpendicular to the selected face. By default, the selected edge will appear vertical and on the

right side of the Sketcher grid. To choose a different orientation for the edge, click the arrow on the right side of the dialog box and choose an orientation from the list that appears.

Tip: If the edge of the selected face is curved or does not provide the desired orientation, you can create a datum axis. You can then select the datum axis to control the orientation of the part on the Sketcher grid.

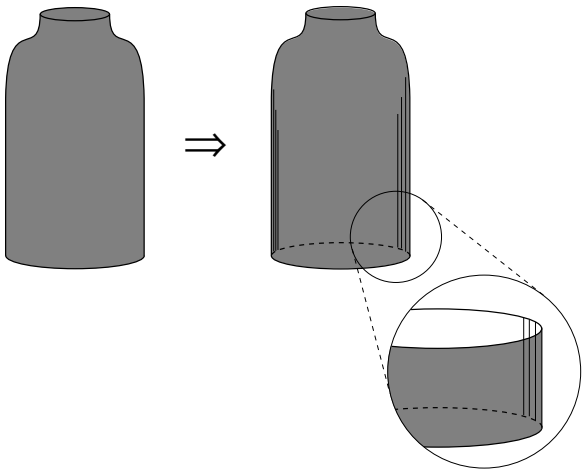
Abaqus/CAE highlights the selected edge, enters the Sketcher, and rotates the part until the selected face aligns with the plane of the Sketcher grid and the selected edge aligns with the grid in the desired orientation.

If you are unsure of the part's orientation relative to the Sketcher grid, use the view manipulation tools from the View Manipulation toolbar to view its position. Use the reset view tool  to return to the original view.

4. Use the Sketcher to sketch the planar shell. In the prompt area, click **Done** to indicate you have finished sketching.

   The part returns to its original orientation with the planar shell positioned on the selected face. The shell feature is created only where it extends beyond the faces of the part; a shell feature cannot overlap a face.

Additional information



- *Adding a shell feature*
- *The Sketch module*
- *What is feature-based modeling?*

Adding a shell-from-solid feature

Select **Shape->Shell->From Solid** from the main menu bar to create a shell feature from the faces of a solid feature. You can add a shell-from-solid feature only to three-dimensional parts.

You add a shell-from-solid feature by selecting the cells to remove from the part; Abaqus/CAE converts any remaining faces associated with the removed cells to shells.

The **From Solid** tool is an easy way to create shells with curved edges, as shown in the following figure. The curved edges of the solid were created by filleting the edges using the round tool.

1. From the main menu bar, select **Shape->Shell->From Solid**.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also add a shell–from–solid feature using the tool, located with the shell tools in the Part module toolbox. For a diagram of the tools in the Part module toolbox, see *Using the Part module toolbox*.

2. Select one or more cells to convert to shells. **[Shift] + Click** additional cells to add them to your selection and **[Ctrl] + Click** a selected cell to unselect it. Click mouse button 2 to indicate you have finished selecting cells to convert.

   Abaqus/CAE converts the selected cells to shells.

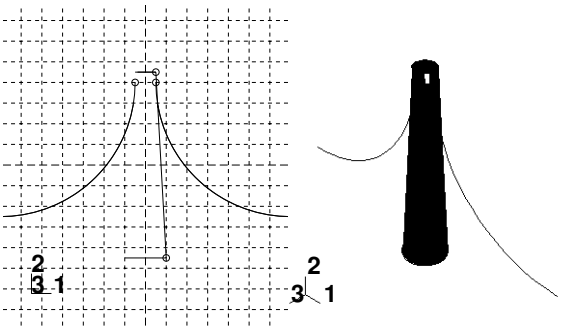
   Tip: Use the **Previous** button ( ) to undo one or more steps; use the cancel button ( ) to stop the creation of the shell from solid.

Additional information

- *Adding a shell feature*
- *The Sketch module*
- *What is feature-based modeling?*

Adding a wire feature

This section describes the Part module tools used to add a wire feature to the part in the current viewport. This section also describes adding a wire feature to an assembly.



In this section:

- *Adding a sketched wire feature*
- *Adding a point-to-point wire feature*
- *Rounding vertices in a wire*
- *Adding a wire-from-edge feature*

Adding a sketched wire feature

Select **Shape->Wire->Sketch** from the main menu bar to add a sketched planar wire feature to the part in the current viewport. The planar wire tool is always available, regardless of the modeling space of the part in the current viewport.

You add a planar wire feature by sketching the feature on a selected plane. Abaqus/CAE removes any portion of the wire that overlaps an existing face. A sketch and the resulting planar wires are illustrated in the following figure:

The sketch fully defines a planar wire feature and can be modified using the Feature Manipulation toolset.

1. From the main menu bar, select **Shape->Wire->Sketch**.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also add a sketched wire feature using the  tool, located with the wire tools in the Part module toolbox. For a diagram of the tools in the Part module toolbox, see *Using the Part module toolbox*.

2. If desired, specify the method you want to use to select an origin for your sketch of the sketched wire feature. Select one of the following options from the **Sketch Origin** field in the prompt area:

   - Select **Auto-Calculate** to place the sketch origin automatically.
   - Select **Specify** to define a custom sketch origin.
   - Select **Session Default** to use the custom origin you specified earlier in the session.

3. If the modeling space of the part is two-dimensional or axisymmetric, Abaqus/CAE enters the Sketcher and aligns the *X*- and *Y*-axes of the part and the sketch.

   If the part is three-dimensional, do the following:

   a. Select the planar face on which the wire will be positioned. If no suitable face exists, you can select a datum plane.

   Tip: If you are unable to select the desired planar face, you can use the **Selection** toolbar to change the selection behavior. For more information, see *Using the selection options*.

   b. Select an edge and the orientation of the edge on the Sketcher grid. The edge must not be perpendicular to the selected face. By default, the selected edge will appear vertical and on the right side of the Sketcher grid. To choose a different orientation for the edge, click the arrow on the right side of the dialog box and choose an orientation from the list that appears.

Tip: If the edge of the selected face is curved or does not provide the desired orientation, you can create a datum axis. You can then select the datum axis to control the orientation of the part on the Sketcher grid.

Abaqus/CAE highlights the selected edge, enters the Sketcher, and rotates the part until the selected face aligns with the plane of the Sketcher grid and the selected edge aligns with the grid in the desired orientation.

If you are unsure of the part's orientation relative to the Sketcher grid, use the view manipulation tools from the View Manipulation toolbar to view its position. Use the reset view tool  to return to the original view.

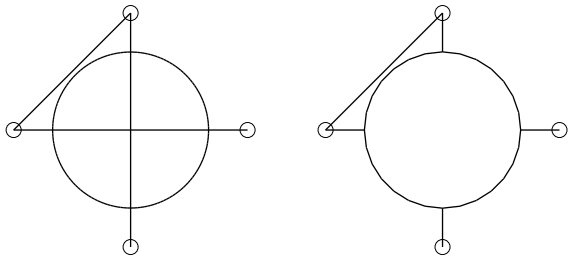
4. If you selected **Specify** as the **Sketch Origin** method, specify the origin location by clicking a point in the viewport or by entering the three-dimensional coordinates of the origin in the prompt area. You can also set this custom origin as the default origin for all sketches in your session by toggling on **Set as session default**.
5. Use the Sketcher to sketch the planar wire. In the prompt area, click **Done** to indicate you have finished sketching.

   The part returns to its original orientation with the planar wire positioned on the selected face. The wire feature is created only where it extends beyond the faces of the part; a wire feature cannot overlap a face.

Additional information

- *What is feature-based modeling?*
- *Adding a wire feature*
- *The Sketch module*

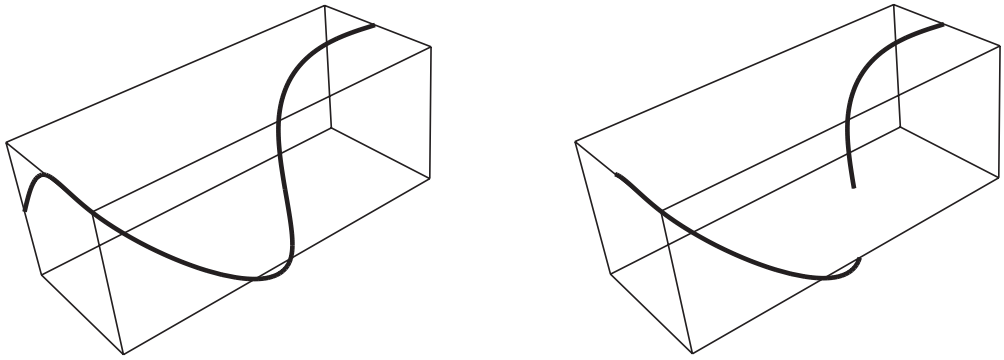
Adding a point-to-point wire feature



You can add a point-to-point wire feature to a part or to an assembly.
For assembly-level wire features, you can modify the wire feature or remove wires from the feature, as described in *Creating or modifying wire features for multiple connectors*.

Assembly-level wire features are nonmeshable. The wire feature contains wires connecting points from the part or assembly in the current viewport or connecting points from the part or assembly to ground. To model connectors you must define one or more wire features on your assembly. When you create a wire feature on a part or an assembly, you can create a geometry set that includes the wires defined in the wire feature. In addition, when you create a wire feature on a part, you can create geometry sets that include the vertices defined in the wire feature.

To add a wire feature on a part, select **Shape->Wire->Point to Point** from the main menu bar in the Part module. The point-to-point wire tool is always available in the Part module, regardless of the modeling space of the part in the current viewport. To add a wire feature on an assembly, select **Connector->Geometry->Create Wire Feature** from the main menu bar in the Interaction module.



You add a point-to-point wire feature to a part by choosing a geometry type, polyline, or spline; for assemblies you can add only a polyline wire feature. You can choose to imprint the wire on the existing part by creating edges, merge the wire with the existing part, or create the wire separate from the existing part. The wire merge options are available only in the Part module.

If you are creating polyline wires, you must next choose a point selection method and pick points to connect from the current part or assembly. You can choose to select disjointed points (that is, not automatically connected end-to-end), chained points (that is, automatically connected end-to-end), or points that are connected to ground. Abaqus/CAE connects the point pairs with a straight line or connects the points to ground depending on the method that you select. A polyline wire feature connecting four points in a part is illustrated in the following figure:

The planar shell feature is shown for reference. The image on the left shows the full length of the point-to-point wire using the **Imprint wire** or **Separate wire** options, while the image on the right shows a point-to-point wire connecting the same set of points using the **Merge wire** option.

If you are creating spline wires on a part, the chained point selection method is the only one available. Abaqus/CAE calculates the shape of the curve by using a cubic spline fit between all points along the spline; in addition, the first and second derivatives of the spline are continuous. A spline wire feature is illustrated in the following figure:

The rectangular solid feature is shown for reference. The image on the left shows the full length of the spline wire using the **Imprint wire** or **Separate wire** options, while the image on the right shows a spline wire connecting the same set of points using the **Merge wire** option.

During creation of the wire feature on a part or assembly, you can modify the point selections. For part-level wire features, in most cases, once you have created the wire feature, you cannot modify it directly. You might be able to remove a wire edge from the feature using the Geometry Edit toolset. (For more information, see *Removing wire edges*). If you want to change the points that are connected or the connection order, you must delete the wire and create a new wire connecting the desired points. Since the point-to-point wire is dependent on points created by other features, you can modify the wire by using the Feature Manipulation toolset to modify the features that created the points.

Although you cannot create a part with a nonplanar wire base feature, you can create a nonplanar point-to-point wire feature by using a single point in space as the base feature and entering coordinates for the remaining points. In this case the starting point is the only point that you can edit to modify the wire. You can also use datum points, in which case you can edit all points.

1. Display the **Create Wire Feature** dialog box using one of the following methods:

   - From the main menu bar in the Part module, select **Shape->Wire->Point to Point**.

     Tip: You can also add a point-to-point wire feature to a part using the tool, located with the wire tools in the Part module toolbox. For a diagram of the tools in the Part module toolbox, see *Using the Part module toolbox*.

   - From the main menu bar in the Interaction module, select **Connector->Geometry->Create Wire Feature**.

     Tip: You can also add a wire feature to an assembly using the tool, located in the Interaction module toolbox. For a diagram of the tools in the Interaction module toolbox, see *Using the Interaction module toolbox*.

2. If you are creating a wire in the Part module, choose **Polyline** to create one or more straight lines or choose **Spline** to create a continuous spline curve.
3. If you are adding a wire feature to a part, specify a merge option in the **Wire Merge Scheme** portion of the dialog box. The wire merge options are available only in the Part module.

   - Choose **Imprint wire** to imprint the newly created wire on the existing part by creating edges.
   - Choose **Merge wire** to merge the newly created wire with the existing part.

- Choose **Separate wire** to create the wire separate from the existing part; no edges are created and the wire is not merged with the existing part.

4. In the **Point Pairs** portion of the dialog box, specify the point selection method.

   - Choose **Disjoint wires** to select points that are not automatically connected end-to-end. Use this method to specify wires to use for modeling connectors (see *Modeling connectors*).

     The first two points that you select become **Point 1** and **Point 2**, respectively, of a point pair; the next two points that you select become **Point 1** and **Point 2**, respectively, of the next point pair; and so on. When you use connectors to model multi-point constraints between two points, the motion of **Point 2** is constrained to the motion of **Point 1**.
   - Choose **Chained wires** to select points that are automatically connected end-to-end. The first point that you select becomes **Point 1** of a point pair, the second point that you select becomes **Point 2** of that point pair and **Point 1** of the next point pair, and so on.

     For spline wires, **Chained wires** is the only selection method available, and points are displayed separately instead of in pairs.
   - Choose **Wires to ground** to select points that are connected to ground. Use this method to specify point-to-ground wires to use for modeling connectors (see *Modeling connectors*). Abaqus/CAE automatically makes each point that you select **Point 2** of a point pair (that is, **Point 2** is connected to ground). However, you might want to connect **Point 1** to ground. If so, you can modify the wire definition after you complete the point selection. Select the row of the point pair that you want to modify, and click **Swap** to exchange the entries for **Point 1** and **Point 2** (as described in Step 5).

5. In the **Point Pairs** portion of the dialog box, click  to select the points that the wire will connect.

   - If you are adding a wire feature to a part, you can select points from the viewport or you can enter the coordinates in the text box in the prompt area. Press **Enter** to accept the coordinates and proceed to the next point in the chain of wires. Abaqus/CAE highlights all the points that you can pick. The possible choices are:

     - Vertices
     - The midpoints of lines and arcs
     - The centers of circles and arcs
     - Datum points

   - If you are adding a wire feature to an assembly, you can select points from the viewport. Abaqus/CAE highlights all the points that you can pick. The possible choices are:

     - Vertices
     - Orphan nodes
     - Reference points

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: If you are unable to select the desired points, you can use the **Selection** toolbar to change the selection behavior. For more information, see *Using the selection options*.

   As you select points, Abaqus/CAE displays a representation of the completed point-to-point wire based on your current selections highlighted in red.

6. When you have finished selecting points, click **Done** in the prompt area.

The **Create Wire Feature** dialog box reappears. The points that you selected to define the wire are listed in the **Point Pairs** table.

7. From the **Point Pairs** table, you can do the following:

   - To add more point pairs to a polyline or to add more points to a spline, repeat Steps 3 through 5.

     Note: When you add points to a spline, the new points will always extend the existing spline from the last existing point. When you add point pairs to a polyline, they will be connected to the existing polyline only if you reselect one of the existing points.

     For polylines, the added point-to-point wire segments are highlighted in magenta. For splines, the entire spline wire is highlighted in red because its shape depends on the entire set of points, both new and existing.

   - To edit a point, select the point in the table, click , and reselect a point. The selection in the viewport is updated to show the newly edited point.
   - To identify a specific point pair in the viewport, select the desired row. For polylines, the line connecting the selected point pair is highlighted in red. For splines, the symbol for the point on the selected row is highlighted.
   - To remove a point pair from a polyline or a point from a spline, select the desired row and click .
   - To exchange the entries for **Point 1** and **Point 2** in a point pair for polylines, select the desired row and click .

   You can also enter table data from an ASCII file. To enter data from a file, click mouse button 3 while holding the cursor over a cell in the table; then select **Read From File** from the menu that appears. For more information, see *Entering tabular data*.

8. In the **Set Creation** portion of the dialog box, do the following:

   - Toggle on **Create set of wires** if you want Abaqus/CAE to create a geometry set of wires.
   - Toggle on **Create set of vertices** if you want Abaqus/CAE to create a geometry set of the **Point 1** entries and a geometry set of the **Point 2** entries in the wire definition. The **Create set of vertices** option is available only in the Part module.

9. Click **OK** to create the point-to-point wire feature.

   Part-level wire features appear as solid lines in the viewport and appear in the Model Tree in the **Features** container under the part.

   Assembly-level wires features are nonmeshable, appear as dashed lines in the viewport, and appear in the Model Tree in the **Features** container under the assembly.

Additional information

- *What is feature-based modeling?*
- *Adding a wire feature*
- *Creating or modifying wire features for multiple connectors*
- *The Sketch module*

Rounding vertices in a wire

Select **Shape->Wire->Round** from the main menu bar to "round," or fillet, a vertex between two edges in a wire part.

1. From the main menu bar, select **Shape->Wire->Round**.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also round a vertex between two edges in a wire part using the tool, located with the wire tools in the Part module toolbox. For a diagram of the tools in the Part module toolbox, see *Using the Part module toolbox*.

   Abaqus/CAE prompts you to select the vertices you want to round and displays prompts in the prompt area to guide you through the procedure.

2. Select the vertices to round. You can **[Shift] + Click** additional vertices to add them to your selection, and **[Ctrl] + Click** a selected vertex to unselect it.

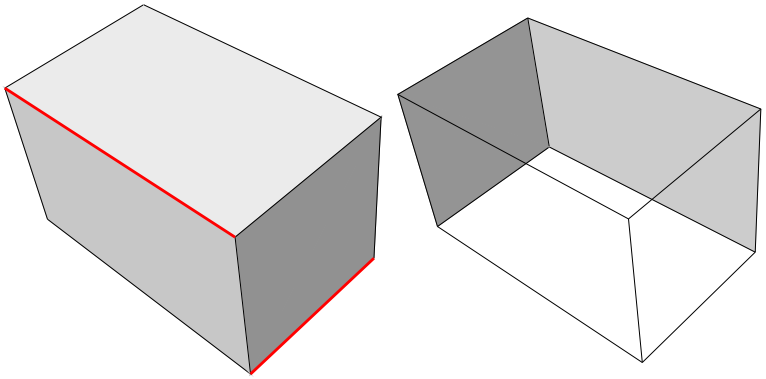
   Tip: If you are unable to select the desired vertices, you can use the **Selection** toolbar to change the selection behavior. For more information, see *Using the selection options*.

3. When you have finished selecting vertices, click **Done** in the prompt area.

   A default radius appears in the prompt area.

4. If necessary, type a new radius in the text field in the prompt area.
5. Click **Done** to accept the new radius and complete the rounding process.

   Abaqus/CAE redraws the part with the selected vertices rounded.



Additional information

- *Adding a wire feature*
- *The Sketch module*

Adding a wire-from-edge feature

Select **Shape->Wire->From Edge** from the main menu bar to replace existing 3D shell or solid edges in the viewport with a wire feature.

You add a wire from edge feature by picking one or more edges from the current part. Abaqus/CAE removes the faces along the selected edges, converts the part from a solid to a shell if necessary, and creates wires to replace the removed edges. A wire-from-edge feature is illustrated in the following figure:

The image on the left shows the selected edges on the original solid part. The image on the right shows the resulting part. Each of the selected edges was associated with two faces; Abaqus/CAE removes those faces and converts the solid to a shell. The selected edges, and all the other edges that are no longer associated with faces, make up the new wire feature.

A wire-from-edge feature cannot be modified.

1. From the main menu bar, select **Shape->Wire->From Edge**.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also add a wire-from-edge feature using the tool, located with the wire tools in the Part module toolbox. For a diagram of the tools in the Part module toolbox, see *Using the Part module toolbox*.

2. Select the edges to be replaced by wires.
3. Click **Done** to create the wire feature.

   Abaqus/CAE displays a dialog box indicating that the faces and cells associated with the selected edges will be deleted.

4. Click **Yes** to continue or **No** to cancel the procedure.

   If you choose **Yes**, Abaqus/CAE removes the faces associated with the selected edges and adds wires to replace all the removed feature edges.

Additional information

- *What is feature-based modeling?*
- *Adding a wire feature*
- *The Sketch module*

Adding a cut feature

This section describes the Part module tools used to add a cut feature to the part in the current viewport.

In this section:

- *Creating an extruded cut*
- *Creating a loft cut*
- *Creating a revolved cut*
- *Creating a swept cut*
- *Cutting a circular hole*

Creating an extruded cut

Select **Shape->Cut->Extrude** from the main menu bar to create an extruded cut through the part geometry in the current viewport. The extruded cut tool is always available, regardless of the modeling space of the part in the current viewport.

You create an extruded cut into a three-dimensional part by sketching the two-dimensional cross-section of the cut on a selected face and defining the distance through which Abaqus/CAE extrudes the cut. You can select one of the following methods to define the distance through which the cut is extruded:

- **Blind** extends the cut from the sketch plane in a selected direction but only to a specified depth.
- **Up to Face** extends the cut from the sketch plane to a selected face.
- **Through All** extends the cut from the sketch plane in a selected direction through the geometry.

The three methods are illustrated in *Figure 1*.

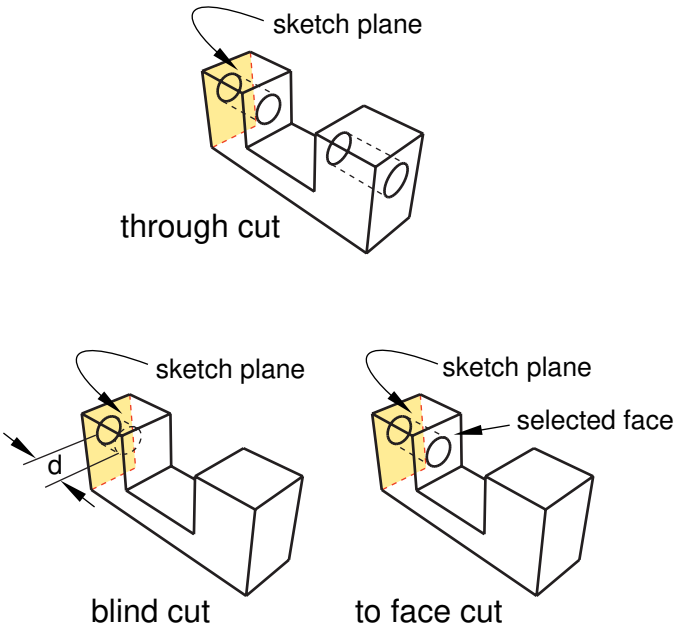

Figure 1: Three methods for creating an extruded cut.

You create an extruded cut in a two-dimensional or axisymmetric planar part by sketching the two-dimensional cross-section of the cut directly on the plane of the part. The cut always passes completely through the part.

When creating an extruded cut in a three-dimensional part, you can select a center point and specify a pitch that Abaqus/CAE uses to twist the cross-section as it is extruded. Alternatively, Abaqus/CAE can expand or contract the cross-section along a specified draft angle as the cross-section is extruded. For more information, see *Including twist in an extrusion*, and *Including draft in an extrusion*.

1. From the main menu bar, select **Shape->Cut->Extrude**.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also create an extruded cut using the tool, located with the cut tools in the Part module toolbox. For a diagram of the tools in the Part module toolbox, see *Using the Part module toolbox*.

2. If desired, specify the method you want to use to select an origin for your sketch of the extruded cut feature. Select one of the following options from the **Sketch Origin** field in the prompt area:
   - Select **Auto-Calculate** to place the sketch origin automatically.
   - Select **Specify** to define a custom sketch origin.
   - Select **Session Default** to use the custom origin you specified earlier in the session.

3. If the current viewport contains a two-dimensional or axisymmetric planar part, Abaqus/CAE enters the Sketcher and you sketch the closed profile of the extruded cut on the plane of the part.

   If the current viewport contains a three-dimensional part, you must do the following:

   a. Select the planar face from which the cut will be extruded. If no suitable face exists, you can select a datum plane or an orphan element face.

      Tip: If you are unable to select the desired planar face, you can use the **Selection** toolbar to change the selection behavior. For more information, see *Using the selection options*.

      The selected face is highlighted in the viewport.

   b. If you selected **Specify** as the **Sketch Origin** method, specify the origin location by clicking a point in the viewport or by entering the three-dimensional coordinates of the origin in the prompt area. You can also set this custom origin as the default origin for all sketches in your session by toggling on **Set as session default**.

   c. Select an edge and the orientation of the edge on the Sketcher grid. The edge must not be perpendicular to the selected face. By default, the selected edge will appear vertical and on the right side of the Sketcher grid. To choose a different orientation for the edge, click the arrow on the right side of the dialog box and choose an orientation from the list that appears.

      Tip: If the edge of the selected face is curved or does not provide the desired orientation, you can create a datum axis. You can then select the datum axis to control the orientation of the part on the Sketcher grid.

      Abaqus/CAE highlights the selected edge, enters the Sketcher, and rotates the part until the selected face aligns with the plane of the Sketcher grid and the selected edge aligns with the grid in the desired orientation.

      If you are unsure of the part's orientation relative to the Sketcher grid, use the view manipulation tools from the View Manipulation toolbar to view its position. Use the reset view tool  to return to the original view.

   d. Use the Sketcher to sketch the closed two-dimensional profile of the extruded cut.

4. In the prompt area, click **Done** to indicate you have finished sketching the profile.

5. If the current viewport contains a two-dimensional or axisymmetric planar part, the part returns to its original orientation, and Abaqus/CAE cuts the plane with the sketched profile.

   If the current viewport contains a three-dimensional part, Abaqus/CAE displays the part in its original orientation showing the base part, your sketched profile, and an arrow indicating the extrusion direction. The **Edit Cut** dialog box appears. Complete the following steps to create the extruded cut in the three-dimensional part:

   a. Click  in the **Edit Cut** dialog box to reverse the extrusion direction, if necessary.

      If the arrow direction is difficult to see, use the rotate tool to rotate the part.

   b. Select one of the following end conditions:

- Select **Blind** and enter a value in the **Depth** field to specify the distance through which Abaqus/CAE will extrude the sketched cut profile.
- Select **Up to Face** to specify that Abaqus/CAE will extrude the cut up to a selected face.
- Select **Through All** to specify that Abaqus/CAE will extrude the cut from the sketch plane completely through the geometry.

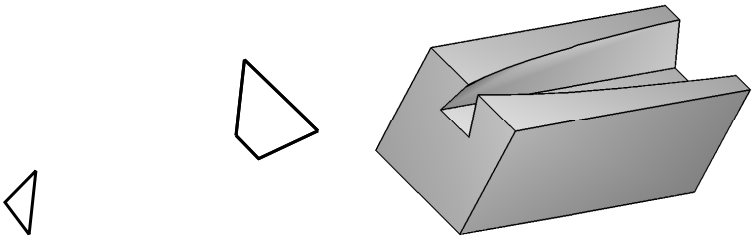
6. If desired, choose one of the following:
   - Select **Twist** and enter the pitch. The pitch is the extrusion distance in which a 360° twist would occur. The sketched cut profile must include an isolated point that indicates the center of twist.
   - Select **Draft** and enter the draft angle (greater than −90° and less than 90°). A positive draft angle indicates that external faces of the profile expand and internal faces contract.
7. Click **OK** to extrude the profile.

   If you selected the twist option and your sketch includes a single isolated point, Abaqus/CAE uses that point as the center of twist. If your sketch does not include an isolated point, Abaqus/CAE returns to the Sketcher for you to create one. If your sketch contains more than one isolated point, Abaqus/CAE returns to the Sketcher and prompts you to select an isolated point as the center of twist.
8. If you selected **Up to Face**, Abaqus/CAE prompts you to select the face to which to extrude the profile. Select a face to meet the following requirements:
   - the selected face does not have to be parallel to the sketch plane,
   - it can be a nonplanar face,
   - it must completely contain the extruded selection, and
   - it cannot be a datum plane or orphan element face.

   Abaqus/CAE creates the extruded cut feature.

   Note:

   Cut features are applied to part geometry only. Any orphan elements within the cut region are unaffected by the cut.



Additional information

- *The Datum toolset*
- *Adding a cut feature*
- *The Sketch module*
- *What is feature-based modeling?*

Creating a loft cut

Select **Shape->Cut->Loft** from the main menu bar to add a loft cut to the part geometry in the current viewport. You can add a loft cut only to three-dimensional parts.

You add a loft cut by creating two or more sections from selected edges and by defining one or more loft paths. Loft sections and the resulting loft cut are illustrated in the following figure (the loft path is not shown in this figure):

You can allow Abaqus/CAE to define a single loft path using a smooth path to connect the center of each loft section (as in the previous figure). If you allow Abaqus/CAE to define the path, you can apply tangency methods to the start and end sections of the loft. The curve and tangencies define the path of the loft feature between sections. Alternatively, you can define one or more loft paths by selecting curves that connect a point on each loft section to a point on the next loft section. Each loft path must provide a continuous line connecting each consecutive loft section. If a loft path is not smooth (if there is more than one tangent to any point along the path), Abaqus/CAE will display an error message when you try to create the loft. For more information about loft sections, loft paths, and loft tangencies, see *What is lofting?*.

Note:

You do not use the Sketcher while adding a loft feature. As a result, all of the edges that define the loft sections and the loft paths must exist in the part geometry before you create the loft. To create a loft path or to create a nonplanar loft section, you can use the tool, located with the wire tools in the Part module toolbox, to create a spline wire (see *Adding a point-to-point wire feature*, for more information).

1. From the main menu bar, select **Shape->Cut->Loft**.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also add a loft cut using the tool, located with the cut tools in the Part module toolbox. For a diagram of the tools in the Part module toolbox, see *Using the Part module toolbox*.

   The **Edit Loft** dialog box appears.
2. Create the loft sections by selecting edges from the part in the viewport. See *Creating loft sections*, for detailed instructions on creating loft sections.
3. When you have finished creating the loft sections, click on the **Transition** tab in the **Edit Loft** dialog box.
4. Create the loft path (or paths) by again selecting edges from the part in the viewport or by using loft tangencies. See *Creating a loft path*, for detailed instructions on creating a loft path.
5. Click **Preview**.

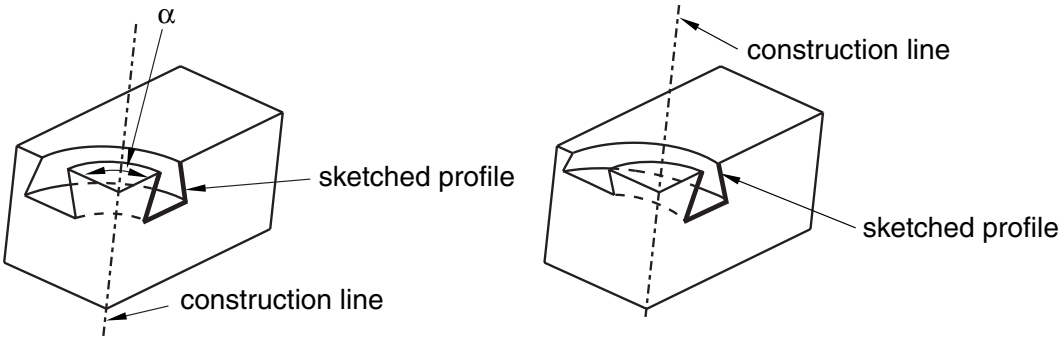
Abaqus/CAE displays a wireframe representation of the loft that would be created with your current settings.

6. If desired, you can add or remove loft sections, change the loft path definition method, or edit the loft tangency options to change the shape of the loft feature. Click **Preview** to see the effect of your changes in the viewport.
7. If desired, you can have Abaqus/CAE test for self-intersection as it creates the loft feature. This test prevents creating a feature that would be difficult or impossible to mesh and analyze, but it becomes computationally expensive as the complexity of the loft feature increases. For more information, see *Self-intersection checks*. To use self-intersection checks, select **Feature->Options** to open the **Feature Options** dialog box, and toggle on **Perform self-intersection checks**.
8. Click **Done** to create the loft and to close the **Edit Loft** dialog box.

   If you choose to test for self-intersection and the test fails, the **Edit Loft** dialog box will reappear so that you can make changes. Otherwise, the loft cut is created in the viewport.

Note:

Cut features are applied to part geometry only. Any orphan elements within the cut region are unaffected by the cut.



Additional information

- *Adding a cut feature*
- *What is feature-based modeling?*

Creating a revolved cut

Select **Shape->Cut->Revolve** from the main menu bar to create a revolved cut through the part geometry in the current viewport. You can cut a revolved cut only through three-dimensional parts.

You add a revolved cut by sketching a closed two-dimensional cross-section and a construction line on a selected face. The construction line serves as an axis of revolution, and Abaqus/CAE creates the revolved cut by rotating the cross-section about the axis using a specified angle of revolution. In addition, you can specify a pitch and a direction along the axis of revolution that Abaqus/CAE uses to translate the sketch along the axis of revolution as it revolves the profile. Two revolved cut features are shown in the following figure; the figure on the right shows a revolved cut with pitch.

1. From the main menu bar, select **Shape->Cut->Revolve**.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also create a revolved cut using the tool, located with the cut tools in the Part module toolbox. For a diagram of the tools in the Part module toolbox, see *Using the Part module toolbox*.

2. If desired, specify the method you want to use to select an origin for your sketch of the revolved cut feature. Select one of the following options from the **Sketch Origin** field in the prompt area:

   - Select **Auto-Calculate** to place the sketch origin automatically.
   - Select **Specify** to define a custom sketch origin.
   - Select **Session Default** to use the custom origin you specified earlier in the session.

3. Select the planar face from which the cut will be revolved. If no suitable face exists, you can select a datum plane or an orphan element face.

   Tip: If you are unable to select the desired planar face, you can use the **Selection** toolbar to change the selection behavior. For more information, see *Using the selection options*.

   The selected face is highlighted in the viewport.

4. If you selected **Specify** as the **Sketch Origin** method, specify the origin location by clicking a point in the viewport or by entering the three-dimensional coordinates of the origin in the prompt area. You can also set this custom origin as the default origin for all sketches in your session by toggling on **Set as session default**.

5. Select an edge and the orientation of the edge on the Sketcher grid. The edge must not be perpendicular to the selected face. By default, the selected edge will appear vertical and on the right side of the Sketcher grid. To choose a different orientation for the edge, click the arrow on the right side of the dialog box and choose an orientation from the list that appears.

   Tip: If the edge of the selected face is curved or does not provide the desired orientation, you can create a datum axis. You can then select the datum axis to control the orientation of the part on the Sketcher grid.

   Abaqus/CAE highlights the selected edge, enters the Sketcher, and rotates the part until the selected face aligns with the plane of the Sketcher grid and the selected edge aligns with the grid in the desired orientation.

   If you are unsure of the part's orientation relative to the Sketcher grid, use the view manipulation tools from the View Manipulation toolbar to view its position. Use the reset view tool  to return to the original view.

6. Use the horizontal , vertical , angle , or oblique  construction line tools to sketch the axis of rotation. You can position the construction line by selecting a datum axis from the underlying part. You cannot select the datum axis directly; you must select a point from either end of the datum axis.
7. Use the Sketcher to sketch the two-dimensional profile of the revolved cut; the sketch must not cross the axis of revolution.
8. In the prompt area, click **Done** to indicate you have finished sketching the profile and the axis. If the sketch contains more than one construction line, Abaqus/CAE prompts you to select the construction line that will serve as the axis of rotation.

   Abaqus/CAE displays the part view that was active prior to entering the Sketcher. The part includes your sketched profile and an arrow indicating the direction of revolution. The **Edit Revolution** dialog box appears.

9. In the **Edit Revolution** dialog box, enter the desired angle of revolution or accept the default value.
10. Click  next to **Revolve direction** to change the arrow direction and the associated direction of revolution.
11. If desired, select the **Include translation** option and enter a positive value for the pitch. The pitch value is the distance through which the profile is translated along the axis of revolution during a rotation of 360°.

    An arrow appears to show the axis of revolution and to indicate the direction of sketch translation along the axis. Click  next to **Pitch direction** in the **Edit Revolution** dialog box to reverse the arrow, if necessary.

12. If desired, toggle on **Sweep sketch normal to path** to rotate the sketched profile normal to the path of revolution. This option is available only when **Include translation** is used.

    The initial profile of the feature will be rotated from the sketch plane to create the feature.

13. Click **OK** to accept the indicated direction and create the revolved cut feature.

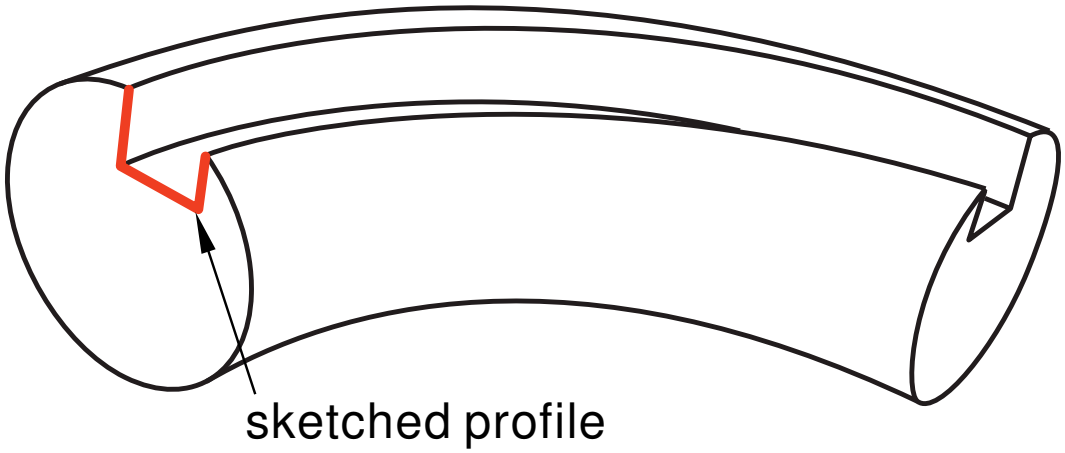
    Abaqus/CAE creates the revolved cut feature using your selected parameters.

Note:

Cut features are applied to part geometry only. Any orphan elements within the cut region are unaffected by the cut.

Additional information

- *Creating construction geometry*
- *Adding a cut feature*
- *Defining the axis of revolution for axisymmetric parts and for revolved features*
- *Controlling the cross-section of a revolved feature with pitch*
- *The Sketch module*
- *What is feature-based modeling?*



Creating a swept cut

Select **Shape->Cut->Sweep** from the main menu bar to create a swept shell cut through the part geometry in the current viewport. You can create a swept cut through only three–dimensional parts.

You add a swept cut feature by first defining a sweep path, then defining a sweep profile. There are different methods available for defining each component:

- You can define a sweep path either by sketching the path on a selected face or by selecting a series of edges or wires that you want the sweep path to follow. The sketch method provides greater flexibility but supports only two-dimensional paths. The edge/wire method enables you to define a three-dimensional sweep path along a feature such as a spline wire or a set of edges in a three-dimensional part.
- You can define a sweep profile either by sketching a sweep profile using the Sketcher or by selecting one of the faces in your model as the profile. The sweep profile is initially perpendicular to the path; you can keep this orientation constant along the entire sweep path, or you can keep the sweep profile perpendicular to the sweep path as it is swept along its length.

The following figure shows an example of sketching a sweep path on a selected face and sketching a closed sweep profile. The top edge of the profile is not shown.

The sketch or set of edges defining the sweep path and the sketch, edge, or edges defining the sweep profile define the swept cut feature; both the sweep path and the sweep profile can be modified using the Feature Manipulation toolset if you define them using the Sketcher. You can define a swept cut whose sweep profile is offset from the sweep path. In this case Abaqus/CAE moves the sweep path to a parallel location that passes through the sweep profile and creates the swept cut feature at that location.

As you define your sweep feature, you can apply a twist or draft to it. For more information about these tools, see *What types of features can you create?*. You can toggle on **Keep profile normal constant** to maintain the same orientation for the sweep profile as it travels along the sweep path; if this option is toggled off, the sweep profile orientation changes with the normal to the sweep path. In addition, you can toggle on **Keep internal boundaries** in the Feature Manipulation toolset to maintain any faces or edges that are generated between the swept shell feature and the existing part. The internal boundaries may create regions that can be structured or swept meshed without having to resort to partitioning.

1. From the main menu bar, select **Shape->Cut->Sweep**.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

Tip: You can also create a swept cut using the tool, located with the cut tools in the Part module toolbox. For a diagram of the tools in the Part module toolbox, see *Using the Part module toolbox*.

2. If you want to sketch the sweep path, do the following:

   a. From the **Path** options, select **Sketch** and click .

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   b. If desired, specify the method you want to use to select an origin for your sketch of the swept solid feature. Select one of the following options from the **Sketch Origin** field in the prompt area:

   - Select **Auto-Calculate** to place the sketch origin automatically.
   - Select **Specify** to define a custom sketch origin.
   - Select **Session Default** to use the custom origin you specified earlier in the session.

   c. Select the planar face on which to sketch the sweep path. If no suitable face exists, you can select a datum plane or an orphan element face.

   Tip: If you are unable to select the desired planar face, you can use the **Selection** toolbar to change the selection behavior. For more information, see *Using the selection options*.

   d. If you selected **Specify** as the **Sketch Origin** method, specify the origin location by clicking a point in the viewport or by entering the three-dimensional coordinates of the origin in the prompt area. You can also set this custom origin as the default origin for all sketches in your session by toggling on **Set as session default**.

   e. Select an edge and the orientation of the edge on the Sketcher grid. The edge must not be perpendicular to the selected face. By default, the selected edge will appear vertical and on the right side of the Sketcher grid. To choose a different orientation for the edge, click the arrow on the right side of the dialog box and choose an orientation from the list that appears.

   Tip: If there is no straight edge with the desired orientation, you can create a datum axis. You can then select the datum axis to control the orientation of the part on the Sketcher grid.

   Abaqus/CAE highlights the selected edge, enters the Sketcher, and rotates the part so that the selected face aligns with the plane of the Sketcher grid and the selected edge aligns with the grid in the desired orientation.

   If you are unsure of the part's orientation relative to the Sketcher grid, use the view manipulation tools from the View Manipulation toolbar to view its position. Use the reset view tool to return to the original view.

   f. Sketch the sweep path. The sweep path must meet the following guidelines:

   - The path can be closed, but the ends must meet smoothly; for example, the ends should not meet at a corner. For examples of valid sweep paths, see *Defining the sweep path and the sweep profile*.
   - The path must be continuous; for example, it must not branch.
   - The resulting solid cannot intersect with itself.

   In the prompt area, click **Done** to indicate you have finished sketching the sweep path.

Abaqus/CAE exits the Sketcher and restores the original view of the part. A highlighted line indicates the sweep path and its direction. Abaqus/CAE also reopens the **Create Cut Sweep** dialog box and adds the word **(Defined)** next to the **Sketch** label in the **Path** options to indicate that the sweep path has been defined in the Sketcher.

3. If you want to specify the sweep path as a series of edges or wires, do the following:

   a. From the **Path** options, select **Edges** and click .

      Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   b. If desired, specify in the prompt area whether you want to select the edges in your sweep path **individually** or **by edge angle**. For more information about selecting objects, see *Using the angle and feature edge method to select multiple objects*.

   c. Select the edges you want to include in the sweep path.

      Abaqus/CAE shows the sweep path on your part and indicates the sweep direction.

   d. In the prompt area, click **Yes** to confirm the sweep path direction or click **Flip** to reverse the sweep path direction.

   Abaqus/CAE reopens the **Create Cut Sweep** dialog box and adds the word **(Defined)** next to the **Edges** label in the **Path** options to indicate that the sweep path has been defined using a series of edges.

4. If you want to sketch the sweep profile, do the following:

   a. From the **Profile** options, select **Sketch** and click .

      Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   b. Sketch the sweep profile. The sweep profile must meet the following guidelines:

      - The profile must be closed.
      - The resulting solid cannot intersect with itself.

      You can sketch the profile anywhere on the Sketcher grid; Abaqus/CAE sweeps the profile along a path parallel to the sweep path. In the prompt area, click **Done** to indicate you have finished sketching the sweep profile.

      Abaqus/CAE exits the Sketcher and restores the original view of the part.

   c. Select an edge and the orientation of the edge on the Sketcher grid. The selected edge must not be parallel to the sweep path direction. By default, the selected edge will appear vertical and on the right side of the Sketcher grid. To choose a different orientation for the edge, click the arrow on the right side of the dialog box and choose an orientation from the list that appears.

      Abaqus/CAE highlights the selected edge, enters the Sketcher again, and rotates the part so that the Sketcher grid lies on a plane normal to the beginning of the sweep path with the sweep path direction pointing out of the screen. In addition, the selected edge aligns with the grid in the desired orientation. The intersection of two dashed lines indicates the origin of the sweep path. Abaqus/CAE also reopens the **Create Cut Sweep** dialog box and adds the word **(Defined)** next to the **Sketch** label in the **Profile** options to indicate that the sweep profile has been defined in the Sketcher.

5. If you want to select a face as the sweep profile, do the following:

   a. From the **Profile** options, select **Face**, then click .

      Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

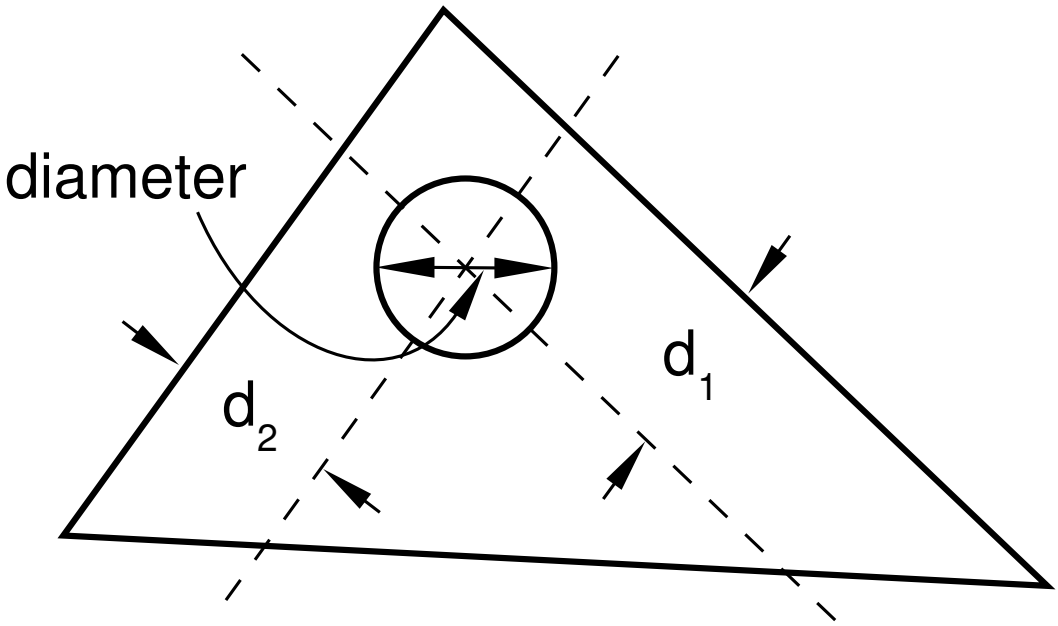
   b. Select a face from the viewport.

Abaqus/CAE highlights the selected face and reopens the **Create Solid Sweep** dialog box with the word **(Defined)** added next to the **Faces** label in the **Profile** options to indicate that the sweep profile has been defined using a face.

6. If desired, do any of the following:
   - Toggle on **Include twist**, and enter the pitch. The pitch is the extrusion distance in which a 360° twist would occur. The sketched extrusion profile must include an isolated point that indicates the center of twist.
   - Toggle on **Include draft**, and enter the draft angle (greater than –90° and less than 90°). A positive draft angle indicates that external faces of the profile expand and internal faces contract. You cannot apply a draft if the **Keep profile normal constant** option is selected.
   - Toggle on **Keep profile normal constant** to maintain the same profile orientation along the entire sweep path. If this option is toggled off, Abaqus/CAE adjusts the profile orientation so that the angle between the sweep profile and the normal to the sweep path is always constant. You cannot toggle on this option if the **Include draft** option is selected.
   - Toggle on **Keep internal boundaries** to maintain any faces or edges that are generated between the swept solid feature and the existing part. The internal boundaries can create regions that can be structured or swept meshed without having to resort to partitioning.
7. Click **OK** to create the new swept cut.

Note:

Cut features are applied to part geometry only. Any orphan elements within the cut region are unaffected by the cut.



Additional information

- *Defining the sweep path and the sweep profile*
- *The Sketch module*
- *What is feature-based modeling?*

Cutting a circular hole

Select **Shape->Cut->Circular Hole** from the main menu bar to cut a circular hole through the part in the current viewport. The circular hole tool is always available, regardless of the modeling space of the part in the current viewport.

You cut a circular hole by specifying the distance from two selected straight edges and specifying the diameter of the hole, as shown in the following figure:

The part must contain at least two straight edges; for example, you cannot use this tool to cut a hole through a circular part.

If the current viewport contains a two-dimensional or axisymmetric planar part, the hole always passes through all of the part. However, if the current viewport contains a three–dimensional part, Abaqus/CAE prompts you to select the type of cut. You can select either **Through All** or **Blind** to define the cut depth.

The distance from the hole to each edge, the diameter of the hole, and the depth of a blind hole are the features that define a circular hole, and all three can be modified using the Feature Manipulation toolset. You cannot change the type of cut—through all or blind—after the cut has been created.

1. From the main menu bar, select **Shape->Cut->Circular Hole**.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also cut a circular hole using the tool, located with the cut tools in the Part module toolbox. For a diagram of the tools in the Part module toolbox, see *Using the Part module toolbox*.

2. If the current viewport contains a two-dimensional part, select the first edge from which to position the center of the hole.

   If the current viewport contains a three-dimensional part, you must do the following:

   a. From the buttons in the prompt area, select one of the following types of cut:

- Click **Through All** to cut a circular hole that extends from a selected face in a selected direction through the part. A through cut is illustrated in the following example:

- Click **Blind** to cut a circular hole that extends from a selected face in a selected direction but only to a specified depth. A blind cut is illustrated in the following example:

b. Select the face from which the hole will be cut.

Tip: If you are unable to select the desired face, you can use the **Selection** toolbar to change the selection behavior. For more information, see *Using the selection options*.

An arrow appears, indicating the direction of the axis of the cut hole.

c. From the buttons in the prompt area, click **Flip** to reverse the arrow, if necessary. Click **OK** to accept the indicated direction.

Tip: If the arrow direction is difficult to see, use the rotate tool to rotate the part.

d. Select the first edge from which to position the center of the hole. The selected edges need not lie in the same plane as the selected face, but they must not be perpendicular to it.

3. In the text field in the prompt area, type the distance from the selected edge to the center of the hole.
4. Select the second edge from which to position the center of the hole. The two edges must not be parallel.
5. In the text field in the prompt area, type the distance from the selected edge to the center of the hole.
6. In the text field in the prompt area, type the diameter of the hole.

   If the current viewport contains a two−dimensional or axisymmetric planar part, Abaqus/CAE cuts the part with the circular hole.

   If the current viewport contains a three−dimensional part and you selected a blind cut, a default hole depth appears in the prompt area. Click mouse button 2 to accept the default value, or enter a new hole depth.

   The part returns to its original orientation with the circular hole cut from the selected face.

Note:

Cut features are applied to part geometry only. Any orphan elements within the cut region are unaffected by the cut.

Additional information

- *Adding a cut feature*
- *The Sketch module*
- *What is feature-based modeling?*

Using the Edit Feature dialog box

When you first select a feature to edit, the **Edit Feature** dialog box appears.

This section describes the options in the **Edit Feature** dialog box; the available options depend on the feature selected. You use the **Edit Feature** dialog box to change the following:

Depth

Use the **Depth** parameter to change the depth of a blind extruded feature. Type a new value for the extrusion depth, and click **Apply** to see the modified feature in the viewport. You cannot change the manner in which the extrusion distance was defined when the feature was first created; for example, from **Blind** to **Up to Face**. For more information, see *Defining the extrusion distance*.

Radius

Use the **Radius** parameter to change the radius of a round/fillet feature. Type a new value for the fillet radius, and click **Apply** to see the modified feature in the viewport. For more information, see *Rounding edges*, and *Rounding vertices in a wire*.

Flip extrude direction

Toggle **Flip extrude direction** to change the extrusion direction of the selected feature. Click **Apply** to see the modified feature in the viewport. This option is available only for extruded features added to a base feature. For more information, see *Controlling the direction of an extruded feature*.

Keep internal boundaries

Toggle **Keep internal boundaries** to maintain any faces or edges that are generated between the feature and the existing part. The internal boundaries may create regions that can be structured or swept meshed without having to resort to partitioning. This option is available only for extruded, revolved, and loft solid and shell features added to a base feature.

Draft angle

Use the **Draft angle** parameter to change the draft of an extruded feature. Type a new value for the draft angle, and click **Apply** to see the modified feature in the viewport. A draft angle of zero will create a straight extrusion. You cannot add draft to an extrusion if it was not defined when the feature was created. For more information, see *Including draft in an extrusion*.

Pitch

Use the **Pitch** parameter to change the twist of an extruded feature or the pitch of a revolved feature. Type a new value for the pitch, and click **Apply** to see the modified feature in the viewport. You cannot add pitch to a feature if it was not defined when the feature was created.

In an extruded feature the pitch defines the extrusion distance in which the profile would be twisted by 360°. For more information, see *Including twist in an extrusion*. Similarly, in a revolved feature the pitch is the distance through which the profile would be translated during a rotation of 360°. For more information, see *Defining the axis of revolution for axisymmetric parts and for revolved features*.

Angle

Use the **Angle** parameter to change the angle of revolution of a revolved feature. Type a new value, and click **Apply** to see the modified feature in the viewport.

Flip revolve direction

Toggle **Flip revolve direction** to reverse the direction of revolution of a revolved feature. Click **Apply** to see the modified feature in the viewport. For more information, see *Controlling the direction of a revolved feature*.

Flip pitch direction

Toggle **Flip pitch direction** to change the direction of translation in a revolved feature with pitch. Click **Apply** to see the modified feature in the viewport. This option is available only for revolved features and works in conjunction with the **Pitch** parameter. For more information, see *Controlling the direction of a revolved feature*.

Sweep sketch normal to path

Toggle **Sweep sketch normal to path** to change the orientation of the initial sketch that is used to create a revolved feature with pitch. Click **Apply** to see the modified feature in the viewport. This option is available only for revolved features with pitch. For more information, see *Controlling the cross-section of a revolved feature with pitch*.

Edit Section Sketch

Use the **Edit Section Sketch** button to change the profile of the selected feature. Make your changes, close the Sketcher, and click **Apply** to see the modified feature in the viewport.

Edit Sweep Path Sketch

Use the **Edit Sweep Path Sketch** button to change the path of a swept feature. Make your changes, close the Sketcher, and click **Apply** to see the modified feature in the viewport. For more information, see *Defining the sweep path and the sweep profile*.

Stitch tolerance

Use the **Stitch tolerance** parameter to increase or decrease the size of the gaps that Abaqus/CAE fixes when you stitch the gaps between free edges in a part. For more information, see *Stitching edges to create faces*.

Regenerate on OK

Toggle **Regenerate on OK** to control feature regeneration. **Regenerate on OK** is toggled on by default. Toggle this option off if you do not want the feature to regenerate when you click **OK**. For more information, see *Regenerating a part or assembly*.

Additional information

- *How is a part defined in Abaqus/CAE?*
- *Creating a new part*
- *Using the Create Part dialog box*

Using the Edit Loft dialog box

This section describes the procedures used to create the components of a solid, shell, or cut loft feature.

In this section:

- *Creating loft sections*
- *Creating a loft path*

Creating loft sections

Loft sections represent the shape that the loft feature will have at a particular point along the loft path. At least two sections are required to create a loft feature. You create loft sections by picking from existing edges from the part in the current viewport.

1. From the **Edit Loft** dialog box, select **Insert Before** or **Insert After** to create the first loft section.
2. Select the edges that define the loft section. **[Shift] + Click** additional edges to add them to your selection, and **[Ctrl] + Click** a selected edge to unselect it. Selected edges are highlighted in red and will remain highlighted until the loft feature is completed.

   A loft section can be comprised of any edges from the current part and must meet the following conditions:

   - For a solid loft or cut loft the section must be closed, and the first and last sections must be planar.
   - For a shell loft if one section is open, all must be open; and, if one section is closed, all must be closed.
   - The section must be one continuous loop with no branches.
   - Edges used in one loft section cannot be used in another section of the same loft.

   All shell loft sections, and intermediate sections for solid lofts and cut lofts, can be nonplanar. To create nonplanar sections, you can select edges that were created using a spline wire or select edges of an existing nonplanar face.
3. In the prompt area, click **Done** to indicate that you have finished selecting edges to define the loft section.

   Abaqus/CAE returns to the **Edit Loft** dialog box, and the section appears in the **Sections** list.
4. Repeat Steps 2 and 3 to define all the loft sections. Use the **Insert Before** and **Insert After** buttons to indicate where in the list you want the next loft section to appear in relation to the loft section that is currently highlighted. The section that is highlighted in the list is also highlighted in magenta in the viewport to distinguish it from the other loft sections. Loft sections are numbered in the order that you create them, but Abaqus/CAE creates the loft feature in the order shown in the **Sections** list. You can change the order of the list only by adding or deleting loft sections.

   You cannot edit completed loft sections.

Additional information

- *What is lofting?*
- *Creating a loft path*
- *Adding a solid loft feature*
- *Adding a shell loft feature*
- *Creating a loft cut*

Creating a loft path

The paths of a loft feature connect a point on the starting section to a point on the ending section. If more than two loft sections are defined, the paths must also pass through a point on each intermediate section. Each loft path must provide a smooth curve (only one tangent line must exist at any point along the path) connecting all the loft sections in the same order that they will be connected when you create the loft feature.

1. From the **Transition** tabbed page in the **Edit Loft** dialog box, choose either of the following methods to create a loft path:

   - **Specify tangencies**. Abaqus/CAE will create a single loft path using a smooth curve connecting the center of each loft section.
   - **Select path**. Select edges to define a loft path.

   You cannot edit the loft path method after the loft feature is created.

2. If you chose **Specify tangencies** to define the loft path, you can choose a **Start Tangency** and an **End Tangency** for the loft feature. You can choose from the following loft tangency options:

   - **None** is the default and the only setting that, if selected, must be applied at both ends of the loft.
   - **Normal**. Loft faces are at a 90° angle near the starting or ending loft section.
   - **Radial**. Loft faces are at a 0° angle near the starting or ending loft section.
   - **Specify**. You specify an angle ranging from 0° to 180° that is applied to the loft faces, and you specify a magnitude between 0 and 100 percent that determines the relative distance through which the angle is applied.

   The tangency effect diminishes with distance and does not affect the loft feature at intermediate sections. For more information and examples of loft tangency, see *Defining loft tangency*.

   You cannot edit the tangency after the loft feature is created.

3. If you chose **Select path**, you must have created at least one suitable smooth curve in the part before starting the loft procedure. Select each loft path as follows:

   a. Click **Add**.

   The **Edit Loft** dialog box disappears.

   b. Select edges to define the loft path. Use **[Shift] + Click** to add additional edges to your selection and **[Ctrl] + Click** to unselect a selected edge. Selected edges are highlighted in blue and will remain highlighted until Abaqus/CAE creates the loft feature.

   You must create a smooth curve connecting one point on each loft section to a point on the next loft section following the same order as the loft section list. Abaqus/CAE will create the loft feature by following each loft path in the order of the loft section list.

   c. Click **Done**.

   The **Edit Loft** dialog box reappears.

   d. If desired, use the preceding steps to add more loft paths. To successfully create a loft feature with multiple loft paths, the paths must not share any points.

   Click **Delete** to remove a highlighted path from the list.

   e. Toggle off **Global Smoothing** if you want the effects of the paths to be localized to adjacent surfaces; Abaqus/CAE will apply simple paths to any edges of the loft for which you did not define a path. If you leave global smoothing on, Abaqus/CAE will apply an averaging function to create complex paths for edges where you did not define a path.

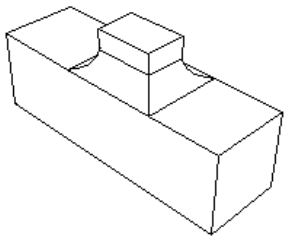
Loft paths cannot be added or deleted after the loft feature is created; loft paths can be edited only by moving the vertices used to create each path.

Additional information

- *What is lofting?*
- *Creating loft sections*
- *Adding a solid loft feature*
- *Adding a shell loft feature*
- *Creating a loft cut*

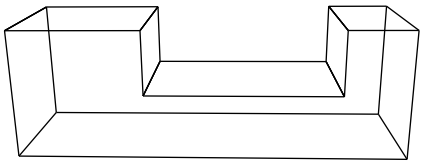
Blending edges

This section describes the Part module tools used to blend edges of the part in the current viewport.



In this section:

- *Rounding edges*
- *Chamfering edges*



Rounding edges

You can round selected edges of the part in the current viewport.

Select **Shape->Blend->Round/Fillet** from the main menu bar to round selected edges of the part in the current viewport. You can "round," or fillet, both convex and concave edges. A part with rounded edges is illustrated in the following example:

You define the radius of the fillet, and Abaqus/CAE applies the radius to all of the selected edges as a group; therefore, subsequent feature manipulation operations, such as edit, delete, and suppress, will be applied to the entire group of selected edges. Consequently, if you select more than one edge to round, you cannot modify just one of the rounded edges. In addition, the shape of the resulting edges can depend on the order in which you apply the fillets, as shown in the following figure. The fillets on the left side of the part were created by selecting all three edges and applying the round/fillet tool to the group of selected edges in a single operation. In contrast, the fillets on the right side of the part were created by selecting each edge individually and applying the round/fillet tool to each edge in sequence.

The round/fillet tool is available only when the current viewport contains a three-dimensional solid or shell part. In addition, you cannot fillet an edge that contains a wire. The radius of a rounded edge defines the feature and can be modified using the Feature Manipulation toolset.

1. From the main menu bar, select **Shape->Blend->Round/Fillet**.

   Abaqus/CAE prompts you to select the edges to round.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also round selected edges using the  tool, located with the blend tools in the Part module toolbox. For a diagram of the tools in the Part module toolbox, see *Using the Part module toolbox*.

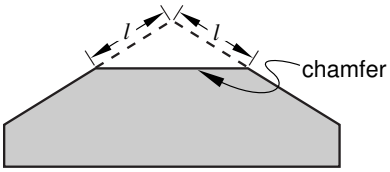
2. Select the edges to round, and click mouse button 2 to commit your selection. **[Shift] + Click** additional edges to add them to your selection, and **[Ctrl] + Click** a selected edge to unselect it.

Tip: If you are unable to select the desired edges, you can use the **Selection** toolbar to change the selection behavior. For more information, see *Using the selection options*.

A default radius appears in the prompt area.

3. If necessary, type a new radius in the text field in the prompt area. Click mouse button 2 to commit the radius.

   Abaqus/CAE redraws the part with the selected edges rounded.



Additional information

- *What is feature-based modeling?*

Chamfering edges

You can chamfer or bevel selected edges of the part in the current viewport.

Select **Shape->Blend->Chamfer** from the main menu bar to chamfer or bevel selected edges of the part in the current viewport. You enter the distance that the chamfer extends into each face, and Abaqus/CAE uses the distance to define the chamfer, as illustrated in the following example:

Abaqus/CAE applies the chamfer to all of the selected edges as a group; therefore, subsequent feature manipulation operations—such as edit, delete, and suppress—will be applied to the entire group of selected edges. Consequently, if you select more than one edge to chamfer, you cannot modify just one of the chamfered edges.

The chamfer tool is available only when the current viewport contains a three–dimensional solid or shell part. In addition, you cannot chamfer an edge that contains a wire. The length of a chamfer defines the feature and can be modified using the Feature Manipulation toolset.

1. From the main menu bar, select **Shape->Blend->Chamfer**.

   Abaqus/CAE prompts you to select the edges to chamfer.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also chamfer selected edges using the tool, located with the blend tools in the Part module toolbox. For a diagram of the tools in the Part module toolbox, see *Using the Part module toolbox*.

2. Select the edges to chamfer, and click mouse button 2 to commit your selection. **[Shift] + Click** additional edges to add them to your selection, and **[Ctrl] + Click** a selected edge to unselect it.

   Tip: If you are unable to select the desired edges, you can use the **Selection** toolbar to change the selection behavior. For more information, see *Using the selection options*.

   A default chamfer length appears in the prompt area.

3. If necessary, type a new chamfer length in the text field in the prompt area. Click mouse button 2 to commit the chamfer length.

   Abaqus/CAE redraws the part with the selected edges chamfered.

Additional information

- *What is feature-based modeling?*

Mirroring a part

Select **Shape->Transform->Mirror** from the main menu bar to transform the part in the current viewport into a mirror image of itself. This operation is similar to copying a part and using the mirror option (*Copying a part*). However, transforming the original part retains the complete feature creation history and the ability to edit those features. You can choose to keep both the original geometry and the mirrored geometry, and you can select any planar face or datum plane as the mirror plane.

The mirror tool is available only when the current viewport contains a three-dimensional solid or shell part. Mirror features, like all features, can be deleted, suppressed, and resumed; however, a mirror feature contains no modifiable parameters, so it cannot be edited after you create it.

1. From the main menu bar, select **Shape->Transform->Mirror**.

   Tip: You can also mirror a part using the  tool, located in the Part module toolbox. For a diagram of the tools in the Part module toolbox, see *Using the Part module toolbox*.

2. From the prompt area, toggle on **Keep original geometry** to retain the original geometry when the part is mirrored.
3. From the prompt area, toggle on **Keep internal boundaries** to retain any intersecting boundaries between the original geometry and the new geometry when the part is mirrored.

   This option has no effect if used without **Keep original geometry**.
4. Select a datum plane or planar face from the viewport.

   Abaqus/CAE creates the mirrored geometry using the options you chose.

Additional information

- *What is feature-based modeling?*

The Property module

You can use the Property module to define materials, sections, and composite layups as well as other properties of a part or part region.

You can use the Property module to perform the following tasks:

- Define materials.
- Define beam section profiles.
- Define sections.
- Assign sections, orientations, normals, and tangents to parts.
- Define composite layups.
- Define a skin reinforcement.
- Define inertia (point mass, rotary inertia, and heat capacitance) on a part.
- Define springs and dashpots between two points or between a point and ground.
- Define material calibrations.

For information on defining inertia, see *Inertia*. For information on defining skin reinforcements, see *Skin and stringer reinforcements*. For information on defining springs and dashpots, see *Springs and dashpots*.

In this section:

- *Entering and exiting the Property module*
- *Understanding properties*
- *Which properties can I assign to a part?*
- *Understanding the Property module editors*
- *Using material libraries*
- *Using the Property module toolbox*
- *Creating and editing materials*
- *Defining general material data*
- *Defining mechanical material models*
- *Defining thermal material models*
- *Defining electrical and magnetic material models*
- *Defining other types of material models*
- *Creating and editing sections*
- *Creating and editing composite layups*
- *Assigning sections, orientations, normals, and tangents to a part*
- *Using discrete orientations for material orientations and composite layup orientations*
- *Creating material calibrations*
- *Using the Special menu in the Property module*
- *Using the Query toolset to obtain assignment information*

Entering and exiting the Property module

You can enter the Property module at any time during an Abaqus/CAE session by clicking **Property** in the **Module** list located in the context bar. When you enter the Property module, **Material**, **Section**, **Profile**, **Assign**, **Special**, **Feature**, and **Tools** menus appear in the main menu bar. A **Part** list appears in the context bar that allows you to select the part to which you want to assign properties.

To exit the Property module, select another module from the **Module** list. You need not take any specific action to save your material, section, and other definitions before exiting the module; they are saved automatically when you save the entire model by selecting **File->Save** or **File->Save As** from the main menu bar.

Additional information

- *Using the Special menu in the Property module*

Understanding properties

You can specify the properties of a part or part region by creating a section and assigning it to the part. In most cases, sections refer to materials that you have defined. Beam sections also refer to profiles that you have defined. This section of the guide explains materials, profiles, sections, rebar, and section assignment. You create materials, profiles, and sections using the Property module editors, as described in *Understanding the Property module editors*.

In this section:

- *Defining materials*
- *Defining profiles*
- *Defining sections*
- *Defining composite layups*
- *Understanding rebar in shell sections*

Defining materials

A material definition specifies all the property data relevant to a material. You specify a material definition by including a set of material behaviors, and you supply the property data with each material behavior you include. You use the material editor to specify all the information that defines each material.

Each material that you create is assigned its own name and is independent of any particular section; you can refer to a single material in as many sections as necessary. Abaqus/CAE assigns the properties of a material to a region of a part when you assign a section referring to that material to the region.

Defining profiles

A profile specifies the properties of a beam section that are related to its cross-sectional shape and size (for example, cross-section area and moments of inertia).
When you define a beam section, you must include a reference to a profile in the section definition.

You can create the following types of profiles:

Shape-based profiles

Shape-based profiles define the specific shape and dimensions of the beam cross-section. Abaqus uses the information provided by the shape-based profile to calculate the engineering properties of the section.

You can create this type of profile by first selecting from a list of shape options and then specifying that particular shape's dimensions. For example, if you select a box shape, you must then specify the height and width of the box as well as the thickness of the four walls. You can select from the following shape options:

- Arbitrary
- Box
- Circular
- Hexagonal
- I, L, T
- Pipe
- Rectangular
- Trapezoidal
- Channel
- Hat

The shape options are shown in *Figure 1*.

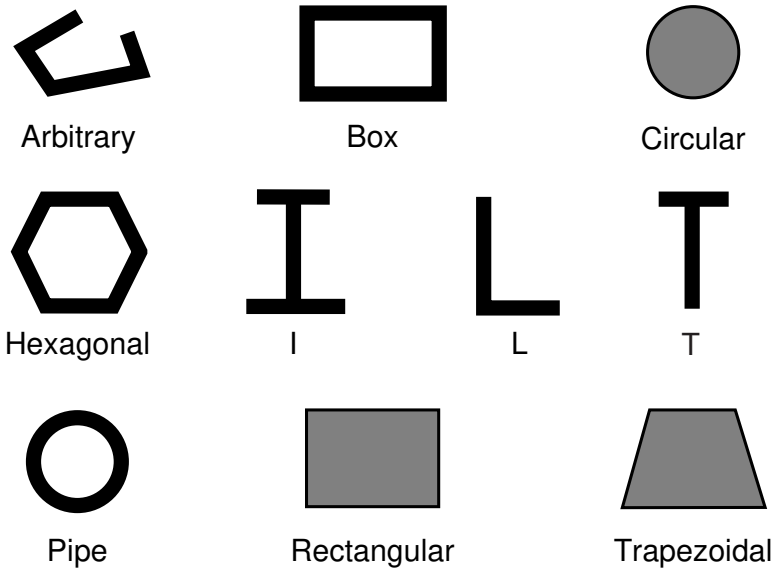


Figure 1: Available shape options.

For detailed information on each profile shape, see *Beam Cross-Section Library*.

Generalized profiles

Generalized profiles specify the engineering properties of the section directly. You can create a generalized profile by specifying values for the area, moments of inertia, torsional constant, and, if applicable, sectorial moment and warping constant. For more information, see *Using a General Beam Section to Define the Section Behavior*.

Each profile that you create has its own name and is independent of any particular beam section; you can refer to a single profile in as many beam sections as necessary. After you have assigned the beam section and beam orientation to the part, you can use the part display options to view an idealized representation of the shape-based or generalized beam profile. Displaying beam profiles is useful for checking that the correct profile has been assigned to a particular region and that the assigned beam orientation results in the expected orientation of the profile. For more information, see *Controlling beam profile display*.

Defining sections

A section contains information about the properties of a part or a region of a part. The information required in the definition of a section depends on the type of region in question. For example, if the region is a deformable wire, shell, or two-dimensional solid, you must assign a section to that region that provides information about the region's cross-sectional geometry. Likewise, a rigid region requires a section that describes its mass properties. Most sections must refer to a material name. Beam sections must also refer to a profile name.

When you assign a section to a part, Abaqus/CAE automatically assigns that section to each instance of the part. As a result, the elements that are created when you mesh those part instances will have the properties specified in that section.

Sections are named and created independently of any particular region, part, or assembly. You can assign a single section to as many different regions as necessary. You can use the Property module to create solid sections, shell sections, beam sections, fluid sections, and other sections.

Solid sections

Solid sections define the section properties of two-dimensional, three-dimensional, and axisymmetric solid regions.

- **Homogeneous solid sections**. Homogeneous solid sections consist of a material name. In addition, if the section will be used with a two-dimensional region, you must also specify the section thickness. (You have the option of specifying a plane stress or plane strain thickness even if the section will be assigned to a three-dimensional region. Abaqus/CAE ignores the thickness information if it is not needed for the region type.)

  For more information, see *Creating homogeneous solid sections*.
- **Generalized plane strain sections**. Generalized plane strain sections consist of a material name, thickness, and wedge angles about the global 1- and 2-axes. You can assign generalized plane strain sections only to two-dimensional planar regions.

  For more information, see *Creating generalized plane strain sections*.
- **Eulerian sections**. Eulerian sections consist of a list of material names. This list specifies all of the materials that can be present in an Eulerian domain. You can assign Eulerian sections only to Eulerian parts.

  For more information, see *Creating Eulerian sections*. For an overview of Eulerian analyses, see *Eulerian analyses*.
- **Composite solid sections**. Composite solid sections consist of layers of materials. For each layer of material, you must specify a material name, thickness, and orientation.

  For more information, see *Creating composite solid sections*.
- **Electromagnetic solid sections**. Electromagnetic solid sections are valid for electromagnetic models and consist of a material name. In addition, if the section will be used with a two-dimensional region, you must also specify the section thickness. (You have the option of specifying a plane stress or plane strain thickness even if the section will be assigned to a three-dimensional region. Abaqus/CAE ignores the thickness information if it is not needed for the region type.)

  For more information, see *Creating electromagnetic solid sections*.

Shell sections

Shell sections define the section properties of shell regions. Shells model structures in which one dimension (the thickness) is significantly smaller than the other two dimensions and in which the stresses in the thickness

direction are negligible. You can define one or more layers of reinforcement (rebar) in shell sections. For more information, see *Understanding rebar in shell sections*.

- **Homogeneous shell sections**. Homogeneous shell sections consist of a shell thickness, material name, section Poisson's ratio, and optional rebar layers. You can choose to provide the section property data before the analysis or to have Abaqus calculate (integrate) the cross-sectional behavior from section integration points during the analysis. If the latter is chosen, options are provided to control the section integration and temperature variation through the thickness.

  For more information, see *Creating homogeneous shell sections*.
- **Composite shell sections**. Composite shell sections consist of layers of materials, a section Poisson's ratio, and optional rebar layers. For each layer of material, you must specify a material name, thickness, and orientation. You can choose to provide the section property data before the analysis or to have Abaqus calculate (integrate) the cross-sectional behavior from section integration points during the analysis. If the latter is chosen, options are provided to control the section integration and temperature variation through the thickness.

  For more information, see *Creating composite shell sections*.
- **Membrane sections**. Membranes represent thin surfaces in space that offer strength in the plane of the surface but have no bending stiffness. Membrane sections consist of a material name, membrane thickness, section Poisson's ratio, and optional rebar layers.

  For more information, see *Creating membrane sections*.
- **Surface sections**. Surface sections represent surfaces in space that have no inherent stiffness and behave like membrane elements with zero thickness. Surface sections consist of optional rebar layers.

  For more information, see *Creating surface sections*.
- **General shell stiffness sections**. General shell stiffness sections allow you to define a shell's mechanical response by directly specifying the stiffness matrix and thermal expansion response. General shell stiffness sections consist of a section stiffness matrix and scaling moduli. Optionally, you can also specify a thermal expansion coefficient and thermal stresses in the section.

  For more information, see *Creating general shell stiffness sections*.

Beam sections

Beams are used in two and three dimensions to model slender, rod-like structures that provide axial strength and bending stiffness. Beams represent structures in which the cross-section is assumed to be small compared to the length. You can assign beam sections only to wire regions. In addition, you must assign a beam section orientation to all regions with beam sections.

- **Beam sections**. Beam sections consist of a section Poisson's ratio and a reference to a profile. Additional information is required depending on whether you choose to calculate (integrate) the section stiffness either before or during analysis.

  For information on profiles, see *Defining profiles*. For more information on beam sections, see *Creating beam sections*.
- **Truss sections**. Trusses, like beams, are used in two and three dimensions to model slender, rod-like structures that provide axial strength but no bending stiffness. Truss sections consist of a material name and cross-sectional area.

  For more information, see *Creating truss sections*.

You can use the part display options to view an idealized representation of the beam or truss profile along the wire region. For more information, see *Controlling beam profile display*.

Other sections

Other sections you can create include gasket sections, cohesive sections, acoustic infinite sections, and acoustic interface sections.

- **Gasket sections** (Abaqus/Standard analyses only). Gaskets model thin sealing components that are positioned between structural components. Gasket sections are used to provide pressure-closure behaviors for sealing components. Gasket sections consist of a material name, initial gasket thickness, initial gap, initial void, and cross-sectional area.

  For more information, see *Creating gasket sections* and *Gaskets*.

- **Cohesive sections**. Cohesive sections are used to model finite thickness adhesives, negligibly thin adhesive layers for debonding applications, as well as gaskets. No specialized gasket behavior (typically defined in terms of pressure versus closure) is available. Cohesive sections consist of a material name, response, initial thickness, and out-of-plane thickness.

  For more information, see *Creating cohesive sections* and *Adhesive joints and bonded interfaces*.

- **Acoustic infinite sections**. Acoustic infinite sections are used to model an acoustic medium undergoing small pressure changes involving exterior domains. Acoustic infinite sections consist of an acoustic medium material name. In addition, if the section will be used with a two-dimensional region, you must also specify the section thickness. (You have the option of specifying a plane stress or plane strain thickness even if the section will be assigned to a three-dimensional region. Abaqus/CAE ignores the thickness information if it is not needed for the region type.)

  For more information, see *Creating acoustic infinite sections*.

- **Acoustic interface sections**. Acoustic interface sections are used to couple an acoustic medium to a structural model. Acoustic interface sections consist of an acoustic medium material name. In addition, if the section will be used with a two-dimensional region, you must also specify the section thickness. (You have the option of specifying a plane stress or plane strain thickness even if the section will be assigned to a three-dimensional region. Abaqus/CAE ignores the thickness information if it is not needed for the region type.)

  For more information, see *Creating acoustic interface sections*.

Warning:

The type of section that you assign to a part must be consistent with the element type that you assign to instances of that part in the Mesh module. For example, if you assign a truss section to a wire part in the Property module, you should assign a truss element type (and not a beam element type) to any instances of that part in the Mesh module.

Defining composite layups

You use a composite layup to model a part that contains many plies, where each ply is defined by a material, a thickness, and a reference orientation. Composite layups are similar to composite shell or composite solid sections. A ply in a composite section is the same as a ply in a composite layup; however, a composite section always contains the same number of plies. In contrast, a composite layup can contain a different number of plies in different regions. Abaqus/CAE converts a composite layup to its constituent composite sections when you analyze your model. Abaqus/CAE allows you to define three types of composite layups—shells, continuum shells, and solids. For more information, see *Composite layups*.

Understanding rebar in shell sections

You can define one or more layers of reinforcement (rebar) in shell sections by specifying a unique layer name for each rebar layer. You also select the name of the material forming each rebar layer and specify the cross-sectional area per bar, spacing, and orientation of the rebar in each layer.

To define the orientation of each rebar layer, you can specify an orientation angle or an orientation name. The angular orientation of a rebar layer is defined relative to the rebar reference orientation. You use the **Assign** menu to assign a rebar reference orientation to shell regions. If you specify an orientation name, you must supply the user subroutine *ORIENT*. For more information, see *Defining rebar layers*, and *Assigning a rebar reference orientation*.

In the Step module you must request output for rebar to include rebar output in the data that Abaqus writes to the output database and to view plots of the rebar orientations in the Visualization module. In the Visualization moduleAbaqus/CAE treats rebar layers as section points for output purposes, and you can create material orientation plots to show the rebar orientation.

For more information on rebar, see *Defining Reinforcement*.

Additional information

- *Understanding output requests*
- *Selecting section point data by category*
- *Plotting material orientations*

Which properties can I assign to a part?

Once you have created a section, you can assign the following properties to a part:

Section

You can assign the section to a region of a part. The **Section Assignment Manager** allows you to view, create, edit, suppress, resume, and delete section assignments. In the Property module, Abaqus/CAE colors a region green to indicate that the region has a section assignment. If there are overlapping section assignments, Abaqus/CAE colors the region yellow.

Beam Section Orientation

You can assign beam section orientations to wire regions. You assign an orientation to a beam section by defining the approximate local 1-direction of the cross-section.

Material Orientation

You can assign material orientations to shell and solid regions. The global coordinate system determines the default material orientation. You can define a material orientation by selecting an existing datum coordinate system or discrete field or by defining a discrete orientation. For an Abaqus/Standard analysis, you can define the material orientation in a user subroutine.

Rebar Reference Orientation

The angular orientation of a rebar layer is defined relative to the rebar reference orientation. You can assign rebar reference orientations to shell regions. The global coordinate system determines the default rebar reference orientation. You can define a rebar reference orientation by selecting an existing datum coordinate system from the viewport and then selecting an axis on the datum coordinate system that approximates the direction of the shell normal.

Element Normal

You can assign shell/membrane normal directions to orphan elements, shell and membrane regions, and axisymmetric parts with wire regions. The shell/membrane normals affect the material orientation assigned to the region. If you reverse the normal of a shell region, the material 2-direction will be reversed. The reversal of the material 2-direction has no effect on the analysis results. However, you should use care when interpreting section point output for shells.

Element Tangent

You can assign beam/truss tangent directions to orphan elements and wire regions. Beam section orientations depend on the beam tangent directions. If you reverse the tangent direction, the local 2-direction will be reversed, and you should use care when interpreting results, in particular when you identify the beam section point locations.

You can use the **Assign** menu in the Property module main menu bar to assign properties to a part. You can select the region to which to assign a property in the following ways:

- Select the region directly in the viewport.
- Select elements individually or using the angle method (to assign shell normals to orphan elements).
- Use the Set toolset to create a set consisting of regions of parts or orphan elements. (The Set toolset is available from the **Tools** menu in the main menu bar.) You can then assign the property to the region or elements defined by the set.

If you assign a section to a region and then rename or delete the section, that section is no longer applied to the region. If a region of your model lacks section properties, your analysis job will fail and the problem will be reported by the Job module.

However, the original names of renamed or deleted sections continue to be associated with the regions to which they have been assigned until you take one of the following actions:

- Assign a different section to the region.
- Create a new section that has the original section name and is the appropriate type for the region (for example, a shell section for a shell region); the properties defined in the new section are applied to the region automatically.
- If you have renamed a section, change the name of the section back to its original name.

(You can use the Query toolset to determine the name of the section assigned to the region; for more information, see *Understanding the role of the Query toolset*.)

Similarly, if you refer to a material in a section definition and then rename or delete the material, the section becomes invalid; properties defined in that section are no longer applied to regions to which the section is assigned. However, the original names of renamed or deleted materials continue to be associated with sections that refer to those materials; therefore, you can use techniques similar to the ones listed above to restore sections.

For detailed instructions on assigning properties to a model and managing section assignments, see the following sections:

- *Assigning a section*
- *Managing section assignments*
- *Assigning a beam orientation*
- *Assigning a material orientation or rebar reference orientation*
- *Assigning shell/membrane normal directions*
- *Assigning beam/truss tangent directions*
- *Using discrete orientations for material orientations and composite layup orientations*

Understanding the Property module editors

When you create or edit a material, profile, or section, you must enter data in the appropriate editor. For example, when you create a material, you must enter data in the material editor. This section provides information on each editor type.

In this section:

- *Creating materials*
- *Creating profiles*
- *Creating sections*
- *Creating composite layups*
- *Selecting material behaviors*
- *Specifying material parameters and data*
- *Evaluating hyperelastic, hyperfoam and viscoelastic material behavior*

Creating materials

To create a material, select **Material->Create** from the main menu bar. An **Edit Material** dialog box appears in which you can enter a name for the material and create or edit material properties. The material editor is shown in *Figure 1*.

Note:

Once you have created a material, it cannot be renamed using the material editor; you must use **Material->Rename** to change the name of an existing material.

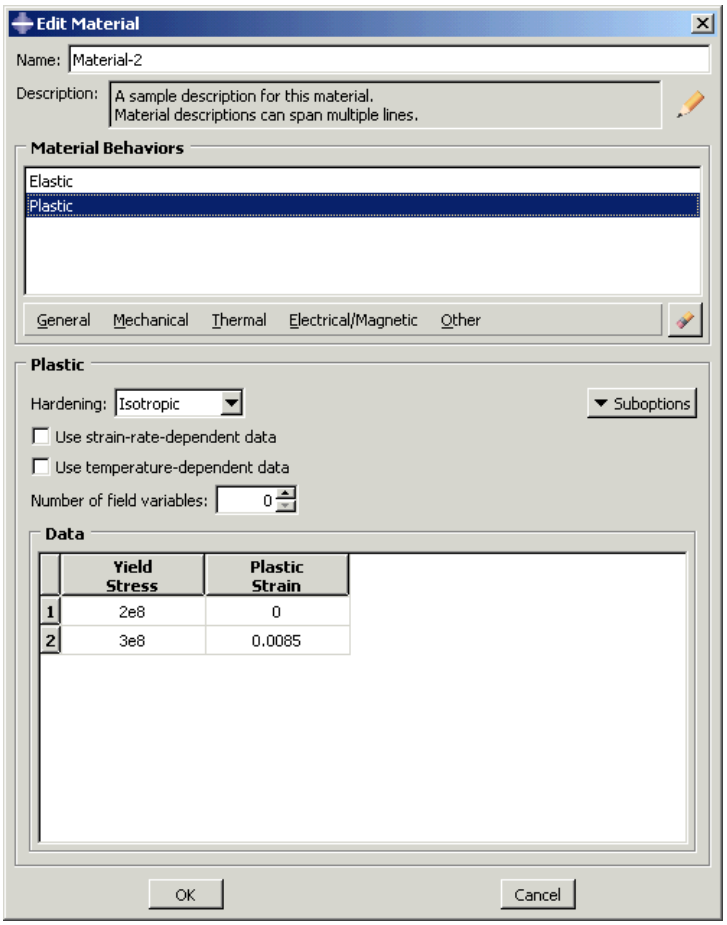

Figure 1: The material editor.

The material editor consists of the following:

Material Behaviors list

A list of the behaviors you have included in the material definition.

Behavior menu

A set of menus beneath the behavior list from which you select material behaviors.

Behavior definition area

The lower portion of the window in which the parameters, tabular data fields, and suboptions associated with a selected behavior appear.

Note:

You can display help on particular aspects of the editor that are not discussed here by selecting **Help->On Context** from the main menu bar and then clicking the editor feature of interest.

Additional information

- *Creating or editing a material*
- *Browsing and modifying material behaviors*
- *Specifying material parameters and data*

Creating profiles

To create a profile, select **Profile->Create** from the main menu bar. A **Create Profile** dialog box appears in which you can enter a name for the profile and select the profile type. Once you have finished entering this information, click **Continue** in the **Create Profile** dialog box to display the profile editor, which allows you to create and edit profiles.

All profile editors display a diagram of the profile shape and text fields in which you can enter all of the data necessary to define the profile. For example, the I-shaped profile editor is shown in *Figure 1*. The editor contains a diagram of the I-shaped profile and data fields in which you can enter each dimension.

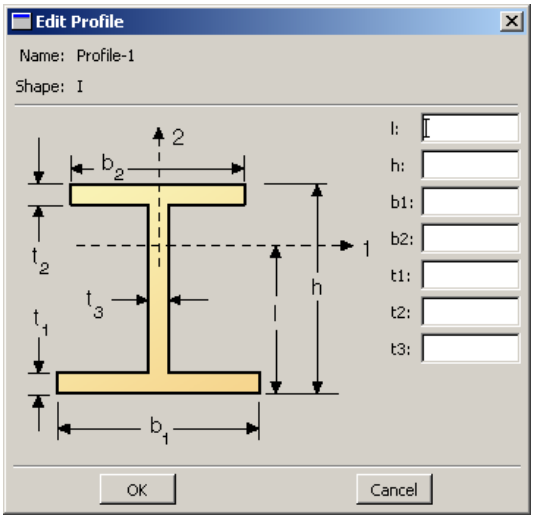

Figure 1: The I-shaped profile editor.

Once you have created a profile, you can refer to that profile in a beam section definition. For example, a box-shaped profile named `SupportBeam` is selected in the beam section editor shown in *Figure 2*.

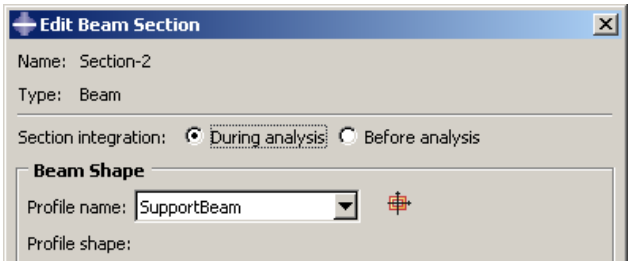

Figure 2: Specifying a profile name in the beam section editor.

For more information on profiles, see *Defining profiles*.

Additional information

- *Defining profiles*
- *Beam Cross-Section Library*

Creating sections

You can use the Property module to create the following types of sections:

- Homogeneous solid sections
- Generalized plane strain sections
- Eulerian sections
- Composite solid sections
- Electromagnetic solid sections
- Homogeneous shell sections
- Composite shell sections
- Membrane sections
- Surface sections
- General shell stiffness sections
- Beam sections
- Truss sections
- Gasket sections
- Cohesive sections
- Acoustic infinite sections
- Acoustic interface sections

To create a section, select **Section->Create** from the main menu bar. A **Create Section** dialog box appears in which you can name the section and specify the type of section that you want to create. Once you have specified a section name and type, click **Continue** in the **Create Section** dialog box to display the section editor, which allows you to create and edit sections.

The format of the section editor varies according to the type of section you are defining. For example, the homogeneous shell section editor is shown in *Figure 1*.

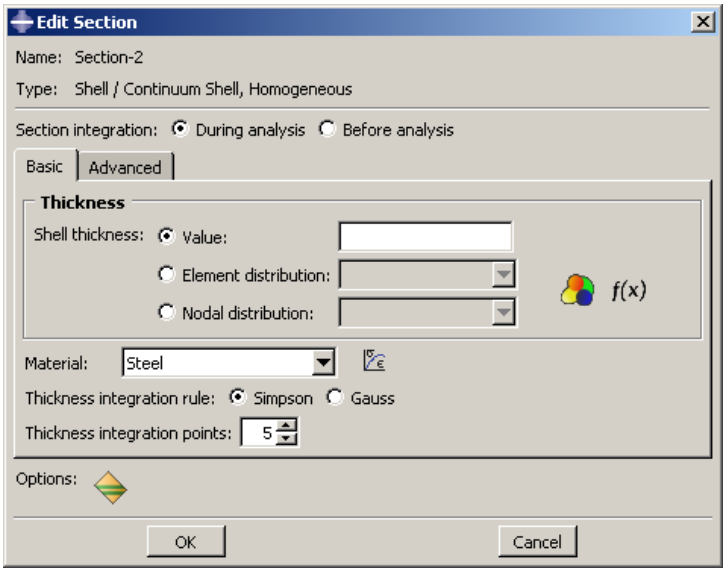

Figure 1: The homogeneous shell section editor.

Note:

You can display help on particular aspects of an editor that are not discussed here by selecting **Help->On Context** from the main menu bar and then clicking the editor feature of interest. A help window will appear containing a relevant section from this guide.

Some editors contain a **Rebar Layers** option (icon), as shown in *Figure 1*. If you click this icon, another dialog box appears in which you can enter data concerning rebar layers, as shown in *Figure 2*.

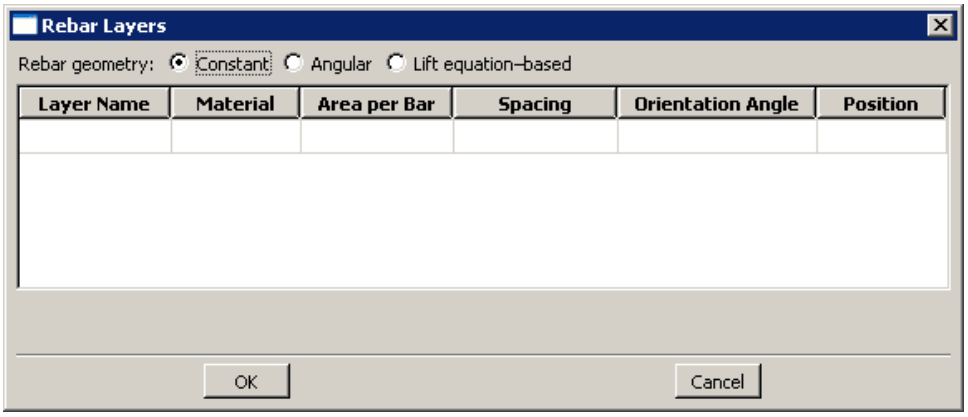

Figure 2: The Rebar Layers dialog box.

Note:

To display context-sensitive help for items in the **Rebar Layers** dialog box, you must select the item of interest and then press **[F1]**. (The **Help** menu in the main menu bar is unavailable while the option dialog box is displayed.)

Once you have entered all the data necessary to define the section, you can click **OK** to close the section editor and to save the section.

For detailed instructions on using section editors, see the following sections :

- *Creating homogeneous solid sections*
- *Creating generalized plane strain sections*
- *Creating Eulerian sections*
- *Creating composite solid sections*
- *Creating electromagnetic solid sections*
- *Creating homogeneous shell sections*
- *Creating composite shell sections*
- *Creating membrane sections*
- *Creating surface sections*
- *Creating general shell stiffness sections*
- *Creating beam sections*
- *Creating truss sections*
- *Creating gasket sections*
- *Creating cohesive sections*

- *Creating acoustic infinite sections*
- *Creating acoustic interface sections*
- *Defining rebar layers*
- *Creating profiles*

Additional information

- *Defining sections*
- *Creating and editing sections*

Creating composite layups

You can use the Property module to create the following types of composite layups:

- Shell
- Continuum shell
- Solid

To create a composite layup, select **Composite->Create** from the main menu bar. A **Create Composite Layup** dialog box appears in which you can name the layup, specify the initial ply count, and specify the type of composite layup that you want to create. Once you have finished entering this information, click **Continue** in the **Create Composite Layup** dialog box to display the composite layup editor, which allows you to create and edit layups.

The format of the composite layup editor varies according to the type of layup you are defining. For example, the shell composite layup editor is shown in *Figure 1*.

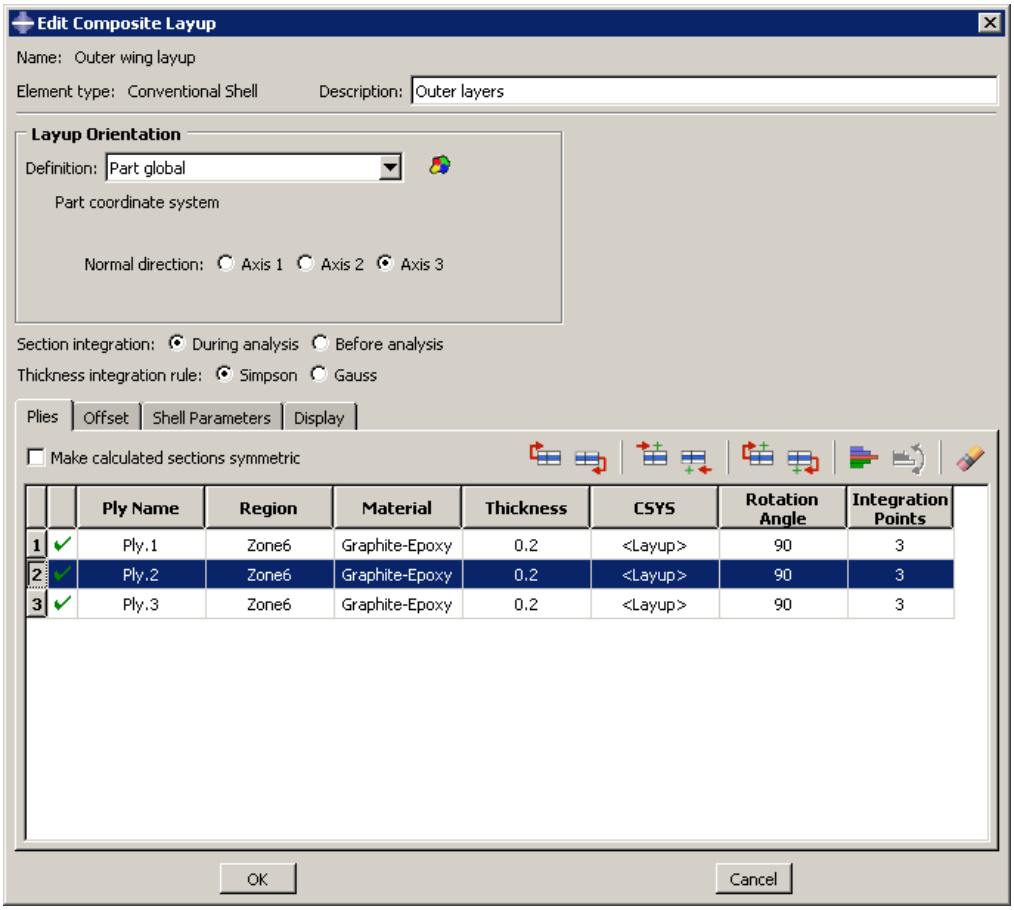

Figure 1: The shell composite layup editor.

Note:

You can display help on particular aspects of an editor that are not discussed here by selecting **Help->On Context** from the main menu bar and then clicking the editor feature of interest. A help window will appear containing a relevant section from this guide.

Once you have entered all the data necessary to define the layup, you can click **OK** to close the editor and to save the composite layup.

For detailed instructions on using composite layup editors, see the following sections:

- *Creating conventional shell composite layups*
- *Creating continuum shell composite layups*
- *Creating solid composite layups*

Additional information

- *Defining composite layups*
- *Creating and editing composite layups*

Selecting material behaviors

The material editor contains several menus that allow you to add most of the material behaviors available in Abaqus/Standard or Abaqus/Explicit to a material definition.
(For information on which material behaviors are available in Abaqus/CAE, see *Abaqus keyword browser table* and *Keyword support from the input file reader*.)

The material editor menus reflect the division of all material behaviors into five categories: **General**, **Mechanical**, **Thermal**, **Electrical/Magnetic**, and **Other**. *Figure 1* shows the elasticity behaviors available under the **Mechanical** menu.

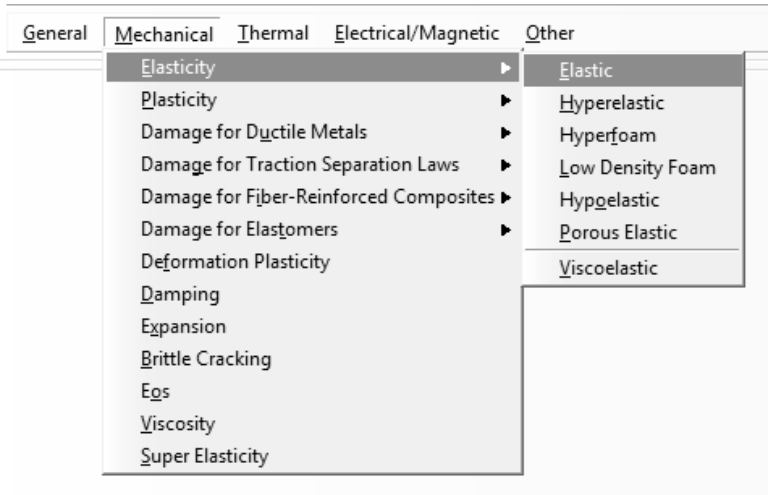

Figure 1: Elasticity behaviors under the Mechanical menu.

The lists of behaviors do not change to exclude behaviors that are invalid for the type of analysis you are running. In addition, Abaqus/CAE does not check that the data that you enter in the editor are valid or that your materials are appropriate for your analysis type. For example, if you request a dynamic analysis, Abaqus/Standard or Abaqus/Explicit requires that you specify the density of the materials used in the model so that it can calculate mass and inertia properties of the model. If you do not provide a material density in the material definition, Abaqus/CAE allows you to create the material; however, Abaqus/CAE will report an error when you submit your analysis job.

When you select a behavior, the name of the behavior appears in the **Material Behaviors** list at the top of the editor, and the behavior becomes part of your material definition. For example, the list in *Figure 2* reflects that the **Elastic** and **Plastic** behaviors have been chosen, as well as the **Fail Stress** suboption of the **Elastic** behavior.

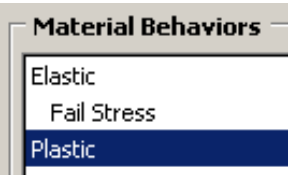

Figure 2: The Material Behaviors list.

Behaviors such as **Elastic** and **Plastic** are primary behaviors. Test data and suboptions such as **Fail Stress** appear beneath the corresponding primary behavior and are indented to indicate their subordinate position.

If you want to remove a behavior or suboption from a material definition, you can select that behavior or suboption from the **Material Behaviors** list and then click .

If you are creating a new material, the selected behavior list is initially blank. As you select behaviors, the behavior name appears in the list; if there are too many behaviors to see at once, a scroll bar appears on the right side of the list.

Additional information

- *Browsing and modifying material behaviors*
- *Specifying material parameters and data*

Specifying material parameters and data

When you select a behavior, the behavior definition area changes to show all of the associated parameters and data items for the selected behavior. The parameters are shown at the top of the behavior description area and the data items at the bottom.

Depending on your analysis requirements, you choose to either accept or change the default parameter values; for example, you choose whether to use isotropic elasticity by using the **Type** combo box on the elasticity form, as shown in *Figure 1*.

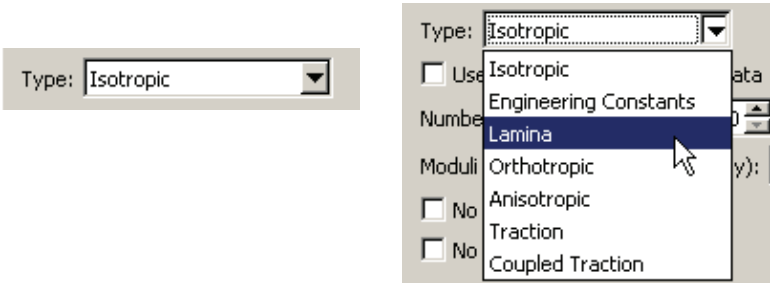

Figure 1: Type combo box.

A table containing fields for the remaining required material data appears beneath the parameter area; for example, *Figure 2* shows the table that appears when you choose isotropic elasticity.

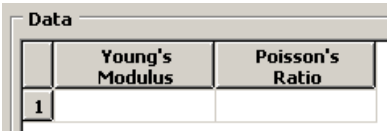

Figure 2: Isotropic elasticity table.

Different fields become available depending on how you have set the parameters. For example, when you choose lamina elasticity rather than isotropic elasticity, the table in *Figure 3* appears.

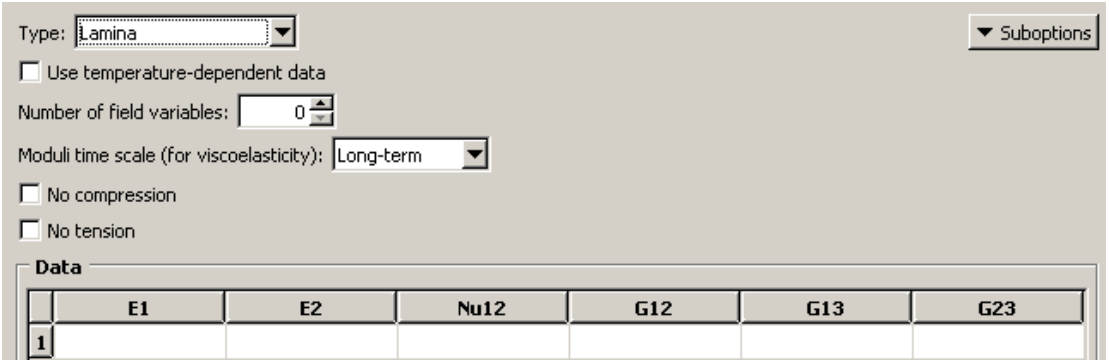

Figure 3: Lamina elasticity table.

You can enter data into the table using the keyboard. Alternatively, you can click mouse button 3 anywhere in the table to view a list of options for specifying tabular data. For example, an option exists for automatically entering data from a file. Another option exists for creating an *X–Y* data object from the data in the table; you can plot the *X–Y* data in the Visualization module and visually check its validity. For detailed information on each option, see *Entering tabular data*.

For detailed information on specific features in the material editor, see the following sections:

- *Creating or editing a material*

- *Browsing and modifying material behaviors*
- *Entering strain-rate-dependent data*
- *Entering temperature-dependent data*

Additional information

• *Browsing and modifying material behaviors*

Evaluating hyperelastic, hyperfoam and viscoelastic material behavior

Abaqus/CAE provides a convenient **Evaluate** option that allows you to view the behavior predicted by a hyperelastic, hyperfoam, or viscoelastic material and that allows you to choose a suitable material formulation.

You can evaluate any hyperelastic or hyperfoam material, but a viscoelastic material can be evaluated and viewed only if it is defined in the time domain and includes hyperelastic, hyperfoam, and/or elastic material data. If your material definition includes viscoelastic data defined in the frequency domain, you cannot evaluate its viscoelastic material behavior in Abaqus/CAE, but its material evaluation data are written to the data (`.dat`) file.

The **Evaluate** option prompts Abaqus/CAE to perform one or more standard tests using an existing material. (For information on standard tests for hyperelastic, hyperfoam, and viscoelastic materials, see *Hyperelasticity*, *Hyperelastic Behavior in Elastomeric Foams*, and *Linear Viscoelasticity*, respectively.) Once the standard tests are completed, Abaqus/CAE enters the Visualization module and displays the test results in new viewports as *X*–*Y* plots. (For more information on *X*–*Y* plots, see *X–Y plotting*.) Abaqus/CAE also displays an informational dialog box containing the stability limits and coefficients for each hyperelastic strain energy potential and the viscoelastic material parameters for the viscoelastic response. The information from the evaluation is saved in the *material_name_i*`.dat` file, where *i* starts at `1` and is incremented for subsequent evaluations of the same material. You can review the evaluation results and adjust the material definition as necessary.

To initiate the evaluation procedure, select **Material->Evaluate->*material name*** from the main menu bar. Alternatively, you can select the material of interest in the **Material Manager** and then click **Evaluate**. The **Evaluate Material** dialog box appears in which you can specify how you want Abaqus/CAE to perform the standard tests.

- For detailed instructions on evaluating hyperelastic material behavior, see *Displaying X–Y plots of hyperelastic material behavior*.
- For detailed instructions on evaluating hyperfoam material behavior, see *Displaying X–Y plots of hyperfoam material behavior*.
- For detailed instructions on evaluating viscoelastic material behavior, see *Displaying X–Y plots of viscoelastic material behavior*.

Note:

The material evaluation procedure generates jobs with the same names as the materials; therefore, these material names must adhere to the same rules as job names (see *Using basic dialog box components*, for more information on naming objects).

The **Evaluate** option is particularly useful in the following scenarios:

Comparing test data with the behavior predicted by a particular strain energy potential

When you define a hyperelastic or hyperfoam material using experimental data, you also specify the strain energy potential that you want to apply to the data. Abaqus uses the experimental data to calculate the coefficients necessary for the specified strain energy potential. However, it is important to verify that an acceptable correlation exists between the behavior predicted by the material definition and the experimental data.

You can use the **Evaluate** option to calculate the material response based on the experimental data using the strain energy potential that you have specified in the material definition. When the tests are complete, Abaqus/CAE enters the Visualization module and displays *X*–*Y* plots of the test results. Each plot includes the experimental data and a curve for each evaluated strain energy potential. Abaqus/CAE also opens a dialog box containing the stability limits and coefficients for each strain energy potential.

For example, the *X*–*Y* plot in *Figure 1* shows the results of a planar test using the Ogden N=3 strain energy potential.

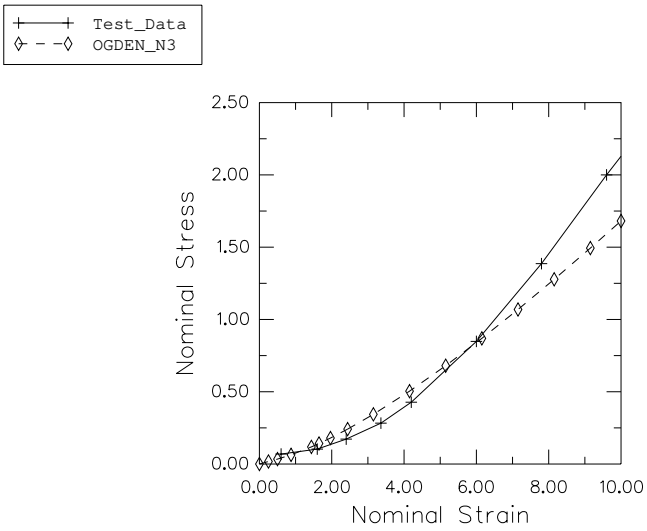

Figure 1: Results of a planar test.

In addition, the following information is reported to the data (`.dat`) file:

- The coefficients calculated for the strain energy potential.
- Any material instabilities that were detected during the tests.

The path to the data (`.dat`) file appears in the message area of the Abaqus/CAE main window once the analysis has completed successfully.

Evaluating multiple strain energy potentials

If you are defining a hyperelastic material using experimental data and you are unsure which strain energy potential to specify, you can select **Unknown** from the **Strain energy potential** list in the material editor. You can then use the **Evaluate** option to perform standard tests with the experimental data using multiple strain energy potentials.

When the tests are complete, Abaqus/CAE enters the Visualization module and displays an *X*–*Y* plot for each test and a dialog box containing the stability limits and coefficients for each strain energy potential. Each plot includes the experimental data and a curve for each evaluated strain energy potential. You can visually compare the strain energy potential curves and the experimental data curve and select the strain energy potential that provides the best fit.

Once you have determined which strain energy potential provides the best fit with the experimental data, you must return to the material editor in the Property module and change the **Strain energy potential** selection from **Unknown** to the strain energy potential that you have chosen.

Viewing behavior predicted by coefficients

If you have acquired coefficients for a particular strain energy potential (either by evaluating one or more hyperelastic strain energy potentials, as described above, or from another source), you may want to verify that the behavior predicted by the strain energy potential acceptably matches your experimental data or meets other criteria.

You can use the **Evaluate** option to plot a curve of the strain energy potential using the coefficients you provided in the material definition. If the material definition also includes experimental data, a curve for that data also appears in the plot.

Viewing response curves for viscoelastic materials

If you have shear or volumetric test results, you may want to verify that the creep and relaxation behavior predicted by Abaqus acceptably matches your experimental data or meets other criteria. Likewise, if you have frequency data, you may want to verify that the predicted storage and loss components of the shear and bulk moduli match your data.

You can use the **Evaluate** option to plot curves using the coefficients you provided in the material definition. If the material definition includes experimental data, curves for those data also appear in the plots. The types of curves produced depend on the material definition. For viscoelastic materials defined using a Prony series, creep test data, or relaxation test data for time, you can produce creep and relaxation plots versus time. For viscoelastic materials defined using frequency data for time, you can produce plots of the storage and loss components of the shear and bulk moduli versus a logarithmic scale of frequencies.

Adjusting material data

If you are unsatisfied with the fit between the test data and the behavior predicted by the material, you can return to the Property module and adjust the test data and then evaluate the material again. You can repeat this process until you are satisfied with the material behavior. In some cases it may be possible to use this approach to optimize the coefficient values included in a hyperelastic material definition. For more information, see "Improving the accuracy and stability of the test data fit," in *Hyperelastic Behavior of Rubberlike Materials* and *Hyperelastic Behavior in Elastomeric Foams* for hyperelastic and hyperfoam materials, respectively.

For detailed instructions on evaluating materials, see the following sections:

- *Displaying X–Y plots of hyperelastic material behavior*
- *Displaying X–Y plots of hyperfoam material behavior*
- *Displaying X–Y plots of viscoelastic material behavior*

For more information on the strain energy potentials available in Abaqus, see "Strain energy potentials," in *Hyperelastic Behavior of Rubberlike Materials*.

Using material libraries

You can use a material library to maintain a consistent set of material property data for use in all Abaqus/CAE analysis models. Material libraries are available only in the Property module.

This section provides information on accessing, using, and managing material libraries.

In this section:

- *Material libraries*
- *Managing material libraries*
- *Adding materials from a library to your model*

Material libraries

Material libraries provide a convenient means of storing material property data for use in multiple analyses. You can create one or more libraries to save and organize material data related to a project, a group of projects, or an entire company.
Use of material libraries allows you to maintain a consistent set of material properties and to quickly add materials to your models.

Material library tools are located in the Model Tree area in the Property module.

Material libraries are considered plug-ins to Abaqus/CAE, although they are loaded automatically without use of the **Plug-ins** menu. Material libraries have the file extension `.lib` and are stored in the `abaqus_plugins` directories located within the Abaqus/CAE installation, your home directory, or the current directory (the directory from which you launched Abaqus/CAE). You can also use the **plugin_central_dir** environment variable in the `abaqus_v6.env` file or the Abaqus solver `custom_v6.env` file to specify one or more additional directory paths. (For more information on the location of the plug-in directories, see *Where are plug-in files stored?*) Abaqus/CAE searches all subdirectories of the specified plug-in locations for material library files.

By default, Abaqus/CAE displays material libraries in a tree format, similar to the Model Tree. In this format you can expand and collapse categories to help locate a desired material. *Figure 1* shows a simple material library containing metal materials. It is organized into categories for aluminum, copper, and steel; the aluminum category has been expanded. You can also view material libraries as an alphabetical list of material names, omitting the categories.

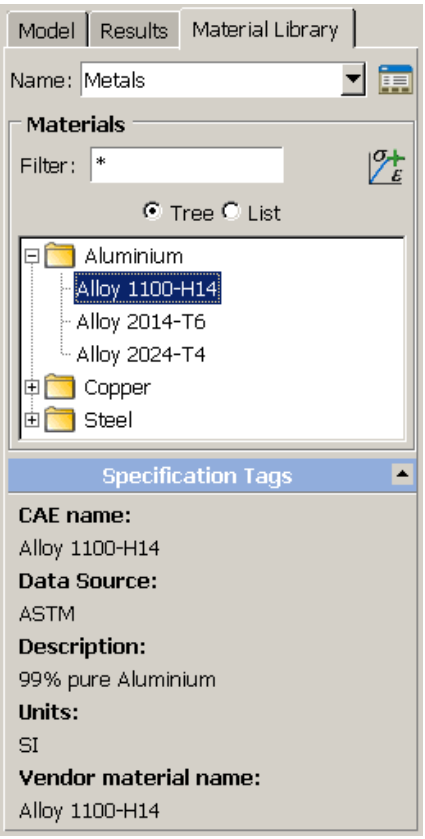

Figure 1: The Material Library.

You can use the **Filter** located above the materials list to search the material names for a list of characters. The filter may include any characters allowed in an Abaqus material name (for more information on object naming, see *Using basic dialog box components*). The filter is not applied to category names, so filtering may result in "empty" categories.

The  tool opens the **Material Library Manager**, where you can create, edit, rename, and reorganize material libraries. You can also use the manager to create, edit, rename, and delete **Specification Tags** to help identify materials in a library.

Figure 1 shows the predefined **Specification Tags**. The  tool copies a selected material from the library to the current model.

Additional information

- *Managing material libraries*
- *Adding materials from a library to your model*

Managing material libraries

The **Material Library Manager** allows you create, edit, and rename material libraries, library categories, and library materials.

The default **Specification Tags** indicate the source of the material data, a description, the units of measure, and a vendor material name. You can create, edit, rename, and delete specification tags for each material in a library. Material properties and categories are presented in alphabetical order, identical to the default view of the library in the main window of Abaqus/CAE; material categories appear first, followed by materials that are not in a category. You can use the manager to copy materials from a model to a library or from a library to a model. The **Material Library Manager** is shown in *Figure 1*.

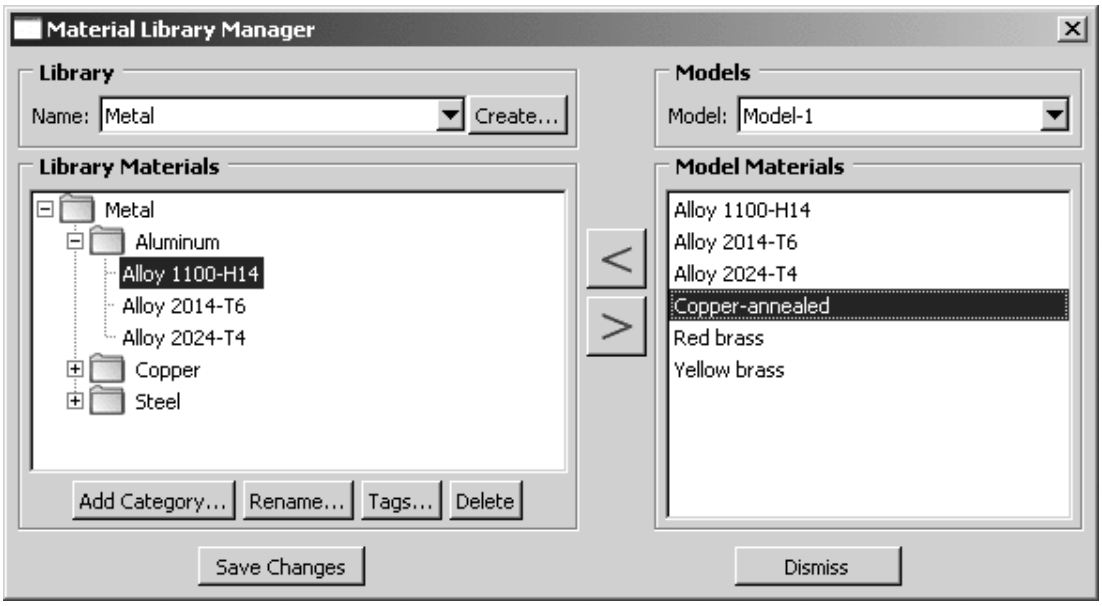

Figure 1: The Material Library Manager.

When you work with material libraries, it is recommended that you carefully consider the material and category names. You can create multiple categories and/or materials with exactly the same name. For example, you could have identical entries for a standard grade of steel, each containing properties in different sets of units. Using suitable category names, you can easily identify each material. However, if you display the library in the list format, the identical entries will all appear in the list. Modifying the material names to include the units information may make it easier to identify the desired material. For example, you can name one material `Steel 1020 US` and another `Steel 1020 SI`. Alternatively, you can click **Tags** in the material library manager to indicate the units in the **Specification Tags** that appear below the materials list in the main window. Renaming a material in the material library will change the name only in the library and does not change the underlying material name copied from or to the Abaqus/CAE model. A material added from the library to a model will still retain the old name.

You cannot view or edit material properties within the material library manager. To view or edit the properties of a material, you must add the material to a model and use the **Edit Material** dialog box (for more information, see *Creating or editing a material*).

1. From the **Material Library** tab in the Model Tree area, click the **Material Library Manager** icon  located to the right of the **Name** field.

   Abaqus/CAE displays the **Material Library Manager**.

2. From the top of the manager, click **Create** to create a new material library, or select a library name to edit an existing library.

3. If you selected **Create** in the previous step, the **Create Material Library** dialog box appears.
   a. Enter a name for the new library.
   b. Select **Home** or **Current** to choose the location of the `abaqus_plugins` directory in which the library will be saved.
   c. Click **OK**.

      Abaqus/CAE creates an empty material library file and opens it for editing in the manager. If necessary, Abaqus/CAE also creates the specified `abaqus_plugins` directory. For more information, see *Material libraries*.

4. To edit the current material library, select an item from the **Library Materials** list on the left side of the manager and choose from the following:

   - If you want to create categories to organize materials in the library, click **Add Category**. The **Create Category** dialog box appears.

     1. Enter a name for the category.
     2. Click **OK** in the **Create Category** dialog box.

        Abaqus/CAE creates the new category.

     The category appears at the same level of the library as the item you selected. For example, if you selected the library name, the new category appears with any other categories directly below the library name; if you selected an existing category, the new category appears within that category.
   - If you want to rename the selected item, click **Rename**. Enter a new name in the dialog box that appears, and click **OK**.

     Note:

     Renaming a library changes the name displayed within Abaqus/CAE; it does not change the name of the library (`.lib`) file.

   - If you want to edit the information that appears for a material when you expand the **Specification Tags** field at the bottom of the material library, click **Tags**. The tags contain the source, description, units, and vendor name of the material. By default, the vendor name tag contains the material name, and the other tags each contain "Imported from CAE." You can use tags to clarify the intended use of materials that have identical names or similar properties.
   - If you want to remove a material or an empty category from the library, select it and click **Delete**. You can use a combination of **[Ctrl] + Click** and **[Shift] + Click** to select multiple items.

     Note:

     You cannot delete a material library from within Abaqus/CAE; you must delete the library file from the saved location on your system.

5. Use the arrows located between the **Library Materials** list and the **Model Materials** list to copy material data from a library to a model, or vice versa.

   When you copy a material, Abaqus/CAE places the new material at the end of the selected category, if any, or at the end of the library.
   a. From the **Models** list in the **Material Library Manager**, select the model to which (or from which) you want to copy a material.
   b. Select the desired material from the **Library Materials** list or the **Model Materials** list. You can use a combination of **[Ctrl] + Click** and **[Shift] + Click** to select multiple items.

c. If you are copying a material into the library, select the category in the **Library Materials** list into which you want Abaqus/CAE to place the material.

d. Click on the appropriate arrow to copy the material.

Abaqus/CAE adds the new material to the end of the selected category for a library or to the end of the materials list for a model.

Changes that you make in the **Material Library Manager** are visible immediately in the manager dialog box. However, they are not committed to the library file until you click **Save Changes**. Abaqus/CAE does not update the library view in the main window until you dismiss the material library manager.

Additional information

- *Material libraries*
- *Adding materials from a library to your model*

Adding materials from a library to your model

To view material libraries, select the **Material Library** tab in the Model Tree area of the Property module. If more than one library is available, select one from the list at the top of the tabbed page. In the default **Tree** view, expand categories to view the materials within each category. To hide the categories and view an alphabetical list of all materials in the current library, select the **List** view.

To add a material from a library to the current model, highlight the material name in the tree or list view, and click the **Add Material** icon  at the upper right corner of the **Materials** list. Alternatively, you can double-click on a material name in the library to add it to the model.

1. Click **Material Library** at the top of the Model Tree area located on the left side of the main window.

   Tip: If the Model Tree is not displayed, select **View->Show Model Tree** from the main menu bar.

2. Select a library name from the **Name** list.

   If Abaqus/CAE did not find any material libraries at the start of the session, you may create a new library. For more information, see *Managing material libraries*.

   Abaqus/CAE displays the library contents. By default, the library is displayed in a tree format where materials may be separated into categories, similar to the Model Tree.

3. Locate the desired material in the library using any of the following methods:

   - Expand categories within the **Tree** view to view their contents.
   - Toggle on **List** to hide the categories and view all materials in the library.
   - Enter a string in the **Filter** field to show only those materials whose names contain that string.

4. Click on the name of a material to select it.
5. If desired, click the arrow to the right of **Specification Tags** (located below the materials list) to view more information about the selected material.
6. Click the **Add Material** icon  at the upper right corner of the **Materials** list to add the material to the current model.

Once you have added a material to your model, use the **Edit Material** dialog box to view or edit the material properties. Use the other tools in the Property module to associate the material with a section and assign the section to part of your model.

Additional information

- *The Property module*
- *Material libraries*
- *Managing material libraries*

Using the Property module toolbox

You can access all the Property module tools through either the main menu bar or the Property module toolbox. *Figure 1* shows the icons for all the property tools in the Property module toolbox.

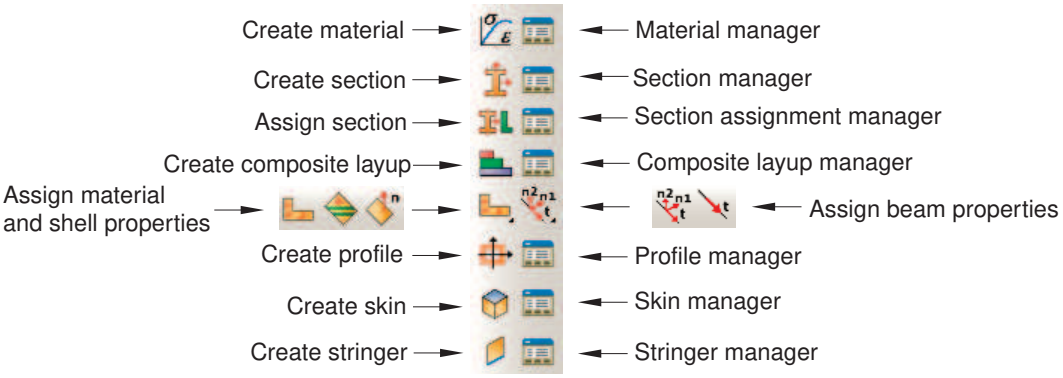

Figure 1: The Property module toolbox.

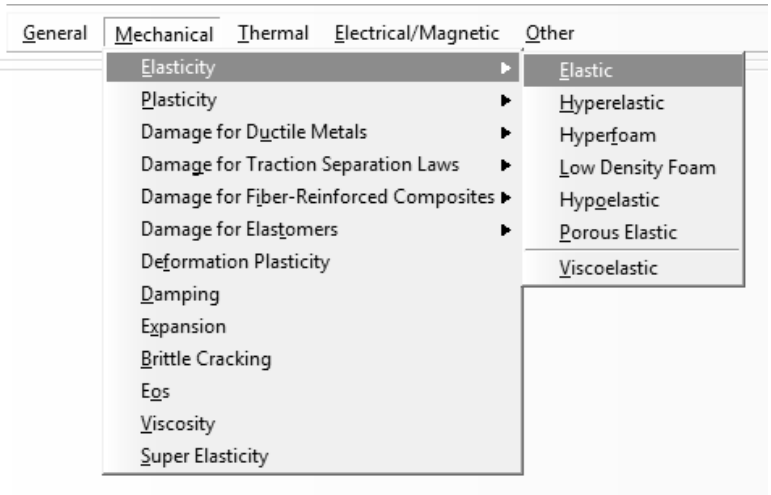
Creating and editing materials

This section describes each feature of the material editor individually.



In this section:

- *Creating or editing a material*
- *Browsing and modifying material behaviors*
- *Entering strain-rate-dependent data*
- *Entering temperature-dependent data*
- *Specifying field variable dependence*
- *Selecting and modifying suboptions or test data*
- *Displaying X–Y plots of hyperelastic material behavior*
- *Displaying X–Y plots of viscoelastic material behavior*
- *Displaying X–Y plots of hyperfoam material behavior*

Creating or editing a material

You use the **Edit Material** dialog box to create a new material or edit an existing material. When you select **Material->Create** from the main menu bar, you can enter the name of your choice for the material or accept the default name, you can provide a description for the material, and you can define the material properties. When you select **Material->Edit**, you can redefine the material description or properties, but you must use **Material->Rename** to change the name of an existing material.

Use the menu bar under the **Material Behaviors** list to add properties to a material. Some of the menu items contain submenus; for example, the following figure shows the behaviors available under the **Mechanical->Elasticity** menu item:

Note:

To display information on a particular material behavior, click and hold that behavior and then press `F1`. A help window appears that contains information about the parameters and data associated with the behavior.

Use the **Material Behaviors** list to select an existing material behavior to edit.

Warning: Abaqus/CAE does not check for missing or invalid material behaviors until you submit the job for analysis. (Any warnings and errors are reported by the Job module.) Therefore, you must be careful to supply valid data for all of the material behaviors that the analysis requires.

1. Display the material editor using one of the following methods:
   - From the main menu bar, select **Material->Create**.

     Tip: You can also click **Create** in the **Material Manager** or select the create material tool in the Property module toolbox.

   - From the main menu bar, select **Material->Edit->*material name***.

     Tip: You can also select a material and click **Edit** in the **Material Manager**.

An **Edit Material** dialog box appears.

2. If you are creating a new material, enter the name of your choice for the material. For more information on naming objects, see *Using basic dialog box components*.
3. If desired, enter a description for the material.

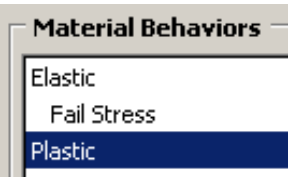
   a. Click  in the **Edit Material** dialog box.

   The material description editor appears.

   b. In the material description editor, type information that you want to record about the material.
   c. Click **OK** to store the description and to close the material description editor.

   When you submit a job, Abaqus/CAE writes material descriptions to the input file using comment lines; the material descriptions are not written to the output database. For more information, see *Adding descriptions to your Abaqus/CAE model*.
4. Use the menu bar or **Material Behaviors** list to select a new or existing material behavior, respectively.

   The behavior definition area in the dialog box changes to show all the parameters and data associated with the selected material behavior.
5. Edit the parameters and data to complete the material definition.
6. If you wish to remove a material behavior, select it and click  to the right of the menu bar.
7. When you have finished editing the material definition, click **OK** to save the material and to close the dialog box.



Additional information

- *Understanding the Property module editors*
- *Creating and editing materials*

Browsing and modifying material behaviors

The selected behavior list at the top of the material editor window displays the behaviors and suboptions that comprise the current material; the list is updated as you add and delete behaviors.

The following figure shows how the list would look if an elastic-plastic material complete with stress-based failure limits were defined:

Using the selected behavior list, you can add, delete, or change materials as follows:

Adding material behaviors

Select the behaviors needed to define your material from the menus just below the selected behavior list. When you select a behavior, its name appears in the list, and the parameters and data associated with the behavior appear in the data area in the bottom portion of the editor window. Suboptions appear beneath the corresponding primary behavior and are indented to indicate their subordinate position.

Deleting material behaviors

Within the selected behavior list, click the behavior or suboption you want to delete; then click the  icon located near the lower right corner of the behavior list. This procedure removes the behavior from both the behaviors list and the material definition. If you delete a behavior that has suboptions shown beneath it in the list, the suboptions are also deleted.

Changing material parameters or data

Within the selected behavior list, click the behavior whose data you want to change. When the parameters and data associated with the behavior appear in the data area in the bottom portion of the window, make the desired changes.

Additional information

- *Understanding the Property module editors*

Entering strain-rate-dependent data

If your material includes strain rate dependence, you can enter data to define how material properties vary with strain rate.

1. + Toggle on **Use strain-rate-dependent data** in the material editor.

   A column labeled **Rate** appears in the tabular data area.

2. Fill in each row with the appropriate values. For special table editing options or to read data from an ASCII file, press mouse button 3. (For more information, see *Entering tabular data*.)

Additional information

• *Understanding the Property module editors*

Entering temperature-dependent data

If your material includes temperature dependence, you can enter data to define how material properties vary with increasing temperature.

1. + Toggle on **Use temperature-dependent data** in the material editor.

   A column labeled **Temp** appears in the tabular data area.

2. Fill in each row with the appropriate values. For special table editing options or to read data from an ASCII file, press mouse button 3. (For more information, see *Entering tabular data*.)

Additional information

• *Understanding the Property module editors*

Specifying field variable dependence

The **Number of field variables** text field in the material editor allows you to specify the number of field variables to be referenced by a given material behavior. Columns for each field variable appear in the table in the data area of the editor.

1. Change the number of field variables in the **Number of field variables** box to the desired value using one of these methods:

   - Click the arrows to the right of the text field to increase or decrease the number of field variables.
   - Type the number directly in the text field.

   Either method adds field variable columns to the table in the data area.

2. Enter the appropriate data in each cell of the table. You can enter data into the table using the keyboard. Alternatively, you can click mouse button 3 anywhere in the table to view a list of options for specifying tabular data. For detailed information on each option, see *Entering tabular data*.)

Additional information

• *Understanding the Property module editors*

Selecting and modifying suboptions or test data

If suboptions or test data are available for the current behavior, the **Suboptions**, **Test Data**, or **Uniaxial Test Data** menus will be available in the upper right corner of the data area. When you select one of the options from the menus, the **Suboption Editor** or the **Test Data Editor** appears in which you can enter the required data.

Note:

To display context-sensitive help for specific buttons, text fields, and other options in the **Suboption Editor** or the **Test Data Editor**, you must select the option of interest and then press **[F1]**. (The **Help** menu in the main menu bar is unavailable while the editors are displayed.) For detailed information on using **[F1]** to obtain help, see *Displaying context-sensitive help*.

1. Click **Suboptions**, **Test Data**, or **Uniaxial Test Data** in the upper right corner of the data area and select the option of your choice from the list that appears.

   The **Suboption Editor** or the **Test Data Editor**, as appropriate for your selection, appears in a separate dialog box.

2. Enter the required data inside the editor and then click **OK** to return to the material editor.

   You can enter data into a suboption or test data table using the keyboard. Alternatively, you can click mouse button 3 anywhere in the table to view a list of options for specifying tabular data. For example, an option exists for creating an *X–Y* data object from the data in the table; you can plot the *X–Y* data in the Visualization module and visually check its validity. Another option exists for automatically entering data from a file. For detailed information on each option, see *Entering tabular data*.

Additional information

- *Understanding the Property module editors*

Displaying *X–Y* plots of hyperelastic material behavior

Abaqus/CAE allows you to evaluate hyperelastic material behavior by automatically creating response curves using selected strain energy potentials. When the curve fitting is complete, Abaqus/CAE opens the Visualization module and displays *X–Y* plots of the test results and a dialog box containing the stability limits for each strain energy potential. You can review the results and adjust the material as necessary. For more information, see *Evaluating hyperelastic, hyperfoam and viscoelastic material behavior*.

1. From the main menu bar, select **Material->Evaluate->*material name***. The material that you select must include hyperelastic material data.

   Tip: You can also select the name of the material in the **Material Manager** and then click **Evaluate**.

   An **Evaluate Material** dialog box appears.

2. If you selected a hyperelastic material that also includes viscoelastic material data, toggle on **Perform hyperelastic evaluation** if it is not already selected.

   If desired, you can also evaluate the viscoelastic behavior of the material. For more information, see *Displaying X–Y plots of viscoelastic material behavior*.

3. In the **Available Input Data** field, do the following:

   a. Select the **Source** option of your choice:

   - Select **Test data** if you want Abaqus to calculate the necessary strain energy potential coefficients from the experimental data specified in the material definition.
   - Select **Coefficients** if you want Abaqus to use the coefficients specified in the material definition.

   b. If you selected **Test data** in the previous step, specify the test data type or types that you want Abaqus to use in calculating the strain energy potential coefficients. (Only data types for which you have specified data in the material definition appear in the list.)

   c. If you intend to evaluate the **Marlow** strain energy potential, specify the test data type that Abaqus will use to define the deviatoric response. You can also specify whether compression, tension, or both types of test data should be used and whether volumetric test data should be used to define the volumetric response. (For more information, see *Marlow Form*.)

   Note:

   If your hyperelastic material model includes lateral nominal strains, temperature-dependent data, or field variables, **Marlow** will be the only strain energy potential available for evaluation.

4. From the list of **Standard Tests**, select one or more tests for which you want response calculations using the data in the material definition.
5. For each test that you select, enter a minimum and maximum strain value that will be the upper and lower limits for the stress-strain response curves.
6. Click the **Strain Energy Potentials** tab, and do the following:

   - If you selected **Test data** as a data source, a list of all the available strain energy potentials appears. From the list, select one or more that you want Abaqus to apply to the experimental data. For more information on the strain energy potentials available in Abaqus see *Strain Energy Potentials*.
   - If you selected **Coefficients** as a data source, the name of the strain energy potential specified in the material definition appears. You can simply review the information and move on to the next step.

7. If the material that you are evaluating also includes viscoelastic material properties, click the **Viscoelastic** tab; you can either toggle off **Perform viscoelastic evaluation**, or select viscoelastic evaluation options. For more information, see *Displaying X–Y plots of viscoelastic material behavior*.
8. Click **OK** to begin the response calculations.

   If the evaluation fails during the extraction of material coefficients due to problems with nonlinear curve-fitting, Abaqus/CAE displays a dialog box containing the name of the data (`.dat`) file; the path to the data file is printed in the message area. The data file provides detailed information on each problem encountered. (For more information on the data file, see *About Output*.)

   If Abaqus completes the tests successfully, Abaqus/CAE enters the Visualization module and displays *X–Y* plots of the test results in new viewports. (For information on *X–Y* plots, see *X–Y plotting*.) The data objects appear in the ***X–Y* Data Manager**; you can copy them to an output database or perform any of the tasks that you can perform on other *X–Y* data in the Visualization module.

   In addition, Abaqus/CAE displays an informational dialog box containing the stability limits and coefficients for each hyperelastic strain energy potential. The dialog box also displays the viscoelastic material parameters if a viscoelastic evaluation was performed. Abaqus/CAE displays in the message area the path to the data (`.dat`) file that contains all the material evaluation information.
9. If desired, return to the Property module to edit the material data or to evaluate other materials.

   For example, if the **Strain energy potential** for the hyperelastic material was previously set to **Unknown**, you can use the evaluation results to complete the material definition using the optimal strain energy potential.

Additional information

• *Hyperelastic Behavior of Rubberlike Materials*

Displaying *X–Y* plots of viscoelastic material behavior

Abaqus/CAE allows you to evaluate viscoelastic material behavior by creating either relaxation and creep curves (for Prony series coefficients, relaxation test data, or creep test data) or shear and bulk modulus curves (for frequency data) based on the material definition.
When the curve fitting is complete, Abaqus/CAE opens the Visualization module and displays *X–Y* plots of the test results and a dialog box containing the material parameters. You can review the results and adjust the material as necessary. For more information, see *Evaluating hyperelastic, hyperfoam and viscoelastic material behavior*.

1. From the main menu bar, select **Material->Evaluate->*material name***. The material that you select must include time domain viscoelastic material data defined in conjunction with hyperelastic and/or elastic material data.

   Tip: You can also select the name of the material in the **Material Manager** and then click **Evaluate**.

   An **Evaluate Material** dialog box appears.

2. If you selected a viscoelastic material that also includes hyperelastic material data, click on the **Viscoelastic** tab; and toggle on **Perform viscoelastic evaluation** if it is not already selected.

   If desired, you can also evaluate the hyperelastic behavior of the material. For more information, see *Displaying X–Y plots of hyperelastic material behavior*.

3. In the **Available Input Data** field, do the following:

   a. Select the **Source** option of your choice:

   - Select **Test data** if you want Abaqus to calculate viscoelastic response using the experimental data specified in the material definition.
   - Select **Coefficients** if you want Abaqus to calculate viscoelastic response using the coefficients specified in the material definition. If the material was defined using a Prony series, relaxation test data, or creep test data for time, Abaqus uses the hyperelastic or elastic coefficient data. If the material was defined using frequency data for time, Abaqus uses the frequency coefficients specified in the viscoelastic material definition.

   b. If you selected **Test data** in the previous step, toggle on the test data type that you want Abaqus to use in calculating the material response. (Only data types for which you have specified data in the material definition appear in the list.)

      Note:

      Combined data cannot be selected at the same time as **Shear** or **Volumetric** data.

4. In the **Normalized Response Plots** field, toggle on **Stress Relaxation** and/or **Creep** to define the response modes that Abaqus will calculate; and enter the time period for the normalized response curves.

   If viscoelasticity is defined using frequency data in the time domain, the **Normalized Response Plots** field is not available. Instead, Abaqus produces shear and bulk modulus response curves on a logarithmic frequency scale.

   Note:

   When you evaluate a viscoelastic material using frequency data, Abaqus obtains expressions for the shear and bulk moduli by converting the Prony series terms from the time domain to the frequency domain. It is recommended that you independently verify the material model in the

domain in which the data will be used. For more information, see *Determination of Isotropic Viscoelastic Material Parameters*.

5. Click **OK** to begin the response calculations.

   If the evaluation fails during the extraction of material coefficients due to problems with nonlinear curve-fitting, Abaqus/CAE displays a dialog box containing the name of the data (`.dat`) file; the path to the data file is printed in the message area. The data file provides detailed information on each problem encountered. (For more information on the data file, see *About Output*.)

   If Abaqus completes the tests successfully, Abaqus/CAE enters the Visualization module and displays *X–Y* plots of the test results in new viewports. (For information on *X–Y* plots, see *X–Y plotting*.) The data objects appear in the ***X–Y* Data Manager**; you can copy them to an output database or perform any of the tasks that you can perform on other *X–Y* data in the Visualization module.

   In addition, Abaqus/CAE displays an informational dialog box containing the viscoelastic material parameters and the stability limits and coefficients for each hyperelastic strain energy potential if a hyperelastic evaluation was performed. Abaqus/CAE also displays in the message area the path to the data (`.dat`) file that contains all the material evaluation information.

6. If desired, return to the Property module to edit the material data or to evaluate other materials.

Additional information

• *Time Domain Viscoelasticity*

Displaying *X–Y* plots of hyperfoam material behavior

Abaqus/CAE allows you to evaluate hyperfoam material behavior by automatically creating response curves. When the curve fitting is complete, Abaqus/CAE opens the Visualization module and displays *X–Y* plots of the test results and a dialog box containing the stability limits for each strain energy potential.
You can review the results and adjust the material as necessary. For more information, see *Evaluating hyperelastic, hyperfoam and viscoelastic material behavior*.

1. From the main menu bar, select **Material->Evaluate->*material name***. The material that you select must include hyperfoam material data.

   Tip: You can also select the name of the material in the **Material Manager** and then click **Evaluate**.

   An **Evaluate Material** dialog box appears.

2. If you selected a hyperfoam material that also includes viscoelastic or hyperelastic material data, toggle on **Perform hyperfoam evaluation** if it is not already selected.

   If desired, you can also evaluate the viscoelastic behavior of the material. For more information, see *Displaying X–Y plots of viscoelastic material behavior*.

3. In the **Available Input Data** field, do the following:

   a. Select the **Source** option of your choice:

   - Select **Test data** if you want Abaqus to calculate the necessary coefficients from the experimental data specified in the material definition.
   - Select **Coefficients** if you want Abaqus to use the coefficients specified in the material definition.

   b. If you selected **Test data** in the previous step, specify the test data type or types that you want Abaqus to use in calculating the coefficients. (Only data types for which you have specified data in the material definition appear in the list.)

4. From the list of **Standard Tests**, select one or more tests for which you want response calculations using the data in the material definition.
5. For each test that you select, enter a minimum and maximum strain value that will be the upper and lower limits for the stress-strain response curves.
6. If the material that you are evaluating also includes viscoelastic material properties, click the **Viscoelastic** tab; you can either toggle off **Perform viscoelastic evaluation**, or select viscoelastic evaluation options. For more information, see *Displaying X–Y plots of viscoelastic material behavior*.
7. Click **OK** to begin the response calculations.

   If the evaluation fails during the extraction of material coefficients due to problems with nonlinear curve-fitting, Abaqus/CAE displays a dialog box containing the name of the data (`.dat`) file; the path to the data file is printed in the message area. The data file provides detailed information on each problem encountered. (For more information on the data file, see *About Output*.)

   If Abaqus completes the tests successfully, Abaqus/CAE enters the Visualization module and displays *X–Y* plots of the test results in new viewports. (For information on *X–Y* plots, see *X–Y plotting*.) The data objects appear in the ***X–Y* Data Manager**; you can copy them to an output database or perform any of the tasks that you can perform on other *X–Y* data in the Visualization module.

   In addition, Abaqus/CAE displays an informational dialog box containing the stability limits and coefficients. The dialog box also displays the viscoelastic material parameters if a viscoelastic evaluation was performed. Abaqus/CAE displays in the message area the path to the data (`.dat`) file that contains all the material evaluation information.

8. If desired, return to the Property module to edit the material data or to evaluate other materials.

Defining general material data

This section describes how you can specify general material data.

For more information, see the following sections:

- *Density*
- *About User Subroutines and Utilities*
- *Regularizing User-Defined Data in Abaqus/Explicit*
- *User-Defined Mechanical Material Behavior*
- *User-Defined Thermal Material Behavior*
- *USDFLD*
- *UVARM*

In this section:

- *Specifying material mass density*
- *Specifying solution-dependent state variables*
- *Regularizing user-defined material data in Abaqus/Explicit*
- *Defining constants for a user material*
- *Defining field variables at a material point*
- *Specifying the number of user variables*

Specifying material mass density

You can define density as a function of temperature and field variables. For acoustic, heat transfer, coupled temperature-displacement, and coupled thermal-electrical elements the density is continually updated to the value corresponding to the current temperature and field variables. However, for all other elements density is a function of the initial values of temperature and field variables and changes in volume only. Abaqus does not update density values if temperatures and field variables change during the analysis.

See *Density*, for more information.

1. From the menu bar in the **Edit Material** dialog box, select **General->Density**.

   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Click the arrow to the right of the **Distribution** field, and select the option of your choice from the list that appears:
   - Select **Uniform** to define density that is uniformly distributed throughout the material.
   - Select an analytical field, labeled with an (A), or a discrete field, labeled with a (D), to define a spatially varying density. Only analytical fields and discrete fields that are valid for density are available in the selection list. See *The Analytical Field toolset* and *The Discrete Field toolset* for more information.

     Alternatively, you can click  to create a new discrete field.
3. Toggle on **Use temperature-dependent data** to define density as a function of temperature.

   A column labeled **Temp** appears in the **Data** table.
4. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the density depends.
5. Enter the following data in the **Data** table:

   ### Mass Density

   Mass density. (Units of ML^{-3}.)

   ### Temp

   Temperature.

   ### Field *n*

   Predefined field variables.

   For detailed information on how to enter data, see *Entering tabular data*.
6. Click **OK** to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors* for more information).

Specifying solution-dependent state variables

Solution-dependent state variables are values in user subroutines that you can define to evolve with the solution of an analysis.
If you refer to a material definition in a user subroutine, you can use the **Edit Material** dialog box to specify the number of solution-dependent variables required at the points or nodes to which that material is applied. See *About User Subroutines and Utilities* for more information.

1. From the menu bar in the **Edit Material** dialog box, select **General->Depvar**.

   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Click the arrows to the right of the **Number of solution-dependent state variables** field to specify how many solution dependent state variables you want to allocate space for at each applicable integration point or contact secondary node.
3. If applicable, enter the state variable number controlling the element deletion flag in the field labeled **Variable number controlling element deletion**. For more information, see *Deleting Elements from a Mesh Using State Variables*.
4. Click **OK** to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Regularizing user-defined material data in Abaqus/Explicit

Interpolating material data as a function of independent variables requires table lookups of the material data values during analysis. The table lookups occur frequently in Abaqus/Explicit and are most economical if the interpolation is from regular data.

If necessary, Abaqus/Explicit uses an error tolerance to regularize the input data. The number of intervals in the range of each independent variable is chosen such that the error between the piecewise linear regularized data and each of your defined points is less than the tolerance times the range of the dependent variable.

For more information, see *Regularizing User-Defined Data in Abaqus/Explicit*.

1. From the menu bar in the **Edit Material** dialog box, select **General->Regularization**.

   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. In the **Rtol** field, enter the tolerance that you want Abaqus to use for regularizing the material data. The default is 0.03.
3. Specify how you want to interpolate strain rate–dependent data:

   - Select **Logarithmic** to interpolate strain rate data using logarithmic intervals rather than uniformly spaced intervals. This option generally provides a better match to typical strain rate–dependent curves.
   - Select **Linear** to use uniform intervals for interpolation of strain rate data.
4. Click **OK** to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Defining constants for a user material

The following user subroutines allow you to create user-defined material models:

- *UMAT* for mechanical material models in Abaqus/Standard.
- *VUMAT* for mechanical material models in Abaqus/Explicit.
- *UMATHT* for thermal material models in Abaqus/Standard.
- *VUMATHT* for thermal material models in Abaqus/Explicit.

You can enter constants in the **Edit Material** dialog box for use in these subroutines. See the following sections for more information:

- *User-Defined Mechanical Material Behavior*
- *User-Defined Thermal Material Behavior*

1. From the menu bar in the **Edit Material** dialog box, select **General->User Material**.

   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. If you are performing an Abaqus/Standard analysis, click the arrow to the right of the **User material type** field, and select the type of user material for which you are defining constants.
3. If you are performing an Abaqus/Standard analysis, toggle on **Use unsymmetric material stiffness matrix** if the material stiffness matrix, $\partial \Delta \boldsymbol{\sigma} / \partial \Delta \boldsymbol{\varepsilon}$, is not symmetric or, in the case of a thermal constitutive model, if $\partial \mathbf{f} / \partial (\partial \theta / \partial \mathbf{x})$ is not symmetric. This parameter causes Abaqus/Standard to use its unsymmetric equation solution procedures.
4. If you are defining a mechanical or thermomechanical material, enter the **Mechanical Constants** in the **Data** table.

   For detailed information on how to enter data, see *Entering tabular data*.
5. If you are defining a thermal or thermomechanical material, enter the **Thermal Constants** in the **Data** table.

   For detailed information on how to enter data, see *Entering tabular data*.
6. Click **OK** to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Defining field variables at a material point

In Abaqus/Standard you can introduce dependence on solution variables with user subroutine *USDFLD*. This subroutine allows you to define field variables at a material point as functions of time, of any of the available material point quantities listed in *Abaqus/Standard Output Variable Identifiers*, and of material directions. Material properties defined as functions of these field variables may, thus, be dependent on the solution.

User subroutine *USDFLD* is called at each point for which the material definition includes a reference to the user subroutine.

1. From the menu bar in the **Edit Material** dialog box, select **General->User Defined Field**.

   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)

2. Click **OK** to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Specifying the number of user variables

You can allocate space at each material calculation point for user-defined output variables defined in user subroutine *UVARM*.

1. From the menu bar in the **Edit Material** dialog box, select **General->User Output Variables**.

   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Click the arrows to the right of the **Number of user-defined variables at each material point** field to specify how many user-defined variables you want to allocate space for at each material calculation point. Any number of user-defined output variables can be used.
3. Click **OK** to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Defining mechanical material models

This section describes how you can specify mechanical material models and related material data.

For more information about mechanical material models, see the following sections:

- *Elastic Mechanical Properties*
- *Inelastic Mechanical Properties*
- *Progressive Damage and Failure*
- *Other Material Properties*

In this section:

- *Defining elasticity*
- *Defining plasticity*
- *Defining damage*
- *Defining other mechanical models*

Defining elasticity

You use the **Edit Material** dialog box to create an elastic material and to specify its elastic material properties.

You can create the following elastic material models:

- **Elastic**
- **Isotropic Hyperelastic**
- **Anisotropic Hyperelastic**
- **Hyperfoam**
- **Low-Density Foam**
- **Hypoelastic**
- **Porous Elastic**
- **Viscoelastic**

For more information, see *Elastic Behavior*.

In this section:

- *Creating a linear elastic material model*
- *Creating an isotropic hyperelastic material model*
- *Creating an anisotropic hyperelastic material model*
- *Creating a hyperfoam material model*
- *Creating a low-density foam material model*
- *Creating a hypoelastic material model*
- *Creating a porous elastic material model*
- *Creating a viscoelastic material model*

Creating a linear elastic material model

Linear elasticity is the simplest form of elasticity available in Abaqus.
The linear elastic model can define isotropic, orthotropic, or anisotropic material behavior and is valid for small elastic strains. See *Specifying elastic material properties* for details on how to define a linear elastic material model.

Failure theories are provided for use with linear elasticity. They can be used to obtain postprocessed output requests.

In this section:

- *Specifying elastic material properties*
- *Defining stress-based failure measures for an elastic model*
- *Defining strain-based failure measures for an elastic model*

Specifying elastic material properties

A linear elastic material model is valid for small elastic strains (normally less than 5%); can be isotropic, orthotropic, or fully anisotropic; and can have properties that depend on temperature and/or other field variables. For more information, see *Linear Elastic Behavior*.

1. From the menu bar in the **Edit Material** dialog box, select **Mechanical->Elasticity->Elastic**.

   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)

2. From the **Type** field, choose the type of data you will supply to specify the elastic material properties.

   - Choose **Isotropic** to specify isotropic elastic properties, as described in *Defining Isotropic Elasticity*.
   - Choose **Engineering Constants** to specify orthotropic elastic properties by giving the engineering constants, as described in *Defining Orthotropic Elasticity by Specifying the Engineering Constants*.
   - Choose **Lamina** to specify orthotropic elastic properties in plane stress, as described in *Defining Orthotropic Elasticity in Plane Stress*.
   - Choose **Orthotropic** to specify orthotropic elastic properties directly, as described in *Defining Orthotropic Elasticity by Specifying the Terms in the Elastic Stiffness Matrix*.
   - Choose **Anisotropic** to specify anisotropic elastic properties, as described in *Defining Fully Anisotropic Elasticity*.
   - Choose **Traction** to specify orthotropic elastic properties for warping elements, as described in *Defining Orthotropic Elasticity for 1-DOF Warping Elements*, or to define uncoupled elastic properties for cohesive elements, as described in *Defining Elasticity in Terms of Tractions and Separations for Cohesive Elements*.
   - Choose **Coupled Traction** to specify coupled elastic properties for cohesive elements, as described in *Defining Elasticity in Terms of Tractions and Separations for Cohesive Elements*.
   - Choose **Shear** to specify a linear isotropic deviatoric material model. For more information, see *Deviatoric Behavior*.
   - Choose **Bilamina** to specify orthotropic elasticity in plane stress with different moduli in tension and compression, as described in *Defining Orthotropic Elasticity in Plane Stress with Different Moduli in Tension and Compression*.

3. To define behavior data that depend on temperature, toggle on **Use temperature-dependent data**.

   A column labeled **Temp** appears in the **Data** table.

4. To define behavior data that depend on field variables, click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables.

   Field variable columns appear in the **Data** table.

5. If you are defining the elastic behavior of a viscoelastic material, click the arrow to the right of the **Moduli time scale (for viscoelasticity)** field to specify either long-term or instantaneous elastic response.
6. Toggle on **No compression** if you want to modify the elastic material response such that compressive stress cannot be generated. For details, see *No Compression or No Tension*.
7. Toggle on **No tension** if you want to modify the elastic material response such that tensile stress cannot be generated. For details, see *No Compression or No Tension*.
8. Enter the material properties in the **Data** table.

   - For **Isotropic** data, enter the Young's modulus, E, and Poisson's ratio, ν.

- For **Engineering Constants** data, enter the generalized Young's moduli in the principal directions, E_1, E_2, E_3; the Poisson's ratios in the principal directions, ν_{12}, ν_{13}, ν_{23}; and the shear moduli in the principal directions, G_{12}, G_{13}, G_{23}.
- For **Lamina** data, enter the Young's moduli, E_1, E_2; the Poisson's ratio, ν_{12}; and the shear moduli, G_{12}, G_{13}, G_{23}. The G_{13} and G_{23} shear moduli are needed to define transverse shear behavior in shells.
- For **Orthotropic** data, enter the 9 elastic stiffness parameters: D_{1111}, D_{1122}, etc. (units of FL^{-2}).
- For **Anisotropic** data, enter the 21 elastic stiffness parameters: D_{1111}, D_{1122}, etc. (units of FL^{-2}).
- For **Traction** data, your entries depend on the element type that you are modeling.
  - For solid cross-section Timoshenko beam elements modeled with warping elements, enter the Young's modulus, E, and the shear moduli in the material directions, G_1 and G_2.
  - For cohesive elements with uncoupled traction, enter the elastic modulus in the normal direction and the two local shear directions, E_{nn}, E_{ss}, and E_{tt}.
- For **Coupled Traction** data, enter the six elastic moduli: E_{nn}, E_{ss}, E_{tt}, E_{ns}, E_{nt}, and E_{st}.
- For **Shear** data, enter the **Shear Modulus**.
- For **Bilamina** data, enter the Tensile Young's moduli, E_{1+}, E_{2+}; the Tensile Poisson's ratio, ν_{12+}; the shear moduli, G_{12}, G_{13}; the Compressive Young's moduli, E_{1-}, E_{2-}; and the Compressive Poisson's ratio, ν_{12-}.

9. To define the plane stress orthotropic failure measures for the material, if desired, click **Suboptions**. For details, see the following sections:

- *Defining stress-based failure measures for an elastic model*"
- *Defining strain-based failure measures for an elastic model*"

10. Click **OK** to create the material and to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Defining stress-based failure measures for an elastic model

Use the **Suboption Editor** to define the stress limits for stress-based failure measures for an elastic material model. For more information, see *Plane Stress Orthotropic Failure Measures*.

1. Create a linear elastic material model as described in *Specifying elastic material properties*."
2. From the **Suboptions** menu in the **Edit Material** dialog box, select **Fail Stress**.
   The **Suboption** Editor appears.
3. To define behavior data that depend on temperature, toggle on **Use temperature-dependent data**.
   A column labeled **Temp** appears in the **Data** table.
4. To define behavior data that depend on field variables, click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables.
   Field variable columns appear in the **Data** table.
5. In the **Data** table, enter the stress limits:

   ### Ten Stress Fiber Dir

   Tensile stress limit in the fiber direction, X_t.

   ### Com Stress Fiber Dir

   Compressive stress limit in the fiber direction, X_c.

   ### Ten Stress Transv Dir

   Tensile stress limit in the transverse direction, Y_t.

   ### Com Stress Transv Dir

   Compressive stress limit in the transverse direction, Y_c.

   ### Shear Strength

   Shear strength in the *X*–*Y* plane, *S*.

   ### Cross-prod Term Coeff

   Cross product term coefficient, f^* ($-1.0 \le f^* \le 1.0$). This value is used only for the Tsai-Wu theory and is ignored if σ_{biax} is provided. The default is zero.

   ### Stress Limit

   Biaxial stress limit, σ_{biax}. This value is used only for the Tsai-Wu theory. If this entry is nonzero, f^* is ignored.

   You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.
6. Click **OK** to return to the **Edit Material** dialog box.

Defining strain-based failure measures for an elastic model

Use the **Suboption Editor** to define the strain limits for strain-based failure measures for an elastic material model. For more information, see *Plane Stress Orthotropic Failure Measures*.

1. Create a linear elastic material model as described in *Specifying elastic material properties*."
2. From the **Suboptions** menu in the **Edit Material** dialog box, select **Fail Strain**.
3. To define behavior data that depend on temperature, toggle on **Use temperature-dependent data**.

   A column labeled **Temp** appears in the **Data** table.
4. To define behavior data that depend on field variables, click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables.

   Field variable columns appear in the **Data** table.
5. In the **Data** table, enter the strain limits:

   #### Ten Strain Fiber Dir

   Tensile strain limit in the fiber direction, $X_{\varepsilon t}$.

   #### Com Strain Fiber Dir

   Compressive strain limit in the fiber direction, $X_{\varepsilon c}$.

   #### Ten Strain Transv Dir

   Tensile strain limit in the transverse direction, $Y_{\varepsilon t}$.

   #### Com Strain Transv Dir

   Compressive strain limit in the transverse direction, $Y_{\varepsilon c}$.

   #### Shear Strain

   Shear strain limit in the *X*–*Y* plane, S_{ε}.

   You may need to expand the dialog box to see all the columns in the **Data**. For detailed information on how to enter data, see *Entering tabular data*.
6. Click **OK** to return to the **Edit Material** dialog box.

Creating an isotropic hyperelastic material model

The isotropic hyperelastic model describes the behavior of nearly incompressible materials that exhibit instantaneous elastic response up to large strains.
For more information, see *Hyperelastic Behavior of Rubberlike Materials*.

In this section:

- *Defining isotropic hyperelastic materials*
- *Entering material parameters to define an isotropic hyperelastic material*
- *Providing test data to define an isotropic hyperelastic material*
- *Specifying uniaxial test data for an isotropic hyperelastic material model*
- *Specifying biaxial test data for an isotropic hyperelastic material model*
- *Specifying planar test data for an isotropic hyperelastic material model*
- *Specifying volumetric test data for an isotropic hyperelastic material model*
- *Defining hysteretic behavior for an isotropic hyperelastic material model*

Defining isotropic hyperelastic materials

Isotropic hyperelastic materials are described in terms of a “strain energy potential,” which defines the strain energy stored in the material per unit of reference volume (volume in the initial configuration) as a function of the strain at that point in the material.
Several forms of strain energy potentials are available in Abaqus to model approximately incompressible isotropic elastomers. For more information on hyperelastic materials, see *Hyperelastic Behavior of Rubberlike Materials*.

When you define a isotropic hyperelastic material, you have the option of either specifying material parameters directly or allowing Abaqus to calculate them from test data that you provide. For detailed instructions, see the following sections:

- *Entering material parameters to define an isotropic hyperelastic material*
- *Providing test data to define an isotropic hyperelastic material*

Entering material parameters to define an isotropic hyperelastic material

You can provide the parameters of the hyperelastic strain energy potentials directly as functions of temperature.

1. From the menu bar in the **Edit Material** dialog box, select **Mechanical->Elasticity->Hyperelastic**. (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Choose **Isotropic** as the material type.
3. Click the arrow to the right of the **Strain energy potential** field, and select the strain energy potential of your choice.

Arruda-Boyce

The Arruda-Boyce model is also known as the eight-chain model. For more information, see *Arruda-Boyce Form*.

Marlow

For more information, see *Marlow Form*.

Mooney-Rivlin

The Mooney-Rivlin model is equivalent to using the polynomial model with N=1. For more information, see *Mooney-Rivlin Form*.

Neo Hooke

The Neo Hookean model is equivalent to using the reduced polynomial model with N=1. For more information, see *Neo-Hookean Form*.

Ogden

For more information, see *Ogden Form*.

Polynomial

For more information, see *Polynomial Form*.

Reduced Polynomial

The reduced polynomial model is equivalent to using the polynomial model with $C_{ij} = 0$ for $j \neq 0$. For more information, see *Reduced Polynomial Form*.

User-defined

You can define the derivatives of the strain energy potential with respect to the strain invariants in user subroutine *UHYPER*. This method is valid only for Abaqus/Standard analyses. For more information, see *User Subroutine Specification in Abaqus/Standard*.

Van der Waals

The Van der Waals model is also known as the Kilian model. For more information, see *Van Der Waals Form*.

Yeoh

The Yeoh model is equivalent to using the reduced polynomial model with N=3. For more information, see *Yeoh Form*.

Unknown

If you define an isotropic hyperelastic material using experimental data, you also have the option of temporarily leaving the particular strain energy potential unspecified. You can use the **Evaluate** option to identify the optimal strain energy potential for the material data and display the material editor again to complete the material definition; see *Evaluating hyperelastic, hyperfoam and viscoelastic material behavior*, for more information.

4. Select **Coefficients** as the **Input source**. This **Input Source** option is invalid for the Marlow model or for an unknown strain energy potential.
5. If you are defining the hyperelastic behavior of a viscoelastic material, click the arrow to the right of the **Moduli time scale (for viscoelasticity)** field to specify either long-term or instantaneous elastic response.
6. If you selected **User-defined** as the strain energy potential, perform the following steps:
   - Toggle on **Include compressibility** to indicate that the material defined by user subroutine *UHYPER* is compressible. Otherwise, Abaqus assumes the material is incompressible.
   - Specify the **Number of property values** needed as data in user subroutine *UHYPER*.
7. If you selected **Ogden**, **Polynomial**, or **Reduced Polynomial** as the strain energy potential, click the arrows to the left of the **Strain energy potential order** field to select a value.
8. To define behavior data that depend on temperature, toggle on **Use temperature-dependent data**.

   A column labeled **Temp** appears in the **Data** table.
9. Enter the material properties in the **Data** table corresponding to the chosen strain energy potential.

Arruda-Boyce

Enter μ, λ_m, and D.

Mooney-Rivlin

Enter C_{10}, C_{01}, and D_1.

Neo Hooke

Enter C_{10} and D_1.

Ogden

Enter μ_i, α_i, and D_i, where *i* goes from 1 to N and N is the value specified for the **Strain energy potential order**.

Polynomial

Enter C_{ij}, where $i + j$ goes from 1 to N, and D_i, where *i* goes from 1 to N, and N is the value specified for the **Strain energy potential order**.

Reduced Polynomial

Enter C_{i0} and D_i, where *i* goes from 1 to N and N is the value specified for the **Strain energy potential order**.

Van der Waals

Enter μ, λ_m, a, β, and D.

Yeoh

Enter C_{10}, C_{20}, C_{30}, D_1, D_2, and D_3.

10. If desired, select **Hysteresis** from the **Suboptions** menu to define hysteretic behavior. See *Defining hysteretic behavior for an isotropic hyperelastic material model*" for details.
11. Click **OK** to create the material and to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Providing test data to define an isotropic hyperelastic material

Abaqus can calculate material parameters from test data that you enter in the **Test Data Editor**.

1. From the menu bar in the **Edit Material** dialog box, select **Mechanical->Elasticity->Hyperelastic**. (For information on displaying the **Edit Material** dialog box, see *Creating and editing materials*.)
2. Choose **Isotropic** as the material type.
3. Click the arrow to the right of the **Strain energy potential** field, and select the strain energy potential of your choice.

Arruda-Boyce

The Arruda-Boyce model is also known as the eight-chain model. For more information, see *Arruda-Boyce Form*.

Marlow

For more information, see *Marlow Form*.

Mooney-Rivlin

The Mooney-Rivlin model is equivalent to using the polynomial model with N=1. For more information, see *Mooney-Rivlin Form*.

Neo Hooke

The Neo Hookean model is equivalent to using the reduced polynomial model with N=1. For more information, see *Neo-Hookean Form*.

Ogden

For more information, see *Ogden Form*.

Polynomial

For more information, see *Polynomial Form*.

Reduced Polynomial

The reduced polynomial model is equivalent to using the polynomial model with $C_{ij} = 0$ for $j \neq 0$. For more information, see *Reduced Polynomial Form*.

User-defined

You can define the derivatives of the strain energy potential with respect to the strain invariants in user subroutine *UHYPER*. This method is valid only for Abaqus/Standard analyses. For more information, see *User Subroutine Specification in Abaqus/Standard*.

Van der Waals

The Van der Waals model is also known as the Kilian model. For more information, see *Van Der Waals Form*.

Yeoh

The Yeoh model is equivalent to using the reduced polynomial model with N=3. For more information, see *Yeoh Form*.

Unknown

If you define an isotropic hyperelastic material using experimental data, you also have the option of temporarily leaving the particular strain energy potential unspecified. You can use the **Evaluate** option to identify the optimal strain energy potential for the material data and then display the material editor again to complete the material definition; see *Evaluating hyperelastic, hyperfoam and viscoelastic material behavior*, for more information.

4. Select **Test data** as the **Input source** to indicate that the material constants are to be computed from data taken from simple tests on a material specimen.
5. If you are defining the hyperelastic behavior of a viscoelastic material, click the arrow to the right of the **Moduli time scale (for viscoelasticity)** field to specify either long-term or instantaneous elastic response.
6. If you selected **Marlow** as the strain energy potential, select the **Data to define deviatoric response** and the **Data to define volumetric response** options of your choice.
   - The deviatoric response is defined by the **Uniaxial**, **Biaxial**, or **Planar** test data specified as described in Step 8.
   - The volumetric response is defined by one of the following methods:
     - **Ignore test data**: Abaqus/Standard assumes fully incompressible behavior, while Abaqus/Explicit assumes compressibility corresponding to a Poisson's ratio of 0.475.
     - **Volumetric test data**: The volumetric test data are specified directly, as described in Step 8.
     - **Poisson's ratio**: Specify a value for the Poisson's ratio of the isotropic hyperelastic material.
     - **Lateral nominal strain**: Lateral nominal strains are specified as part of the uniaxial, biaxial, or planar test data, as described in Step 8.
7. If you selected **Ogden**, **Polynomial**, or **Reduced Polynomial** as the strain energy potential, click the arrows to the left of the **Strain energy potential order** field to select a value.
8. If you selected **Van der Waals** as the strain energy potential, choose the method for specifying **Beta**:
   - Select **Fitted value** to determine the value of β from a nonlinear least-squares fit of the test data.
   - Select **Specify**, and enter a value to specify β directly. Allowable values are $\mathbf{0 \leq \beta \leq 1}$. It is recommended to set β=0 if only one type of test data is available.
9. You can specify the experimental stress-strain data for as many as four simple tests: uniaxial, equibiaxial, planar, and, if the material is compressible, a volumetric compression test. Use the **Test Data** menu to specify the experimental data. For details, see the following sections:
   - *Specifying uniaxial test data for an isotropic hyperelastic material model*"

- *Specifying biaxial test data for an isotropic hyperelastic material model*"
- *Specifying planar test data for an isotropic hyperelastic material model*"
- *Specifying volumetric test data for an isotropic hyperelastic material model*"

10. If desired, select **Hysteresis** from the **Suboptions** menu to define hysteretic behavior. See *Defining hysteretic behavior for an isotropic hyperelastic material model*" for details.
11. Click **OK** to create the material and to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Specifying uniaxial test data for an isotropic hyperelastic material model

Use the **Test Data Editor** to specify uniaxial test data from which Abaqus can calibrate hyperelastic material coefficients. For more information, see *Hyperelastic Behavior of Rubberlike Materials*.

1. Create an isotropic hyperelastic material model as described in *Providing test data to define an isotropic hyperelastic material*."
2. From the **Test Data** menu in the **Edit Material** dialog box, select **Uniaxial Test Data**.

   A **Test Data Editor** appears.
3. Toggle on **Apply smoothing** if you want Abaqus to apply a smoothing filter to the stress-strain data. This option is particularly recommended if you are using the Marlow model.
4. If you have requested data smoothing, click the arrows to the right of the **Apply smoothing** field to specify the number of data points to the right and left of each data point within which Abaqus will fit a least-squares polynomial.
5. If you are defining a Marlow model, you can select the following options:
   - To include lateral nominal strain data, toggle on **Include lateral nominal strain**.

     A column labeled **Lateral Nominal Strain** appears in the **Data** table.
   - To define behavior data that depend on temperature, toggle on **Use temperature-dependent data**.

     A column labeled **Temp** appears in the **Data** table.
   - To define behavior data that depend on field variables, click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables.

     Field variable columns appear in the **Data** table.
6. In the **Data** table, enter the test data:

   #### Nominal Stress

   Nominal stress, T_U.

   #### Nominal Strain

   Nominal strain, ϵ_U.

   #### Lateral Nominal Strain

   Nominal lateral strain, $\epsilon_2 = \epsilon_3$.

   #### Temp

   Temperature, θ.

   #### Field *n*

   Predefined field variables.

   You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.
7. Click **OK** to return to the **Edit Material** dialog box.

Specifying biaxial test data for an isotropic hyperelastic material model

Use the **Test Data Editor** to specify biaxial test data from which Abaqus can calibrate hyperelastic material coefficients. For more information, see *Hyperelastic Behavior of Rubberlike Materials*.

1. Create an isotropic hyperelastic material model as described in *Providing test data to define an isotropic hyperelastic material*."
2. From the **Test Data** menu in the **Edit Material** dialog box, select **Biaxial Test Data**.

   A **Test Data Editor** appears.
3. Toggle on **Apply smoothing** if you want Abaqus to apply a smoothing filter to the stress-strain data. This option is particularly recommended if you are using a Marlow model.
4. If you have requested data smoothing, click the arrows to the right of the **Apply smoothing** field to specify the number of data points to the right and left of each data point within which Abaqus will fit a least-squares polynomial.
5. If you are defining a Marlow model, you can select the following options:
   - To include lateral nominal strain data, toggle on **Include lateral nominal strain**.

     A column labeled **Lateral Nominal Strain** appears in the **Data** table.
   - To define behavior data that depend on temperature, toggle on **Use temperature-dependent data**.

     A column labeled **Temp** appears in the **Data** table.
   - To define behavior data that depend on field variables, click the arrow to the right of the **Number of field variables** field to increase or decrease the number of field variables.

     Field variable columns appear in the **Data** table.
6. In the **Data** table, enter the test data:

   #### Nominal Stress

   Nominal stress, $\boldsymbol{T_B}$.

   #### Nominal Strain

   Nominal strain, $\boldsymbol{\epsilon_B}$.

   #### Lateral Nominal Strain

   Nominal lateral strain, $\boldsymbol{\epsilon_3}$.

   #### Temp

   Temperature, $\boldsymbol{\theta}$.

   #### Field *n*

   Predefined field variables.

   You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.
7. Click **OK** to return to the **Edit Material** dialog box.

Specifying planar test data for an isotropic hyperelastic material model

Use the **Test Data Editor** to specify planar test data from which Abaqus can calibrate hyperelastic material coefficients. For more information, see *Hyperelastic Behavior of Rubberlike Materials*.

1. Create an isotropic hyperelastic material model as described in *Providing test data to define an isotropic hyperelastic material*."
2. From the **Test Data** menu in the **Edit Material** dialog box, select **Planar Test Data**.

   A **Test Data Editor** appears.
3. Toggle on **Apply smoothing** if you want Abaqus to apply a smoothing filter to the stress-strain data. This option is particularly recommended if you are using a Marlow model.
4. If you have requested data smoothing, click the arrows to the right of the **Apply smoothing** field to specify the number of data points to the right and left of each data point within which Abaqus will fit a least-squares polynomial.
5. If you are defining a Marlow model, you can select the following options:
   - To include lateral nominal strain data, toggle on **Include lateral nominal strain**.

     A column labeled **Lateral Nominal Strain** appears in the **Data** table.
   - To define behavior data that depend on temperature, toggle on **Use temperature-dependent data**.

     A column labeled **Temp** appears in the **Data** table.
   - To define behavior data that depend on field variables, click the arrow to the right of the **Number of field variables** field to increase or decrease the number of field variables.

     Field variable columns appear in the **Data** table.
6. In the **Data** table, enter the test data:

   #### Nominal Stress

   Nominal stress, T_S.

   #### Nominal Strain

   Nominal strain, ϵ_S.

   #### Lateral Nominal Strain

   Nominal lateral strain, ϵ_3.

   #### Temp

   Temperature, θ.

   #### Field *n*

   Predefined field variables.

   You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.
7. Click **OK** to return to the **Edit Material** dialog box.

Specifying volumetric test data for an isotropic hyperelastic material model

Use the **Test Data Editor** to specify volumetric test data from which Abaqus can calibrate hyperelastic material coefficients. For more information, see *Hyperelastic Behavior of Rubberlike Materials*.

1. Create an isotropic hyperelastic material model as described in *Providing test data to define an isotropic hyperelastic material*."
2. From the **Test Data** menu in the **Edit Material** dialog box, select **Volumetric Test Data**.

   A **Test Data Editor** appears.
3. Toggle on **Apply smoothing** if you want Abaqus to apply a smoothing filter to the stress-strain data. This option is particularly recommended if you are using a Marlow model.
4. If you have requested data smoothing, click the arrows to the right of the **Apply smoothing** field to specify the number of data points to the right and left of each data point within which Abaqus will fit a least-squares polynomial.
5. If you are defining a Marlow model, you can select the following options:

   - To define behavior data that depend on temperature, toggle on **Use temperature-dependent data**.

     A column labeled **Temp** appears in the **Data** table.
   - To define behavior data that depend on field variables, click the arrow to the right of the **Number of field variables** field to increase or decrease the number of field variables.

     Field variable columns appear in the **Data** table.
6. In the **Data** table, enter the test data:

   ### Pressure

   Total pressure stress, p.

   ### Volume Ratio

   Volume ratio (current volume/original volume), J.

   ### Temp

   Temperature, θ.

   ### Field n

   Predefined field variables.

   You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.
7. Click **OK** to return to the **Edit Material** dialog box.

Defining hysteretic behavior for an isotropic hyperelastic material model

Use the **Suboption Editor** to define the strain-rate-dependent response of an isotropic hyperelastic material that exhibits pronounced hysteresis under cyclic loading. For more information, see *Hysteresis in Elastomers*.

1. Create an isotropic hyperelastic material model as described in *Entering material parameters to define an isotropic hyperelastic material*" or *Providing test data to define an isotropic hyperelastic material*."
2. From the **Suboptions** menu in the **Edit Material** dialog box, select **Hysteresis**.

   The **Suboption Editor** appears.

   In the **Data** table of the **Suboption Editor**, enter the creep behavior data:

   ### Stress Scaling Factor

   Stress scaling factor, S.

   ### Creep Parameter

   Creep parameter, A.

   ### Eff Stress Exponent

   Effective stress exponent, m.

   ### Creep Strain Exponent

   Creep strain exponent, C.

   You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.
3. Click **OK** to return to the **Edit Material** dialog box.

Creating an anisotropic hyperelastic material model

The anisotropic hyperelastic model provides a modeling capability for materials that exhibit highly anisotropic and nonlinear elastic behavior, such as biomedical soft tissues and fiber-reinforced elastomers. For more information, see *Anisotropic Hyperelastic Behavior*.

In Abaqus/CAE the local direction vectors of the material are orthogonal and align with the axes of the assigned material orientation. The best practice is to assign the orientation using discrete orientations in Abaqus/CAE. For information about defining discrete orientations, see *Using discrete orientations for material orientations and composite layup orientations*.

1. From the menu bar in the **Edit Material** dialog box, select **Mechanical->Elasticity->Hyperelastic**.
   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Choose **Anisotropic** as the material type.
3. Click the arrow to the right of the **Strain energy potential** field, and select the strain energy potential of your choice.

Fung-Anisotropic

For the fully anisotropic strain-based Fung model, you must specify 21 independent components b_{ijkl}. For more information, see *Generalized Fung Form*.

Fung-Orthotropic

For the orthotropic strain-based Fung model, you must specify 9 independent components b_{ijkl}. For more information, see *Generalized Fung Form*.

Holzapfel

This form of invariant-based strain energy potential is used for modeling arterial layers with distributed collagen fiber orientations. For more information, see *Holzapfel-Gasser-Ogden Form*.

User

You can use a user subroutine to define the form of a strain-based or invariant-based strain energy potential directly. For more information, see *User-Defined Form: Strain-Based*, and *User-Defined Form: Invariant-Based*.

4. To define material parameters that depend on field variables, click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables.
   Field variable columns appear in the data table.
5. For the **Fung-Anisotropic**, **Fung-Orthotropic**, and **Holzapfel** forms of strain energy potential, toggle on **Use temperature-dependent coefficients** to define material parameters that depend on temperature.
   A column labeled **Temp** appears in the data table.
6. If you are defining the hyperelastic behavior of a viscoelastic material, click the arrow to the right of the **Moduli** field to specify either **Long-term** or **Instantaneous** elastic response. See *Viscoelasticity*, for more information.
7. For the Holzapfel strain energy potential, click the arrows to the right of the **Number of local directions** field to increase or decrease the number of preferred local directions (or fiber directions) in the material. The default (and minimum) is 1. See *Creating an anisotropic hyperelastic material model* below and *Holzapfel-Gasser-Ogden Form*, for more information.

8. For a user-defined strain energy potential, you must specify the following options:
   - Choose **Strain** or **Invariant** as the formulation defined by your user subroutine.
   - Choose **Incompressible** or **Compressible** as the type of material defined by your user subroutine. See *Compressibility*, for more information.
   - Specify the **Number of property values** needed as data in your user subroutine.

9. Enter the material parameters in the data table corresponding to the chosen strain energy potential.

Fung-Anisotropic

Enter b_{1111}, b_{1122}, b_{2222}, b_{1133}, b_{2233}, b_{3333}, b_{1112}, b_{2212}, b_{3312}, b_{1212}, b_{1113}, b_{2213}, b_{3313}, b_{1213}, b_{1313}, b_{1123}, b_{2223}, b_{3323}, b_{1223}, b_{1323}, b_{2323}, c (units of FL^{-2}), and D (units of $F^{-1}L^2$).

Fung-Orthotropic

Enter b_{1111}, b_{1122}, b_{2222}, b_{1133}, b_{2233}, b_{3333}, b_{1212}, b_{1313}, b_{2323}, c (units of FL^{-2}), and D (units of $F^{-1}L^2$).

Holzapfel

Enter C_{10} (units of FL^{-2}), D (units of $F^{-1}L^2$), k_1 (units of FL^{-2}), k_2, and the fiber dispersion parameter κ ($0 \le \kappa \le 1/3$).

You may need to expand the dialog box to see all the columns in the data table. For detailed information on how to enter data, see *Entering tabular data*.

10. Click **OK** to create the material and to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Creating a hyperfoam material model

You can create a hyperfoam material model to describe a cellular solid whose porosity permits very large volumetric changes.
See *Hyperelastic Behavior in Elastomeric Foams* for more information on hyperfoam materials.

In this section:

- *Defining hyperfoam materials*
- *Entering material parameters to define a hyperelastic foam material*
- *Providing test data to define a hyperelastic foam material model*
- *Specifying uniaxial test data for a hyperelastic foam material model*
- *Specifying biaxial test data for a hyperelastic foam material model*
- *Specifying simple shear test data for a hyperelastic foam material model*
- *Specifying planar test data for a hyperelastic foam material model*
- *Specifying volumetric test data for a hyperelastic foam material model*

Defining hyperfoam materials

When you define a hyperfoam material, you have the option of either specifying material parameters directly or allowing Abaqus to calculate them from test data that you provide.

For detailed instructions, see the following sections:

- *Entering material parameters to define a hyperelastic foam material*
- *Providing test data to define a hyperelastic foam material model*

See *Hyperelastic Behavior in Elastomeric Foams* for more information on hyperfoam materials.

Entering material parameters to define a hyperelastic foam material

You can provide the parameters of the hyperelastic foam strain energy potentials directly as functions of temperature.

1. From the menu bar in the **Edit Material** dialog box, select **Mechanical->Elasticity->Hyperfoam**.
   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Click the arrows to the right of the **Strain energy potential order** field to increase or decrease the order of the strain energy potential, N.
3. To specify material parameters that depend on temperature, toggle on **Use temperature-dependent data**.
   A column labeled **Temp** appears in the **Data** table.
4. If you are defining the hyperfoam behavior of a viscoelastic material, click the arrow to the right of the **Moduli time scale (for viscoelasticity)** field to specify either long-term or instantaneous elastic response.
5. In the **Data** table, enter the material parameters: :

   ### mu*i*, alpha*i*, and nu*i*

   Material parameters μ_i, α_i, and ν_i.

   ### Temp

   Temperature.

   You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.
6. Click **OK** to create the material and to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Providing test data to define a hyperelastic foam material model

Abaqus can calculate material parameters from test data that you enter in the **Test Data Editor**.

1. From the menu bar in the **Edit Material** dialog box, select **Mechanical->Elasticity->Hyperfoam**. (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Toggle on **Use test data (Suboptions must be specified)**.
3. Click the arrows to the right of the **Strain energy potential order** field to increase or decrease the order of the strain energy potential, N.
4. Indicate how you want to define Poisson effects:
   - Toggle on **Use constant Poisson's ratio** if you want to enter a Poisson's ratio that will remain constant throughout the calculations.
   - Toggle off **Use constant Poisson's ratio** if you want Poisson effects defined from volumentric test data and/or lateral strains in other test data.
5. If you are defining the hyperfoam behavior of a viscoelastic material, click the arrow to the right of the **Moduli time scale (for viscoelasticity)** field to specify either long-term or instantaneous elastic response.
6. Use the **Test Data** menu to specify the experimental data from which Abaqus can calculate material parameters. For detailed instructions, see the following sections:
   - *Specifying uniaxial test data for a hyperelastic foam material model*"
   - *Specifying biaxial test data for a hyperelastic foam material model*"
   - *Specifying simple shear test data for a hyperelastic foam material model*"
   - *Specifying planar test data for a hyperelastic foam material model*"
   - *Specifying volumetric test data for a hyperelastic foam material model*"
7. Click **OK** to create the material and to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Specifying uniaxial test data for a hyperelastic foam material model

Use the **Test Data Editor** to specify uniaxial test data from which Abaqus can calibrate hyperelastic foam material coefficients. For more information, see *Hyperelastic Behavior in Elastomeric Foams*.

1. Create a hyperelastic foam material model as described in *Providing test data to define a hyperelastic foam material model*."
2. From the **Suboptions** menu in the **Edit Material** dialog box, select **Uniaxial Test Data**.

   A **Test Data Editor** appears.
3. In the **Data** table, enter the uniaxial test data:

   #### Nominal Stress

   Nominal stress, T_U.

   #### Nominal Strain

   Nominal strain, ϵ_U.

   #### Lateral Nominal Strain

   Nominal lateral strain, $\epsilon_2 = \epsilon_3$. This parameter is unnecessary if you have already entered a constant Poisson's ratio in the **Edit Material** dialog box.

   You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.
4. Click **OK** to return to the **Edit Material** dialog box.

Specifying biaxial test data for a hyperelastic foam material model

Use the **Test Data Editor** to specify biaxial test data from which Abaqus can calibrate hyperfoam material coefficients. For more information, see *Hyperelastic Behavior in Elastomeric Foams*.

1. Create a hyperelastic foam material model as described in *Providing test data to define a hyperelastic foam material model*."
2. From the **Suboptions** menu in the **Edit Material** dialog box, select **Biaxial Test Data**.

   A **Test Data Editor** appears.
3. In the **Data** table, enter the test data:

   #### Nominal Stress

   Nominal stress, T_L.

   #### Nominal Strain

   Nominal strain, ϵ_B.

   #### Lateral Nominal Strain

   Nominal transverse strain, ϵ_3. This parameter is unnecessary if you have already entered a constant Poisson's ratio in the **Edit Material** dialog box.

   You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.
4. Click **OK** to return to the **Edit Material** dialog box.

Specifying simple shear test data for a hyperelastic foam material model

Use the **Test Data Editor** to specify simple shear test data from which Abaqus can calibrate hyperfoam material coefficients. For more information, see *Hyperelastic Behavior in Elastomeric Foams*.

1. Create a hyperelastic foam material model as described in *Providing test data to define a hyperelastic foam material model*."
2. From the **Suboptions** menu in the **Edit Material** dialog box, select **Simple Shear Test Data**.

   A **Test Data Editor** appears.
3. In the **Data** table, enter the test data:

   #### Nominal Stress

   Nominal shear stress, T_S.

   #### Nominal Strain

   Nominal shear strain, γ.

   #### Nominal transverse stress

   Nominal transverse stress, T_T (normal to edge with shear stress). This stress value is optional, but strongly recommended. If given, a more accurate material response will be obtained.

   You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.
4. Click **OK** to return to the **Edit Material** dialog box.

Specifying planar test data for a hyperelastic foam material model

Use the **Test Data Editor** to specify planar test data from which Abaqus can calibrate hyperfoam material coefficients. Planar test data alone is inadequate; you must also include uniaxial and/or biaxial test data in the material definition. See the following sections for more information:

- *Hyperelastic Behavior in Elastomeric Foams*
- *Specifying uniaxial test data for a hyperelastic foam material model*"
- *Specifying biaxial test data for a hyperelastic foam material model*"

1. Create a hyperelastic foam material model as described in *Providing test data to define a hyperelastic foam material model*."
2. From the **Suboptions** menu in the **Edit Material** dialog box, select **Planar Test Data**.

   A **Test Data Editor** appears.
3. In the **Data** table, enter the test data:

   #### Nominal Stress

   Nominal stress, T_L.

   #### Nominal Strain

   Nominal strain in the direction of loading, ϵ_P.

   #### Nominal Lateral Strain

   Nominal transverse strain, ϵ_3. This parameter is unnecessary if you have already entered a constant Poisson's ratio in the **Edit Material** dialog box.

   You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.
4. Click **OK** to return to the **Edit Material** dialog box.

Specifying volumetric test data for a hyperelastic foam material model

Use the **Test Data Editor** to specify volumetric test data from which Abaqus can calibrate hyperfoam material coefficients. For more information, see *Hyperelastic Behavior of Rubberlike Materials*.

1. Create a hyperelastic foam material model as described in *Providing test data to define a hyperelastic foam material model*."
2. From the **Test Data** menu in the **Edit Material** dialog box, select **Volumetric Test Data**.

   A **Test Data Editor** appears.
3. In the **Data** table, enter the test data:

   #### Pressure

   Pressure, p.

   #### Volume Ratio

   Volume ratio (current volume/original volume), J.

   You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.
4. Click **OK** to return to the **Edit Material** dialog box.

Creating a low-density foam material model

You can create a material model to describe a low-density, highly compressible elastomeric foam with significant rate-sensitive behavior (such as polyurethane foam).
Abaqus calculates material parameters from test data that you enter in the **Test Data Editor**. You must provide uniaxial test data for both tension and compression. Your test data must specify the uniaxial stress-strain curve for different strain-rate values.

In this section:

- *Specifying low-density foam material properties*
- *Specifying uniaxial tension test data for a low-density foam material model*
- *Specifying uniaxial compression test data for a low-density foam material model*

Specifying low-density foam material properties

Enter the properties in the **Edit Material** dialog box, as described below. See *Low-Density Foams*, for more information on low-density foam materials.

1. From the menu bar in the **Edit Material** dialog box, select **Mechanical->Elasticity->Low Density Foam**.

   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)

2. Select the **Strain rate measure**.

   - Choose **Volumetric** (default) to use the nominal volumetric strain rate that does not produce rate-sensitive behavior under volume-preserving deformation modes (e.g., simple shear).
   - Choose **Principal** to cause Abaqus to use the strain rate evaluated along each principal direction.

   See *Strain Rate in Abaqus/Explicit*, for more details.

3. Toggle on **Extrapolate stress-strain curve beyond maximum strain rate** to activate strain-rate extrapolation based on slope (with respect to the strain rate). See *Extrapolation of Stress-Strain Curves*, for more details.
4. Toggle on **Maximum allowable principal tensile stress** to enter a cutoff value that the foam material can sustain. The maximum principal tensile stresses computed by Abaqus will be forced to stay at or below this value. See *Tension Cutoff and Failure in Abaqus/Explicit*, for more details.
5. If you specified a value for the **Maximum allowable principal tensile stress**, toggle on **Remove elements exceeding maximum** to cause Abaqus to delete any elements in which the maximum principal tensile stress is reached. This is a simple method for modeling rupture.
6. You can accept the default values for **Relaxation coefficients** or enter new values for **mu0**, **mu1**, and **alpha**. See *Relaxation Coefficients in Abaqus/Explicit*, for a detailed description of these material parameters.
7. To define the uniaxial test data for the material, click **Uniaxial Test Data**. For details, see the following sections:

   - *Specifying uniaxial tension test data for a low-density foam material model*"
   - *Specifying uniaxial compression test data for a low-density foam material model*"

8. Click **OK** to create the material and to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Specifying uniaxial tension test data for a low-density foam material model

Use the **Test Data Editor** to specify uniaxial test data for tension.

1. Create a low-density foam material model as described in *Specifying low-density foam material properties*."
2. From the **Uniaxial Test Data** menu in the **Edit Material** dialog box, select **Uniaxial Tension Test Data**.

   A **Test Data Editor** appears.
3. To specify test data that depend on temperature, toggle on **Use temperature-dependent data**.

   A column labeled **Temp** appears in the **Data** table.
4. To specify test data that depend on field variables, click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables.

   Field variable columns appear in the **Data** table.
5. In the **Data** table, enter the test data:

   ### Nominal Stress

   Nominal stress, T_U.

   ### Nominal Strain

   Nominal strain, ϵ_U.

   ### Nominal Strain Rate

   Nominal strain rate, $\dot{\epsilon}_U$. (Provide positive values to specify the loading response and negative values to specify unloading.)

   ### Temp

   Temperature, θ.

   ### Field *n*

   Predefined field variables.

   You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.
6. Click **OK** to return to the **Edit Material** dialog box.

Specifying uniaxial compression test data for a low-density foam material model

Use the **Test Data Editor** to specify uniaxial test data for compression.

1. Create a low-density foam material model as described in *Specifying low-density foam material properties*."
2. From the **Uniaxial Test Data** menu in the **Edit Material** dialog box, select **Uniaxial Compression Test Data**.

   A **Test Data Editor** appears.
3. To specify test data that depend on temperature, toggle on **Use temperature-dependent data**.

   A column labeled **Temp** appears in the **Data** table.
4. To specify test data that depend on field variables, click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables.

   Field variable columns appear in the **Data** table.
5. In the **Data** table, enter the test data:

   ### Nominal Stress

   Enter the absolute value of nominal stress, T_U.

   ### Nominal Strain

   Enter the absolute value of nominal strain, ϵ_U.

   ### Nominal Strain Rate

   Nominal strain rate, $\dot{\epsilon}_U$. (Provide positive values to specify the loading response and negative values to specify unloading.)

   ### Temp

   Temperature, θ.

   ### Field *n*

   Predefined field variables.

   You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.
6. Click **OK** to return to the **Edit Material** dialog box.

Creating a hypoelastic material model

You can create a hypoelastic material definition to describe a nonlinear, small-strain elastic material. You have the option of either entering hypoelastic material parameters directly in the material editor or defining material parameters in user subroutine *UHYPEL*. User subroutine *UHYPEL* allows you to specify temperature-dependent data.

For more information, see the following sections:

- *Hypoelastic Behavior*
- *UHYPEL*

1. From the menu bar in the **Edit Material** dialog box, select **Mechanical->Elasticity->Hypoelastic**. (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Select one of the following options for specifying material parameters:
   - Toggle on **Use user subroutine UHYPEL**.
   - Enter material parameters in the **Data** area:

Young's Modulus

Instantaneous Young's modulus, *E*.

Poisson's Ratio

Instantaneous Poisson's ratio, ν.

I1

First strain invariant, I_1.

I2

Second strain invariant, I_2.

I3

Third strain invariant, I_3.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

3. Click **OK** to create the material and to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Creating a porous elastic material model

A porous elastic material model defines the elastic parameters for a porous material. For more information, see *Elastic Behavior of Porous Materials*.

1. From the menu bar in the **Edit Material** dialog box, select **Mechanical->Elasticity->Porous Elastic**.
   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Click the arrow to the right of the **Shear** field and select an option for defining deviatoric elastic behavior in the porous material:
   - Select **G** to specify a constant shear modulus. In this case the shear behavior is unaffected by compaction of the material.

     A **Shear Modulus** column appears in the **Data** table.
   - Select **Poisson** to allow Abaqus to calculate the instantaneous shear modulus from the bulk modulus and Poisson's ratio. In this case, the elastic shear stiffness increases as the material is compacted.

     A **Poisson's ratio** column appear in the **Data** table.
3. To define behavior data that depend on temperature, toggle on **Use temperature-dependent data**.
   A column labeled **Temp** appears in the **Data** table.
4. To define behavior data that depend on field variables, click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables.
   Field variable columns appear in the **Data** table.
5. In the **Data** table, enter the material parameters:

Log Bulk Modulus

Logarithmic bulk modulus, κ. (Dimensionless.)

G

Shear modulus, *G*. Enter this value if you selected **G** from the list of **Shear** options.

Poisson's ratio

Poisson's ratio, ν. Enter this value if you selected **Poisson** from the list of **Shear** options.

Tensile Limit

Elastic tensile limit, p_t^{el}. (This value cannot be negative.)

Temp

Temperature, θ.

Field *n*

Predefined field variables.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

6. Click **OK** to create the material and to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Creating a viscoelastic material model

You can define viscoelastic behavior in a material as a function of frequency (for steady-state, small-vibration analyses) or as a function of reduced time (for time-dependent analyses).
For more information, see the following sections:

- *Time Domain Viscoelasticity*
- *Frequency Domain Viscoelasticity*

In this section:

- *Defining viscoelastic materials*
- *Defining time domain viscoelasticity*
- *Specifying thermorheologically simple (TRS) temperature dependence for time domain viscoelasticity*
- *Defining frequency domain viscoelasticity*
- *Specifying shear test data*
- *Specifying volumetric test data*
- *Specifying combined test data*

Defining viscoelastic materials

You can define viscoelasticity in the **Edit Material** dialog box.

For detailed instructions, see the following sections:

- *Defining time domain viscoelasticity*
- *Defining frequency domain viscoelasticity*

For more information on viscoelasticity, see *Time Domain Viscoelasticity* and *Defining frequency domain viscoelasticity*.

Defining time domain viscoelasticity

This type of material model describes the isotropic rate-dependent behavior of materials for which the dissipative losses caused by internal damping effects must be modeled in the time domain.

Abaqus assumes that the time domain viscoelasticity is defined by a Prony series expansion. You can specify the Prony series parameters directly for each term in the Prony series. Alternatively, Abaqus can calculate the terms in the Prony series using time-dependent creep test data, time-dependent relaxation test data, or frequency-dependent cyclic test data that you provide.

For more information on time domain viscoelasticity, see *Time Domain Viscoelasticity*.

1. From the menu bar in the **Edit Material** dialog box, select **Mechanical->Elasticity->Viscoelastic**. (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Click the arrow to the right of the **Domain** field, and select **Time**.
3. Click the arrow to the right of the **Time** field, and select the option of your choice for determining viscoelastic material parameters:
   - Select **Prony** if you want to enter the Prony series parameters for each term directly.
   - Select **Creep test data** if you want Abaqus to calculate the parameters in the Prony series from creep test data that you provide. If you select this option, you must enter shear test data and/or volumetric test data in the **Test Data Editor**.
   - Select **Relaxation test data** if you want Abaqus to calculate the Prony series parameters from relaxation test data. If you select this option, you must enter shear test data and/or volumetric test data in the **Test Data Editor**.
   - Select **Frequency data** if you want Abaqus to calculate the Prony series parameters from frequency-dependent cyclic test data.
4. If you selected any of the test data options from the **Time** option list, you can specify two additional parameters related to the calibration of Prony series parameters:
   - Click the arrows to the right of the **Maximum number of terms in the Prony series** field to specify the maximum number of terms (*N*) in the Prony series. Abaqus will perform the least-squares fit from $\boldsymbol{N = 1}$ to $\boldsymbol{N =}$ NMAX until convergence is achieved for the lowest *N* with respect to the error tolerance.
   - In the **Allowable average root-mean-square error** field, enter the error tolerance for the data points in the least-squares fit.
5. If you selected **Prony** from the list of **Time** options, enter the Prony parameters in the **Data** table.

g_i Prony

Shear relaxation or shear traction relaxation modulus ratio, $\overline{g}_i^P$.

k_i Prony

Bulk relaxation or normal traction relaxation modulus ratio, $\overline{k}_i^P$.

tau_i Prony

Relaxation time, τ_i.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

6. If you selected **Frequency data** from the list of **Time** options, enter the frequency-dependent test data in the **Data** table.

Omega g* real

Real part of ωg^*.

Omega g* imag

Imaginary part of ωg^*.

Omega k* real

Real part of ωk^*.

Omega k* imag

Imaginary part of ωk^*.

Frequency

Frequency, *f*, in cycles per time.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

7. If applicable, click **Test Data** to specify test data from which to define viscoelastic behavior. See the following sections for details:
   - *Specifying shear test data*"
   - *Specifying volumetric test data*"
   - *Specifying combined test data*"
8. To specify thermorheologically simple (TRS) temperature effects, use the **Suboptions** menu. For details, see *Specifying thermorheologically simple (TRS) temperature dependence for time domain viscoelasticity*.
9. Click **OK** to create the material and to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Specifying thermorheologically simple (TRS) temperature dependence for time domain viscoelasticity

You can define the shift function either by entering parameters for the Williams-Landel-Ferry approximation or by using user subroutine *UTRS*. For more information on temperature effects in time domain viscoelasticity, see *Time Domain Viscoelasticity*.

1. Create a time domain viscoelastic material as described in *Defining time domain viscoelasticity*."
2. From the **Suboptions** menu in the **Edit Material** dialog box, select **Trs**.
   The **Suboption Editor** appears.
3. Click the arrow to the right of the **Shift function** field, and select the option of your choice.
   - Select **WLF** to define the shift function using the Williams-Landel-Ferry approximation.
   - Select **User Subroutine UTRS** to define the shift function using user subroutine *UTRS*.
4. If you selected **WLF** from the list of **Shift** function options, enter the required data in the **Data** table:

   #### Theta 0

   Reference temperature, θ_0.

   #### C1

   Calibration constant, C_1.

   #### C2

   Calibration constant, C_2.

   You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.
5. Click **OK** to return to the **Edit Material** dialog box.

Defining frequency domain viscoelasticity

This type of material model describes frequency-dependent material behavior in small, steady-state harmonic oscillations. In these cases the dissipative losses caused by internal damping effects must be modeled in the frequency domain.

The dissipative part of the material behavior is defined by giving the real and imaginary parts of g^* and k^* (for compressible materials) as functions of frequency. The moduli can be defined as functions of the frequency in one of three ways: by a power law, by tabular input, or by a Prony series expression for the shear and bulk relaxation moduli.

For more information on frequency domain viscoelasticity, see *Frequency Domain Viscoelasticity*.

1. From the menu bar in the **Edit Material** dialog box, select **Mechanical->Elasticity->Viscoelastic**. (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Click the arrow to the right of the **Domain** field, and select **Frequency**.
3. Click the arrow to the right of the **Frequency** field, and select the option of your choice for determining viscoelastic material parameters:
   - Select **Formula** to define the frequency dependence by the power law formulae.
   - Select **Tabular** to define the frequency response in tabular form. You must provide the real and imaginary parts of ωg^* and ωk^*—where ω is the circular frequency—as functions of frequency in cycles per time.
   - Select **Prony** if you want Abaqus to calculate the frequency dependence from a time domain Prony series description of the dimensionless shear and bulk relaxation moduli.
   - Select **Creep test data** if you want Abaqus to calculate the parameters in the Prony series from creep test data that you provide. If you select this option, you must enter shear test data and/or volumetric test data in the **Test Data Editor**.
   - Select **Relaxation test data** if you want Abaqus to calculate the Prony series parameters from relaxation test data. If you select this option, you must enter shear test data and/or volumetric test data in the **Test Data Editor**.
4. If you selected **Creep test data** or **Relaxation test data** from the **Frequency** option list, you can specify two additional parameters related to the calibration of Prony series parameters:
   - Click the arrows to the right of the **Maximum number of terms in the Prony series** field to specify the maximum number of terms (*N*) in the Prony series. Abaqus will perform the least-squares fit from $N = 1$ to $N =$ NMAX until convergence is achieved for the lowest *N* with respect to the error tolerance.
   - In the **Allowable average root-mean-square error** field, enter the error tolerance of the data points in the least-squares fit.
5. If you selected **Tabular** from the **Frequency** option list, you can specify two additional options:

Type

This parameter specifies whether you are defining continuum material properties or effective thickness-direction gasket properties.

Select **Isotropic** if you are defining continuum material properties. This choice is appropriate when the viscoelasic material model is used for any continuum, structural, or special-purpose elements whose material response is modeled using continuum material properties.

Select **Traction** if you are defining effective thickness-direction gasket properties. This option is supported only for gasket elements whose behavior is modeled directly using a gasket behavior model.

Preload

This parameter specifies the nature of preload used for defining frequency domain viscoelastic material properties or effective thickness-direction gasket properties.

Select **Uniaxial** to specify that the material properties correspond to a uniaxial test.

Select **Volumetric** to specify that the material properties correspond to a volumetric test. This setting cannot be used to define effective thickness-direction gasket properties.

Select **Uniaxial and Volumetric** to specify that the material properties correspond to both types of tests. This setting cannot be used to define effective thickness-direction gasket properties.

Select **None** if you choose not to specify a preload parameter.

6. If you selected **Formula** from the list of **Frequency** options, enter the following data in the **Data** table:

g1*real

Real part of g_1^*.

g1*imag

Imaginary part of g_1^*.

a

Value of a.

k1*real

Real part of k_1^*.

k1*imag

Imaginary part of k_1^*. If the material is incompressible, this value is ignored.

b

Value of b. If the material is incompressible, this value is ignored.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

7. If you selected **Tabular** from the list of **Frequency** options, enter the data relevant to your **Type** and **Preload** selections (not all of the following parameters will apply):

Omega g* real

Real part of ωg^*. $(\omega \Re(g^*) = G_\ell / G_\infty)$

Omega g* imag

Imaginary part of ωg^*. $(\omega \mathfrak{I}(g^*) = 1 - G_s/G_\infty)$

Omega k* real

Real part of ωk^*. $(\omega \mathfrak{R}(k^*) = \mathbf{K}_\ell/\mathbf{K}_\infty)$ If the material is incompressible, this value is ignored.

Omega k* imag

Imaginary part of ωk^*. $(\omega \mathfrak{I}(k^*) = 1 - \mathbf{K}_s/\mathbf{K}_\infty)$ If the material is incompressible, this value is ignored.

Frequency

Frequency, *f*, in cycles per time.

Loss Modulus

Uniaxial or bulk loss modulus.

Storage Modulus

Uniaxial or bulk storage modulus.

Uniaxial Strain

Uniaxial nominal strain (defines the level of uniaxial preload).

Volume Ratio

Volume ratio, *J* (current volume/original volume; defines the level of volumetric preload).

Normalized Loss Modulus

Real part of ωk^*. $(\omega \mathfrak{R}(k^*) = \mathbf{K}_\ell/\mathbf{K}_\infty)$ for thickness-direction gasket behavior with no preload.

Normalized Shear Modulus

Imaginary part of ωk^*. $(\omega \mathfrak{I}(k^*) = 1 - \mathbf{K}_s/\mathbf{K}_\infty)$ for thickness-direction gasket behavior with no preload.

You may need to expand the dialog box to see all the columns. For detailed information on how to enter data, see *Entering tabular data*.

8. If you selected **Prony** from the list of **Frequency** options, enter the following data in the **Data** table:

g_i Prony

$\bar{g}_i^P$, the modulus ratio in the first term in the Prony series expansion of the shear relaxation modulus.

k_i Prony

$\bar{k}_i^P$, the modulus ratio in the first term in the Prony series expansion of the bulk relaxation modulus.

tau_i Prony

τ_i, the relaxation time for the first term in the Prony series expansion.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

9. If applicable, use the **Test Data** menu to specify test data from which to define viscoelastic behavior. See the following sections for details:
   - *Specifying shear test data*"
   - *Specifying volumetric test data*"
   - *Specifying combined test data*"

10. Click **OK** to create the material and to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Specifying shear test data

You can use the **Test Data Editor** to specify the normalized shear creep compliance or relaxation modulus as a function of time. For information on using shear test data to define viscoelastic material behavior, see *Time Domain Viscoelasticity*, or *Frequency Domain Viscoelasticity*.

1. Create a viscoelastic material model as described in *Defining time domain viscoelasticity*" or *Defining frequency domain viscoelasticity*."
2. From the **Test Data** menu in the **Edit Material** dialog box, select **Shear Test Data**.
   A **Test Data Editor** appears.
3. In the **Long-term normalized shear compliance or modulus** field, enter either the long-term, normalized shear compliance, $j_S(\infty)$, for creep test data or the long-term, normalized shear modulus, $g_R(\infty)$, for relaxation test data.
4. In the **Data** table, enter the following data:

   #### js or gR

   The normalized shear compliance, $j_S(t)$, ($(j_S(t) \geq 1)$) for creep test data or the normalized shear relaxation modulus, $g_R(t)$, ($(0 \leq g_R(t) \leq 1)$) for relaxation test data.

   #### Time

   Time, *t*. $(t > 0)$

   For detailed information on how to enter data, see *Entering tabular data*.
5. Click **OK** to return to the **Edit Material** dialog box.

Specifying volumetric test data

You can use the **Test Data Editor** to specify the normalized bulk creep compliance or relaxation modulus as a function of time. For information on using volumetric test data to define viscoelastic material behavior, see *Time Domain Viscoelasticity*, or *Frequency Domain Viscoelasticity*.

1. Create a viscoelastic material model as described in *Defining time domain viscoelasticity*" or *Defining frequency domain viscoelasticity*."
2. From the **Test Data** menu in the **Edit Material** dialog box, select **Volumetric Test Data**.
   A **Test Data Editor** appears.
3. In the **Long-term normalized volumetric compliance or modulus** field, enter either the long-term, normalized volumetric compliance, $j_K(\infty)$, for creep test data or the long-term, normalized volumetric modulus, $k_R(\infty)$, for relaxation test data.
4. In the **Data** table, enter the following data:

   ### jK or kR

   The normalized volumetric compliance, $j_K(t), \quad (j_K(t) \geq 1)$, for creep test data or the normalized volumetric modulus, $k_R(t), \quad (0 \leq k_R(t) \leq 1)$, for relaxation test data.

   ### Time

   Time, *t*. $(t > 0)$

   For detailed information on how to enter data, see *Entering tabular data*.
5. Click **OK** to return to the **Edit Material** dialog box.

Specifying combined test data

You can use the **Test Data Editor** to specify simultaneously the normalized shear and bulk creep compliances or relaxation moduli as a function of time. For information on using combined test data to define viscoelastic material behavior, see *Time Domain Viscoelasticity*, or *Frequency Domain Viscoelasticity*.

1. Create a viscoelastic material model as described in *Defining time domain viscoelasticity*" or *Defining frequency domain viscoelasticity*."
2. From the **Test Data** menu in the **Edit Material** dialog box, select **Combined Test Data**.
   A **Test Data Editor** appears.
3. In the **Long-term normalized shear compliance or modulus** field, enter either the long-term, normalized shear compliance, $j_S(\infty)$, for creep test data or the long-term, normalized shear modulus, $g_R(\infty)$, for relaxation test data.
4. In the **Long-term normalized volumetric compliance or modulus** field, enter either the long-term, normalized volumetric compliance, $j_K(\infty)$, for creep test data or the long-term, normalized volumetric modulus, $k_R(\infty)$, for relaxation test data.
5. In the **Data** table, enter the following data:

   #### js or gR

   The normalized shear compliance, $j_S(t)$, ($(j_S(t) \geq 1)$) for creep test data or the normalized shear relaxation modulus, $g_R(t)$, ($(0 \leq g_R(t) \leq 1)$) for relaxation test data.

   #### jK or kR

   The normalized volumetric compliance, $j_K(t), \quad (j_K(t) \geq 1)$, for creep test data or the normalized volumetric modulus, $k_R(t), \quad (0 \leq k_R(t) \leq 1)$, for relaxation test data.

   #### Time

   Time, *t*. $(t > 0)$

   For detailed information on how to enter data, see *Entering tabular data*.
6. Click **OK** to return to the **Edit Material** dialog box.

Defining plasticity

You use the **Edit Material** dialog box to create a plastic material and to specify its material properties.

You can create the following plastic material models:

- **Classical metal plasticity**
- **Cap plasticity**
- **Cast iron plasticity**
- **Clay plasticity**
- **Concrete damaged plasticity**
- **Concrete smeared cracking**
- **Crushable foam plasticity**
- **Drucker-Prager plasticity**
- **Mohr-Coulomb plasticity**
- **Porous metal plasticity**
- **Creep**
- **Swelling**
- **Viscous**

For more information, see *Inelastic Behavior*.

In this section:

- *Defining classical metal plasticity*
- *Defining cap plasticity*
- *Defining cast iron plasticity*
- *Defining clay plasticity*
- *Defining concrete damaged plasticity*
- *Defining concrete smeared cracking*
- *Defining crushable foam plasticity*
- *Defining Drucker-Prager plasticity*
- *Defining Mohr-Coulomb plasticity*
- *Defining porous metal plasticity*
- *Defining a creep law*
- *Defining swelling*
- *Defining the viscous component of a two-layer viscoplasticity model*

Defining classical metal plasticity

The classical metal plasticity model allows you to define the yield and inelastic flow of a metal at relatively low temperatures, where loading is relatively monotonic and creep effects are unimportant.
For more information, see *Classical Metal Plasticity*.

In this section:

- *Specify hardening behavior for classical metal plasticity*
- *Using an isotropic hardening model to define classical metal plasticity*
- *Using a linear kinematic cyclic hardening model to define classical metal plasticity*
- *Using the Johnson-Cook hardening model to define classical metal plasticity*
- *Specifying user subroutine UHARD to define classical metal plasticity*
- *Using a nonlinear isotropic/kinematic cyclic hardening model to define classical metal plasticity*
- *Defining the isotropic hardening component of a nonlinear isotropic/kinematic hardening model*
- *Defining rate-dependent yield with yield stress ratios*
- *Defining anisotropic yield and creep*
- *Using the Oak Ridge National Laboratory (ORNL) constitutive model in plasticity and creep calculations*
- *Specifying cycled yield stress data for the ORNL model*
- *Specifying the annealing temperature of an elastic-plastic material*
- *Defining tensile failure*

Specify hardening behavior for classical metal plasticity

When you use the **Edit Material** dialog box to define the classical plastic behavior of a material, you must select an option for specifying the hardening behavior.

The following hardening options are available:

Option	Hardening behavior
Isotropic	Model hardening where the yield surface changes size uniformly in all directions such that the yield stress increases (or decreases) in all stress directions as plastic straining occurs
Kinematic	Model cyclic loading of a material with a constant rate of hardening
Johnson-Cook	Model isotropic hardening in Abaqus/Explicit, where the yield stress is provided as an analytical function of equivalent plastic strain, strain rate, and temperature
User	Describe yield stress for isotropic hardening through user subroutine *UHARD*
Combined	Model cyclic loading of a material with nonlinear isotropic/kinematic hardening

For general information on selecting a **Hardening** option, see *Hardening*.

- *Using an isotropic hardening model to define classical metal plasticity*
- *Using a linear kinematic cyclic hardening model to define classical metal plasticity*
- *Using the Johnson-Cook hardening model to define classical metal plasticity*
- *Specifying user subroutine UHARD to define classical metal plasticity*
- *Using a nonlinear isotropic/kinematic cyclic hardening model to define classical metal plasticity*

Using an isotropic hardening model to define classical metal plasticity

The isotropic hardening model is useful for cases involving gross plastic straining or for cases where the straining at each point is essentially in the same direction in strain space throughout the analysis.

1. From the menu in the **Edit Material** dialog box, select **Mechanical->Plasticity->Plastic**.

   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Click the arrow to the right of the **Hardening** field, and select **Isotropic**.
3. Select **Use strain-rate-dependent data** if you want enter test data showing yield stress values versus equivalent plastic strain at different equivalent plastic strain rates.

   A **Rate** column appears in the **Data** table.

   Alternatively, if you want to define strain rate dependence using yield stress ratios, you must select **Rate Dependent** from the **Suboptions** menu. See *Defining rate-dependent yield with yield stress ratios*" for details. For background information on rate dependence, see *Rate-Dependent Yield*.
4. Select **Use temperature-dependent data** to define behavior data that depend on temperature.

   A column labeled **Temp** appears in the **Data** table.
5. To define behavior data that depend on field variables, click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables.
6. Enter the following data in the **Data** table:

Yield Stress

The stress at which yield is initiated.

Plastic Strain

Plastic strain.

Rate

Equivalent plastic strain rate, $\dot{\bar{\varepsilon}}^{pl}$, for which the stress-strain curve applies.

Temp

Temperature.

Field *n*

Predefined field variables.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

7. If desired, use the **Suboptions** menu to enter additional data.

   See the following sections for details:

   - *Defining rate-dependent yield with yield stress ratios*
   - *Specifying the annealing temperature of an elastic-plastic material*
   - *Defining tensile failure*

8. Click **OK** to create the material and to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (For more information, see *Browsing and modifying material behaviors*.)

Using a linear kinematic cyclic hardening model to define classical metal plasticity

Use the linear kinematic model to define a constant rate of cyclic hardening. See *Models for Metals Subjected to Cyclic Loading*, for more information.

1. From the menu bar in the **Edit Material** dialog box, select **Mechanical->Plasticity->Plastic**.
   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Click the arrow to the right of the **Hardening** field, and select **Kinematic**.
3. Toggle on **Use temperature-dependent data** to define behavior data that depend on temperature.
   A column labeled **Temp** appears in the **Data** table.
4. Enter the following data in the **Data** table:

Yield Stress

The stress at which yield is initiated.

Plastic Strain

Plastic strain.

Temp

Temperature.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

5. If desired, use the **Suboptions** menu to enter additional data. See the following sections for details:
   - *Defining anisotropic yield and creep*"
   - *Using the Oak Ridge National Laboratory (ORNL) constitutive model in plasticity and creep calculations*"
   - *Specifying cycled yield stress data for the ORNL model*"
   - *Specifying the annealing temperature of an elastic-plastic material*"
6. Click **OK** to create the material and to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Using the Johnson-Cook hardening model to define classical metal plasticity

The Johnson-Cook plasticity model is particularly suited to model high-strain-rate deformation of metals. This model is a particular type of Mises plasticity that includes analytical forms of the hardening law and rate dependence. It is generally used in adiabatic transient dynamic analysis. For more information, see *Johnson-Cook Plasticity*.

1. From the menu in the **Edit Material** dialog box, select **Mechanical->Plasticity->Plastic**.
   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Click the arrow to the right of the **Hardening** field, and select **Johnson-Cook**.
3. Enter the following data in the **Data** table:

A, B, n, and m

Material parameters measured at or below the transition temperature.

Melting Temp

Melting temperature, θ_{melt}, above which the material is melted and behaves like a fluid.

Transition Temp

Transition temperature, $\theta_{\text{transition}}$. There is no temperature dependence on the expression of the yield stress at or below the transition temperature.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

4. If desired, use the **Suboptions** menu to enter additional data.
   See the following sections for details:
   - *Defining rate-dependent yield with yield stress ratios*
   - *Specifying the annealing temperature of an elastic-plastic material*
   - *Defining tensile failure*
5. Click **OK** to create the material and to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Specifying user subroutine UHARD to define classical metal plasticity

User subroutine *UHARD* allows you to define the yield surface size and hardening parameters for isotropic plasticity or combined hardening models.

1. From the menu bar in the **Edit Material** dialog box, select **Mechanical->Plasticity->Plastic**.
   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Click the arrow to the right of the **Hardening** field, and select **User**.
3. In the **Data** table, enter the number of **Hardening Properties** needed as data in user subroutine *UHARD*.
4. Click **OK** to create the material and to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Using a nonlinear isotropic/kinematic cyclic hardening model to define classical metal plasticity

The evolution law of this model consists of two components:

- A nonlinear kinematic hardening component, which describes the translation of the yield surface in stress space through the backstress, $\boldsymbol{\alpha}$.
- An isotropic hardening component, which describes the change of the equivalent stress defining the size of the yield surface, σ^0, as a function of plastic deformation.

You can define the kinematic hardening component by selecting **Combined** from the list of **Hardening** options in the **Edit Material** dialog box and entering the required data.

You can define the isotropic hardening component by selecting **Cyclic Hardening** from the **Suboptions** menu and entering data in the **Suboption Editor** that appears.

For more information on cyclic hardening, see *Models for Metals Subjected to Cyclic Loading*.

1. From the menu bar in the **Edit Material** dialog box, select **Mechanical**->**Plasticity**->**Plastic**.
   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Click the arrow to the right of the **Hardening** field, and select **Combined**.
3. Click the arrow to the right of the **Data type** field, and specify how you want to define the kinematic hardening component of the model:
   - Select **Half Cycle** to provide stress-strain data obtained from the first half cycle of a unidirectional tension or compression experiment.
   - Select **Parameters** to specify the kinematic hardening parameters C_k and γ_k directly.
   - Select **Stabilized** to provide stress-strain data obtained from the stabilized cycle of a specimen that is subjected to symmetric strain cycles.
4. To specify the number of backstresses to include in the model, click the arrows to the right of the **Number of backstresses** field. The default number of backstresses is 1. The maximum number of backstresses allowed is 10.
   If you selected **Parameters** from the list of **Data type** options, additional columns appear in the table to specify the kinematic hardening parameters for multiple backstresses.
5. Toggle on **Use temperature-dependent data** to define behavior data that depend on temperature.
   A column labeled **Temp** appears in the **Data** table.
6. To define behavior data that depend on field variables, click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables.
7. If you selected **Stabilized** from the list of **Data type** options, you can choose to toggle on **Use strain-range-dependent data**. This option is useful if the shapes of the stress-strain curves are significantly different for different strain ranges.
8. In the **Data** table, enter the data relevant to your **Data type** selection (not all of the following parameters will apply):

Yield Stress

The stress at which yield is initiated.

Plastic Strain

Plastic strain.

Yield Stress At Zero Plastic Strain

Yield stress at zero plastic strain, $\sigma|_0$.

Kinematic Hard Parameter C1

Kinematic hardening parameter, C_1.

Gamma 1

Kinematic hardening parameter, γ_1.

Kinematic Hard Parameter C*k* and Gamma *k*

Kinematic hardening parameters C_k and γ_k for multiple backstresses.

Temp

Temperature.

Field *n*

Predefined field variables.

Strain Range

The strain range at which the stress-strain curve is obtained.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

9. To define the isotropic hardening component of the model, select **Cyclic Hardening** from the **Suboptions** menu, and enter the required data in the **Suboption Editor** that appears. See *Defining the isotropic hardening component of a nonlinear isotropic/kinematic hardening model*" for details.
10. If desired, use other options from the **Suboptions** menu to enter additional data. See the following sections for details:
    - *Defining anisotropic yield and creep*"
    - *Specifying the annealing temperature of an elastic-plastic material*"
11. Click **OK** to create the material and to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Defining the isotropic hardening component of a nonlinear isotropic/kinematic hardening model

The **Suboption Editor** allows you to define the evolution of the elastic domain for the nonlinear isotropic/kinematic hardening model. For more information, see the following sections:

- *Models for Metals Subjected to Cyclic Loading*
- *Using a nonlinear isotropic/kinematic cyclic hardening model to define classical metal plasticity*"

1. Create a material model as described in *Using a nonlinear isotropic/kinematic cyclic hardening model to define classical metal plasticity*."
2. From the **Suboptions** menu in the **Edit Material** dialog box, select **Cyclic Hardening**.

   A **Suboption Editor** appears.
3. Toggle on **Use temperature-dependent data** to define data that depend on temperature.

   A column labeled **Temp** appears in the **Data** table.
4. To define data that depend on field variables, click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables.
5. Specify how you want to define the isotropic hardening component:
   - Toggle on **Use parameters** if you want to enter the material parameters of the exponential law.
   - Toggle off **Use parameters** if you want to define the evolution of the yield surface size as a function of the equivalent plastic strain in tabular form.
6. If you toggled on **Use parameters**, enter the following data in the **Data** table:

Equiv Stress

Equivalent stress defining the size of the elastic range at zero plastic strain.

Q-infinity

Isotropic hardening parameter, Q_∞.

Hardening Param b

Isotropic hardening parameter, b.

Temp

Temperature.

Field *n*

Predefined field variables.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

7. If you toggled off **Use parameters**, enter the following data in the **Data** table:

Equiv Stress

Equivalent stress defining the size of the elastic range.

Equiv Plastic Strain

Equivalent plastic strain.

Temp

Temperature.

Field *n*

Predefined field variables.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

8. Click **OK** to return to the **Edit Material** dialog box.

Defining rate-dependent yield with yield stress ratios

Abaqus allows you to define a material's yield behavior accurately when the yield strength depends on the rate of straining and the anticipated strain rates are significant. You can define strain rate dependence in two ways:

- Enter hardening curves at different strain rates directly, as described in the following sections:
  - *Using an isotropic hardening model to define classical metal plasticity*"
  - *Defining Drucker-Prager hardening*"
- Define yield stress ratios to specify the rate dependence independently, as described in the procedure below.

For more information on strain rate dependence, see *Rate-Dependent Yield*.

1. Create a material model as described in described in one of the following sections:
   - *Using an isotropic hardening model to define classical metal plasticity*"
   - *Using the Johnson-Cook hardening model to define classical metal plasticity*"
   - *Defining Drucker-Prager hardening*"
2. From the **Suboptions** menu in the **Edit Material** dialog box, select **Rate Dependent**.
   A **Suboption Editor** appears.
3. Click the arrow to the right of the **Hardening** field, and select a method for defining hardening dependencies:
   - Select **Power Law** to define yield stress ratios with the Cowper-Symonds overstress law.
   - Select **Tabular** to enter yield stress ratios directly in tabular form as a function of equivalent plastic strain rates.
   - Select **Johnson-Cook** to use an analytical Johnson-Cook form to define *R*.
4. If applicable, toggle on **Use temperature-dependent data** to define data that depend on temperature.
   A column labeled **Temp** appears in the **Data** table.
5. If applicable, click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the data depend.
6. If you selected **Power Law** from the list of **Hardening** options, enter the following data in the **Data** table:

Mulitiplier

Material parameter, *D*.

Exponent

Material parameter, *n*.

Temp

Temperature.

Field *n*

Predefined field variables.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

7. If you selected **Yield Ratio** from the list of **Hardening** options, enter the following data in the **Data** table:

Yld Stress Ratio

Yield stress ratio, $R = \overline{\sigma}/\sigma^0$.

Eq Plastic Strain Rate

Equivalent plastic strain rate, $\dot{\bar{\varepsilon}}^{pl}$ (or $\left|\dot{\varepsilon}^{pl}_{axial}\right|$, the absolute value of the axial plastic strain rate in uniaxial compression, for the crushable foam model).

Temp

Temperature.

Field *n*

Predefined field variables.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

8. If you selected **Johnson-Cook** from the list of **Hardening** options, enter the following data in the **Data** table:

C

Material constant, *C*, which is independent of temperature and field variables.

Epsilon dot zero

Material constant, $\dot{\varepsilon}_0$, which is independent of temperature and field variables.

For detailed information on how to enter data, see *Entering tabular data*.

9. Click **OK** to return to the **Edit Material** dialog box.

Defining anisotropic yield and creep

Abaqus provides an anisotropic yield and creep model for materials that exhibit different yield or creep behavior in different directions. You can define anisotropic yield or creep by specifying stress ratios that are applied in Hill's potential function. For more information, see *Hill Anisotropic Yield/Creep*.

1. Create a material model as described in one of the following sections
   - *Using an isotropic hardening model to define classical metal plasticity*"
   - *Using a linear kinematic cyclic hardening model to define classical metal plasticity*"
   - *Using a nonlinear isotropic/kinematic cyclic hardening model to define classical metal plasticity*"
   - *Defining a creep law*"
   - *Defining the viscous component of a two-layer viscoplasticity model*"
   - *Defining clay plasticity*"
2. From the **Suboptions** menu in the **Edit Material** dialog box, select **Potential**.
   A **Suboption Editor** appears.
3. Toggle on **Use temperature-dependent data** to define data that depend on temperature.
   A column labeled **Temp** appears in the **Data** table.
4. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the data depend.
5. Enter the following data in the **Data** table:

R11, R22, R33, R12, R13, and R23

Yield or creep stress ratios.

Temp

Temperature.

Field *n*

Predefined field variables.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

6. Click **OK** to return to the **Edit Material** dialog box.

Using the Oak Ridge National Laboratory (ORNL) constitutive model in plasticity and creep calculations

The ORNL constitutive model in Abaqus/Standard applies to Types 304 and 316 stainless steel, as specified in nuclear standard *NE F9–5T(1981)*. The constitutive theory is uncoupled into a rate-independent plasticity response and a rate-dependent creep response, each of which is governed by a separate constitutive law. For more information, see *ORNL – Oak Ridge National Laboratory Constitutive Model*, and *ORNL constitutive theory*.

1. Create a material model as described in one of the following sections:
   - *Using a linear kinematic cyclic hardening model to define classical metal plasticity*"
   - *Defining a creep law*"
2. From the **Suboptions** menu in the **Edit Material** dialog box, select **Ornl**.

   A **Suboption Editor** appears.
3. In the **Saturation rates for kinematic shift** field, enter a value for A, the parameter equal to the saturation rates for kinematic shift caused by creep strain. This parameter is defined by Equation (15) of Section 4.3.3--3 of the Nuclear Standard. The default value is 0.3. Set A=0.0 to use the 1986 revision of the Standard.
4. In the **Rate of kinematic shift wrt creep strain** field, enter a value for H, the parameter equal to the rate of kinematic shift with respect to creep strain. This parameter is defined by Equation (7) of Section 4.3.2–1 of the Nuclear Standard. Set H=0.0 to use the 1986 revision of the Standard. If you omit this parameter, Abaqus determines the value of H according to Section 4.3.3–3 of the 1981 revision of the Standard.
5. If desired, toggle on **Invoke reset procedure** to invoke the optional α reset procedure described in Section 4.3.5 of the Nuclear Standard.
6. Click **OK** to return to the **Edit Material** dialog box.

Specifying cycled yield stress data for the ORNL model

You can use the **Suboption** editor to specify the tenth-cycle yield stress and hardening values for the ORNL constitutive model. This option is relevant only if you also follow the procedure described in *Using the Oak Ridge National Laboratory (ORNL) constitutive model in plasticity and creep calculations*."

1. Create a material model as described in *Using a linear kinematic cyclic hardening model to define classical metal plasticity*."
2. From the **Suboptions** menu in the **Edit Material** dialog box, select **Cycled Plastic**.

   A **Suboption Editor** appears.
3. Toggle on **Use temperature-dependent data** to define data that depend on temperature.

   A column labeled **Temp** appears in the **Data** table.
4. In the **Data** table, enter values for the yield stress, plastic strain, and, if applicable, temperature.

   For detailed information on how to enter data, see *Entering tabular data*.
5. Click **OK** to return to the **Edit Material** dialog box.

Specifying the annealing temperature of an elastic-plastic material

When the temperature of a material point exceeds its annealing temperature, Abaqus assumes that the material point loses its hardening memory. You can specify an annealing temperature and, if desired, define it in terms of field variables. See *Annealing or Melting*, for more information.

1. Create a material model as described in one of the following sections
   - *Using an isotropic hardening model to define classical metal plasticity*"
   - *Using a linear kinematic cyclic hardening model to define classical metal plasticity*"
   - *Using a nonlinear isotropic/kinematic cyclic hardening model to define classical metal plasticity*"
   - *Using the Johnson-Cook hardening model to define classical metal plasticity*"
2. From the **Suboptions** menu in the **Edit Material** dialog box, select **Anneal Temperature**.
   A **Suboption Editor** appears.
3. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the anneal temperature depends.
4. Enter the following data in the **Data** table:

   ## Anneal Temperature

   Value of the annealing temperature, θ.

   ## Field *n*

   Predefined field variables.

   For detailed information on how to enter data, see *Entering tabular data*.
5. Click **OK** to return to the **Edit Material** dialog box.

Defining tensile failure

The tensile failure model uses the hydrostatic pressure stress as a failure measure to model dynamic spall (the crumbling of a material) or a pressure cutoff.
For more information, see *Tensile Failure Model*.

1. Create a material model as described in one of the following sections:
   - *Using an isotropic hardening model to define classical metal plasticity*
   - *Using the Johnson-Cook hardening model to define classical metal plasticity*
2. From the **Suboptions** menu in the **Edit Material** dialog box, select **Tensile Failure**.
   A **Suboption Editor** appears.
3. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the hydrostatic cutoff stress depends.
4. Select **Use temperature-dependent data** to define the data that depend on temperature.
   A column labeled **Temp** appears in the **Data** table.
5. Specify the failure choice for the failed material points.
   - Select **Allow element deletion when the failure criterion is met** to allow element removal.
   - Specify behavior for the pressure stress and deviatoric stresses.
     1. From the **Pressure** list, select the behavior for the pressure stress.
        - Select **BRITTLE** to require the pressure stress to be compressive when the failure criterion is met.
        - Select **DUCTILE** to limit the pressure stress by the hydrostatic cutoff stress when the failure criterion is met.
     2. From the **Shear** list, select the behavior for the deviatoric stresses.
        - Select **BRITTLE** to set the deviatoric stress to zero when the failure criterion is met.
        - Select **DUCTILE** to specify that the deviatoric stresses are unaffected when the failure criterion is met.
6. Enter the following data in the **Data** table:

   #### Hydrostatic cutoff stress

   Value of the hydrostatic cutoff stress, σ_{cutoff} (positive in tension).

   #### Temp

   Temperature.

   #### Field *n*

   Predefined field variables.

   For detailed information on how to enter data, see *Entering tabular data*.
7. Click **OK** to return to the **Edit Material** dialog box.

Defining cap plasticity

Abaqus allows you to define yield surface parameters for elastic-plastic materials that use the modified Drucker-Prager\Cap plasticity model.
See *Modified Drucker-Prager/Cap Model* for more information.

In this section:

- *Specifying cap plasticity behavior*
- *Defining hardening parameters for a cap plasticity model*
- *Defining creep parameters for a cap plasticity model*

Specifying cap plasticity behavior

You can use the modified Drucker-Prager/Cap plasticity model to simulate geological materials that exhibit pressure-dependent yield. The addition of a cap yield surface helps control volume dilatancy when the material yields in shear and provides an inelastic hardening mechanism to represent plastic compaction. You can also define inelastic time-dependent (creep) behavior coupled with the plastic behavior in an Abaqus/Standard analysis.

For more information on cap plasticity, see *Modified Drucker-Prager/Cap Model*.

1. From the menu bar in the **Edit Material** dialog box, select **Mechanical->Plasticity->Cap Plasticity**.
   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Toggle on **Use temperature-dependent data** to define data that depend on temperature.
   A column labeled **Temp** appears in the **Data** table.
3. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the data depend.
4. In the **Data** table, enter the following data:

Material Cohesion

Material cohesion, d, in the p–t plane (Abaqus/Standard) or in the p–q plane (Abaqus/Explicit). (Units of FL^{-2}.)

Angle of Friction

Material angle of friction, β, in the p–t plane (Abaqus/Standard) or in the p–q plane (Abaqus/Explicit). Enter the value in degrees.

Cap Eccentricity

Cap eccentricity parameter, R. Its value must be greater than zero (typically $0.0001 \leq R \leq 1000.0$).

Init Yld Surf Pos

Initial cap yield surface position, $\varepsilon_{vol}^{pl}\big|_0$.

Transition Surf Rad

Transition surface radius parameter, α. Its value should be a small number compared to unity. If you leave this field blank, the default is 0.0 (i.e., no transition surface). If you include creep properties in the material model, you must set α equal to zero.

Flow Stress Ratio

The ratio of the flow stress in triaxial tension to the flow stress in triaxial compression, K. The value of K should be such that $0.778 \leq K \leq 1.0$. If you leave this field blank or enter a value of 0.0, Abaqus uses a value of 1.0 by default. If you include creep properties in the material model, you should set K equal to 1.0. This parameter applies only to Abaqus/Standard analyses.

Temp

Temperature.

Field *n*

Predefined field variables.

5. To define the hardening part of the cap plasticity model, select **Cap Hardening** from the **Suboptions** menu. See *Defining hardening parameters for a cap plasticity model*" for detailed instructions.
6. If you want to specify cap creep behavior, select one of the following options from the **Suboptions** menu:

   - Select **Cap Creep Cohesion** to choose a cohesion creep mechanism that follows the type of plasticity active in the shear-failure plasticity.
   - Select **Cap Creep Consolidation** to choose a consolidation mechanism that follows the type of plasticity active in the cap plasticity region.

   See *Defining creep parameters for a cap plasticity model*" for detailed instructions. For more information on cap creep behavior, see *Creep Formulation*.
7. Click **OK** to create the material and to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Defining hardening parameters for a cap plasticity model

The hardening curve specified for this model interprets yielding in the hydrostatic pressure sense: the hydrostatic pressure yield stress is defined as a tabular function of the volumetric inelastic strain, and, if desired, a function of temperature and other predefined field variables. The range of values for which you define p_b should be sufficient to include all values of effective pressure stress that the material will be subjected to during the analysis.

See *Modified Drucker-Prager/Cap Model*, for more information.

1. Create a material model as described in *Specifying cap plasticity behavior*."
2. From the **Suboptions** menu in the **Edit Material** dialog box, select **Cap Hardening**.

   A **Suboption Editor** appears.
3. Toggle on **Use temperature-dependent data** to define data that depend on temperature.

   A column labeled **Temp** appears in the **Data** table.
4. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the data depend.
5. In the **Data** table, enter the following data:

Yield Stress

Hydrostatic pressure yield stress. (The initial tabular value must be greater than zero, and values must increase with increasing volumetric inelastic strain.)

Vol Plas Strain

Absolute value of the corresponding volumetric inelastic strain.

Temp

Temperature.

Field *n*

Predefined field variables.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

6. Click **OK** to return to the **Edit Material** dialog box.

Defining creep parameters for a cap plasticity model

The cap creep model has two possible mechanisms that are active in different loading regions: one is a cohesion mechanism, which follows the type of plasticity active in the shear-failure plasticity region, and the other is a consolidation mechanism, which follows the type of plasticity active in the cap plasticity region.

For more information, see *Creep Formulation*.

1. Create a material model as described in *Specifying cap plasticity behavior*.
2. From the **Suboptions** menu in the **Edit Material** dialog box, select either **Cap Creep Cohesion** or **Cap Creep Consolidation**. (See *Creep Formulation* for detailed information on the two creep mechanisms.)

   A **Suboption Editor** appears.
3. Click the arrow to the right of the **Law** field, and select the creep law of your choice. See *Specifying Creep Laws* for the data required for each creep law.
4. To define behavior data that depend on temperature, toggle on **Use temperature-dependent data**.

   A column labeled **Temp** appears in the **Data** table.
5. To define behavior data that depend on field variables, click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables.

   Field variable columns appear in the **Data** table.
6. If you selected the **Time**, **SinghM**, or **Time Power** creep law, specify whether to use the total time or the creep time. See *Time-Dependent Behavior* for more information.
7. Click **OK** to return to the **Edit Material** dialog box.

Defining cast iron plasticity

The cast iron plasticity model describes the mechanical behavior of gray cast iron, a material whose microstructure consisting of graphite flakes in a steel matrix. The model definition includes the plastic Poisson's ratio and information on hardening under compression and tension. See *Cast Iron Plasticity*, for more information.

1. From the menu bar in the **Edit Material** dialog box, select **Mechanical->Plasticity->Cast Iron Plasticity**.

   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)

2. Display the **Plasticity** tabbed page, and do the following:
   a. Toggle on **Use temperature-dependent data** to define data that depend on temperature.

      A column labeled **Temp** appears in the **Data** table.

   b. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the data depend.
   c. Enter the following data in the **Data** table:

Plastic Poisson's Ratio

Value of the plastic "Poisson's ratio," ν_{pl}, where $-1.0 < \nu_{pl} \leq 0.5$. (Dimensionless.) The default value is 0.04.

Temp

Temperature, θ.

Field *n*

Predefined field variables.

For detailed information on how to enter data, see *Entering tabular data*.

3. Display the **Compression Hardening** tabbed page, and do the following:
   a. Toggle on **Use temperature-dependent data** to define data that depend on temperature.

      A column labeled **Temp** appears in the **Data** table.

   b. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the data depend.
   c. Enter the following data in the **Data** table:

Sigmac

Yield stress in compression, σ_c.

Epsilonc

Absolute value of the corresponding plastic strain. (The first tabular value entered must always be zero.)

Temp

Temperature.

Field *n*

Predefined field variables.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

4. Display the **Tension Hardening** tabbed page, and do the following:
   a. Toggle on **Use temperature-dependent data** to define data that depend on temperature.

      A column labeled **Temp** appears in the **Data** table.
   b. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the data depend.
   c. Enter the following data in the **Data** table:

Sigmat

Yield stress in uniaxial tension, σ_t.

Epsilont

Corresponding plastic strain. (The first tabular value entered must always be zero.)

Temp

Temperature.

Field *n*

Predefined field variables.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

5. Click **OK** to create the material and to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Defining clay plasticity

The clay plasticity model allows you to specify the plastic part of the material behavior for elastic-plastic materials that use the extended Cam-clay plasticity model.
See *Critical State (Clay) Plasticity Model* for more details.

In this section:

- *Specifying clay plasticity behavior*
- *Defining compressive clay hardening for a clay plasticity model*
- *Defining tensile clay hardening for a clay plasticity model*
- *Specifying softening regularization for a clay plasticity model*

Specifying clay plasticity behavior

The Abaqus/Standard clay plasticity model describes the inelastic response of cohesionless soils. This model provides a reasonable match to the experimentally observed behavior of saturated clays. You can define the inelastic material behavior by a yield function that depends on the three stress invariants, an associated flow assumption to define the plastic strain rate, and a strain hardening theory that changes the size of the yield surface according to the inelastic volumetric strain.

For more information, see *Critical State (Clay) Plasticity Model*.

1. From the menu bar in the **Edit Material** dialog box, select **Mechanical->Plasticity->Clay Plasticity**. (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Click the arrow to the right of the **Hardening** field, and select the hardening law form of your choice:
   - Select **Exponential** to specify an exponential hardening/softening law.
   - Select **Tabular** to specify a piecewise linear hardening/softening relationship.

   See *Hardening Law*, for more information.
3. If you selected the **Exponential** form of the hardening law, you have the option of entering a value for **Intercept**. This parameter corresponds to e_1, the intercept of the virgin consolidation line with the void ratio axis in a plot of void ratio versus the logarithm of pressure stress.

   If you specify a value for **Intercept**, Abaqus ignores any value specified for the initial yield surface size, a_0, in the **Data** table.
4. Toggle on **Use temperature-dependent data** to define data that depend on temperature.

   A column labeled **Temp** appears in the **Data** table.
5. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the data depend.
6. If you selected the **Exponential** form of the hardening law, enter the following data in the **Data** table:

Log Plas Bulk Mod

Logarithmic plastic bulk modulus, λ (dimensionless).

Stress Ratio

Stress ratio at critical state, M.

Init Yld Surf Size

Initial yield surface size, a_0 (units of FL^{-2}). Abaqus ignores this data item if you have specified a value for **Intercept**.

Wet Yld Surf Size

Parameter defining the size of the yield surface on the “wet” side of critical state, β. If this value is omitted or set to zero, a value of 1.0 is assumed.

Flow Stress Ratio

Ratio of the flow stress in triaxial tension to the flow stress in triaxial compression, K. $0.778 \le K \le 1.0$. If this value is left blank or set to zero, a value of 1.0 is assumed.

Temp

Temperature.

Field n

Predefined field variables.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

7. If you selected the **Tabular** form of the hardening law, enter the following data in the **Data** table:

Stress Ratio

Stress ratio at critical state, M.

Init Vol Plas Strain

Initial volumetric plastic strain, $\varepsilon_{\text{vol}}^{pl}\big|_0$ corresponding to $p_c|_0$.

Wet Yld Surf Size

Parameter defining the size of the yield surface on the "wet" side of critical state, β. If this value is omitted or set to zero, a value of 1.0 is assumed.

Flow Stress Ratio

Ratio of the flow stress in triaxial tension to the flow stress in triaxial compression, K. $0.778 \le K \le 1.0$. If this value is left blank or set to zero, a value of 1.0 is assumed.

Temp

Temperature.

Field n

Predefined field variables.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

8. If you selected the **Tabular** form of the hardening law, select **Compressive Clay Hardening** from the **Suboptions** menu to provide the hydrostatic compression yield stress as a function of volumetric plastic strain to define piecewise linear hardening/softening of the Cam-clay plasticity yield surface. See *Defining compressive clay hardening for a clay plasticity model*" for detailed instructions.

9. If you selected the **Tabular** form of the hardening law, select **Tensile Clay Hardening** from the **Suboptions** menu to provide the hydrostatic tension yield stress as a function of volumetric plastic strain to define piecewise linear hardening/softening of the Cam-clay plasticity yield surface. See *Defining tensile clay hardening for a clay plasticity model*" for detailed instructions.
10. If desired, select **Potential** from the **Suboptions** menu to specify anisotropic yield behavior. See *Defining anisotropic yield and creep*" for more information.
11. If desired, select **Softening Regularization** from the **Suboptions** menu to specify a regularization scheme to mitigate potential mesh independence of the results. See *Specifying softening regularization for a clay plasticity model*" for detailed instructions.
12. Click **OK** to create the material and to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Defining compressive clay hardening for a clay plasticity model

The **Suboption Editor** allows you to provide the hydrostatic compression yield stress as a function of volumetric plastic strain to define piecewise linear hardening/softening of the Cam-clay plasticity yield surface. For more information on this form of the hardening law, see *Piecewise Linear Form*.

1. Create a material model as described in *Specifying clay plasticity behavior*."
2. From the **Suboptions** menu in the **Edit Material** dialog box, select **Compressive Clay Hardening**.

   A **Suboption Editor** appears.
3. Toggle on **Use temperature-dependent data** to define data that depend on temperature.

   A column labeled **Temp** appears in the **Data** table.
4. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the data depend.
5. In the **Data** table, enter the following data:

   ### Yield Stress

   Value of the hydrostatic pressure stress at yield, p_c. p_c is given as a positive value and must increase with increasing volumetric plastic strain.

   ### Vol Plas Strain

   Absolute value of the corresponding compressive volumetric plastic strain. (The first tabular value must always be zero.)

   ### Temp

   Temperature.

   ### Field *n*

   Predefined field variables.

   You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.
6. Click **OK** to return to the **Edit Material** dialog box.

Defining tensile clay hardening for a clay plasticity model

The **Suboption Editor** allows you to provide the hydrostatic tensile yield stress as a function of volumetric plastic strain to define piecewise linear hardening/softening of the Cam-clay plasticity yield surface. For more information on this form of the hardening law, see *Piecewise Linear Form*.

1. Create a material model as described in *Specifying clay plasticity behavior*."
2. From the **Suboptions** menu in the **Edit Material** dialog box, select **Tensile Clay Hardening**.

   A **Suboption Editor** appears.
3. Toggle on **Use temperature-dependent data** to define data that depend on temperature.

   A column labeled **Temp** appears in the **Data** table.
4. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the data depend.
5. In the **Data** table, enter the following data:

   #### Yield Stress

   Value of the hydrostatic pressure stress at yield, p_t. p_t can be zero or a negative value and must decrease with increasing volumetric plastic strain.

   #### Vol Plas Strain

   Absolute value of the corresponding compressive volumetric plastic strain. (The first tabular value must always be zero.)

   #### Temp

   Temperature.

   #### Field *n*

   Predefined field variables.

   You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.
6. Click **OK** to return to the **Edit Material** dialog box.

Specifying softening regularization for a clay plasticity model

The **Suboption Editor** allows you to specify a regularization scheme to mitigate potential mesh dependence of results in the Cam-clay plasticity model in the event that it exhibits strain localization with increasing plastic deformation For more information, see *Softening Regularization*.

1. Create a material model as described in *Specifying clay plasticity behavior*."
2. From the **Suboptions** menu in the **Edit Material** dialog box, select **Softening Regularization**.

   A **Suboption Editor** appears.
3. Toggle on **Use temperature-dependent data** to define data that depend on temperature.

   A column labeled **Temp** appears in the **Data** table.
4. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the data depend.
5. In the **Data** table, enter the following data:

Crack Band Length

Crack band length, $l_c^{(m)}$. This value must be greater than zero.

Exponent

Exponent, n_r. This value must be greater than zero.

Bound

Bound on the magnitude of regularization, f_{max}. This value must be greater than zero.

Temp

Temperature.

Field *n*

Predefined field variables.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

6. Click **OK** to return to the **Edit Material** dialog box.

Defining concrete damaged plasticity

The concrete damaged plasticity model provides a general capability for modeling concrete and other quasi-brittle materials in all types of structures.
This model uses concepts of isotropic damaged elasticity in combination with isotropic tensile and compressive plasticity to represent the inelastic behavior of concrete. See *Concrete Damaged Plasticity*, for more information.

In this section:

- *Defining a concrete damaged plasticity model*
- *Defining concrete compression damage*
- *Defining concrete tension damage*

Defining a concrete damaged plasticity model

The concrete damaged plasticity model is based on the assumption of scalar (isotropic) damage and is designed for applications in which the concrete is subjected to arbitrary loading conditions, including cyclic loading. The model takes into consideration the degradation of the elastic stiffness induced by plastic straining both in tension and compression. It also accounts for stiffness recovery effects under cyclic loading.

For more information, see *Concrete Damaged Plasticity*.

1. From the menu bar in the **Edit Material** dialog box, select **Mechanical->Plasticity->Concrete Damaged Plasticity**.

   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Click the **Plasticity** tab, if necessary, to display the **Plasticity** tabbed page.
3. Toggle on **Use temperature-dependent data** to define data that depend on temperature.

   A column labeled **Temp** appears in the **Data** table.
4. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the data depend.
5. Enter the following data in the **Data** table:

Dilation Angle

Dilation angle, ψ, in the *p*–*q* plane. Enter the value in degrees.

Eccentricity

Flow potential eccentricity, ϵ. The eccentricity is a small positive number that defines the rate at which the hyperbolic flow potential approaches its asymptote. The default is $\epsilon = 0.1$.

fb0/fc0

σ_{b0}/σ_{c0}, the ratio of initial equibiaxial compressive yield stress to initial uniaxial compressive yield stress. The default value is 1.16

K

K_c, the ratio of the second stress invariant on the tensile meridian, $q_{(\mathrm{TM})}$, to that on the compressive meridian, $q_{(\mathrm{CM})}$, at initial yield for any given value of the pressure invariant *p* such that the maximum principal stress is negative, $\widehat{\sigma}_{\max} < 0$. It must satisfy the condition $0.5 < K_c \leq 1.0$. The default value is $2/3$.

Viscosity Parameter

Viscosity parameter, μ, used for the visco-plastic regularization of the concrete constitutive equations in Abaqus/Standard analyses. This parameter is ignored in Abaqus/Explicit. The default value is 0.0. (Units of T.)

Temp

Temperature.

Field *n*

Predefined field variables.

6. Click the **Compressive Behavior** tab to display the **Compressive Behavior** tabbed page. (For information on compressive hardening, see *Defining Compressive Behavior*.)
7. Toggle on **Use strain-rate-dependent data** if the compressive stress data are a function of strain rate.
8. Toggle on **Use temperature-dependent data** to define data that depend on temperature.

   A column labeled **Temp** appears in the **Data** table.
9. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the data depend.
10. Enter the following data in the **Data** table:

Yield Stress

Yield stress in compression, σ_c. (Units of $\mathbf{FL^{-2}}$.)

Inelastic Strain

Inelastic (crushing) strain, $\tilde{\varepsilon}_c^{in}$.

Rate

Inelastic (crushing) strain rate, $\dot{\tilde{\varepsilon}}_c^{in}$. (Units of $\mathbf{T^{-1}}$.)

Temp

Temperature.

Field *n*

Predefined field variables.

11. If desired, select **Compression Damage** from the **Suboptions** menu to specify damage in tabular form. (If you omit damage data, the model behaves as a plasticity model.) See *Defining concrete compression damage*" for details.
12. Click the **Tensile Behavior** tab to display the **Tensile Behavior** tabbed page. (For information on tension stiffening, see *Defining Tension Stiffening*.)
13. Click the arrow to the right of the **Type** field, and select a method for defining the postcracking behavior:
    - Select **Strain** to specify the postcracking behavior by entering the postfailure stress/cracking-strain relationship.
    - Select **Displacement** to define the postcracking behavior by entering the postfailure stress/cracking-displacement relationship.
    - Select **GFI** to define the postcracking behavior by entering the failure stress and the fracture energy.
14. Toggle on **Use strain-rate-dependent data** if the postcracking stress depends on strain rate.
15. Toggle on **Use temperature-dependent data** to define data that depend on temperature.

    A column labeled **Temp** appears in the **Data** table.

16. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the data depend.
17. In the **Data** table, enter the data relevant to your **Type** choice from Step 13 (not all of the following will apply):

Yield Stress

If you selected **Strain** or **Displacement** from the list of **Type** options, enter the remaining direct stress after cracking, σ_t. (Units of $\mathbf{FL^{-2}}$.)

If you selected **GFI** from the list of **Type** options, enter the failure stress, σ_{t0}. (Units of $\mathbf{FL^{-2}}$.)

Cracking Strain

Direct cracking strain, $\tilde{\varepsilon}_t^{ck}$.

Displacement

Direct cracking displacement, u_t^{ck}. (Units of L.)

Fracture Energy

Fracture energy, G_f. (Units of $\mathbf{FL^{-1}}$.)

Rate

If you selected **Strain** from the list of **Type** options, enter the direct cracking strain rate, $\dot{\tilde{\varepsilon}}_t^{ck}$. (Units of $\mathbf{T^{-1}}$.)

If you selected **Displacement** or **GFI** from the list of **Type** options, enter the direct cracking displacement rate, $\dot{u}_t^{ck}$. (Units of $\mathbf{LT^{-1}}$.)

Temp

Temperature.

Field *n*

Predefined field variables.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

18. If desired, select **Tension Damage** from the **Suboptions** menu to specify damage in tabular form. (If you omit damage data, the model behaves as a plasticity model.) See *Defining concrete tension damage*" for details.
19. Click **OK** to create the material and to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Defining concrete compression damage

You can define the uniaxial compression damage variable, d_c, as a tabular function of inelastic (crushing) strain. For more information, see *Defining Damage and Stiffness Recovery*.

1. Create a material model as described in *Defining a concrete damaged plasticity model*."
2. From the **Suboptions** menu on the **Compressive Behavior** tabbed page, select **Compression Damage**.

   A **Suboption Editor** appears.
3. In the **Tension recovery** field, enter a value for the stiffness recovery factor w_t, which determines the amount of tension stiffness that is recovered as the loading changes from compression to tension.

   If $w_t = 1$, the material fully recovers the tensile stiffness; if $w_t = 0$, there is no stiffness recovery.

   Intermediate values of w_t $(0 \le w_t \le 1)$ result in partial recovery of the tensile stiffness. The default value is 0.0.
4. Toggle on **Use temperature-dependent data** to define data that depend on temperature.

   A column labeled **Temp** appears in the **Data** table.
5. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the data depend.
6. Enter the following data in the **Data** table:

Damage Parameter

Compressive damage variable, d_c.

Inelastic Strain

Inelastic (crushing) strain, $\tilde{\varepsilon}_c^{in}$.

Temp

Temperature.

Field *n*

Predefined field variables.

7. Click **OK** to return to the **Edit Material** dialog box.

Defining concrete tension damage

You can define the uniaxial tension damage variable, d_t, as a tabular function of either cracking strain or cracking displacement.For more information, see *Defining Damage and Stiffness Recovery*.

1. Create a material model as described in *Defining a concrete damaged plasticity model*."
2. From the **Suboptions** menu in the **Tensile Behavior** tabbed page, select **Tension Damage**.
   A **Suboption Editor** appears.
3. Click the arrow to the right of the **Type** field, and select a method for defining the tensile damage variable:
   - Select **Strain** to specify the tensile damage variable as a function of cracking strain.
   - Select **Displacement** to specify the tensile damage variable as a function of cracking displacement.
4. In the **Compression recovery** field, enter a value for the stiffness recovery factor, w_c, which determines the amount of compression stiffness that is recovered as the loading changes from tension to compression.
   If $w_c = 1$, the material fully recovers the compressive stiffness; if $w_c = 0$, there is no stiffness recovery.
   Intermediate values of w_c $(0 \le w_c \le 1)$ result in partial recovery of the compressive stiffness. The default value is **1.0**, which corresponds to the assumption that as cracks close the compressive stiffness is unaffected by tensile damage.
5. Toggle on **Use temperature-dependent data** to define data that depend on temperature.
   A column labeled **Temp** appears in the **Data** table.
6. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the data depend.
7. In the **Data** table, enter the data relevant to your **Type** selection from Step 3 (not all of the following will apply):

Damage Parameter

Tensile damage variable, d_t.

Cracking Strain

Direct cracking strain, $\tilde{\varepsilon}_t^{ck}$.

Displacement

Direct cracking displacement, u_t^{ck}. (Units of L.)

Temp

Temperature.

Field *n*

Predefined field variables.

8. Click **OK** to return to the **Edit Material** dialog box.

Defining concrete smeared cracking

You can use the concrete smeared cracking model to define the properties of plain concrete outside the elastic range in an Abaqus/Standard analysis.
For more information, see *Concrete Smeared Cracking*.

In this section:

- *Specifying a concrete smeared cracking model*
- *Defining tension stiffening for a concrete smeared cracking model*
- *Defining shear retention for a concrete smeared cracking model*
- *Defining the shape of the failure surface for a concrete smeared cracking model*

Specifying a concrete smeared cracking model

The concrete smeared cracking model allows you to define concrete behavior for relatively monotonic loadings under fairly low confining pressures. Abaqus assumes that cracking is the most important aspect of the behavior, and representation of cracking and postcracking behavior dominates the modeling. For more information, see *Concrete Smeared Cracking*.

1. From the menu bar in the **Edit Material** dialog box, select **Mechanical->Plasticity->Concrete Smeared Cracking**.

   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Toggle on **Use temperature-dependent data** to define data that depend on temperature.

   A column labeled **Temp** appears in the **Data** table.
3. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the data depend.
4. Enter the following data in the **Data** table:

Comp Stress

Absolute value of compressive stress. (Units of FL^{-2}.)

Plastic Strain

Absolute value of plastic strain. The first stress-strain point given at each value of temperature and field variable must be at zero plastic strain and will define the initial yield point for that temperature and field variable.

Temp

Temperature.

Field *n*

Predefined field variables.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

5. Select **Tension Stiffening** from the **Suboptions** menu to model the postfailure behavior for direct straining across cracks. See *Defining tension stiffening for a concrete smeared cracking model*" for details.
6. If desired, select **Shear Retention** from the **Suboptions** menu to define how shear stiffness diminishes as the concrete cracks. See *Defining shear retention for a concrete smeared cracking model*" for details.
7. If desired, select **Failure Ratios** from the **Suboptions** menu to define the shape of the failure surface. See *Defining the shape of the failure surface for a concrete smeared cracking model*" for details.
8. Click **OK** to create the material and to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Defining tension stiffening for a concrete smeared cracking model

You can model postfailure behavior for direct straining across cracks with tension stiffening, which allows you to define the strain-softening behavior for cracked concrete. This behavior also allows the effects of the reinforcement interaction with concrete to be simulated in a simple manner.

You can specify tension stiffening by means of a postfailure stress-strain relation or by applying a fracture energy cracking criterion. See *Tension Stiffening*, for more information.

Tension stiffening information is required for the concrete smeared cracking model.

1. Create a material model as described in *Specifying a concrete smeared cracking model*."
2. From the **Suboptions** menu, select **Tension Stiffening**.

   A **Suboption Editor** appears.
3. Click the arrow to the right of the **Type** field, and select a method for defining postcracking behavior:
   - Select **Displacement** to enter the displacement at which a linear loss of strength after cracking gives zero stress.
   - Select **Strain** to enter the postfailure stress-strain relationship directly.
4. Toggle on **Use temperature-dependent data** to define data that depend on temperature.

   A column labeled **Temp** appears in the **Data** table.
5. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the data depend.
6. In the **Data** table, enter the data relevant to your **Type** choice from Step 3 (not all of the following will apply):

   #### Disp

   Displacement, u_0, at which a linear loss of strength after cracking gives zero stress. (Units of L.)

   #### sigma/sigma_c

   Fraction of remaining stress to stress at cracking.

   #### epsilon-epsilon_c

   Absolute value of the direct strain minus the direct strain at cracking.

   #### Temp

   Temperature.

   #### Field *n*

   Predefined field variables.

   You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.
7. Click **OK** to return to the **Edit Material** dialog box.

Defining shear retention for a concrete smeared cracking model

As concrete cracks, its shear stiffness is diminished. You can define this effect by specifying the reduction in the shear modulus as a function of the opening strain across the crack. You can also specify a reduced shear modulus for closed cracks. See *Cracked Shear Retention*, for more information.

If you do not define shear retention for a concrete smeared cracking model, Abaqus/Standard automatically assumes that the shear response is unaffected by cracking (full shear retention). This assumption is often reasonable: in many cases, the overall response is not strongly dependent on the amount of shear retention.

1. Create a material model as described in *Specifying a concrete smeared cracking model*."
2. From the **Suboptions** menu, select **Shear Retention**.

   A **Suboption Editor** appears.
3. Toggle on **Use temperature-dependent data** to define data that depend on temperature.

   A column labeled **Temp** appears in the **Data** table.
4. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the data depend.
5. Enter the following data in the **Data** table:

Rho_close

The multiplying factor, ϱ^{close}, that defines the modulus for shearing of closed cracks as a fraction of the elastic shear modulus of the uncracked concrete. The default value is 1.0.

Eps_max

The maximum direct strain across the crack, ε^{max}. The default value is a very large number (full shear retention).

Temp

Temperature.

Field *n*

Predefined field variables.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

6. Click **OK** to return to the **Edit Material** dialog box.

Defining the shape of the failure surface for a concrete smeared cracking model

You can specify failure ratios to define the shape of the failure surface. If you do not define the shape of the failure surface, Abaqus uses the default values listed below.

1. Create a material model as described in *Specifying a concrete smeared cracking model*."
2. From the **Suboptions** menu, select **Failure Ratios**.

   A **Suboption Editor** appears.
3. Toggle on **Use temperature-dependent data** to define data that depend on temperature.

   A column labeled **Temp** appears in the **Data** table.
4. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the data depend.
5. Enter the following data in the **Data** table:

Ratio 1

Ratio of the ultimate biaxial compressive stress to the uniaxial compressive ultimate stress. The default value is 1.16.

Ratio 2

Absolute value of the ratio of uniaxial tensile stress at failure to the uniaxial compressive stress at failure. The default value is 0.09.

Ratio 3

Ratio of the magnitude of a principal component of plastic strain at ultimate stress in biaxial compression to the plastic strain at ultimate stress in uniaxial compression. The default value is 1.28.

Ratio 4

Ratio of the tensile principal stress value at cracking in plane stress, when the other nonzero principal stress component is at the ultimate compressive stress value, to the tensile cracking stress under uniaxial tension. The default value is 1/3.

Temp

Temperature.

Field *n*

Predefined field variables.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

6. Click **OK** to return to the **Edit Material** dialog box.

Defining crushable foam plasticity

The crushable foam model allows you to define not only crushable foams that are typically used as energy absorption structures, but also other crushable materials other than foams.
See *Crushable Foam Plasticity Models* for more information.

In this section:

- *Specifying a crushable foam model*
- *Defining crushable foam hardening*
- *Defining rate dependence for a crushable foam plasticity model*

Specifying a crushable foam model

You can use the crushable foam model to model the enhanced ability of a foam material to deform in compression due to cell wall buckling processes.
This model is based on the assumption that the resulting deformation is not recoverable instantaneously and can be idealized as plastic for short duration events. See *Crushable Foam Plasticity Models*, for more information.

1. From the menu bar in the **Edit Material** dialog box, select **Mechanical->Plasticity->Crushable Foam**.

   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)

2. Click the arrow to the right of the **Hardening** field, and select a hardening model:

   - Select **Volumetric** to specify a model that assumes that the yield surface is controlled by the volumetric compacting plastic strain experienced by the material.
   - Select **Isotropic** to specify a model that uses a yield surface that is an ellipse centered at the origin in the *p–q* stress plane. The yield surface evolves in a self-similar manner, and the evolution is governed by the equivalent plastic strain.

3. Toggle on **Use temperature-dependent data** to define data that depend on temperature.

   A column labeled **Temp** appears in the **Data** table.

4. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the data depend.
5. In the **Data** table, enter the data relevant to your **Hardening** choice from Step 2 (not all of the following will apply):

Compression Yield Stress Ratio

Yield stress ratio for compression loading, $k = \sigma_c^0/p_c^0$; $0 < k < 3$. Enter the ratio of initial yield stress in uniaxial compression to initial yield stress in hydrostatic compression.

Hydrostatic Yield Stress Ratio

Yield stress ratio for hydrostatic loading, $k_t = p_t/p_c^0$; $k_t \geq 0$. Enter the ratio of yield stress in hydrostatic tension to initial yield stress in hydrostatic compression, provided as a positive value. The default value is 1.0.

Plastic Poisson's Ratio

Plastic Poisson's ratio, ν_p; $-1 < \nu_p \leq 0.5$.

Temp

Temperature.

Field *n*

Predefined field variables.

You might need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

6. Select **Foam Hardening** from the **Suboptions** menu to define hardening data for the crushable foam model. See *Defining crushable foam hardening*" for details.
7. If desired, select **Rate Dependent** from the **Suboptions** menu to specify strain-rate-dependent material behavior. See *Defining rate dependence for a crushable foam plasticity model*" for details.
8. Click **OK** to create the material and to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Defining crushable foam hardening

You must provide crushable foam hardening data to complete a crushable foam plasticity definition. See *Crushable Foam Plasticity Models*, for more information.

1. Create a material model as described in *Specifying a crushable foam model*."
2. From the **Suboptions** menu, select **Crushable Foam Hardening**.

   A **Suboption Editor** appears.
3. Toggle on **Use temperature-dependent data** to define data that depend on temperature.

   A column labeled **Temp** appears in the **Data** table.
4. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the data depend.
5. Enter the following data in the **Data** table:

Yield Stress

Yield stress in uniaxial compression, σ_c, provided as a positive value.

Vol Plastic Strain

Absolute value of the corresponding plastic strain. (The first tabular value entered must always be zero.)

Temp

Temperature.

Field *n*

Predefined field variables.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

6. Click **OK** to return to the **Edit Material** dialog box.

Defining rate dependence for a crushable foam plasticity model

As strain rates increase, many materials show an increase in the yield stress. For many crushable foam materials this increase in yield stress becomes important when the strain rates are in the range of 0.1–1 per second and can be very important if the strain rates are in the range of 10–100 per second, as commonly occurs in high-energy dynamic events.

For more information on strain rate dependence, see *Crushable Foam Plasticity Models*, and *Rate-Dependent Yield*.

1. Create a material model as described in *Specifying a crushable foam model*."
2. From the **Suboptions** menu in the **Edit Material** dialog box, select **Rate Dependent**.

   A **Suboption Editor** appears.
3. Click the arrow to the right of the **Hardening** field, and select a method for defining hardening dependencies:
   - Select **Power Law** to define yield stress ratios with the Cowper-Symonds overstress law.
   - Select **Tabular** to enter yield stress ratios directly in tabular form as a function of equivalent plastic strain rates.
4. If applicable, toggle on **Use temperature-dependent data** to define data that depend on temperature.

   A column labeled **Temp** appears in the **Data** table.
5. If applicable, click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the data depend.
6. If you selected **Power Law** from the list of **Hardening** options, enter the following data in the **Data** table:

Mulitiplier

Material parameter, D.

Exponent

Material parameter, n.

Temp

Temperature.

Field *n*

Predefined field variables.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

7. If you selected **Yield Ratio** from the list of **Hardening** options, enter the following data in the **Data** table:

Yld Stress Ratio

Yield stress ratio, $R = \bar{\sigma}/\sigma^0$.

Eq Plastic Strain Rate

Equivalent plastic strain rate, $\dot{\bar{\varepsilon}}^{pl}$ (or $\left|\dot{\varepsilon}^{pl}_{axial}\right|$, the absolute value of the axial plastic strain rate in uniaxial compression, for the crushable foam model).

Temp

Temperature.

Field *n*

Predefined field variables.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

8. Click **OK** to return to the **Edit Material** dialog box.

Defining Drucker-Prager plasticity

You can define a Drucker-Prager model to model frictional materials, which are typically granular-like soils and rock and exhibit pressure-dependent yield.
See *Extended Drucker-Prager Models* for more information.

In this section:

- *Defining a Drucker-Prager model*
- *Defining Drucker-Prager hardening*
- *Defining Drucker-Prager creep*
- *Specifying triaxial test data for a Drucker-Prager material model*

Defining a Drucker-Prager model

The extended Drucker-Prager family of plasticity models describes the behavior of granular materials or polymers in which the yield behavior depends on the equivalent pressure stress. The inelastic deformation may sometimes be associated with frictional mechanisms such as sliding of particles across each other. See *Extended Drucker-Prager Models*, for more information.

1. From the menu bar in the **Edit Material** dialog box, select **Mechanical->Plasticity->Drucker Prager**. (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Click the arrow to the right of the **Shear criterion** field, and specify which yield criterion you want to define. See the following sections for more information:
   - *Linear Drucker-Prager Model*
   - *Hyperbolic and General Exponent Models*
3. If you are performing an Abaqus/Standard analysis, enter a value for the **Flow potential eccentricity**, ϵ.

   The eccentricity is a small positive number that defines the rate at which the hyperbolic flow potential approaches its asymptote. The default is $\epsilon = 0.1$ for the exponent model, and if $\psi = \beta$, it is set to $\epsilon = (d'|_0 - p_t|_0 \tan\beta) / (\bar{\sigma}|_0 \tan\beta)$ for the hyperbolic model to ensure associated flow. See *Extended Drucker-Prager Models*, for more information.
4. If you selected **Exponent Form** from the list of **Shear criterion** options, you can toggle on **Use Suboption Triaxial Test Data** to request that Abaqus compute the material constants from triaxial test data at different levels of confining pressure. See *General Exponent Model*, for more information.
5. Toggle on **Use temperature-dependent data** to define data that depend on temperature.

   A column labeled **Temp** appears in the **Data** table.
6. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the data depend.
7. In the **Data** table, enter the data relevant to your **Shear criterion** choice (not all of the following will apply):

Angle of Friction

If you selected **Linear** from the list of **Shear criterion** options, enter the material angle of friction, β, in the *p–t* plane.

If you selected **Hyperbolic** from the list of **Shear criterion** options, enter the material angle of friction, β, at high confining pressure in the *p–q* plane.

Enter the value in degrees.

Flow Stress Ratio

The ratio of the flow stress in triaxial tension to the flow stress in triaxial compression, *K*.

$0.778 \le K \le 1.0$. If you leave this field blank or enter a value of 0.0 is entered, Abaqus uses a default of 1.0. If you plan to define creep behavior, set *K* to 1.0.

Dilation Angle

If you selected **Linear** from the list of **Shear criterion** options, enter the dilation angle, ψ, in the p–t plane.

If you selected **Hyperbolic** or **Exponent Form** from the list of **Shear criterion** options, enter the dilation angle, ψ, at high confining pressure in the p–q plane.

Enter the value in degrees.

Init Tension

Initial hydrostatic tension strength, $p_t|_0$. (Units of FL^{-2}.)

a

Material constant a.

b

Exponent b. To ensure a convex yield surface, $b \geq 1$.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

8. Select **Drucker Prager Hardening** from the **Suboptions** menu to specify hardening data for the Drucker-Prager model. See *Defining Drucker-Prager hardening*" for details.
9. If desired, select **Drucker Prager Creep** from the **Suboptions** menu to specify creep data for the Drucker-Prager model. This option is valid only if you have selected **Linear** from the list of **Shear criterion** options and are performing an Abaqus/Standard analysis. See *Defining Drucker-Prager creep*" for details.
10. If you toggled on **Use Suboption Triaxial Test Data** in Step 4, select **Triaxial Test Data** from the **Suboptions** menu to enter the triaxial test data. See *Specifying triaxial test data for a Drucker-Prager material model*" for details.
11. Click **OK** to create the material and to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Defining Drucker-Prager hardening

Use the **Suboption Editor** to specify hardening data for a Drucker-Prager model. For more information on Drucker-Prager hardening, see *Hardening and Rate Dependence*.

1. Create a material model as described in *Defining a Drucker-Prager model*."
2. From the **Suboptions** menu in the **Edit Material** dialog box, select **Drucker Prager Hardening**.

   A **Suboption Editor** appears.
3. Select the **Hardening behavior type** of your choice.

   The evolution of the yield surface with plastic deformation is described in terms of the equivalent stress $\bar{\sigma}$, which you can choose to be either the uniaxial **Compression** yield stress, the uniaxial **Tension** yield stress, or the **Shear** (cohesion) yield stress
4. Toggle on **Use strain-rate-dependent data** if you want enter data showing yield stress values versus equivalent plastic strain at different equivalent plastic strain rates.

   A **Rate** column appears in the **Data** table.

   Alternatively, if you want to define strain rate dependence using yield stress ratios, you must select **Rate Dependent** from the **Suboptions** menu in the **Edit Material** dialog box. See *Defining rate-dependent yield with yield stress ratios*" for details. For background information on rate dependence, see *Rate-Dependent Yield*.
5. Toggle on **Use temperature-dependent data** to define data that depend on temperature.

   A column labeled **Temp** appears in the **Data** table.
6. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the data depend.
7. Enter the following data in the **Data** table:

Yield Stress

Yield stress.

Abs Plastic Strain

Absolute value of the corresponding plastic strain. (The first tabular value entered must always be zero.)

Rate

Equivalent plastic strain rate, $\dot{\bar{\varepsilon}}^{pl}$, for which this hardening curve applies.

Temp

Temperature.

Field *n*

Predefined field variables.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

8. Click **OK** to return to the **Edit Material** dialog box.

Defining Drucker-Prager creep

You can define classical "creep" behavior of materials that exhibit plasticity according to the extended Drucker-Prager models in Abaqus/Standard analyses. The creep behavior in such materials is intimately tied to the plasticity behavior (through the definitions of creep flow potentials and definitions of test data), so you must include both Drucker-Prager plasticity and Drucker-Prager hardening data in the material definition.

The creep data that you enter must be consistent with the **Hardening behavior type** that you select when defining Drucker-Prager hardening (see *Defining Drucker-Prager hardening*" for details).

For more information, see *Creep Models for the Linear Drucker-Prager Model*.

1. Create a material model as described in *Defining a Drucker-Prager model*."
2. From the **Suboptions** menu in the **Edit Material** dialog box, select **Drucker Prager Creep**.

   A **Suboption Editor** appears.
3. Click the arrow to the right of the **Law** field, and select the creep law option of your choice:
   - Select **Strain** to choose a strain hardening power law.
   - Select **Time** to choose a time hardening power law
   - Select **SinghM** to choose a Singh-Mitchell type law.
   - Select **User** to specify the creep law with user subroutine *CREEP*.

   For more information, see *Specifying a Creep Law*.
4. Toggle on **Use temperature-dependent data** to define data that depend on temperature.

   A column labeled **Temp** appears in the **Data** table.
5. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the data depend.
6. If you selected either the **Strain** or the **Time** creep law option, enter the following data in the **Data** table:

   #### A, n, and m

   Creep material parameters.

   #### Temp

   Temperature.

   #### Field *n*

   Predefined field variables.

   You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.
7. If you selected the **SinghM** creep law option, enter the following data in the **Data** table:

   #### A, alpha, m, and t1

   Creep material parameters A, α, t_1, and m.

Temp

Temperature.

Field *n*

Predefined field variables.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

8. Click **OK** to return to the **Edit Material** dialog box.

Specifying triaxial test data for a Drucker-Prager material model

Abaqus can use triaxial test data to calibrate the material parameters that define the **Exponent Form** of Drucker-Prager plasticity. See *General Exponent Model*, for more information.

1. Create a material model as described in *Defining a Drucker-Prager model*."
2. From the **Suboptions** menu in the **Edit Material** dialog box, select **Triaxial Test Data**.

   A **Suboption Editor** appears.
3. Enter values for **Material constant a**, **Material constant b**, and **Material constant pt** if they are known and held fixed at the input value. Alternatively, you can leave one or more of the fields blank if you want Abaqus to calibrate the values from the triaxial test data.
4. Enter the following data in the **Data** table:

   ## Confining Stress

   Sign and magnitude of the confining stress, $\sigma_1 = \sigma_2$.

   ## Loading Dirn Stress

   Sign and magnitude of the stress in the loading direction, σ_3.

   For detailed information on how to enter data, see *Entering tabular data*.
5. Click **OK** to return to the **Edit Material** dialog box.

Defining Mohr-Coulomb plasticity

You can use the Mohr-Coulomb plasticity model for geotechnical engineering design applications. The model uses the classical Mohr-Coloumb yield criterion: a straight line in the meridional plane and an irregular hexagonal section in the deviatoric plane. However, the Abaqus Mohr-Coulomb model has a completely smooth flow potential instead of the classical hexagonal pyramid: the flow potential is a hyperbola in the meridional plane, and it uses the smooth deviatoric section proposed by Menétrey and Willam. See *Mohr-Coulomb Plasticity*, for more information.

1. From the menu bar in the **Edit Material** dialog box, select **Mechanical->Plasticity->Mohr Coulomb Plasticity**.

   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Click the **Plasticity** tab, if necessary, to display the **Plasticity** tabbed page.
3. Choose how you want to define **Deviatoric eccentricity**, *e*:
   - Select **Calulated default** to allow Abaqus to calculate the deviatoric eccentricity as $e = (3 - \sin\phi) / (3 + \sin\phi)$, where ϕ is the Mohr-Coulomb **Friction Angle** that you specify in the **Data** table.
   - Select **Specify**, and enter a value for deviatoric eccentricity in the field provided. The range of values *e* can have is $1/2 < e \leq 1$.
4. Enter a value for **Meridional eccentricity**, ϵ.

   The meridional eccentricity is a small positive number that defines the rate at which the flow potential approaches its asymptote.
5. Toggle on **Use temperature-dependent data** to define data that depend on temperature.

   A column labeled **Temp** appears in the **Data** table.
6. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the data depend.
7. Enter the following data in the **Data** table:

   #### Friction Angle

   Friction angle, ϕ, at high confining pressure in the p–$R_{mc}q$ plane. Enter the value in degrees.

   #### Dilation Angle

   Dilation angle, ψ, at high confining pressure in the p–$R_{mw}q$ plane. Enter the value in degrees.

   #### Temp

   Temperature.

   #### Field *n*

   Predefined field variables.

   You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.
8. Click the **Cohesion** tab to display the **Cohesion** tabbed page.
9. Toggle on **Use temperature-dependent data** to define data that depend on temperature.

A column labeled **Temp** appears in the **Data** table.

10. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the data depend.
11. Enter the following data in the **Data** table:

Cohesion Yield Stress

Cohesion yield stress.

Abs Plastic Strain

Absolute value of the corresponding plastic strain. (The first tabular value entered must always be zero.)

Temp

Temperature.

Field *n*

Predefined field variables.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

12. If desired, toggle on **Specify tension cutoff** and click the **Tension Cutoff** tab to specify tension cutoff stress data to limit the load-carrying capacity of the material model near the tensile region.
13. Toggle on **Use temperature-dependent data** to define data that depend on temperature.

    A column labeled **Temp** appears in the **Data** table.
14. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the data depend.
15. Enter the following data in the **Data** table:

Tension Cutoff Stress

Yield stress in uniaxial tension, σ_t.

Tensile Plastic Strain

Corresponding plastic strain. (The first tabular value entered must always be zero.)

Temp

Temperature.

Field *n*

Predefined field variables.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

16. Click **OK** to create the material and to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Defining porous metal plasticity

You can use the porous metal plasticity model for materials with a dilute concentration of voids in which the relative density is greater than 0.9.
See *Porous Metal Plasticity* for more information.

In this section:

- *Defining a porous metal plasticity model*
- *Defining porous material failure criteria*
- *Defining void nucleation in a porous material*

Defining a porous metal plasticity model

The porous metal plasticity model describes materials that exhibit damage in the form of void initiation and growth. You can also use this model for some powder metal process simulations at high relative densities (relative density is defined as the ratio of the volume of solid material to the total volume of the material). The model is based on Gurson's porous metal plasticity theory with void nucleation and is intended for use with materials that have a relative density that is greater than 0.9. The model is adequate for relatively monotonic loading.

See *Porous Metal Plasticity* for more information.

1. From the menu bar in the **Edit Material** dialog box, select **Mechanical->Plasticity->Porous Metal Plasticity**.

   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Enter a value for the initial **Relative density** of the material.
3. Toggle on **Use temperature-dependent data** to define data that depend on temperature.

   A column labeled **Temp** appears in the **Data** table.
4. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the data depend.
5. Enter the following data in the **Data** table:

   ### q1, q2, and q3

   Material parameters q_1, q_2, q_3.

   For typical metals the ranges of the parameters reported in the literature are q_1 = 1.0 to 1.5, q_2 = 1.0, and $q_3 = q_1^2$ = 1.0 to 2.25 (see *Necking of a round tensile bar*). The original Gurson model is recovered when $q_1 = q_2 = q_3$ = 1.0.

   ### Temp

   Temperature.

   ### Field *n*

   Predefined field variables.

   You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.
6. If desired, select **Porous Failure Criteria** from the **Suboption** menu to specify material failure criteria for an Abaqus/Explicit analysis. See *Defining porous material failure criteria* for details.
7. If desired, select **Void Nucleation** from the **Suboption** menu to define the nucleation of voids in the porous material. See *Defining void nucleation in a porous material* for details.
8. Click **OK** to create the material and to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors* for more information).

Defining porous material failure criteria

You use the **Suboption Editor** to define failure in a porous metal plasticity model. See *Failure Criteria in Abaqus/Explicit* for more information.

1. Create a material model as described in *Defining a porous metal plasticity model*.
2. From the **Suboptions** menu in the **Edit Material** dialog box, select **Porous Failure Criteria**.
   A **Suboption Editor** appears.
3. Enter a value for the **Total volume void fraction at total failure**, $f_F > 0$. The default is 1.
4. Enter a value for the **Critical void volume fraction** (threshold of rapid loss of stress carrying capacity), $f_c \geq 0$. The default is f_F.
5. Click **OK** to return to the **Edit Material** dialog box.

Defining void nucleation in a porous material

You use the **Suboption Editor** to define the nucleation of voids in a porous metal plasticity model. See *Void Growth and Nucleation* for more information.

1. Create a material model as described in *Defining a porous metal plasticity model*.
2. From the **Suboptions** menu in the **Edit Material** dialog box, select **Void Nucleation**.

   A **Suboption Editor** appears.
3. Toggle on **Use temperature-dependent data** to define data that depend on temperature.

   A column labeled **Temp** appears in the **Data** table.
4. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the data depend.
5. Enter the following data in the **Data** table:

Mean

Mean value of the nucleation-strain normal distribution, ε_N.

Standard Deviation

Standard deviation of the nucleation-strain normal distribution, s_N.

Volume Fraction

Volume fraction of nucleating voids, f_N.

Temp

Temperature.

Field *n*

Predefined field variables.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

6. Click **OK** to return to the **Edit Material** dialog box.

Defining a creep law

In an Abaqus/Standard analysis, you can define classical deviatoric metal creep behavior in a user subroutine or by providing parameters for the creep laws.
You can define creep behavior in user subroutine *CREEP*.

See *Rate-Dependent Plasticity: Creep and Swelling* for more information.

1. From the menu bar in the **Edit Material** dialog box, select **Mechanical->Plasticity->Creep**.

   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Click the arrow to the right of the **Law** field, and select the creep law of your choice. See *Creep Behavior* for the data required for each creep law.
3. To define behavior data that depend on temperature, toggle on **Use temperature-dependent data**.

   A column labeled **Temp** appears in the **Data** table.
4. To define behavior data that depend on field variables, click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables.

   Field variable columns appear in the **Data** table.
5. If desired, select **Ornl** from the **Suboptions** menu to implement the creep rules specified by the Oak Ridge National Laboratory constitutive model. See *Using the Oak Ridge National Laboratory (ORNL) constitutive model in plasticity and creep calculations* for more information.
6. If desired, select **Potential** from the **Suboptions** menu to specify anisotropic creep behavior. See *Defining anisotropic yield and creep* for more information.
7. Click **OK** to create the material and to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors* for more information).

Defining swelling

You can enter swelling data in tabular form.
In addition, user subroutine *CREEP* (*CREEP*) provides a very general capability for implementing viscoplastic models such as creep and swelling models.

See *Volumetric Swelling Behavior* for more information.

In this section:

- *Defining a volumetric swelling model*
- *Defining anisotropic swelling*

Defining a volumetric swelling model

As with the creep laws, volumetric swelling laws are usually complex and are most conveniently specified in user subroutine *CREEP*. However, you can also enter tabular swelling data in the **Edit Material** dialog box. See *Volumetric Swelling Behavior*, for more information.

1. From the menu bar in the **Edit Material** dialog box, select **Mechanical->Plasticity->Swelling**.
   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Click the arrow to the right of the **Law** field, and select an option for specifying swelling data:
   - Select **Input** to enter tabular data in the **Edit Material** dialog box.
   - Select **User-defined** to define the swelling behavior in user subroutine *CREEP*
3. If you selected **Input** in Step 2, toggle on **Use temperature-dependent data** to define data that depend on temperature.
   A column labeled **Temp** appears in the **Data** table.
4. If you selected **Input** in Step 2, click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the data depend.
5. If you selected **Input** in Step 2, enter the following data in the **Data** table:

Strain Rate

Volumetric swelling strain rate.

Temp

Temperature.

Field *n*

Predefined field variables.

6. If desired, select **Ratios** from the **Suboptions** menu to define anisotropic swelling. See *Defining anisotropic swelling*" for details.
7. Click **OK** to create the material and to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Defining anisotropic swelling

You can specify ratios in the **Suboptions Editor** to define the swelling rate in each material direction. See *Volumetric Swelling Behavior*, for more information.

1. Create a material model as described in *Defining a volumetric swelling model*."
2. From the **Suboptions** menu in the **Edit Material** dialog box, select **Ratios**.

   A **Suboption Editor** appears.
3. Toggle on **Use temperature-dependent data** to define data that depend on temperature.

   A column labeled **Temp** appears in the **Data** table.
4. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the data depend.
5. Enter the following data in the **Data** table:

r11, r22, and r33

Anisotropic swelling ratios, r_{11}., r_{22}., and r_{33}..

Temp

Temperature.

Field *n*

Predefined field variables.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

6. Click **OK** to return to the **Edit Material** dialog box.

Defining the viscous component of a two-layer viscoplasticity model

The two-layer viscoplasticity model in Abaqus/Standard is useful for modeling materials in which significant time-dependent behavior as well as plasticity is observed. For metals this typically occurs at elevated temperatures.

This model consists of three parts: elastic, plastic, and viscous. You can define the viscous behavior of the material by selecting a creep law and entering viscosity parameters. See *Two-Layer Viscoplasticity* for more information.

1. From the menu bar in the **Edit Material** dialog box, select **Mechanical->Plasticity->Viscous**.

   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Click the arrow to the right of the **Law** field, and select the creep law of your choice. See *Viscous Behavior* and *Creep Behavior* for the data required for each creep law.
3. To define behavior data that depend on temperature, toggle on **Use temperature-dependent data**.

   A column labeled **Temp** appears in the **Data** table.
4. To define behavior data that depend on field variables, click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables.

   Field variable columns appear in the **Data** table.
5. If desired, select **Potential** from the **Suboptions** menu to define anisotropic viscosity. See *Defining anisotropic yield and creep* for details.
6. Click **OK** to create the material and to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors* for more information).

Defining damage

You use the **Edit Material** dialog box to specify material damage initiation criteria and associated damage evolution.
Once an initiation criterion is met, Abaqus applies the associated damage evolution law to determine the material degradation. You can specify the following types of damage in Abaqus/CAE:

- **Ductile**
- **FLD**
- **FLSD**
- **Johnson-Cook**
- **Maxe** or **Quade**
- **Maxs** or **Quads**
- **Maxps** or **Maxpe**
- **M-K**
- **MSFLD**
- **Shear**
- **Hosford-Coulomb**
- **Hashin**
- **LaRC05**
- **Mullins Effect**

You can define multiple damage initiation criteria and damage evolution models to accurately represent the behavior of a material. When a damage initiation criterion is met, material damage has begun. Abaqus uses the damage evolution definition associated with the initiation criterion to evaluate the extent of the damage. If you do not define damage evolution, Abaqus continues to evaluate the damage initiation criterion to provide an indication of the extent to which the analysis has exceeded the initiation point.

In addition to damage initiation and evolution, Abaqus/Standard uses a viscous regularization scheme to improve convergence as fiber-reinforced composite materials (Hashin damage model) are damaged.

For more information on material damage, see *Progressive Damage and Failure*.

In this section:

- *Ductile damage*
- *Forming limit diagram (FLD) damage*
- *Forming limit stress diagram (FLSD) damage*

- *Damage stabilization*

Ductile damage

The **Ductile** damage initiation criterion is a model for predicting the onset of damage due to nucleation, growth, and coalescence of voids in ductile metals. The model assumes that the equivalent plastic strain at the onset of damage is a function of stress triaxiality and strain rate. The ductile criterion can be used in conjunction with the Mises, Johnson-Cook, Hill, and Drucker-Prager plasticity models, including equation of state.

1. From the menu bar in the **Edit Material** dialog box, select **Mechanical->Damage for Ductile Metals->Ductile Damage**.

   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Enter the material parameter, **Accumulation power**, equal to the value of the power coefficient, *N*.
3. To define material damage data that depend on the lode angle, toggle on **Use lode-dependent data**.

   A column labeled **lode-dependent** appears in the **Data** table.
4. To define material damage data that depend on temperature, toggle on **Use temperature-dependent data**.

   A column labeled **Temp** appears in the **Data** table.
5. To define behavior data that depend on field variables, click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables.

   Field variable columns appear in the **Data** table.
6. Enter damage parameters in the **Data** table:

Fracture Strain

Equivalent fracture strain at damage initiation.

Stress Triaxiality

The stress triaxiality is defined as $\eta = -p/q$, where p is the pressure stress and q is the Mises equivalent stress.

Strain Rate

The equivalent plastic strain rate, $\dot{\bar{\varepsilon}}^{pl}$.

Temp

Temperature, θ.

Field *n*

Predefined field variables.

You might need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

7. Select **Suboptions->Damage Evolution** to define the material degradation that takes place once damage begins.

   For more information, see *Damage evolution*."

8. Click **OK** to exit the material editor.

• *Damage Initiation for Ductile Metals*

Forming limit diagram (FLD) damage

A forming limit diagram (FLD) is a plot of the forming limit strains in the space of principal (in-plane) logarithmic strains. The **FLD** damage initiation criterion is intended to predict the onset of necking instability in sheet metal forming. The maximum strains that a sheet material can sustain prior to the onset of necking are referred to as the forming limit strains.

Damage due to bending deformation cannot be evaluated using this model. For more information, see *Damage Initiation for Ductile Metals*.

1. From the menu bar in the **Edit Material** dialog box, select **Mechanical->Damage for Ductile Metals->FLD Damage**.

   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)

2. To define material damage data that depend on temperature, toggle on **Use temperature-dependent data**.

   A column labeled **Temp** appears in the **Data** table.

3. To define behavior data that depend on field variables, click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables.

   Field variable columns appear in the **Data** table.

4. Enter damage parameters in the **Data** table:

Major Principal Strain

The maximum value of the in-plane principal limit strain.

Minor Principal Strain

The minimum value of the in-plane principal limit strain.

Temp

Temperature, θ.

Field *n*

Predefined field variables.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

5. Select **Suboptions->Damage Evolution** to define the material degradation that takes place once damage begins.

   For more information, see *Damage evolution*."

6. Click **OK** to exit the material editor.

Forming limit stress diagram (FLSD) damage

The **FLSD** damage initiation criterion is intended to predict the onset of necking instability in sheet metal forming. The strain-based forming limit curves (as used in the *FLD criterion*) are converted to stress-based curves to reduce the dependence on the strain path. This improves the performance of the FLSD damage model under conditions of arbitrary loading.

Similar to the FLD criterion, damage due to bending deformation cannot be evaluated using this model. For more information, see *Damage Initiation for Ductile Metals*.

1. From the menu bar in the **Edit Material** dialog box, select **Mechanical->Damage for Ductile Metals->FLSD Damage**.

   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)

2. To define material damage data that depend on temperature, toggle on **Use temperature-dependent data**.

   A column labeled **Temp** appears in the **Data** table.

3. To define behavior data that depend on field variables, click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables.

   Field variable columns appear in the **Data** table.

4. Enter damage parameters in the **Data** table:

Major Principal Stress

The maximum value of the in-plane principal limit stress.

Minor Principal Stress

The minimum value of the in-plane principal limit stress.

Temp

Temperature, θ.

Field n

Predefined field variables.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

5. Select **Suboptions->Damage Evolution** to define the material degradation that takes place once damage begins.

   For more information, see *Damage evolution*."

6. Click **OK** to exit the material editor.

Johnson-Cook damage

The **Johnson-Cook** damage initiation criterion is a special case of the ductile damage criterion model for predicting the onset of damage due to nucleation, growth, and coalescence of voids in ductile metals.
The model assumes that the equivalent plastic strain at the onset of damage is a function of stress triaxiality and strain rate. The Johnson-Cook criterion can be used in conjunction with the Mises, Johnson-Cook, Hill, and Drucker-Prager plasticity models, including equation of state.

1. From the menu bar in the **Edit Material** dialog box, select **Mechanical->Damage for Ductile Metals->Johnson-Cook Damage**.

   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Enter the material parameter, **Accumulation power**, equal to the value of the power coefficient, *N*.
3. Enter the damage parameters in the **Data** table:

   d_1–d_5

   Failure parameters.

   #### Melting temperature

   θ_{melt}.

   #### Transition temperature

   $\theta_{\text{transition}}$.

   #### Reference strain rate

   $\dot{\varepsilon}_0$

   You might need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.
4. Select **Suboptions->Damage Evolution** to define the material degradation that takes place once damage begins.

   For more information, see *Damage evolution*.
5. Click **OK** to exit the material editor.

- *Ductile damage*
- *Damage Initiation for Ductile Metals*

Maximum or quadratic nominal strain damage

The **Maxe** and **Quade** damage initiation criteria are used to predict damage initiation in cohesive elements where the cohesive layers are defined in terms of traction-separation.
Both forms evaluate the strain ratios between a given strain value and the peak nominal strain value in each of three directions. ε_n^o, ε_s^o, and ε_t^o represent the peak values of the nominal strain when the deformation is either purely normal to the interface or purely in the first or the second shear direction, respectively. The **Maxe** criterion is based on the maximum value of the three ratios, whereas the **Quade** criterion is based on a quadratic combination of all three ratios.

1. From the menu bar in the **Edit Material** dialog box, select **Mechanical->Damage for Traction Separation Laws->Maxe Damage** or **Quade Damage**.

   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)

2. If you are using the extended finite element method (XFEM) to model fracture, you can specify the crack propagation direction when the damage initiation criterion is satisfied. The crack can extend at a direction **Normal** to the local 1-direction (default) or **Parallel** to the local 1-direction.
3. Enter the **Tolerance**. The value should be equal to the tolerance within which the damage initiation criterion must be satisfied.
4. To define the separate tolerance used for crack growth, toggle on **Growth Tolerance** and enter the **Growth Tolerance**.

   If this parameter is included but no value is specified, keep the toggle on for **default**.
5. To define the separate tolerance used for unstable crack growth, toggle on **Unstable Growth Tolerance** and enter the **Unstable Growth Tolerance**.

   If this parameter is included but no value is specified, keep the toggle on for **infinite**.
6. Select the arrow to the right of the **Position** field, and select the method for computing the stress/strain fields ahead of the crack tip to determine if the damage initiation criterion is satisfied and to determine the crack propagation direction (if needed):

   - Select **Centroid** to use the stress/strain at the element centroid.
   - Select **Crack tip** to use the stress/strain extrapolated to the crack tip.
   - Select **Combined** to use the stress/strain extrapolated to the crack tip to determine if the damage initiation criterion is satisfied and to use the stress/strain at the element centroid to determine the crack propagation direction (if needed).

7. To define the material damage data that depend on the effective rate of separation, toggle on **Use rate-dependent data**.

   A column labeled **rate-dependent** appears in the **Data** table.
8. To define material damage data that depend on temperature, toggle on **Use temperature-dependent data**.

   A column labeled **Temp** appears in the **Data** table.
9. To define behavior data that depend on field variables, click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables.

   Field variable columns appear in the **Data** table.
10. Enter damage parameters in the **Data** table:

Nominal Strain Normal-only Mode

Nominal strain at damage initiation in a normal-only mode.

Nominal Strain Shear-only mode First Direction

Nominal strain at damage initiation in a shear-only mode that involves separation only along the first shear direction.

Nominal Strain Shear-only mode Second Direction

Nominal strain at damage initiation in a shear-only mode that involves separation only along the second shear direction.

Temp

Temperature, θ.

Field *n*

Predefined field variables.

You might need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

11. Select **Suboptions->Damage Evolution** to define the material degradation that takes place once damage begins.

    For more information, see *Damage evolution*."

12. Select **Suboptions->Damage Stabilization Cohesive** to enter viscous coefficients and improve the model convergence.

    For more information, see *Damage stabilization*."

13. Click **OK** to exit the material editor.

• *Defining the Constitutive Response of Cohesive Elements Using a Traction-Separation Description*

Maximum or quadratic nominal stress damage

The **Maxs** and **Quads** damage initiation criteria are used to predict damage initiation in cohesive elements where the cohesive layers are defined in terms of traction-separation. Both forms evaluate the stress ratios between a given stress value and the peak nominal stress value in each of three directions. t_n^o, t_s^o, and t_t^o represent the peak values of the nominal stress when the deformation is either purely normal to the interface or purely in the first or the second shear direction, respectively. The **Maxs** criterion is based on the maximum value of the three ratios, whereas the **Quads** criterion is based on a quadratic combination of all three ratios.

1. From the menu bar in the **Edit Material** dialog box, select **Mechanical->Damage for Traction Separation Laws->Maxs Damage** or **Quads Damage**.

   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)

2. If you are using the extended finite element method (XFEM) to model fracture, you can choose the crack propagation direction when the damage initiation criterion is satisfied. The crack can extend at a direction normal to the element local 1-direction (default) or parallel to the element local 1-direction.
3. Enter the **Tolerance**. The value should be equal to the tolerance within which the damage initiation criterion must be satisfied.
4. To define the separate tolerance used for crack growth, toggle on **Growth Tolerance** and enter the **Growth Tolerance**.

   If this parameter is included but no value is specified, keep the toggle on for **default**.

5. To define the separate tolerance used for unstable crack growth, toggle on **Unstable Growth Tolerance** and enter the **Unstable Growth Tolerance**.

   If this parameter is included but no value is specified, keep the toggle on for **infinite**.

6. Select the arrow to the right of the **Position** field, and select the method for computing the stress/strain fields ahead of the crack tip to determine if the damage initiation criterion is satisfied and to determine the crack propagation direction (if needed):

   - Select **Centroid** to use the stress/strain at the element centroid.
   - Select **Crack tip** to use the stress/strain extrapolated to the crack tip.
   - Select **Combined** to use the stress/strain extrapolated to the crack tip to determine if the damage initiation criterion is satisfied and to use the stress/strain at the element centroid to determine the crack propagation direction (if needed).

7. To define the material damage data that depend on effective rate of separation, toggle on **Use rate-dependent data**.

   A column labeled **rate-dependent** appears in the **Data** table.

8. To define material damage data that depend on temperature, toggle on **Use temperature-dependent data**.

   A column labeled **Temp** appears in the **Data** table.

9. To define behavior data that depend on field variables, click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables.

   Field variable columns appear in the **Data** table.

10. Enter damage parameters in the **Data** table:

Maximum Nominal Stress Normal-only Mode

Nominal stress at damage initiation in a normal-only mode.

Maximum Nominal Stress Shear-only mode First Direction

Nominal stress at damage initiation in a shear-only mode that involves separation only along the first shear direction.

Maximum Nominal Stress Shear-only mode Second Direction

Nominal stress at damage initiation in a shear-only mode that involves separation only along the second shear direction.

Temp

Temperature, θ.

Field *n*

Predefined field variables.

You might need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

11. Select **Suboptions->Damage Evolution** to define the material degradation that takes place once damage begins.

    For more information, see *Damage evolution*."

12. Select **Suboptions->Damage Stabilization Cohesive** to enter viscous coefficients and improve the model convergence.

    For more information, see *Damage stabilization*."

13. Click **OK** to exit the material editor.

• *Defining the Constitutive Response of Cohesive Elements Using a Traction-Separation Description*

Maximum principal stress or strain damage

The **Maxps** and **Maxpe** damage initiation criteria are used to predict damage initiation in the XFEM enriched region.

1. From the menu bar in the **Edit Material** dialog box, select **Mechanical->Damage for Traction Separation Laws->Maxps Damage** or **Maxpe Damage**.

   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)

2. Enter the **Tolerance**. The value should be equal to the tolerance within which the damage initiation criterion must be satisfied.
3. To define the separate tolerance used for crack growth, toggle on **Growth Tolerance** and enter the **Growth Tolerance**.

   If this parameter is included but no value is specified, keep the toggle on for **default**.

4. To define the separate tolerance used for unstable crack growth, toggle on **Unstable Growth Tolerance** and enter the **Unstable Growth Tolerance**.

   If this parameter is included but no value is specified, keep the toggle on for **infinite**.

5. Select the arrow to the right of the **Position** field, and select the method for computing the stress/strain fields ahead of the crack tip to determine if the damage initiation criterion is satisfied and to determine the crack propagation direction (if needed):

   - Select **Centroid** to use the stress/strain at the element centroid.
   - Select **Crack tip** to use the stress/strain extrapolated to the crack tip.
   - Select **Combined** to use the stress/strain extrapolated to the crack tip to determine if the damage initiation criterion is satisfied and to use the stress/strain at the element centroid to determine the crack propagation direction (if needed).
   - Select **Nonlocal** to use the stress/strain extrapolated to the crack tip to determine if the damage initiation criterion is satisfied and to use the stress/strain averaged over a group of elements around the crack tip in the enriched region to determine the crack propagation direction (if needed).

6. To define material damage data that depend on temperature, toggle on **Use temperature-dependent data**.

   A column labeled **Temp** appears in the **Data** table.

7. To define behavior data that depend on field variables, click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables.

   Field variable columns appear in the **Data** table.

8. Enter the **Angsmooth**. The value should be equal to the maximum allowed difference (in degrees) below which the normals of the crack facets are included in the moving least-squares approximation to smooth out the crack normals to obtain the crack propagation direction along the crack front, and it can be used only in conjunction with **Position=Nonlocal** in enriched elements.
9. Enter the **R Crack Direction**. The value should be equal to the radius around the crack tip within which the elements are included for calculating the averaged stress/strain and for smoothing out the normals of the individual crack facets along the crack front used to obtain the crack propagation direction, and it can be used only in conjunction with **Position=Nonlocal**.
10. Select the arrow to the right of the **IniSmooth** field, and it can be used only in conjunction with **Position=Nonlocal** in enriched elements:

    - Select **Yes** to indicate the normals of pre-existing crack facets in elements are included in the moving least-squares approximation to smooth out the crack normals to obtain the crack propagation direction along the crack front.

- Select **No** to Indicate the normals of pre-existing crack facets in elements are excluded from the moving least-squares approximation to smooth out the crack normals to obtain the crack propagation direction along the crack front..

11. Select the arrow to the right of the **Smoothing** field, and it can be used only in conjunction with **Position=Nonlocal**:

- Select **None** to use the stress/strain at the integration points directly for averaging.
- Select **Nodal** to assemble the stress/strain to element nodes and then interpolate to the integration points for averaging.

12. Select the arrow to the right of the **Npoly** field, and is used to specify the number of terms in the polynomial used for the moving least-squares approximation to smooth out the crack normals, only in conjunction with **Position=Nonlocal** in enriched elements:

- Select **Least Square** to set NPOLY=0 and to suppress the moving least-squares approximation.
- Select **Linear** to set NPOLY=4 and to use a linear polynomial approximation.
- Select **Quadratic** to set NPOLY=7 and to use a quadratic polynomial approximation.
- Select **Cubic** to set NPOLY=10 and to use a cubic polynomial approximation.

13. Select the arrow to the right of the **Weighting Method** field, and it can be used only in conjunction with **Position=Nonlocal**:

- Select **Uniform** to average the stress/strain with a uniform weight function.
- Select **Gauss** to average the stress/strain with a Gaussian weight function.
- Select **Cubic Spline** to average the stress/strain with a cubic spline weight function.
- Select **User** to average the stress/strain with a user-defined weight function.

14. Enter damage parameters in the **Data** table:

Maximum Principal Stress or Maximum Principal Strain

Maximum principal stress or strain at damage initiation.

Temp

Temperature, θ.

Field *n*

Predefined field variables.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

15. Select **Suboptions->Damage Evolution** to define the material degradation that takes place once damage begins.

For more information, see *Damage evolution*."

16. Select **Suboptions->Damage Stabilization Cohesive** to enter the viscous coefficient and improve the model convergence.

For more information, see *Damage stabilization*."

17. Click **OK** to exit the material editor.

• *Modeling Discontinuities as an Enriched Feature Using the Extended Finite Element Method*

Marciniak-Kuczynski (M-K) damage

The **M-K** damage initiation criterion is used to predict sheet metal forming limits for arbitrary loading paths. The model introduces thickness imperfections, in the form of grooves, in the sheet material to simulate defects. Damage occurs when the ratio of deformation in the grooves relative to deformation in the original sheet thickness exceeds a critical value. By default, Abaqus evaluates four grooves at equally spaced angles of 0°, 45°, 90°, and 135° with respect to the local 1-direction of the material at each time increment and uses the worst result to determine damage initiation. The M-K criterion can be used in conjunction with the Mises and Johnson-Cook plasticity models, including kinematic hardening.

For more information, see *Damage Initiation for Ductile Metals*.

1. From the menu bar in the **Edit Material** dialog box, select **Mechanical->Damage for Ductile Metals->M-K Damage**.

   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)

2. To define material damage data that depend on temperature, toggle on **Use temperature-dependent data**.

   A column labeled **Temp** appears in the **Data** table.

3. To define behavior data that depend on field variables, click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables.

   Field variable columns appear in the **Data** table.

4. If desired, modify the critical deformation severity factors F_{eq}, F_{nn}, and F_{nt}.

   The severity factors each have a default value of 10 and are related to the ratios of equivalent plastic, normal, and tangential strain in the groove area compared to the nominal thickness area. Abaqus/Explicit will ignore severity factors that are set to 0. If all of these parameters are set equal to zero, the M-K criterion is based solely on nonconvergence of the equilibrium and compatibility equations.

5. Select the **Frequency**—the number of increments between calculating the M-K criterion.

   Using the default frequency, 1, can be expensive since Abaqus evaluates each groove at every increment.

6. Select the **Number of imperfections**—the number of angular groove positions to evaluate.

   The groove positions are equally spaced, starting at 0° and ending at $180\frac{(n-1)}{n}$ with respect to the local 1-direction of the material.

7. Enter damage parameters in the **Data** table:

Groove Size

The ratio of the thickness at the groove to the nominal material thickness.

Angle

The starting angle (in degrees) with respect to the 1-direction of the local material orientation.

Temp

Temperature, θ.

Field *n*

Predefined field variables.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

8. Select **Suboptions->Damage Evolution** to define the material degradation that takes place once damage begins.

   For more information, see *Damage evolution*."

9. Click **OK** to exit the material editor.

Müschenborn-Sonne forming limit diagram (MSFLD) damage

The **MSFLD** damage initiation criterion is used to predict sheet metal forming limits for arbitrary loading paths. The model works on the basis of equivalent plastic strain and assumes that the forming limit curve represents the sum of the highest attainable equivalent plastic strains. The approach requires transforming the original forming limit curve (without predeformation effects) from the space of major versus minor strains to the space of equivalent plastic strain, $\bar{\varepsilon}^{pl}$, versus the ratio of principal strain rates, $\alpha = \dot{\varepsilon}_{\text{minor}} / \dot{\varepsilon}_{\text{major}}$.

Damage due to bending deformation cannot be evaluated using this model. For more information, see *Damage Initiation for Ductile Metals*.

1. From the menu bar in the **Edit Material** dialog box, select **Mechanical->Damage for Ductile Metals->MSFLD Damage**.

   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Choose one of the following **Definitions**:
   - Select **MSFLD** to enter data in the form of equivalent plastic strains and ratios of minor to major strain rates.
   - Select **FLD** to enter data in the form of major and minor principal strains and the equivalent plastic strain and to have Abaqus transform the data into the Müschenborn-Sonne form.
3. Enter the material parameter, **Accumulation power**, equal to the value of the power coefficient, *N*.
4. If desired, you can change the value of ω ($0 < \omega \leq 1$). Omega is used to filter the ratio of principal strains rates, preventing the ratio from jumping to a higher value due to sudden changes in the strain direction (deformation path); the default value is $\omega = 1$.
5. To define material damage data that depend on temperature, toggle on **Use temperature-dependent data**.

   A column labeled **Temp** appears in the **Data** table.
6. To define behavior data that depend on field variables, click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables.

   Field variable columns appear in the **Data** table.
7. Enter damage parameters in the **Data** area (parameters followed by **MSFLD** or **FLD** are used only for that definition type):

Plastic Strain at Initiation (MSFLD)

Equivalent plastic strain at initiation of localized necking.

Ratio of Principal Strains (MSFLD)

Ratio of minor to major principal strains, α.

Major Principal Strain (FLD)

Major principal strain at damage initiation.

Minor Principal Strain (FLD)

Minor principal strain at damage initiation.

Plastic Strain Rate

Equivalent plastic strain rate.

Temp

Temperature, θ.

Field n

Predefined field variables.

You might need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

8. Select **Suboptions->Damage Evolution** to define the material degradation that takes place once damage begins.

   For more information, see *Damage evolution*."

9. Click **OK** to exit the material editor.

• *Damage Initiation for Ductile Metals*

Shear damage

The **Shear** damage initiation criterion is a model for predicting the onset of damage due to shear band localization. The model assumes that the equivalent plastic strain at the onset of damage is a function of the shear stress ratio and strain rate. The shear criterion can be used in conjunction with the Mises, Johnson-Cook, Hill, and Drucker-Prager plasticity models, including equation of state.

1. From the menu bar in the **Edit Material** dialog box, select **Mechanical->Damage for Ductile Metals->Shear Damage**.

   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)

2. Enter the material parameter, k_s.
3. Enter the material parameter, **Accumulation power**, equal to the value of the power coefficient, *N*.
4. To define material damage data that depend on temperature, toggle on **Use temperature-dependent data**.

   A column labeled **Temp** appears in the **Data** table.

5. To define behavior data that depend on field variables, click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables.

   Field variable columns appear in the **Data** table.

6. Enter the damage parameters in the **Data** table:

Fracture Strain

Equivalent fracture strain at damage initiation.

Shear Stress Ratio

The shear stress ratio is defined as $\theta_s = (q + k_s p) / \tau_{max}$, where q is the Mises equivalent stress, p is the pressure stress, and τ_{max} is the maximum shear stress.

Strain Rate

The equivalent plastic strain rate, $\dot{\bar{\varepsilon}}^{pl}$.

Temp

Temperature, θ.

Field *n*

Predefined field variables.

You might need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

7. Select **Suboptions->Damage Evolution** to define the material degradation that takes place once damage begins.

   For more information, see *Damage evolution*."

8. Click **OK** to exit the material editor.

• *Damage Initiation for Ductile Metals*

Hosford-Coulomb damage

The **Hosford-Coulomb** damage initiation criterion is a special case of the ductile criterion in which the equivalent plastic strain at the onset of damage is a function of the stress triaxiality, material parameters, and strain rate.

The Hosford-Coulomb criterion can be used in conjunction with the Mises, Johnson-Cook, Hill, and Drucker-Prager plasticity models. It can also be specified together with any other initiation criteria; each initiation criterion is treated independently.

1. From the menu bar in the **Edit Material** dialog box, select **Mechanical->Damage for Ductile Metals->Hosford-Coulomb Damage**.

   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Enter the material parameter, **Accumulation power**, equal to the value of the power coefficient, *N*.
3. To define material damage data that depend on temperature, toggle on **Use temperature-dependent data**.

   A column labeled **Temp** appears in the **Data** table.
4. To define behavior data that depend on field variables, click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables.

   Field variable columns appear in the **Data** table.
5. Enter the damage parameters in the **Data** table:

a

Material parameter a.

b

Material parameter b.

c

Material parameter c.

n

Material parameter n.

d

Material parameter d.

$\dot{\varepsilon}_0$

Reference strain rate.

Temp

Temperature, θ.

Field *n*

Predefined field variables.

You might have to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

6. Select **Suboptions->Damage Evolution** to define the material degradation that takes place once damage begins.

   For more information, see *Damage evolution*.

7. Click **OK** to exit the material editor.

• *Damage Initiation for Ductile Metals*

Hashin damage

The **Hashin** damage model predicts anisotropic damage in elastic-brittle materials. It is primarily intended for use with fiber-reinforced composite materials and takes into account four different failure modes: fiber tension, fiber compression, matrix tension, and matrix compression.

For more information, see *Damage Initiation for Fiber-Reinforced Composites*.

1. From the menu bar in the **Edit Material** dialog box, select **Mechanical->Damage for Fiber-Reinforced Composites->Hashin Damage**.

   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)

2. Select $\alpha = 0$ to use the model proposed in 1973 and $\alpha = 1$ to use the 1980 model. (For more information, see *Damage Initiation for Fiber-Reinforced Composites*.)
3. To define material damage data that depend on temperature, toggle on **Use temperature-dependent data**.

   A column labeled **Temp** appears in the **Data** table.

4. To define behavior data that depend on field variables, click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables.

   Field variable columns appear in the **Data** table.

5. Enter damage parameters in the **Data** table:

Longitudinal Tensile Strength

Longitudinal tensile strength.

Longitudinal Compressive Strength

Longitudinal compressive strength.

Transverse Tensile Strength

Transverse tensile strength.

Transverse Compressive Strength

Transverse compressive strength.

Longitudinal Shear Strength

Longitudinal shear strength.

Transverse Shear Strength

Transverse shear strength.

Temp

Temperature, θ.

Field *n*

Predefined field variables.

You might need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

6. Select **Suboptions->Damage Evolution** to define the material degradation that takes place once damage begins.

   For more information, see *Damage evolution*."

7. Select **Suboptions->Damage Stabilization** to enter viscous coefficients and improve the model convergence.

   For more information, see *Damage stabilization*."

8. Click **OK** to exit the material editor.

LaRC05 damage

The **LaRC05** damage 3D model predicts polymer-matrix fiber-reinforced composites materials.
It is primarily intended for use with unidirectional fiber-reinforced composite materials and takes into account four different failure modes: matrix cracking, fiber kinking, fiber splitting, and fiber tension.

1. From the menu bar in the **Edit Material** dialog box, select **Mechanical->Damage for Fiber-Reinforced Composites->LaRC05 Damage**.

   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)

2. Enter the **Tolerance**.

   The value should be equal to the tolerance within which the damage initiation criterion must be satisfied.

3. To define material damage data that depend on temperature, toggle on **Use temperature-dependent data**.

   A column labeled **Temp** appears in the **Data** table.

4. To define behavior data that depend on field variables, click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables.

   Field variable columns appear in the **Data** table.

5. Enter the damage parameters in the **Data** table:

Longitudinal Tensile Strength

Longitudinal tensile strength.

Longitudinal Compressive Strength

Longitudinal compressive strength.

Transverse Tensile Strength

Transverse tensile strength.

Transverse Compressive Strength

Transverse compressive strength.

In Plane Shear Strength

In Plane shear strength.

Fracture plane angle for pure compression

Fracture plane angle for pure compression.

Misalignment angle at failure for pure compression

Misalignment angle at failure for pure compression.

Transverse Shear Strength

Transverse shear strength.

Longitudinal shear friction coefficient

Longitudinal shear friction coefficient.

Transverse shear friction coefficient

Transverse shear friction coefficient.

Temp

Temperature, θ.

Field *n*

Predefined field variables.

You might have to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

6. Select **Suboptions->Damage Evolution** to define the material degradation that takes place once damage begins.

   For more information, see *Damage evolution*.

7. Select **Suboptions->Damage Stabilization** to enter viscous coefficients and improve the model convergence.

   For more information, see *Damage stabilization*.

8. Click **OK** to exit the material editor.

• *Damage Initiation for Fiber-Reinforced Composites*

Mullins effect

The Mullins effect material behavior models stress softening of filled rubber elastomers under quasi-static cyclic loading. Abaqus provides three methods to define the Mullins effect in a material:

- Specify the Mullins effect parameters directly as functions of temperature and/or field variables.
- Use experimental unloading-reloading test data to calibrate the Mullins effect parameters.
- Use user subroutine *UMULLINS* in Abaqus/Standard and *VUMULLINS* in Abaqus/Explicit.

For more information about the Mullins effect, including the meaning of the Mullins coefficients r, m, and β, see *Stress Softening in Elastomers*.

1. From the menu bar in the **Edit Material** dialog box, select **Mechanical->Damage for Elastomers->Mullins Effect**.

   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)

2. To define the Mullins data using material constants only, perform the following steps:
   a. From the **Definition** field, select **Constants**.
   b. To define material damage data that depend on temperature, toggle on **Use temperature-dependent data**.

      A column labeled **Temp** appears in the **Data** table.

   c. To define behavior data that depend on field variables, click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables.

      Field variable columns appear in the **Data** table.

   d. Enter damage parameters in the **Data** table:

r

Value of the r coefficient in the Mullins effect model. r must be greater than 1.

m

Value of the m coefficient in the Mullins effect model. m must be greater than or equal to zero, and the values of m and β cannot both be zero.

beta

Value of the β coefficient in the Mullins effect model. β must be greater than or equal to zero, and the values of m and β cannot both be zero.

Temp

Temperature, θ.

Field *n*

Predefined field variables.

If you include temperature values in your data, you can specify multiple rows of material data. You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

3. To specify experimental unloading-reloading test data to calibrate the parameters for the Mullins effect, perform the following steps:
   a. From the **Definition** field, select **Test Data Input**.
   b. If desired, enter values for one or two of the damage parameters r, m, and β from the **Define Parameters** options. For this type of Mullins effect definition, Abaqus/CAE uses test data you provide to calculate the remaining damage parameters.

      To provide a value for a damage parameter, toggle it on and specify its value in the appropriate field:

      r

      Value of the r coefficient in the Mullins effect model. r must be greater than 1.

      m

      Value of the m coefficient in the Mullins effect model. m must be greater than or equal to zero, and the values of m and β cannot both be zero.

      beta

      Value of the β coefficient in the Mullins effect model. β must be greater than or equal to zero, and the values of m and β cannot both be zero.

   c. From the **Add Test** menu in the **Edit Material** dialog box, select **Biaxial Test**, **Planar Test**, or **Uniaxial Test** to add the selected type of unloading-reloading curve to the material model.

      You can add multiple versions of each type of test to the material model. Abaqus/CAE names each test you create according to its type and the order in which it was created, so the first two uniaxial material tests you define would be named **Uniaxial Test 1** and **Uniaxial Test 2**.
   d. In the **Test data** table, enter the test data for the selected test:

      Nominal Stress

      Nominal stress, T_U.

      Nominal Strain

      Nominal strain, ϵ_U.

      For detailed information on how to enter tabular data, see *Entering tabular data*.
   e. Repeat the previous two steps to specify additional data calibration tests.
   f. If you want to delete a calibration test, highlight its name in the **Tests** list and click **Delete Test**. When you delete a test, Abaqus/CAE removes the test from the list and renames the existing tests so that the test numbering remains consecutive. For example, if you create three biaxial tests and delete the first one (**Biaxial Test 1**), **Biaxial Test 2** is renamed **Biaxial Test 1**, and **Biaxial Test 3** is renamed **Biaxial Test 2**.
4. To define the Mullins effect by specifying the damage variable in the user subroutine *UMULLINS* in Abaqus/Standard and *VUMULLINS* in Abaqus/Explicit, perform the following steps:
   a. From the **Definition** field, select **User Defined**.

b. In the **Mullins Properties** field, enter values to specify an array of material properties for this user-defined hyperelastic material. Abaqus/CAE uses this array to populate the variable `PROPS` passed to user subroutine *UMULLINS* and *VUMULLINS*.

See the following sections for more information:

- *Specifying general job settings*
- *UMULLINS*
- *VUMULLINS*

5. Click **OK** to exit the material editor.

Damage evolution

The damage evolution definition defines how the material degrades after one or more damage initiation criteria are met.
Multiple forms of damage evolution might act on a material at the same time—one for each damage initiation criterion that was defined.

The procedure below includes data entries for every type of damage evolution available in the Property module. The selections vary with the current damage initiation form.

1. When you create a damage initiation criterion in the **Edit Material** dialog box, select **Suboptions->Damage Evolution** to specify the associated damage evolution parameters.

   (For information on entering damage initiation criteria, see *Defining damage*.)

2. Select the **Type** of damage evolution:

Displacement

Displacement damage evolution defines damage as a function of the total (for elastic materials in cohesive elements) or the plastic (for bulk elastic-plastic materials) displacement after damage initiation. This type corresponds to the **Displacement at Failure** field in the **Data** table.

Energy

Energy damage evolution defines damage in terms of the energy required for failure (fracture energy) after the initiation of damage. This type corresponds to the **Fracture Energy** field in the **Data** table.

3. Select the **Softening** method:

Linear

Linear softening specifies a linear softening stress-strain response for linear elastic materials or a linear evolution of the damage variable with deformation for elastic-plastic materials. Linear softening is the default method.

Exponential

Exponential softening specifies an exponential softening stress-strain response for linear elastic materials or an exponential evolution of the damage variable with deformation for elastic-plastic materials.

Tabular

Tabular softening specifies the evolution of the damage variable with deformation in tabular form and is available only when you select **Displacement** for the type. The **Displacement at Failure** field in the **Data** table is replaced by a **Damage Variable** field and a **Displacement** field, and you can add additional rows to define the displacements.

4. Select the **Mixed mode behavior** (for materials associated with cohesive elements only):

Mode-Independent

Mode-independent is the default selection.

Tabular

Tabular mixed mode behavior specifies the fracture energy or displacement (total or plastic) directly as a function of the shear-normal mode mix for cohesive elements. This method must be used when you select the **Displacement** type with cohesive elements.

Power Law

Power law mixed mode behavior specifies the fracture energy as a function of the mode mix by means of a power law mixed mode fracture criterion; it is available only when you select the **Energy** type with cohesive elements. The **Fracture Energy** field in the **Data** table is replaced by fracture energy in the normal mode and first direction and second direction shear mode components.

BK

The BK mixed mode behavior specifies the fracture energy as a function of the mode mix by means of the Benzeggagh-Kenane mixed mode fracture criterion. The **Data** table entries are the same as those for the **Power Law**.

5. Select the **Degradation** to determine how Abaqus combines damage evolution when multiple forms are active:

Maximum

The maximum degradation form indicates that the current damage evolution mechanism will interact with other damage evolution mechanisms in a maximum sense to determine the total damage from multiple mechanisms. Maximum is the default selection.

Multiplicative

The multiplicative degradation form indicates that the current damage evolution mechanism will interact in a multiplicative manner with other damage evolution mechanisms defined using this form to determine the total damage from multiple mechanisms. Other damage evolution mechanisms defined using the maximum degradation will interact with the combination of those using the multiplicative form.

6. Select the **Mode Mix Ratio** to use in conjunction with the **Mixed mode behavior** definition (for cohesive elements):

Energy

The energy mixed mode ratio defines the mode mix in terms of a ratio of fracture energy in the different modes. This definition is the default, and it must be used when you select **Power Law** or **BK** for the **Mixed mode behavior**.

Traction

The traction mixed mode ratio defines the mode mix in terms of a ratio of traction components.

7. When you select **Power Law** or **BK** for the **Mixed mode behavior** for cohesive elements, toggle on **Power** and enter the exponent in the power law or the Benzeggagh-Kenane criterion that defines the variation of fracture energy with mode mix for cohesive elements.

8. For the Hashin damage evolution model, the **Data** table contains the following fields:
   - **Fiber Tensile Fracture Energy**
   - **Fiber Compressive Fracture Energy**
   - **Matrix Tensile Fracture Energy**
   - **Matrix Compressive Fracture Energy**

   For more information, see *Damage Evolution and Element Removal for Fiber-Reinforced Composites*.
9. To define the damage evolution data that depend on the effective rate of separation, toggle on **Use rate-dependent data**.

   A column labeled **rate-dependent** appears in the **Data** table.
10. To define damage evolution data that depend on temperature, toggle on **Use temperature-dependent data**.

    A column labeled **Temp** appears in the **Data** table.
11. To define damage evolution data that depend on field variables, click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables.

    Field variable columns appear in the **Data** table.
12. Enter damage evolution parameters in the **Data** table.

    You might need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.
13. Click **OK** to save the damage evolution data and return to the material editor.

- *Damage Evolution and Element Removal for Ductile Metals*
- *Damage Evolution and Element Removal for Fiber-Reinforced Composites*
- *Connector Damage Behavior*

Damage stabilization

This option is used to specify viscosity coefficients used in the viscous regularization scheme for the damage model for traction separation laws and fiber-reinforced materials. Viscous regularization is intended to improve convergence as the material fails.

Defining damage stabilization for traction separation laws

Damage stabilization is available for use with the following damage models for traction separation laws:

- Maxe and Quade damage models. (For information on entering the Maxe and Quade damage initiation criterion in Abaqus/CAE, see *Maximum or quadratic nominal strain damage*.)
- Maxs and Quads damage models. (For information on entering the Maxs and Quads damage initiation criterion in Abaqus/CAE, see *Maximum or quadratic nominal stress damage*.)
- Maxps and Maxpe damage models. (For information on entering the Maxps and Maxpe damage initiation criterion in Abaqus/CAE, see *Maximum principal stress or strain damage*.)

You define damage stabilization for traction separation laws by entering the viscosity coefficient.

Defining damage stabilization for fiber-reinforced materials

Damage stabilization is available for use with the following damage model for fiber-reinforced materials:

- Hashin damage model. (For information on entering the Hashin damage initiation criterion in Abaqus/CAE, see *Hashin damage*.)

For more information, see *Viscous Regularization*.

You define damage stabilization for fiber-reinforced materials by entering viscosity coefficients for each of the potential failure modes:

- Fiber tensile failure
- Fiber compressive failure
- Matrix tensile failure
- Matrix compressive failure

Each of the viscous coefficients should be small compared to the increment size.

Defining other mechanical models

You can model deformation plasticity, damping, expansion, brittle cracking, equations of state, viscosity, superelasticity and crush stress.

In this section:

- *Defining deformation plasticity*
- *Defining damping*
- *Defining thermal expansion*
- *Defining brittle cracking*
- *Defining equations of state*
- *Defining viscosity*
- *Defining superelasticity*
- *Defining crush stress*
- *Defining plasticity correction*

Defining deformation plasticity

Abaqus/Standard provides a deformation theory Ramberg-Osgood plasticity model for use in developing fully plastic solutions for fracture mechanics applications in ductile metals. The model is most commonly applied in static loading with small-displacement analysis for which the fully plastic solution must be developed in a part of the model.

See *Deformation Plasticity*, for more information.

1. From the menu bar in the **Edit Material** dialog box, select **Mechanical->Deformation Plasticity**.
   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Toggle on **Use temperature-dependent data** to define data that depend on temperature.
   A column labeled **Temp** appears in the **Data** table.
3. Enter the following data in the **Data** table:

Young's Modulus

Young's modulus, E, defined as the slope of the stress-strain curve at zero stress.

Poisson's Ratio

Poisson's ratio, ν.

Yield Stress

Yield stress, σ^0.

Exponent

Hardening exponent, n, for the plastic (nonlinear term).

Yield Offset

Yield offset, α.

Temp

Temperature.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

4. Click **OK** to create the material and to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Defining damping

You can define damping for mode-based analyses and for direct-integration dynamic analysis in Abaqus/Standard and for explicit dynamic analysis in Abaqus/Explicit. See *About Dynamic Analysis Procedures*, and *Material Damping*, for more information.

1. From the menu bar in the **Edit Material** dialog box, select **Mechanical->Damping**.

   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. In the **Alpha** field, enter a value for the α_R factor to create Rayleigh mass proportional damping. The default is 0. (Units of T^{-1}.)
3. In the **Beta** field, enter a value for the β_R factor to create Rayleigh stiffness proportional damping. The default is 0. (Units of T.)
4. In the **Composite** field, enter a value for the fraction of critical damping to be used with this material in calculating composite damping factors for the modes. The default is 0. (This value applies only to Abaqus/Standard analyses.)
5. In the **Structural** field, enter a value for the s factor to create imaginary stiffness proportional damping. The default is 0.
6. Click **OK** to create the material and to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Defining thermal expansion

You can define thermal expansion either by entering thermal expansion coefficients in the **Edit Material** dialog box or, if the thermal strains are complicated functions of field and state variables, with user subroutine *UEXPAN*. See *Thermal Expansion*, for more information.

1. From the menu bar in the **Edit Material** dialog box, select **Mechanical->Expansion**.

   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Click the arrow to the right of the **Type** field, and specify the directional dependence of the thermal expansion.
3. Toggle on **Use user subroutine UEXPAN** if you want to define the increments of thermal strain in user subroutine *UEXPAN*.
4. If you toggled on **Use user subroutine UEXPAN**, click **OK** to create the material and to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors* for more information).

   If you choose to specify thermal expansion coefficients directly in the **Edit Material** dialog box, perform the remaining steps in this procedure.
5. If the thermal expansion is temperature- or field-variable-dependent, enter a value for the **Reference temperature**, θ^0.
6. Toggle on **Use temperature-dependent data** to define data that depend on temperature.

   A column labeled **Temp** appears in the **Data** table.
7. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the data depend.
8. Enter the applicable data in the **Data** table:

Expansion Coeff alpha

Isotropic thermal expansion coefficient, α. (Units of θ^{-1}.)

alpha11, alpha22, and alpha33

Three values to define orthotropic thermal expansion, α_{11}, α_{22}, and α_{33}. (Units of θ^{-1}.)

alpha11, alpha22, alpha33, alpha12, alpha13, and alpha23

Six values to define anisotropic thermal expansion, α_{11}, α_{22}, α_{33}, α_{12}, α_{13}, and α_{23}. (Units of θ^{-1}.)

Temp

Temperature.

Field *n*

Predefined field variables.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

9. Click **OK** to create the material and to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Defining brittle cracking

You can use the brittle cracking model in Abaqus/Explicit for applications in which the concrete behavior is dominated by tensile cracking and compressive failure is unimportant.
See *Cracking Model for Concrete* for more information.

In this section:

- *Defining a brittle cracking model*
- *Defining brittle shear*
- *Defining brittle failure*

Defining a brittle cracking model

The brittle cracking model in Abaqus/Explicit is most accurate in applications where the brittle behavior dominates and it is adequate to assume that the material is linear elastic in compression. You can use this model for plain concrete and for other materials such as ceramics or brittle rocks, but it is primarily intended for the analysis of reinforced concrete structures. See *Cracking Model for Concrete*, for more information.

1. From the menu bar in the **Edit Material** dialog box, select **Mechanical->Brittle Cracking**.
   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Click the arrow to the right of the **Type** field, and select a method for defining the postcracking behavior:
   - Select **Strain** to specify the postcracking behavior by entering the postfailure stress-strain relationship directly.
   - Select **Displacement** to define the postcracking behavior by entering the postfailure stress/displacement relationship directly.
   - Select **GFI** to define the postcracking behavior by entering the failure stress and the Mode I fracture energy.
3. Toggle on **Use temperature-dependent data** to define data that depend on temperature.
   A column labeled **Temp** appears in the **Data** table.
4. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the data depend.
5. If you selected **Strain** or **Displacement** from the list of **Type** options, enter the following data in the **Data** table:

Direct stress after cracking

Remaining direct stress after cracking, σ_t^I. (Units of $\mathbf{FL^{-2}}$.)

Direct cracking strain

Direct cracking strain, ε_{nn}^{ck}. (Enter this value if you selected **Strain** from the list of **Type** options.)

Direct cracking displacement

Direct cracking displacement, u_n^{ck}. (Units of L.) (Enter this value if you selected **Displacement** from the list of **Type** options.)

Temp

Temperature.

Field *n*

Predefined field variables.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

6. If you selected **GFI** from the list of **Type** options, enter the following data in the **Data** table:

Failure stress

Failure stress, σ_{tu}^{I}. (Units of $\mathbf{FL^{-2}}$.)

Mode I fracture energy

Mode I fracture energy, G_f^I. (Units of $\mathbf{FL^{-1}}$.)

Temp

Temperature.

Field *n*

Predefined field variables.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

7. Select **Brittle Shear** from the **Suboptions** menu to define the postcracking shear behavior of the material. See *Defining brittle shear*" for details.
8. If desired, select **Brittle Failure** from the **Suboptions** menu to specify the brittle failure criterion. See *Defining brittle failure*" for details.
9. Click **OK** to create the material and to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Defining brittle shear

An important feature of the cracking model is that, while crack initiation is based on Mode I fracture only, postcracked behavior includes Mode II as well as Mode I.

Mode II shear behavior is based on the common observation that the shear behavior depends on the amount of crack opening. More specifically, the cracked shear modulus is reduced as the crack opens. Therefore, Abaqus/Explicit offers a shear retention model in which the postcracked shear stiffness is defined as a function of the opening strain across the crack.

You must provide postcracking shear data to complete a brittle cracking model definition. See *Shear Retention Model*, for more information.

1. Create a material model as described in *Defining a brittle cracking model*."
2. From the **Suboptions** menu in the **Edit Material** dialog box, select **Brittle Shear**.

   A **Suboption Editor** appears.
3. Click the arrow to the right of the **Type** field, and select a method for specifying postcracking shear behavior:
   - Select **Retention Factor** to specify the postcracking shear behavior by entering the shear retention factor-crack opening strain relationship directly.
   - Select **Power Law** to specify the postcracking shear behavior by entering the mateiral parameters for the power law shear retention model.
4. Toggle on **Use temperature-dependent data** to define data that depend on temperature.

   A column labeled **Temp** appears in the **Data** table.
5. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the data depend.
6. If you selected **Retention Factor** from the list of **Type** options, enter the following data in the **Data** table:

   #### Shear retention factor

   Shear retention factor, ρ.

   #### Crack opening strain

   Crack opening strain, ϵ_{nn}^{ck}.

   #### Temp

   Temperature.

   #### Field *n*

   Predefined field variables.

   You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.
7. If you selected **Power Law** from the list of **Type** options, enter the following data in the **Data** table:

e and p

Material parameters $\tilde{\varepsilon}^{ck}_{max}$ and p.

Temp

Temperature.

Field *n*

Predefined field variables.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

8. Click **OK** to return to the **Edit Material** dialog box.

Defining brittle failure

When one, two, or all three local direct cracking strain or displacement components at a material point reach the value defined as the failure strain or displacement, the material point fails and all the stress components are set to zero. If all of the material points in an element fail, the element is removed from the mesh. See *Brittle Failure Criterion*, for more information.

1. Create a material model as described in *Defining a brittle cracking model*."
2. From the **Suboptions** menu in the **Edit Material** dialog box, select **Brittle Failure**.

   A **Suboption Editor** appears.
3. Select an option from the list of **Failure criteria**:
   - Select **Unidirectional** to indicate that an element will be removed when any local direct cracking strain (or displacement) component reaches the failure value.
   - Select **Bidirectional** to indicate that an element will be removed when any two direct cracking strain (or displacement) components reach the failure value.
   - Select **Tridirectional** to indicate that an element will be removed when all three possible direct cracking strain (or displacement) components reach the failure value.
4. Toggle on **Use temperature-dependent data** to define data that depend on temperature.

   A column labeled **Temp** appears in the **Data** table.
5. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the data depend.
6. Enter the following data in the **Data** table:

Direct cracking failure strain or displacement

The value you enter depends on the method you chose in the **Edit Material** dialog box for specifying postcracking behavior (as described in *Defining a brittle cracking model*").

If you selected **Strain**, enter the direct cracking failure strain, $\left(\tilde{\varepsilon}_{nn}^{ck}\right)_f$.

If you selected **Displacement** or **GFI**, enter the direct cracking failure displacement, $\left(u_n^{ck}\right)_f$. (Units of L.)

Temp

Temperature.

Field *n*

Predefined field variables.

7. Click **OK** to return to the **Edit Material** dialog box.

Defining equations of state

The **Edit Material** dialog box allows you to define a hydrodynamic model in the form of an equation of state.

In this section:

- *Defining an equation of state*
- *Defining an ignition and growth equation of state*
- *Defining plastic compaction behavior for an equation of state*
- *Defining detonation points for an explosive material*
- *Defining tensile failure for an equation of state*

Defining an equation of state

You can use the **Edit Material** dialog box to define a hydrodynamic material model in which the material's volumetric strength is determined by an equation of state.
For more information, see *Equation of State*.

1. From the menu in the **Edit Material** dialog box, select **Mechanical->Eos**.

   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)

2. Click the arrow to the right of the **Type** field, and select the type of equation of state that you want to define:

   - Select **Ideal Gas** to define an ideal gas equation of state. For more information, see *Ideal Gas Equation of State*.
   - Select **JWL** to define a Jones-Wilkins-Lee explosive equation of state. For more information, see *JWL High Explosive Equation of State*.
   - Select **Us-Up** to define a linear $U_s - U_p$ equation of state. For more information, see *Mie-Grüneisen Equations of State*.
   - Select **Ignition and growth** to define an equation of state that models shock initiation and detonation wave propagation. For more information, see *Ignition and Growth Equation of State*.
   - Select **Tabular** to define a tabulated equation of state linear in energy. For more information, see *Tabulated Equation of State*.

3. If you selected **Ideal Gas** in Step 2, enter the following data in the **Data** table:

Gas Constant

Gas constant, R. (Units of $JM^{-1}K^{-1}$.)

Ambient Pressure

The ambient pressure, p_A (Units of FL^{-2}).

For detailed information on how to enter data, see *Entering tabular data*.

4. If you selected **JWL** in Step 2, enter the following data in the **Data** table:

Detonation Wave Speed

Detonation wave speed, C_d. (Units of LT^{-1}.)

A and B

Material constants A, and B. (Units of FL^{-2}.)

omega, R1, and R2

Material constants ω, R_1, and R_2. (Dimensionless.)

Detonation Energy Dens

Detonation energy density, E_0. (Units of JM^{-1}.)

Pre-deton Bulk Modulus

Pre-detonation bulk modulus, K_{pd}. (Units of FL^{-2}.)

For detailed information on how to enter data, see *Entering tabular data*.

5. If you selected **Us-Up** in Step 2, enter the following data in the **Data** table:

c0

Reference sound speed, c_0. (Units of LT^{-1}.)

s

Slope of the $U_s - U_p$ curve, s. (Dimensionless.)

Gamma0

Grüneisen ratio, Γ_0. (Dimensionless.)

For detailed information on how to enter data, see *Entering tabular data*.

6. If you selected **Tabular** in Step 2, enter the following data in the **Data** table. The volumetric strain values must be arranged in descending order (that is, from the most tensile to the most compressive states).

f1

f_1. (Units of FL^{-2}.)

f2

f_2. (Dimensionless.)

epsilon_vol

Volumetric strain ε_{vol}. (Dimensionless.)

For detailed information on how to enter data, see *Entering tabular data*.

7. If you selected **Ignition and growth** in Step 2, see *Defining an ignition and growth equation of state* for detailed instructions.
8. If you selected **JWL** in Step 2, select **Detonation Point** from the **Suboptions** menu to define detonation points for the explosive material. For detailed instructions, see *Defining detonation points for an explosive material*.
9. If you selected **Us-Up** or **Tabular** in Step 2, you can select **Eos Compaction** from the **Suboptions** menu to specify plastic compaction behavior for a ductile porous material. For detailed instructions, see *Defining plastic compaction behavior for an equation of state*.
10. If you selected **JWL**, **Us-Up**, or **Tabular** in Step 2, you can select **Tensile Failure** from the **Suboptions** menu to specify a tensile failure model and criterion. For detailed instructions, see *Defining tensile failure for an equation of state*.

11. Click **OK** to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Defining an ignition and growth equation of state

The ignition and growth equation of state models shock initiation and detonation wave propagation for a solid high-explosive material.

For more information, see *Ignition and Growth Equation of State*.

1. Define an ignition and growth equation of state, as described in *Defining an equation of state*.
2. In the **Detonation energy** field, enter a value for E_d. The default value is 0.
3. On the **Solid Phase** tabbed page, enter the following material constants for the unreacted solid explosive in the **Data** table:

A and B

Material constants A and B. (Units of FL^{-2}.)

omega, R1, and R2

Material constants ω, R_1, and R_2. (Dimensionless.)

For detailed information on how to enter data, see *Entering tabular data*.

4. On the **Gas Phase** tabbed page, enter the following material constants for the reacted gas product in the **Data** table:

A and B

Material constants A and B. (Units of FL^{-2}.)

omega, R1, and R2

Material constants ω, R_1, and R_2. (Dimensionless.)

For detailed information on how to enter data, see *Entering tabular data*.

5. On the **Reaction Rate** tabbed page, enter the following data in the **Data** table:

I

Constant. (Units of T^{-1}.)

a

Product covolume. (Dimensionless.)

b

Exponent on the unreacted fraction (ignition term). (Dimensionless.)

x

Exponent (ignition term). (Dimensionless.)

G1

First burn rate coefficient. (Units depend on units of pressure.)

c

Exponent on the unreacted fraction (growth term). (Dimensionless.)

d

Exponent on the reacted fraction (growth term). (Dimensionless.)

y

Pressure exponent (growth term). (Dimensionless.)

G2

Second burn rate coefficient. (Units depend on units of pressure.)

e

Exponent on the unreacted fraction (completion term). (Dimensionless.)

g

Exponent on the reacted fraction (completion term). (Dimensionless.)

z

Pressure exponent (completion term). (Dimensionless.)

Fig(max)

Initial reacted fraction, F_{ig}^{max}. (Dimensionless.)

FG1(max)

Maximum reacted fraction for the growth term, F_{G1}^{max}. (Dimensionless.)

FG2(min)

Minimum reacted fraction for the completion term, F_{G2}^{min}. (Dimensionless.)

For detailed information on how to enter data, see *Entering tabular data*.

6. On the **Gas Specific** tabbed page, enter specific heat data for the reacted gas product.
   a. Toggle on **Use temperature-dependent data** to define data that depend on temperature. A column labeled **Temp** appears in the **Data** table.
   b. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the data depend.

c. Enter the following data in the **Data** table:

Specific Heat

Specific heat of the reacted gas product, per unit mass. (Units of $JM^{-1}\theta^{-1}$.)

Temp

Temperature.

Field *n*

Predefined field variables.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

7. Click **OK** to create the material and to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Defining plastic compaction behavior for an equation of state

If you define a linear $U_s - U_p$ or tabulated equation of state (as described in *Defining an equation of state*"), you can use the **Suboption Editor** to specify plastic compaction behavior for a ductile porous material. For more information, see *P–alpha Equation of State*.

1. Define a $U_s - U_p$ or tabulated equation of state, as described in *Defining an equation of state*."
2. From the **Suboptions** menu in the **Edit Material** dialog box, select **Eos Compaction**.

   A **Suboption Editor** appears.
3. In the **Reference sound speed in the porous material** field, enter a value for c_e. (Units of LT^{-1}.)
4. In the **Value of the porosity of the unloaded material** field, enter a value for n_0. (Dimensionless.)
5. In the **Pressure required to initialize plastic behavior** field, enter a value for p_e. (Units of FL^{-2}.)
6. In the **Compaction pressure at which all pores are crushed** field, enter a value for p_s. (Units of FL^{-2}.)
7. Click **OK** to return to the **Edit Material** dialog box.

Defining detonation points for an explosive material

You can define any number of detonation points for an explosive material. Coordinates of the points must be defined along with a detonation delay time. Each material point responds to the first detonation point that it sees. For more information, see *JWL High Explosive Equation of State*.

1. Define a Jones-Wilkins-Lee (JWL) equation of state, as described in *Defining an equation of state*."
2. From the **Suboptions** menu in the **Edit Material** dialog box, select **Detonation Point**.
   A **Suboption Editor** appears.
3. Enter the following data in the **Data** table:

   X

   Coordinate 1 of the detonation point.

   Y

   Coordinate 2 of the detonation point.

   Z

   Coordinate 3 of the detonation point.

   Detonation Delay Time

   Detonation delay time (total time, as defined in *Conventions*). The default is 0.

   For detailed information on how to enter data, see *Entering tabular data*.
4. Click **OK** to return to the **Edit Material** dialog box.

Defining tensile failure for an equation of state

The tensile failure model for an equation of state uses the hydrostatic pressure stress as a failure measure to model dynamic spall (the crumbling of a material) or pressure cutoff.
For more information, see *Tensile Failure Model*.

1. Define a Jones-Wilkins-Lee (JWL), Us-Up, or tabular equation of state, as described in *Defining an equation of state*.
2. From the **Suboptions** menu in the **Edit Material** dialog box, select **Tensile Failure**.

   A **Suboption Editor** appears.
3. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the hydrostatic cutoff stress depends.
4. Select **Use temperature-dependent data** to define the data that depend on temperature.

   A column labeled **Temp** appears in the **Data** table.
5. Specify the failure choice for the failed material points.

   - Select **Allow element deletion when the failure criterion is met** to allow element removal.
   - Specify behavior for the pressure stress and deviatoric stresses.

     1. From the **Pressure** list, select the behavior for the pressure stress.

        - Select **BRITTLE** to require the pressure stress to be compressive when the failure criterion is met.
        - Select **DUCTILE** to limit the pressure stress by the hydrostatic cutoff stress when the failure criterion is met.

     2. From the **Shear** list, select the behavior for the deviatoric stresses.

        - Select **BRITTLE** to set the deviatoric stress to zero when the failure criterion is met.
        - Select **DUCTILE** to specify that the deviatoric stresses are unaffected when the failure criterion is met.
6. Enter the following data in the **Data** table:

   #### Hydrostatic cutoff stress

   Value of the hydrostatic cutoff stress, σ_{cutoff} (positive in tension).

   #### Temp

   Temperature.

   #### Field *n*

   Predefined field variables.

   For detailed information on how to enter data, see *Entering tabular data*.
7. Click **OK** to return to the **Edit Material** dialog box.

Defining viscosity

You can define Newtonian viscosity for a material. See *Viscosity*, for more information.

1. From the menu bar in the **Edit Material** dialog box, select **Mechanical->Viscosity**.
   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Toggle on **Use temperature-dependent data** to define data that depend on temperature.
   A column labeled **Temp** appears in the **Data** table.
3. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the data depend.
4. Enter the following data in the **Data** table:

Dynamic Viscosity

Dynamic viscosity.

Temp

Temperature.

Field *n*

Predefined field variables.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

5. Click **OK** to create the material and to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Defining superelasticity

You can use the superelastic material model to model Nitinol-type materials that undergo solid-solid, martensitic phase transformation and exhibit superelastic response.
This model can also be used to model the stress-induced transformation of austenite to single variant martensite, the stress-induced transformation of martensite to austenite, reorientation of martensite, and the shape setting process.

In this section:

- *Defining a superelasticity model*
- *Defining superelastic hardening*
- *Defining superelastic hardening modifications*

Defining a superelasticity model

The superelastic model and the plasticity model for superelastic materials are based on the uniaxial stress-strain response of phase transforming materials.
Such materials (e.g., Nitinol) are in the austenite phase under no loading conditions. Austenite is assumed to follow isotropic linear elasticity. On loading the material, the austenite phase starts transforming into martensite beyond a certain stress.

In the superelastic model martensite is also assumed to follow isotropic linear elasticity. During the phase transformation, elastic properties are calculated from the elastic constants of austenite and martensite.

In the plasticity model for superelastic materials martensite is assumed to follow an elastoplastic response, with elasticity characterized by the linear elastic model and the plastic behavior represented by the Drucker-Prager model. Martensite exhibits plastic behavior after full transformation.

1. From the menu bar in the **Edit Material** dialog box, select **Mechanical->Superelasticity**.
   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Toggle on **Nonassociated** to specify the volumetric transformation strain, ε_V^L. Otherwise, Abaqus assumes the volumetric transformation strain is equal to the uniaxial transformation strain, ε^L.
3. Enter the following data in the **Data** table:

Young's Modulus (Martensite)

Young's modulus of martensite, E_M.

Poisson's Ratio (Martensite)

Poisson's ratio of martensite, ν_M.

Transformation Strain

Uniaxial transformation strain, ε^L.

Start of Transformation (Loading)

Stress at which the transformation begins during loading in tension, σ_{tL}^S.

End of Transformation (Loading)

Stress at which the transformation ends during loading in tension, σ_{tL}^E.

Start of Transformation (Unloading)

Stress at which the reverse transformation begins during unloading in tension, σ_{tU}^S.

End of Transformation (Unloading)

Stress at which the reverse transformation ends during unloading in tension, σ_{tU}^E.

Start of Transformation in Compression (Loading)

Stress at which the transformation begins during loading in compression, as a positive value, σ_{cL}^{S}.

Reference Temperature

Reference temperature, T_0.

Loading

Slope of the stress versus temperature curve for loading, $\left(\frac{\delta\sigma}{\delta T}\right)_L$.

Unloading

Slope of the stress versus temperature curve for unloading, $\left(\frac{\delta\sigma}{\delta T}\right)_U$.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

4. Select **Superelastic Hardening** from the **Suboptions** menu to define piecewise linear hardening of martensite. See *Defining superelastic hardening* for details.
5. Select **Superelastic Hardening Modifications** from the **Suboptions** menu to specify the variation of the transformation stress levels of a superelastic material as a function of the plastic strain. See *Defining superelastic hardening modifications* for details.
6. Click **OK** to create the material and to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

- *Superelasticity*
- *Plasticity Model for Superelastic Materials*

Defining superelastic hardening

You specify the dependence of the yield stress on the total strain to define the piecewise linear hardening of martensite.

1. Create a material model as described in *Defining a superelasticity model*.
2. From the **Suboptions** menu in the **Edit Material** dialog box, select **Superelastic Hardening**.

   A **Suboption Editor** appears.
3. Enter the following data in the **Data** table:

   Yield Stress

   Yield stress.

   Total Strain

   Total strain.

   For detailed information on how to enter data, see *Entering tabular data*.
4. Click **OK** to return to the **Edit Material** dialog box.

• *Plasticity Model for Superelastic Materials*

Defining superelastic hardening modifications

You specify the variation of the transformation stress levels of a superelastic material as a function of the plastic strain. You can specify the data describing the change in transformation stress levels as a function of the plastic strain, or you can use a user subroutine to define this dependency.

1. Create a material model as described in *Defining a superelasticity model*.
2. Define superelastic hardening as described in *Defining superelastic hardening*.
3. From the **Suboptions** menu in the **Edit Material** dialog box, select **Superelastic Hardening Modifications**.

   A **Suboption Editor** appears.

4. To specify the data describing the change in transformation stress levels as a function of the plastic strain, enter the following data in the **Data** table:

   #### Start of Transformation (Loading)

   Stress at which the transformation begins during loading in tension, σ_{tL}^{S}.

   #### End of Transformation (Loading)

   Stress at which the transformation ends during loading in tension, σ_{tL}^{E}.

   #### Start of Transformation (Unloading)

   Stress at which the reverse transformation begins during unloading in tension, σ_{tU}^{S}.

   #### End of Transformation (Unloading)

   Stress at which the reverse transformation ends during unloading in tension, σ_{tU}^{E}.

   #### Plastic Strain

   Plastic strain.

   You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

5. Toggle on **User** to define the dependence of the transformation stress levels on plastic strain in user subroutine *USUPERELASHARDMOD* (for Abaqus/Standard) or *VUSUPERELASHARDMOD* (for Abaqus/Explicit), and do the following:
   a. Click the arrows to the right of the **Number of properties** field to increase or decrease the number of hardening properties you want to specify in the data table.
   b. In the **Data** table, enter the hardening properties.

      You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

6. Click **OK** to return to the **Edit Material** dialog box.

• *Plasticity Model for Superelastic Materials*

Defining crush stress

You can use the crush stress material model to specify the compressive crush stress magnitude of a material at an active crush front for the CZone capability.
See *CZone Crush Stress* for more information.

In this section:

- *Defining a crush stress model*
- *Defining crush stress velocity factor*

Defining a crush stress model

The crush stress can be thought of as the stress of the crushing body at the crushing interface. The crush stress is specified as a material property but does not directly influence the constitutive calculations associated with element integration points; rather, the crush stress limits the contact pressure magnitude at an actively crushing interface. See *CZone Analysis* for more information.

In the crush stress model, the composite material can be a constant or can vary as a function of the angle, θ, between the local x-direction of the crushable element and the contact normal direction projected to the plane of the element.

1. From the menu bar in the **Edit Material** dialog box, select **Mechanical->Crush Stress**.

   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Toggle on **Use temperature-dependent data** to define data that depend on temperature.

   A column labeled **Temp** appears in the **Data** table.
3. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the data depend.
4. Enter the following data in the **Data** table:

Crush Stress

Crush stress.

Material angle (degrees)

Material angle in degrees.

Temp

Temperature.

Field *n*

Predefined field variables.

You can expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

5. Select **Velocity Factor** from the **Suboptions** menu to define how the approach velocity at a crushing interface influences a material's resistance to crushing (see *Defining crush stress velocity factor* for details).
6. Click **OK** to create the material and to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Defining crush stress velocity factor

You can specify the influence of the approach velocity at a crushing interface on a material's resistance to crushing.

1. Create a material model as described in *Defining a crush stress model*.
2. From the **Suboptions** menu in the **Edit Material** dialog box, select **Velocity Factor**.

   A **Suboption Editor** appears.

3. Enter the following data in the **Data** table:

   #### Scaling factor

   Scaling factor.

   #### Relative velocity

   Relative velocity between the two surfaces.

   For detailed information on how to enter data, see *Entering tabular data*.

4. Click **OK** to return to the **Edit Material** dialog box.

Defining plasticity correction

You can use the plasticity correction material model to estimate the elastic-plastic response of the material with linear elasticity.

In this section:

- *Defining a Ramberg-Osgood model*
- *Defining a Tabular model*

Defining a Ramberg-Osgood model

The Ramberg-Osgood model is based on the observation that the stress versus plastic strain response is linear when plotted in the logarithmic scale.
The total strain is decomposed into the elastic and plastic component.

1. From the menu bar in the **Edit Material** dialog box, select **Mechanical->Plasticity Correction**.
   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Select the **Definition** as **Ramberg-Osgood** to define this plastic response for the evaluation of the plasticity correction.
3. Toggle on **Use temperature-dependent data** to define data that depend on temperature.
   A column labeled **Temp** appears in the **Data** table.
4. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the data depend.
5. Enter the following data in the **Data** table:

K, n

Material constants K,n.

Temp

Temperature.

Field *n*

Predefined field variables.

You can expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

6. Click **OK** to create the material and to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors* for more information).

Defining a Tabular model

The tabular model of plasticity correction allows you to specify the hardening curve directly by providing the yield stress as a function of the equivalent plastic strain.

1. From the menu bar in the **Edit Material** dialog box, select **Mechanical->Plasticity Correction**.

   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Select the **Definition** as **Tabular** to define this plastic response for the evaluation of the plasticity correction.
3. Toggle on **Use temperature-dependent data** to define data that depend on temperature.

   A column labeled **Temp** appears in the **Data** table.
4. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the data depend.
5. Enter the following data in the **Data** table:

   #### Yield Stress

   Yield stress.

   #### Plastic Strain

   Plastic strain.

   #### Temp

   Temperature.

   #### Field *n*

   Predefined field variables.

   You can expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.
6. Click **OK** to create the material and to close the **Edit Material** dialog box.
7. **Optional:** Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors* for more information).

Defining thermal material models

This section describes how you can define a thermal material model.

In this section:

- *Specifying thermal conductivity*
- *Including volumetric heat flux due to internal heat generation*
- *Specifying an inelastic heat fraction*
- *Specifying a joule heat fraction*
- *Specifying latent heat data*
- *Defining specific heat*
- *Defining thermal conductance for gasket/cohesive elements*
- *Defining thermal radiation for cohesive elements*

Specifying thermal conductivity

You can use the **Edit Material** dialog box to specify isotropic, orthotropic, or fully anisotropic thermal conductivity. For more information, see *Conductivity*.

1. From the menu bar in the **Edit Material** dialog box, select **Thermal->Conductivity**.

   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Click the arrow to the right of the **Type** field, and specify the directional dependence of the thermal conductivity.
3. Toggle on **Use temperature-dependent data** to define conductivity as a function of temperature.

   A column labeled **Temp** appears in the **Data** table.
4. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which conductivity depends.
5. Enter the applicable data in the **Data** table:

Conductivity

Isotropic conductivity, k. (Units of $JT^{-1}L^{-1}\theta^{-1}$.)

k11, k22, and k33

Three values for orthotropic conductivity, k_{11}, k_{22}, and k_{33}. (Units of $JT^{-1}L^{-1}\theta^{-1}$.)

k11, k12, k22, k13, k23, and k33

Six values for anisotropic conductivity, k_{11}, k_{12}, k_{22}, k_{13}, k_{23} and k_{33}. (Units of $JT^{-1}L^{-1}\theta^{-1}$.)

Temp

Temperature.

Field *n*

Predefined field variables.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

6. Click **OK** to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Including volumetric heat flux due to internal heat generation

You can define a heat flux due to internal heat generation in conjunction with user subroutines.

User subroutine *HETVAL* allows you to define a heat flux due to internal heat generation for heat transfer, coupled thermal-electric, or coupled temperature-displacement analyses. User subroutine *VHETVAL* allows you to define a heat flux due to internal heat generation for coupled temperature-displacement analyses.

Abaqus/Standard calls user subroutine *HETVAL* and Abaqus/Explicit calls *VHETVAL* at each point for which the material definition includes a reference to the user subroutine.

1. From the menu bar in the **Edit Material** dialog box, select **Thermal->Heat Generation**.

   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Click **OK** to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (for more information, see *Browsing and modifying material behaviors*).
3. Enter the Job module and display the job editor for the analysis job of interest. (For more information, see *Creating, editing, and manipulating jobs*.)
4. In the job editor, click the **General** tab, and specify the file containing user subroutine *HETVAL* or *VHETVAL*. For more information, see *Specifying general job settings*.

Note:

You can specify only one user subroutine file in the job editor; if your analysis involves more than one user subroutine, you must combine the user subroutines into one file and then specify that file.

- *HETVAL*
- *VHETVAL*

Specifying an inelastic heat fraction

You can specify an inelastic heat fraction to provide for inelastic energy dissipation as a heat source in an adiabatic or fully coupled thermal-stress analysis.

Inelastic heat fractions are typically used in the simulation of high-speed manufacturing processes involving large amounts of inelastic strain, where the heating of the material caused by its deformation significantly influences temperature-dependent material properties. The generated heat is treated as a volumetric heat flux source term in the heat balance equation.

See the following sections for more information:

- *Inelastic Energy Dissipation as a Heat Source*
- *Adiabatic Analysis*

1. From the menu bar in the **Edit Material** dialog box, select **Thermal->Inelastic Heat Fraction**.
   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. In the **Fraction** field, enter the fraction of inelastic dissipation rate that appears as a heat flux per unit volume. The fraction may include a unit conversion factor if required. The default value is 0.9.
3. Click **OK** to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Specifying a joule heat fraction

Joule heating arises when the energy dissipated by an electrical current flowing through a conductor is converted into thermal energy. A joule heat fraction is the fraction of dissipated electrical energy released as heat in coupled thermal-electrical problems.

See the following sections for more information:

- *Coupled Thermal-Electrical Analysis*
- *Specifying the Amount of Thermal Energy Generated due to Electrical Current*

1. From the menu bar in the **Edit Material** dialog box, select **Thermal->Joule Heat Fraction**.
   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. In the **Fraction** field, enter the fraction of electrical energy released as heat, including any unit conversion factor. The default value is 1.0.
3. Click **OK** to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Specifying latent heat data

A material's latent heat models large changes in internal energy during phase change of the material. The latent heat is assumed to be released over a range of temperatures from a lower (solidus) temperature to an upper (liquidus) temperature.

If the phase change occurs within a known temperature range, you can enter the solidus and liquidus temperatures directly in the **Edit Material** dialog box. Otherwise you must model the effect with a user subroutine. See *Latent Heat*, for more information.

1. From the menu bar in the **Edit Material** dialog box, select **Thermal->Latent Heat**.
   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Enter the following data in the **Data** table:

Latent Heat

Latent heat per unit mass. (Units of JM^{-1}.)

Solidus Temp

Low end of the temperature range within which the phase changes occurs.

Liquidus Temp

High end of the temperature range within which the phase changes occurs.

For detailed information on how to enter data, see *Entering tabular data*.

3. Click **OK** to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Defining specific heat

You can define the specific heat per unit mass of a material as a function of temperature and field variables. When possible, you should model large changes in internal energy during a phase change with a latent heat definition rather than a specific heat definition. See the following sections for more information:

- *Specific Heat*
- *Specifying latent heat data*

1. From the menu bar in the **Edit Material** dialog box, select **Thermal->Specific Heat**.
   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Choose the specific heat **Type**:
   - Use **Constant Volume** for a structural model in Abaqus/Standard or Abaqus/Explicit.
3. Toggle on **Use temperature-dependent data** to define specific heat as a function of temperature.
   A column labeled **Temp** appears in the **Data** table.
4. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the specific heat depends.
5. Enter the following data in the **Data** table:

Specific Heat

Specific heat per unit mass. (Units of $JM^{-1}\theta^{-1}$.)

Temp

Temperature

Field *n*

Predefined field variables.

For detailed information on how to enter data, see *Entering tabular data*.

6. Click **OK** to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Defining thermal conductance for gasket/cohesive elements

You can use the **Edit Material** dialog box to define thermal interaction between the top and bottom surfaces of a coupled temperature-displacement gasket element and coupled temperature-displacement cohesive elements.

For more information, see:

- *Defining a Thermal Interaction for a Cohesive Element*
- *Defining a Thermal Interaction for a Gasket Element*

1. From the menu in the **Edit Material** dialog box, select **Thermal->Gap Conductance**.
   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Toggle on **Use pressure-dependent data** to define the gap conductance parameters as a function of pressure.
3. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the gap conductance depends.
4. Enter the following data in the **Data** table:

Gap Conductance

Gap conductance or cohesive separation, k.

Gap Clearance, Gap Pressure, or Closure

Gap clearance, gap pressure (if **Use pressure-dependent data** is toggled on), or closure (for coupled temperature-displacement gasket elements).

Field *n*

Predefined field variables.

For detailed information on how to enter data, see *Entering tabular data*.

5. Toggle on **User Defined** to define the gap conductance in user subroutine *GAPCON*. Other parameter settings and any data lines are ignored.
6. Click **OK** to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Defining thermal radiation for cohesive elements

You can use the **Edit Material** dialog box to define radiative heat transfer between the top and bottom surfaces when the surfaces are separated by a narrow gap. For more information, see *Defining a Thermal Interaction for a Cohesive Element*.

1. From the menu in the **Edit Material** dialog box, select **Thermal->Gap Radiation**.
   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Enter values for **Secondary Surface Emissivity** and **Main Surface Emissivity**.
3. Enter the following data in the **Data** table:

Effective View Factor

Effective view factor.

Gap Clearance

Gap clearance.

Repeat this data line as often as necessary to define the dependence of the view factor on gap clearance.

For detailed information on how to enter data, see *Entering tabular data*.

4. Click **OK** to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Defining electrical and magnetic material models

This section describes how you can define an electrical or magnetic material model.

In this section:

- *Defining electrical conductivity*
- *Defining dielectric material properties*
- *Defining piezoelectric properties*
- *Defining magnetic permeability*

Defining electrical conductivity

If you are using a material in a coupled thermal-electrical or coupled thermal-electrical-structural analysis, you must define the material's electrical conductivity. For a time-harmonic eddy current analysis, the material's electrical conductivity must be used to define the electromagnetic response of a conductor. You can specify electrical conductivity that is isotropic, orthotropic, or fully anisotropic. See the following sections for more information:

- *Electrical Conductivity*
- *Coupled Thermal-Electrical Analysis*
- *Fully Coupled Thermal-Electrical-Structural Analysis*
- *Eddy Current Analysis*

1. From the menu bar in the **Edit Material** dialog box, select **Electrical/Magnetic->Electrical Conductivity**.

   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Click the arrow to the right of the **Type** field, and specify the directional dependence of the electrical conductivity.
3. Toggle on **Use frequency-dependent data** to define electrical conductivity that varies with frequency.

   A column labeled **Frequency** appears in the **Data** table.
4. Toggle on **Use temperature-dependent data** to define electrical conductivity as a function of temperature.

   A column labeled **Temp** appears in the **Data** table.
5. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which electrical conductivity depends.
6. Enter the applicable data in the **Data** table:

Conductivity

Isotropic electrical conductivity. (Units of $CT^{-1}L^{-1}\varphi^{-1}$.)

s11(E), s22(E), and s33(E)

Three values for orthotropic electrical conductivity, σ_{11}^{E}, σ_{22}^{E}, and σ_{33}^{E}. (Units of $CT^{-1}L^{-1}\varphi^{-1}$.)

s11(E), s12(E), s22(E), s13(E), s23(E), and s33(E)

Six values for anisotropic electrical conductivity, σ_{11}^{E}, σ_{12}^{E}, σ_{22}^{E}, σ_{13}^{E}, σ_{23}^{E}, and σ_{33}^{E}. (Units of $CT^{-1}L^{-1}\varphi^{-1}$.)

Frequency

Frequency in cycles/time.

Temp

Temperature.

Field *n*

Predefined field variables.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

7. Click **OK** to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Defining dielectric material properties

The **Edit Material** dialog box allows you to define the dielectric properties (electrical permittivity) of a fully constrained material for use in a coupled piezoelectric analysis. For more information, see *Piezoelectric Behavior*.

1. From the menu bar in the **Edit Material** dialog box, select **Electrical/Magnetic->Dielectric (Electrical Permittivity)**.

   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Click the arrow to the right of the **Type** field, and specify the directional dependence of the dielectric constant.
3. Toggle on **Use temperature-dependent data** to define the dielectric constant as a function of temperature.

   A column labeled **Temp** appears in the **Data** table.
4. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the dielectric constant depends.
5. Enter the applicable data in the **Data** table:

Dielectric constant

Dielectric constant for isotropic behavior. (Units of $C\varphi^{-1}L^{-1}$.)

D11, D22, and D33

Three values to define orthotropic behavior, $D_{11}^{\varphi(\varepsilon)}$, $D_{22}^{\varphi(\varepsilon)}$, and $D_{33}^{\varphi(\varepsilon)}$. (Units of $C\varphi^{-1}L^{-1}$.)

D11, D12, D22, D13, D23, D33

Six values to define anisotropic behavior, $D_{11}^{\varphi(\varepsilon)}$, $D_{12}^{\varphi(\varepsilon)}$, $D_{22}^{\varphi(\varepsilon)}$, $D_{13}^{\varphi(\varepsilon)}$, $D_{23}^{\varphi(\varepsilon)}$, $D_{33}^{\varphi(\varepsilon)}$. (Units of $C\varphi^{-1}L^{-1}$.)

Temp

Temperature.

Field *n*

Predefined field variables.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

6. Click **OK** to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Defining piezoelectric properties

You can define piezoelectric material properties by providing the stress coefficients, e^{φ}_{mij}, or the strain coefficients, d^{φ}_{mkl}. For more information, see *Piezoelectric Behavior*.

1. From the menu bar in the **Edit Material** dialog box, select **Electrical/Magnetic->Piezoelectric**.

   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Toggle on **Use temperature-dependent data** to define piezoelectric properties as a function of temperature.

   A column labeled **Temp** appears in the **Data** table.
3. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the piezoelectric properties depend.
4. In the **Data** table, enter the piezoelectric stress or strain coefficient matrix. For more information, see *Specifying Piezoelectric Material Properties*. Enter values for temperature and field variables if applicable.

   For detailed information on how to enter data, see *Entering tabular data*.
5. Click **OK** to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Defining magnetic permeability

For a time-harmonic eddy current analysis, you must define the material's magnetic permeability. You can specify magnetic permeability that is isotropic, orthotropic, or fully anisotropic. See the following sections for more information:

- *Magnetic Permeability*
- *Eddy Current Analysis*

1. From the menu bar in the **Edit Material** dialog box, select **Electrical/Magnetic->Magnetic Permeability**.

   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)

2. Toggle on **Specify using nonlinear B-H curve** to define nonlinear magnetic permeability.

   Columns labeled **B** and **H** replace the **Magnetic Permeability** column used for linear data in the **Data** table.

3. Click the arrow to the right of the **Type** field, and specify the directional dependence of the magnetic permeability.
4. Toggle on **Use frequency-dependent data** to define magnetic permeability that varies with frequency.

   A column labeled **Frequency** appears in the **Data** table.

   Note:

   Frequency dependence is not available for nonlinear magnetic permeability.

5. Toggle on **Use temperature-dependent data** to define magnetic permeability as a function of temperature.

   A column labeled **Temp** appears in the **Data** table.

6. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which magnetic permeability depends.
7. Enter the applicable data in the **Data** table:

B

Strength of the magnetic flux density vector.

You must provide a single set of values for isotropic nonlinear magnetic permeability and a set of values for each of the three principal directions for orthotropic nonlinear magnetic permeability.

H

Strength of the magnetic field vector.

You must provide a single set of values for isotropic nonlinear magnetic permeability and a set of values for each of the three principal directions for orthotropic nonlinear magnetic permeability.

Magnetic Permeability

Isotropic linear magnetic permeability. (Units of FA^{-2}.)

mu11(E), mu22(E), and mu33(E)

Three values for orthotropic linear magnetic permeability, μ_{11}, μ_{22}, and μ_{33}. (Units of FA^{-2}.)

mu11(E), mu12(E), mu22(E), mu13(E), mu23(E), and mu33(E)

Six values for anisotropic linear magnetic permeability, μ_{11}, μ_{12}, μ_{22}, μ_{13}, μ_{23}, and μ_{33}. (Units of FA^{-2}.)

Frequency

Frequency in cycles/time.

Temp

Temperature.

Field *n*

Predefined field variables.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

8. Click **OK** to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Defining other types of material models

This section describes how you can define additional types of material models.

In this section:

- *Defining an acoustic medium*
- *Defining mass diffusion*
- *Defining a fluid-filled porous material*
- *Defining gasket behavior*

Defining an acoustic medium

You can define an acoustic medium to model sound propagation problems in a purely acoustic analysis or in a coupled acoustic-structural analysis. For more information, see *Acoustic Medium*.

1. From the menu bar in the **Edit Material** dialog box, select **Other->Acoustic Medium**.

   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Display the **Bulk Modulus** tabbed page.
3. Toggle on **Use temperature-dependent data** to define the bulk modulus as a function of temperature.

   A column labeled **Temp** appears in the **Data** table.
4. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the bulk modulus depends.
5. Enter the following data in the **Data** table:

Bulk Modulus

Bulk modulus, K_f. (Units of FL^{-2}.) For more information, see *Defining an Acoustic Medium*.

Temp

Temperature.

Field *n*

Predefined field variables.

For detailed information on how to enter data, see *Entering tabular data*.

6. If desired, display the **Volumetric Drag** tabbed page, and toggle on **Include volumetric drag**. For more information, see *Volumetric Drag*.

   If you want to omit volumetric drag data, skip to Step 11.
7. Toggle on **Use temperature-dependent data** to define the volumetric drag data as a function of temperature.

   A column labeled **Temp** appears in the **Data** table.
8. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the volumetric drag data depend.
9. Enter the following data in the **Data** table:

Volumetric Drag

Volumetric drag coefficient. (Units of FTL^{-4}.)

Frequency

Frequency. (Cycles/time.) Frequency dependence is active only during frequency domain procedures in Abaqus/Standard.

Temp

Temperature.

Field *n*

Predefined field variables.

For detailed information on how to enter data, see *Entering tabular data*.

10. Click **OK** to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Defining mass diffusion

You can use the **Edit Material** dialog box to define certain aspects of mass diffusion.

In this section:

- *Defining diffusivity*
- *Defining general temperature-driven mass diffusion*
- *Defining pressure-driven mass diffusion*
- *Defining solubility*

Defining diffusivity

Diffusivity defines the diffusion, or movement, of one material through another. The governing equations for mass diffusion are an extension of Fick's equations: they allow for nonuniform solubility of the diffusing substance in the base material and for mass diffusion driven by gradients of temperature and pressure. See the following sections for more information:

- *Diffusivity*
- *Mass Diffusion Analysis*

1. From the menu bar in the **Edit Material** dialog box, select **Other->Mass Diffusion->Diffusivity**. (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Click the arrow to the right of the **Type** field, and specify the directional dependence of the diffusivity.
3. Select a **Law** option to specify how you want to define diffusivity behavior:
   - Select **General** to choose general mass diffusion behavior.
   - Select **Fick** to choose Fick's diffusion law.

   For more information, see *Defining Diffusivity*.
4. Toggle on **Use temperature-dependent data** to define diffusivity data as a function of temperature. A column labeled **Temp** appears in the **Data** table.
5. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the diffusivity data depend.
6. In the **Data** table, enter the applicable data:

D

Isotropic diffusivity. (Units of L^2T^{-1}.)

D11, D22, and D33

Orthotropic diffusivity terms. (Units of L^2T^{-1}.)

D11, D12, D22, D13, D23, D33

Anisotropic diffusivity terms. (Units of L^2T^{-1}.)

Concentration

Mass concentration of the diffusing material.

Temp

Temperature.

Field *n*

Predefined field variables.

You may need to expand the dialog box to see all the columns in the **Data** table. For detailed information on how to enter data, see *Entering tabular data*.

7. To describe temperature-driven diffusion, select **Soret Effect** from the **Suboptions** menu. (This option is valid only if you selected **General** in Step 3.) See *Defining general temperature-driven mass diffusion*" for detailed instructions.
8. To describe pressure-driven mass diffusion, select **Pressure Effect** from the **Suboptions** menu. See *Defining pressure-driven mass diffusion*" for detailed instructions.
9. Click **OK** to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Defining general temperature-driven mass diffusion

The Soret effect factor, κ_s, governs temperature-driven mass diffusion. You can define the Soret effect factor as a function of concentration, temperature, and/or field variables. See *Diffusivity*, for more information.

Note:

You can specify the Soret effect factor only if you select general mass diffusion behavior in the diffusivity definition. (If you select Fick's diffusion law, the Soret effect factor is calculated automatically.) For more information, see *Fick's Law*.

1. Define diffusivity as described in *Defining diffusivity*."
2. From the **Suboptions** menu in the **Edit Material** dialog box, select **Soret Effect**.

   A **Suboption Editor** appears.
3. Toggle on **Use temperature-dependent data** to define the Soret effect factor as a function of temperature.

   A column labeled **Temp** appears in the **Data** table.
4. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables included in the definition of the Soret effect factor.
5. Enter the following data in the **Data** table:

kappa_s

Soret effect factor, κ_s. (Units of $F^{1/2}L^{-1}$.)

Concentration

Mass concentration of the diffusing material.

Temp

Temperature.

Field *n*

Predefined field variables.

6. Click **OK** to return to the **Edit Material** dialog box.

Defining pressure-driven mass diffusion

The pressure stress factor, κ_p, governs mass diffusion driven by the gradient of the equivalent pressure stress. You can define the pressure stress factor as a function of concentration, temperature, and/or field variables. See *Diffusivity*, for more information.

1. Define diffusivity as described in *Defining diffusivity*."
2. From the **Suboptions** menu in the **Edit Material** dialog box, select **Pressure Effect**.

   A **Suboption Editor** appears.
3. Toggle on **Use temperature-dependent data** to define the pressure stress factor as a function of temperature.

   A column labeled **Temp** appears in the **Data** table.
4. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables included in the definition of the pressure stress factor.
5. Enter the following data in the **Data** table:

kappa_p

Pressure stress factor, κ_p. (Units of $LF^{-1/2}$.)

Concentration

Mass concentration of the diffusing material.

Temp

Temperature.

Field *n*

Predefined field variables.

6. Click **OK** to return to the **Edit Material** dialog box.

Defining solubility

Solubility, s, is used to define the "normalized concentration," ϕ, of the diffusing phase in a mass diffusion process:

$$\phi = c/s,$$

where c is the concentration. The normalized concentration is often also referred to as the "activity" of the diffusing material, and the gradients of the normalized concentration, along with gradients of temperature and pressure stress, drive the diffusion process. For more information, see the following sections:

- *Diffusivity*
- *Mass Diffusion Analysis*

1. From the menu bar in the **Edit Material** dialog box, select **Other->Mass Diffusion->Solubility**.
   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Toggle on **Use temperature-dependent data** to define solubility as a function of temperature.
   A column labeled **Temp** appears in the **Data** table.
3. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the solubility depends.
4. Enter the following data in the **Data** table:

Solubility

Solubility. (Units of $\text{PLF}^{-1/2}$.)

Temp

Temperature.

Field *n*

Predefined field variables.

For detailed information on how to enter data, see *Entering tabular data*.

5. Click **OK** to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Defining a fluid-filled porous material

You can define specific properties for a fluid-filled porous material.
This type of porous medium is considered in a coupled pore fluid diffusion/stress analysis (*Coupled Pore Fluid Diffusion and Stress Analysis*).

In this section:

- *Defining a swelling gel*
- *Defining moisture swelling*
- *Defining anisotropic swelling*
- *Defining permeability*
- *Defining pore fluid expansion*
- *Defining porous bulk moduli*
- *Defining sorption*
- *Defining normal flow across gap surfaces*
- *Defining tangential flow across gap surfaces*
- *Defining thermal convection across gap surfaces*

Defining a swelling gel

You can model the growth of gel particles that swell and trap wetting liquid in a partially saturated porous medium. For more information, see *Swelling Gel*.

1. From the menu bar in the **Edit Material** dialog box, select **Other->Pore Fluid->Gel**.
   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Enter the following data in the **Data** table:

r_a(dry)

Radius of gel particles when completely dry, r_a^{dry}. (Units of L.)

r_a(f)

Fully swollen radius of gel particles, r_a^f. (Units of L.)

k_a

Number of gel particles per unit volume, k_a. (Units of L^{-3}.)

tau_1

Relaxation time constant for long-term swelling of gel particles, τ_1. (Units of T.)

3. Click **OK** to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Defining moisture swelling

The **Edit material** dialog box allows you to define the saturation-driven volumetric swelling of the solid skeleton of a porous medium in partially saturated flow conditions. You can use this type of material definition in the analysis of coupled wetting liquid flow and porous medium stress. See the following sections for more information:

- *Moisture Swelling*
- *Coupled Pore Fluid Diffusion and Stress Analysis*

1. From the menu bar in the **Edit Material** dialog box, select **Other->Pore Fluid->Moisture Swelling**. (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Enter the following data in the **Data** table:

Strain

Volumetric moisture swelling strain, ε^{ms}.

Saturation

Saturation, *s*. This value must lie in the range $0.0 \leq s \leq 1.0$.

For detailed information on how to enter data, see *Entering tabular data*.

3. If you want to define anisotropic swelling, select **Ratios** from the **Suboptions** menu. See *Defining anisotropic swelling*" for detailed instructions.
4. Click **OK** to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Defining anisotropic swelling

You can include anisotropy in moisture swelling behavior by defining the ratios r_{11}, r_{22}, and r_{33} such that two or more of the three ratios differ. The orientation of the moisture swelling strain directions depends on the user-specified local orientation (see *Orientations*).

1. Define moisture swelling behavior, as described in *Defining moisture swelling*."
2. From the **Suboptions** menu in the **Edit Material** dialog box, select **Ratios**.

   A **Suboption Editor** appears.
3. Toggle on **Use temperature-dependent data** to define the anisotropy ratios as a function of temperature.

   A column labeled **Temp** appears in the **Data** table.
4. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables included in the definition of the anisotropy ratios.
5. In the **Data** table, enter the anisotropy ratios r_{11}, r_{22}, and r_{33}. Enter values for temperature and field variables if applicable.

   For detailed information on how to enter data, see *Entering tabular data*.
6. Click **OK** to return to the **Edit Material** dialog box.

Defining permeability

Permeability is the relationship between the volumetric flow rate per unit area of a particular wetting liquid through a porous medium and the gradient of the effective fluid pressure.

You can use the **Edit Material** dialog box to define certain aspects of permeability.

For more information, see *Permeability*.

In this section:

- *Defining permeability in an Abaqus/Standard analysis*
- *Defining the saturation dependence of permeability*
- *Defining the velocity dependence of permeability*

Defining permeability in an Abaqus/Standard analysis

You must specify permeability for a wetting liquid in Abaqus/Standard for an effective stress/wetting liquid diffusion analysis. For more information, see *Permeability*.

1. From the menu bar in the **Edit Material** dialog box, select **Other->Pore Fluid->Permeability**.
   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Click the arrow to the right of the **Type** field, and specify the directional dependence of the permeability.
3. Enter a value for **Specific weight of wetting liquid**.
4. Toggle on **Use temperature-dependent data** to define permeability as a function of temperature.
   A column labeled **Temp** appears in the **Data** table.
5. Enter the applicable data in the **Data** table:

   ### k

   Isotropic permeability of the fully saturated medium, k. (Units of LT^{-1}.)

   ### k11, k22, and k33

   Three values for orthotropic permeability, k_{11}, k_{22}, and k_{33}. (Units of LT^{-1}.)

   ### k11, k12, k22, k13, k23, and k33

   Six values for anisotropic permeability, k_{11}, k_{12}, k_{22}, k_{13}, k_{23}, and k_{33}. (Units of LT^{-1}.)

   ### Void Ratio

   Void ratio, e.

   ### Temp

   Temperature.

   For detailed information on how to enter data, see *Entering tabular data*.
6. If you want to define the dependence of permeability on saturation, select **Saturation Dependence** from the **Suboptions** menu. See *Defining the saturation dependence of permeability*" for detailed instructions.
7. If you want to define the dependence of permeability on velocity, select **Velocity Dependence** from the **Suboptions** menu. See *Defining the velocity dependence of permeability*" for detailed instructions.
8. Click **OK** to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Additional information

- *Permeability*
- *Coupled Pore Fluid Diffusion and Stress Analysis*

Defining the saturation dependence of permeability

You can define the dependence of permeability, $\overline{\mathbf{k}}$, on saturation, *s*, by specifying k_s. Abaqus/Standard assumes by default that $k_s = s^3$ for $s < 1.0$; $k_s = 1.0$ for $s \geq 1.0$. The tabular definition of $k_s\,(s)$ must specify $k_s = 1.0$ for $s \geq 1.0$.

For more information, see *Permeability*.

1. Define permeability, as described in *Defining permeability in an Abaqus/Standard analysis*."
2. From the **Suboptions** menu in the **Edit Material** dialog box, select **Saturation Dependence**. A **Suboption Editor** appears.
3. Enter the following data in the **Data** table:

k_s

The dependence of permeability on saturation of the wetting liquid.

Saturation

The fluid saturation ($s = 1$ for a fully saturated medium; $s = 0$ for a completely dry medium). For detailed information on how to enter data, see *Entering tabular data*.

4. Click **OK** to return to the **Edit Material** dialog box.

Defining the velocity dependence of permeability

Permeability is defined, in general, by Forchheimer's law, which accounts for changes in permeability as a function of fluid flow velocity. The **Suboption Editor** allows you define the velocity coefficient as a function of the void ratio of the material. For more information, see *Permeability*.

1. Define permeability, as described in *Defining permeability in an Abaqus/Standard analysis*."
2. From the **Suboptions** menu in the **Edit Material** dialog box, select **Velocity Dependence**.

   A **Suboption Editor** appears.
3. Enter the following data in the **Data** table:

   #### Beta

   Velocity coefficient, $\beta(e)$.

   #### Void ratio

   Void ratio, e.

   For detailed information on how to enter data, see *Entering tabular data*.
4. Click **OK** to return to the **Edit Material** dialog box.

Defining pore fluid expansion

You can use the **Edit Material** dialog box to define thermal expansion for the pore fluid in a porous medium. For more information, see *Thermal Expansion*.

1. From the menu bar in the **Edit Material** dialog box, select **Other->Pore Fluid->Pore Fluid Expansion**.

   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. In the **Reference temperature** field, enter a value for reference temperature if the coefficient of thermal expansion is a function of temperature or field variables
3. Toggle on **Use temperature-dependent data** to define the expansion coefficient as a function of temperature.

   A column labeled **Temp** appears in the **Data** table.
4. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the expansion coefficient depends.
5. Enter the following data in the **Data** table:

   #### Expansion Coeff

   Thermal expansion coefficient, α. (Units of θ^{-1}.)

   #### Temp

   Temperature.

   #### Field *n*

   Predefined field variables.

   For detailed information on how to enter data, see *Entering tabular data*.
6. Click **OK** to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Defining porous bulk moduli

You can define the bulk moduli of solid grains and a permeating fluid such that their compressibility can be considered in the analysis of a porous medium. For more information, see *Porous Bulk Moduli*.

1. From the menu bar in the **Edit Material** dialog box, select **Other->Pore Fluid->Porous Bulk Moduli**. (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Toggle on **Use temperature-dependent data** to define the bulk moduli as a function of temperature. A column labeled **Temp** appears in the **Data** table.
3. Enter the following data in the **Data** table:

Bulk mod of grains

Bulk modulus of solid grains. (Units of FL^{-2}.)

Bulk mod of fluids

Bulk modulus of permeating fluid. (Units of FL^{-2}.)

Temp

Temperature.

For detailed information on how to enter data, see *Entering tabular data*.

4. Click **OK** to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Defining sorption

You can define absorption and exsorption behaviors of a partially saturated porous medium in the analysis of coupled wetting liquid flow and porous medium stress. For more information, see *Sorption*.

1. From the menu bar in the **Edit Material** dialog box, select **Other->Pore Fluid->Sorption**.
   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Display the **Absorption** tabbed page.
3. Click the arrow to the right of the **Law** field, and specify how you want to define absorption behavior:
   - Select **Log** to define absorption behavior by the analytical logarithmic form.
   - Select **Tabular** to define absorption behavior in tabulated form.
4. If you selected **Log** in the previous step, enter the following data in the **Data** table:

   #### A

   A. This value must be positive. (Dimensionless.)

   #### B

   B. This value must be positive. (Units of L^2F^{-1}.)

   #### s0

   s_0. This value must lie in the range $0.01 \le s_0 < s_1 < 0.9$. The default is 0.01.

   #### s1

   s_1. This value must lie in the range $0.01 \le s_0 < s_1 < 0.9$. The default is 0.01 plus a very small positive number (since s_1 cannot be equal to s_0).
5. If you selected **Tabular** in Step 3, enter the following data in the **Data** table:

   #### Pore Pressure

   Pore pressure, u_w, with the condition $u_w \le 0.0$. (Units of FL^{-2}.)

   #### Saturation

   Saturation, *s*. This value must lie in the range $0.01 \le s \le 1.0$
6. If you want to include exsorption behavior in the sorption definition, display the **Exsorption** tabbed page, and toggle on **Include exsorption**. Otherwise, skip to Step 12.
7. Click the arrow to the right of the **Law** field, and specify how you want to define exsorption behavior:
   - Select **Log** to define exsorption behavior by the analytical logarithmic form.
   - Select **Tabular** to define exsorption behavior in tabulated form.

8. Toggle on **Include scanning** to define the behavior between absorption and exsorption by a scanning line of constant slope, $(du_w/ds)|_s$. This slope should be larger than the slope of any segment of the absorption or exsorption behaviors.

   If you define sorption behavior without specifying a scanning line slope, Abaqus uses a slope of 1.05 times the largest value of du_w/ds provided in the absorption and exsorption behavior definitions.
9. If you toggled on **Include scanning**, enter a value for the slope of the scanning line in the **Slope** field.
10. If you selected **Log** in Step 7, enter the following data in the **Data** table:

A

A. This value must be positive. (Dimensionless.)

B

B. This value must be positive. (Units of L^2F^{-1}.)

s0

s_0. This value must lie in the range $0.01 \le s_0 < s_1 < 0.9$. The default is 0.01.

s1

s_1. This value must lie in the range $0.01 \le s_0 < s_1 < 0.9$. The default is 0.01 plus a very small positive number (since s_1 cannot be equal to s_0).

11. If you selected **Tabular** in Step 7, enter the following data in the **Data** table:

Pore Pressure

Pore pressure, u_w, with the condition $u_w \le 0.0$. (Units of FL^{-2}.)

Saturation

Saturation, *s*. This value must lie in the range $0.01 \le s \le 1.0$

12. Click **OK** to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Defining normal flow across gap surfaces

You can model normal flow across gap surfaces by defining a fluid leak-off coefficient for the pore fluid material. This coefficient defines a pressure-flow relationship between the cohesive element's middle nodes and their adjacent surface nodes. The fluid leak-off coefficients can be interpreted as the permeability of a finite layer of material on the cohesive element surfaces. See the following sections for more information:

- *Defining the Constitutive Response of Fluid within the Cohesive Element Gap*
- *UFLUIDLEAKOFF*

1. From the menu bar in the **Edit Material** dialog box, select **Other->Pore Fluid->Fluid Leakoff**.
   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Click the arrow to the right of the **Type** field, and specify how you want to define the fluid leak-off coefficients:
   - Select **Coefficients** to enter the coefficients directly in the **Edit Material** dialog box.
   - Select **User** to define the coefficients in user subroutine *UFLUIDLEAKOFF*. If you select this option, skip to Step 6.
3. Toggle on **Use temperature-dependent data** to define the fluid leak-off coefficients as a function of temperature.
   A column labeled **Temp** appears in the **Data** table.
4. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the fluid leak-off coefficients depend.
5. Enter the following data in the **Data** table:

Top Coefficient

Fluid leak-off coefficient at the top element surface.

Bottom Coefficient

Fluid leak-off coefficient at the bottom element surface.

Temp

Temperature.

Field *n*

Predefined field variables.

For detailed information on how to enter data, see *Entering tabular data*.

6. Click **OK** to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Defining tangential flow across gap surfaces

You can use the **Edit Material** dialog box to define tangential flow constitutive parameters for pore pressure cohesive elements. For more information, see *Defining the Constitutive Response of Fluid within the Cohesive Element Gap*.

1. From the menu bar in the **Edit Material** dialog box, select **Other->Pore Fluid->Gap Flow**.
   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Click the arrow to the right of the **Type** field, and specify how you want to define the flow parameters:
   - Select **Newtonian** to define the viscosity for a Newtonian fluid.
   - Select **Power law** to define the consistency and exponent for a power law fluid.
   - Select **Bingham plastic** to define the consistency and yield stress for a Bingham plastic fluid.
   - Select **Herschel-Bulkley** to define the consistency, exponent, and yield stress for a Herschel-Bulkley fluid.
3. Toggle on **Use temperature-dependent data** to define the flow parameters as a function of temperature.
   A column labeled **Temp** appears in the **Data** table.
4. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the flow parameters depend.
5. If you selected **Newtonian** in Step 2, you can toggle on **Maximum permeability** to enter the maximum permeability value that Abaqus can use.
6. If you selected **Newtonian** in Step 2, enter the following data in the **Data** table:

Viscosity

Pore fluid viscosity, μ.

Temp

Temperature.

Field *n*

Predefined field variables.

For detailed information on how to enter data, see *Entering tabular data*.

7. If you selected **Power law** in Step 2, enter the following data in the **Data** table:

Consistency

Fluid consistency, K.

Exponent

Power law exponent, α.

Temp

Temperature.

Field *n*

Predefined field variables.

For detailed information on how to enter data, see *Entering tabular data*.

8. If you selected **Bingham plastic** in Step 2, enter the following data in the **Data** table:

Consistency

Fluid consistency, K.

Exponent

Power law exponent, α.

Yield Stress

Yield stress, τ_0.

Temp

Temperature.

Field *n*

Predefined field variables.

For detailed information on how to enter data, see *Entering tabular data*.

9. If you selected **Herschel-Bulkley** in Step 2, enter the following data in the **Data** table:

Consistency

Fluid consistency, K.

Yield Stress

Yield stress, τ_0.

Temp

Temperature.

Field *n*

Predefined field variables.

For detailed information on how to enter data, see *Entering tabular data*.

10. Click **OK** to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Defining thermal convection across gap surfaces

You can use the **Edit Material** dialog box to define convective heat transfer with gap flow as well as thermal convection between the gap fluid cohesive elements. For more information, see *Defining Thermal Convection for a Cohesive Element*.

1. From the menu bar in the **Edit Material** dialog box, select **Other->Pore Fluid->Gap Convection**.
   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Click the arrow to the right of the **Type** field, and specify how you want to define the Nusselt number:
   - Select **Flux** to define a constant flux solution for convective heat transfer.
   - Select **Temperature** to define a constant temperature solution for convective heat transfer.
   - Select **Tabular** to specify the Nusselt number as a function of temperature and/or field variables.
3. If you selected **Tabular** in Step 2, toggle on **Use temperature-dependent data** to define the Nusselt number as a function of temperature.
   A column labeled **Temp** appears in the **Data** table.
4. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the flow parameters depend.
5. If you selected **Tabular** in Step 2, enter the following data in the **Data** table:

Nusselt Number

The Nusselt number.

Temp

Temperature.

Field *n*

Predefined field variables.

For detailed information on how to enter data, see *Entering tabular data*.

6. Click **OK** to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Defining gasket behavior

You can use the **Edit Material** dialog box to define gasket behavior.

In this section:

- *Defining gasket behavior in the thickness direction*
- *Specifying a gasket contact area or contact width for average pressure output*
- *Defining the elastic transverse shear behavior of a gasket*
- *Defining the membrane behavior of a gasket*

Defining gasket behavior in the thickness direction

Abaqus/Standard measures the thickness-direction deformation as the closure between the bottom and top faces of the gasket element; therefore, the thickness-direction behavior must always be defined in terms of closure. In all cases you can define the thickness-direction behavior as a function of temperature and/or field variables. For more information, see the following sections:

- *Defining the Thickness-Direction Behavior of the Gasket*
- *Defining the Gasket Behavior Directly Using a Gasket Behavior Model*

1. From the menu bar in the **Edit Material** dialog box, select **Other->Gasket->Gasket Thickness Behavior**.

   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)
2. Click the arrow to the right of the **Type** field, and specify how you want to define gasket thickness-direction behavior:

   - Select **Elastic-Plastic** to define an elastic-plastic model. For more information, see *Defining a Nonlinear Elastic-Plastic Model*.
   - Select **Damage** to define a damage elasticity model. For more information, see *Defining a Nonlinear Elastic Model with Damage*.
3. Click the arrow to the right of the **Units** field, and specify a unit system for defining thickness-direction behavior:

   - Select **Stress** to define thickness-direction behavior in terms of pressure versus closure. This option is available for all gasket element types.
   - Select **Force** to define thickness-direction behavior in terms of force versus closure or force per unit length versus closure, depending on the element type with which this behavior is used. This option is valid only for link elements and three-dimensional line elements.

     If you select this option, you can select **Contact Area** from the **Suboptions** menu to define contact area or contact width versus closure curves to output an average pressure through variable CS11. See *Specifying a gasket contact area or contact width for average pressure output*" for detailed instructions.

   For more information about selecting a unit system, see *Choosing a Unit System Used to Define the Thickness-Direction Behavior*.
4. Display the **Loading** tabbed page.
5. Click the arrow to the right of the **Yield onset method** field, and select a method for defining the onset of yield:

   - Select **Relative slope drop** to define yield onset as the point at which the slope of the loading curve decreases by a certain percentage from the maximum slope recorded up to that point. Enter the relative drop value in the field provided. The default is 0.1 (or 10%).
   - Select **Closure value** to specify a closure value at which yield occurs. Enter the closure value in the field provided.
6. In the **Tensile stiffness factor** field, enter a the fraction of the initial compressive stiffness that defines the stiffness in tension. The default is 0.001. For more information, see *Numerical Stabilization of the Thickness-Direction Behavior*.
7. Toggle on **Use temperature-dependent data** to define the gasket thickness behavior as a function of temperature.

A column labeled **Temp** appears in the **Data** table.

8. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the gasket thickness behavior depends.
9. In the **Data** table, define loading in terms of pressure versus closure, force versus closure, or force per unit length versus closure. Enter values for temperature and field variables if applicable. For detailed information on how to enter data, see *Entering tabular data*.
10. Display the **Unloading** tabbed page, and toggle on **Include user-specified unloading curves** if desired. The user-specified unloading curves are in addition to the default unloading curve, which is the scaled portion of the loading curve before the point of yield onset.

    If you leave this option toggled off, skip to Step 13.
11. Toggle on **Use temperature-dependent data** to define the unloading curve as a function of temperature.

    A column labeled **Temp** appears in the **Data** table.
12. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the unloading curve depends.
13. In the **Data** table, specify the unloading curve:

    - If you selected **Damage** in Step 2, provide data points of pressure (or force or force per unit length) versus elastic closure up to a given maximum closure. Enter values for temperature and field variables if applicable. For more information, see *Defining a Nonlinear Elastic Model with Damage*.
    - If you selected **Elastic-Plastic** in Step 2, provide data points of pressure (or force or force per unit length) versus closure (elastic plus plastic) for each given plastic closure in ascending values of closure. For more information, see *Defining a Nonlinear Elastic-Plastic Model*.

    For detailed information on how to enter data, see *Entering tabular data*.
14. Click **OK** to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Specifying a gasket contact area or contact width for average pressure output

When you define the thickness-direction behavior of the gasket in terms of force or force per unit length versus closure, Abaqus/Standard provides the thickness-direction force or force per unit length as output variable S11. In this case you can define either a contact width or contact area versus closure curve that will be used to obtain the average "contact" pressure at each integration point as output variable CS11.

For more information, see *Defining the Contact Area for Average Contact Pressure Output*.

1. Define gasket thickness-direction behavior as described in *Defining gasket behavior in the thickness direction*."
2. From the **Suboptions** menu in the **Edit Material** dialog box, select **Contact Area**.

   A **Suboption Editor** appears.
3. Toggle on **Use temperature-dependent data** to define the data as a function of temperature.

   A column labeled **Temp** appears in the **Data** table.
4. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the data depend.
5. In the **Data** table, define the contact area or contact width versus closure curve. Include temperature and field variable data if applicable. For detailed information on how to enter data, see *Entering tabular data*.
6. Click **OK** to return to the **Edit Material** dialog box.

Defining the elastic transverse shear behavior of a gasket

Abaqus/Standard measures the relative displacement between the bottom and top of the gasket element along the local 2- or 3-directions to define the transverse shear in the gasket. You can use the **Edit Material** dialog box to specify the elastic transverse stiffness as stress (or force, or force per unit length) per unit displacement. For more information, see *Defining the Transverse Shear Behavior of the Gasket*.

1. From the menu bar in the **Edit Material** dialog box, select **Other->Gasket->Gasket Transverse Shear Elastic**.

   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)

2. Click the arrow to the right of the **Units** field, and select the unit system in which you will define the transverse shear behavior:

   - Select **Stress** to define the transverse shear stiffness in terms of stress per unit displacement.
   - Select **Force** to define the transverse shear stiffness in terms of force per unit displacement or force per unit length per unit displacement, depending on the element type to which this behavior refers.

   The unit system that you select for transverse shear behavior must be consistent with the unit system selected for thickness-direction behavior (see *Defining gasket behavior in the thickness direction*"). For more information, see *Choosing a Unit System to Define the Transverse Shear Behavior*.

3. Toggle on **Use temperature-dependent data** to define the shear stiffness as a function of temperature.

   A column labeled **Temp** appears in the **Data** table.

4. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the shear stiffness depends.
5. In the **Data** table, specify the shear stiffness. Include temperature and field variable data if applicable. For detailed information on how to enter data, see *Entering tabular data*.
6. Click **OK** to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Defining the membrane behavior of a gasket

You can define the linear elastic behavior of the gasket by providing Young's modulus and Poisson's ratio. These data can be a function of temperature and/or field variables. If you do not specify the linear elastic behavior of the gasket, the gasket has no membrane stiffness. In this case you must ensure that the nodes of the elements are restrained adequately in the directions orthogonal to the thickness direction of the gasket.

1. From the menu bar in the **Edit Material** dialog box, select **Other->Gasket->Gasket Membrane Elastic**.

   (For information on displaying the **Edit Material** dialog box, see *Creating or editing a material*.)

2. Toggle on **Use temperature-dependent data** to define the data as a function of temperature.

   A column labeled **Temp** appears in the **Data** table.

3. Click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables on which the data depend.
4. In the **Data** table, enter Young's modulus and Poisson's ratio data. Include temperature and field variable data if applicable. For detailed information on how to enter data, see *Entering tabular data*.
5. Click **OK** to close the **Edit Material** dialog box. Alternatively, you can select another material behavior to define from the menus in the **Edit Material** dialog box (see *Browsing and modifying material behaviors*, for more information).

Creating and editing sections

This section describes how to create and edit sections using the section editor.

In this section:

- *Creating homogeneous solid sections*
- *Creating generalized plane strain sections*
- *Creating Eulerian sections*
- *Creating composite solid sections*
- *Creating electromagnetic solid sections*
- *Creating homogeneous shell sections*
- *Creating composite shell sections*
- *Creating membrane sections*
- *Creating surface sections*
- *Creating general shell stiffness sections*
- *Creating beam sections*
- *Creating truss sections*
- *Creating gasket sections*
- *Creating cohesive sections*
- *Creating acoustic infinite sections*
- *Creating acoustic interface sections*
- *Defining rebar layers*
- *Creating profiles*

Creating homogeneous solid sections

Homogeneous solid sections are used to define the section properties of two-dimensional, three-dimensional, and axisymmetric solid regions. For more information, see *Solid (Continuum) Elements*.

1. From the main menu bar, select **Section->Create**.

   A **Create Section** dialog box appears.

   Tip: You can also click **Create** in the **Section Manager** or select the create section tool in the Property module toolbox.

2. Enter a section name. For more information on naming objects, see *Using basic dialog box components*.
3. Select **Solid** as the section **Category** and **Homogeneous** as the section **Type**, and click **Continue**.

   The solid section editor appears.

4. Select a material for the solid section. If desired, click to create a material; see *Creating or editing a material*, for more information.
5. Enter a value for the section **Plane stress/strain thickness**. If the section will be used with a two-dimensional region, you must specify the section thickness. Abaqus/CAE ignores the thickness information if it is not needed for the region type.
6. Click **OK** to save your changes and to close the solid section editor.

Creating generalized plane strain sections

Generalized plane strain sections are used to define the section properties of two-dimensional planar regions.

You must create a reference point to indicate the reference node required by generalized plane strain elements. In addition to the material and the section thickness at the reference point, you can specify wedge angles about the global 1- and 2-axes, as defined in *Figure 1*. For more information, see *Generalized Plane Strain Elements*.

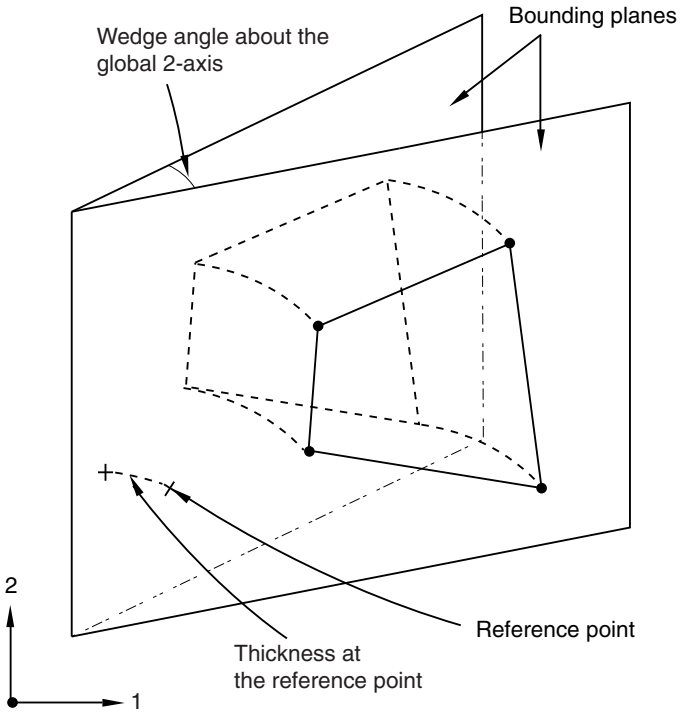

Figure 1: Generalized plane strain section definition.

1. From the main menu bar, select **Section->Create**.

   A **Create Section** dialog box appears.

   Tip: You can also click **Create** in the **Section Manager** or select the create section tool in the Property module toolbox.

2. Enter a section name. For more information on naming objects, see *Using basic dialog box components*.
3. Select **Solid** as the section **Category** and **Generalized plane strain** as the section **Type**, and click **Continue**.

   The generalized plane strain section editor appears.

4. Select a material for the section. If desired, click to create a material; see *Creating or editing a material*, for more information.
5. Enter a value for the material **Thickness at the reference point**.
6. Enter a value for the **Wedge angle about global 1-axis**, the rotation about the global 1-axis at the reference point in radians.
7. Enter a value for the **Wedge angle about global 2-axis**, the rotation about the global 2-axis at the reference point in radians.

8. Click **OK** to save your changes and to close the generalized plane strain section editor.

Additional information

- *The reference point*
- *Creating sections*
- *Choosing the Element's Dimensionality*

Creating Eulerian sections

Eulerian sections are used to specify the materials that can be present in an Eulerian domain. Eulerian sections can be assigned only to Eulerian-type parts, and a single Eulerian section must be assigned to an entire Eulerian part.

An Eulerian section does not create material within an Eulerian part; rather, it provides a list of materials that may exist within the part. The Eulerian part contains only void by default. After creating an Eulerian section, you can add material to the part using a material assignment predefined field (see *Defining a material assignment field*). For more information, see *Eulerian Analysis*. For an overview of modeling Eulerian analyses in Abaqus/CAE, see *Eulerian analyses*."

1. From the main menu bar, select **Section->Create**.

   A **Create Section** dialog box appears.

   Tip: You can also click **Create** in the **Section Manager** or select the create section tool  in the Property module toolbox.

2. Enter a section name. For more information on naming objects, see *Using basic dialog box components*.
3. Select **Solid** as the section **Category** and **Eulerian** as the section **Type**, and click **Continue**.

   The Eulerian section editor appears.
4. Each material present in the Eulerian section is represented by a row in the **Material Instances** table. To add rows to the table, click mouse button 3 on a row and select **Insert Row Before** or **Insert Row After** from the menu that appears.
5. For each row in the **Material Instances** table, enter the following data:

Base Material

A material that may be present in the Eulerian part. Click in the **Base Material** column, then click the arrow that appears to display the list of available materials, and select the appropriate material.

Instance Name

A name that is used to refer to the base material in assembly-related modules, such as when you are defining the initial composition of an Eulerian domain using the material assignment predefined field (see *Defining a material assignment field*). Separate output is created for each material instance name (see *Viewing output from Eulerian analyses*). In some situations it may be necessary to create multiple, unique material instance names that refer to the same base material; for example, if you want separate output data for different regions of the model that contain the same base material. Abaqus/CAE automatically creates a material instance name when you select a base material; however, you can overwrite this default instance name if desired.

6. Click **OK** to save your changes and to close the Eulerian section editor.

Creating composite solid sections

Composite solid sections are used to define the section properties of three-dimensional regions that are composed of layers of different materials in different orientations. For more information, see *Defining Composite Solid Elements in Abaqus/Standard*.

Composite solid sections can be used only in Abaqus/Standard. Composite solid sections must be assigned only to three-dimensional brick elements with only displacement degrees of freedom. Composite solid elements are primarily intended for modeling convenience. In most cases you should model a composite section as a shell or continuum shell. However, you should use a composite solid section for the following cases:

- When the transverse shear effects are predominant.
- When you cannot ignore the normal stress.
- When you require accurate interlaminate stresses, such as near localized regions of complex loading or geometry.

If the region to which you assign your composite solid section contains multiple elements through its thickness, each element will contain all the material layers defined in the data table, and the analysis results will not be as expected.

1. From the main menu bar, select **Section->Create**.

   A **Create Section** dialog box appears.

   Tip: You can also click **Create** in the **Section Manager** or select the create section tool  in the Property module toolbox.

2. Enter a section name. For more information on naming objects, see *Using basic dialog box components*.
3. Select **Solid** as the section **Category** and **Composite** as the section **Type**, and click **Continue**.

   The composite solid section editor appears.
4. Optionally, enter a layup name. Abaqus/CAE displays this name in a ply stack plot. For more information on naming objects, see *Using basic dialog box components*.
5. If the layers of material in the section are symmetric about a central core, toggle on **Symmetric layers**. Enter the material layers in the data table, starting with the bottom layer in the first row and ending with the central layer. During the analysis Abaqus appends layers to the section definition by repeating the entered layers (including the central layer) in the reverse order to the top of the section. If you name the material layers, each generated layer is labeled in ply stack plots and the output database by adding `Sym_` to the beginning of the repeated layer's original name.
6. Each layer of the composite solid section is represented by a row in the data table.

   Note:

   The stacking direction for the composite layers is determined by the material orientation assigned to the solid region. See *Assigning a material orientation*, for more information.

   To add rows to the table, click mouse button three on a row and select

   Insert Row Before

   or

   Insert Row After

   from the menu that appears. For each layer, enter the following data:

Material

The name of the material forming this layer. Click in the **Material** column, then click the arrow that appears to display the list of available materials, and select the material forming the layer.

Element Relative Thickness

The relative thickness of the layer within each element. Abaqus determines the overall section thickness from the element geometry, which may vary from element to element where the section is defined. Hence, the thickness values that you specify for each layer are relative to the thickness of each element. The actual thickness of a layer is the element thickness times the fraction of the total thickness that is accounted for by each layer. You do not have to use physical units to specify the thickness ratios for the layers, and the sum of the layer relative thicknesses does not have to add to one. For more information, see *Creating a composite layup*.

Orientation Angle

The orientation. The orientation can be specified either as an angle in degrees or as an orientation name. The orientation angle is measured positive counterclockwise around the normal and relative to the section orientation definition.

If you specify an orientation name, Abaqus/CAE assumes a user-defined orientation. You must supply the user subroutine *ORIENT* that contains the definition of the user-defined orientation for the specified orientation name. You cannot define a variable orientation angle using a discrete field; to define ply-by-ply orientation distributions in a composite solid, you must use the composite layup editor (see *Creating and editing composite layups*).

Integration Points

The number of integration points through the thickness. You can specify only odd numbers.

Ply Name

The name of the layer. Abaqus/CAE displays this name when you are viewing the composite plies in the Visualization module and in a ply stack plot.

Naming the layers in a composite solid section is optional. However, if you provide a name for any layer, you must provide names for all of the layers in the section.

7. Click **OK** to save your changes and to close the composite solid section editor.

Creating electromagnetic solid sections

Electromagnetic solid sections are used to define the section properties of two-dimensional and three-dimensional solid regions and must be assigned only to electromagnetic elements in an electromagnetic model. For more information, see *Solid (Continuum) Elements*.

1. From the main menu bar, select **Section->Create**.

   A **Create Section** dialog box appears.

   Tip: You can also click **Create** in the **Section Manager** or select the create section tool  in the Property module toolbox.

2. Enter a section name. For more information on naming objects, see *Using basic dialog box components*.
3. Select **Solid** as the section **Category** and **Electromagnetic, Solid** as the section **Type**, and click **Continue**.

   The electromagnetic solid section editor appears.

4. Select a material for the electromagnetic solid section. If desired, click  to create a material; see *Creating or editing a material*, for more information.
5. Enter a value for the section **Plane stress/strain thickness**. If the section will be used with a two-dimensional region, you must specify the section thickness. Abaqus/CAE ignores the thickness information if it is not needed for the region type.
6. Click **OK** to save your changes and to close the electromagnetic solid section editor.

Creating homogeneous shell sections

This section describes how to create a homogeneous shell section.

Shell section behavior is defined in terms of the response of the shell section to stretching, bending, shear, and torsion. For more information, see *Shell Section Behavior*.

When you create shell sections, you must choose a section integration method. You can choose to provide the section property data before the analysis (a pre-integrated shell section) or to have Abaqus calculate (integrate) the cross-sectional behavior from section integration points during the analysis.

Shell sections integrated during analysis allow the cross-sectional behavior to be calculated by numerical integration through the shell thickness, thus providing complete generality in material modeling. Any number of material points can be defined through the thickness, and the material response can vary from point to point. This type of shell section is generally used with nonlinear material behavior in the section. It must be used with shells that provide for heat transfer. For more information, see *Using a Shell Section Integrated during the Analysis to Define the Section Behavior*.

Linear moment-bending and force-membrane strain relationships can be defined using pre-integrated shell sections. In this case all calculations are done in terms of section forces and moments. The section properties are specified by an elastic material; optionally, you can also apply an idealization based on assumptions about the expected behavior of the shell. Use a pre-integrated shell section if the response of the shell is linear elastic and its behavior is not dependent on changes in temperature or predefined field variables. For more information, see *Using a General Shell Section to Define the Section Behavior*.

In this section:

- *Creating a homogeneous shell section*
- *Specifying basic properties for homogeneous shell sections*
- *Specifying advanced properties for homogeneous shell section*

Creating a homogeneous shell section

You can create a homogeneous shell section.

1. From the main menu bar, select **Section->Create**.

   A **Create Section** dialog box appears.

   Tip: You can also click **Create** in the **Section Manager** or select the create section tool in the Property module toolbox.

2. Enter a section name. For more information on naming objects, see *Using basic dialog box components*.
3. Select **Shell** as the section **Category** and **Homogeneous** as the section **Type**, and click **Continue**.

   The shell section editor appears.
4. Choose the **Section integration** method. Choose **During analysis** to specify properties for homogeneous shell sections integrated during the analysis. Choose **Before analysis** to specify properties for pre-integrated homogeneous shell sections.

Specifying basic properties for homogeneous shell sections

On the **Basic** tabbed page:

1. Specify the **Shell thickness**.
   - Choose **Value**, and enter a value for the shell thickness. In continuum shells this value is used to estimate certain section properties, such as hourglass stiffness, which are later computed using the actual thickness computed from the element geometry.
   - Choose **Element distribution**; and select either an analytical field, labeled with an (A), or an element-based discrete field, labeled with a (D), to define a spatially varying element-based shell thickness. Alternatively, you can click  to create a new analytical field or click  to create a new discrete field. See *The Analytical Field toolset* and *The Discrete Field toolset* for more information.
   - Choose **Nodal distribution**; and select either an analytical field, labeled with an (A), or a node-based discrete field, labeled with a (D), to define a spatially varying node-based shell thickness.

     Alternatively, you can click  to create a new analytical field or click  to create a new discrete field. See *The Analytical Field toolset* and *The Discrete Field toolset* for more information.

2. Select a material for the shell section. If desired, click  to create a material; see *Creating or editing a material*, for more information. Linear or nonlinear material behavior can be associated with the section definition. However, if the material response is linear, a more economical approach is to use a generalized shell section.
3. If you are specifying properties for homogeneous shell sections integrated before the analysis, you can specify an **Idealization** to apply to the section based on assumptions about the expected behavior of the shell. For more information, see *Idealizing the Section Response*.
   - Select **No idealization** to account for the complete stiffness of the shell section as determined from the material assignment.
   - Select **Membrane only** if the predominant response of the shell will be in-plane stretching; bending stiffness terms are eliminated from the shell stiffness calculations.
   - Select **Bending only** if the predominant response of the shell will be pure bending; membrane stiffness terms are eliminated from the shell stiffness calculations.
4. If you are specifying properties for homogeneous shell sections integrated during the analysis, select the **Thickness integration rule**.
   - Choose **Simpson** to use Simpson's rule for the shell section integration.
   - Choose **Gauss** to use Gauss quadrature for the shell section integration.

   See *Defining the Shell Section Integration*, for more information.
5. If you are specifying properties for homogeneous shell sections integrated during the analysis, enter the number of thickness integration points. The default number of integration points through the thickness is 5 for Simpson's rule integration and 3 for Gauss quadrature integration. To specify a new value for the number of integration points, you can type the number directly or click the arrows in the **Thickness integration points** text field.
   - If you are using the **Simpson** integration rule, you can specify only odd numbers ranging from 3 to 15.
   - If you are using the **Gauss** integration rule, you can specify numbers ranging from 2 to 15.

Specifying advanced properties for homogeneous shell section

On the **Advanced** tabbed page:

1. Specify the **Section Poisson's ratio** to define the shell thickness behavior.
   - In conventional shell elements that permit finite membrane strains in large-deformation analysis, specifying the section Poisson's ratio causes the shell thickness to change as a function of membrane strains:
     - Toggle on **Use analysis default** to use the default value. In Abaqus/Standard the default value is 0.5, which will enforce incompressible behavior of the element for membrane strains. In Abaqus/Explicit the default is to base the change in thickness on the element material definition.
     - Toggle on **Specify value**, and enter a value for the Poisson's ratio. This value must be between −1.0 and 0.5. A value of 0.0 will enforce constant shell thickness, and a negative value will result in an increase in the shell thickness in response to tensile membrane strains.
   - In continuum shell elements specifying the section Poisson's ratio defines the thickness behavior for both small- and large-displacement analysis:
     - Toggle on **Use analysis default** to indicate that the change in thickness is based on the element material definition.
     - Toggle on **Specify value**, and enter a value for the Poisson's ratio to cause the shell thickness to change as a function of membrane strains. This value must be between −1.0 and 0.5. A value of 0.5 cannot be used with continuum shells. A value of 0.0 will enforce constant shell thickness, and a negative value will result in an increase in the shell thickness in response to tensile membrane strains.
2. For continuum shell elements, toggle on **Thickness modulus**, and enter a value for the effective thickness modulus. If you do not specify a thickness modulus, Abaqus will try to compute it based on the initial elastic material properties.
3. If you are specifying properties for homogeneous shell sections integrated during the analysis, select a method for defining the **Temperature variation** through the section:
   - Choose **Linear through thickness** to indicate that the temperature at the reference surface and the temperature gradient or gradients through the section are specified. You can use the Load module to specify these temperatures.
   - Choose **Piecewise linear over *n* values** to enter the number of temperature points (values) through the section in the text field provided. You can use the Load module to specify the temperature at each of these points.
4. Toggle on **Density**, and enter a value for the mass per unit surface area of the shell. The mass of the shell includes a contribution from the density in addition to any contribution from the selected material.
5. For most shell sections Abaqus will calculate the transverse shear stiffness values required in the element formulation. If desired, toggle on **Specify values** from the **Transverse Shear Stiffnesses** options to include nondefault transverse shear stiffness effects in the section definition, and enter values for K_{11}, the shear stiffness of the section in the first direction; K_{12}, the coupling term in the shear stiffness of the section; and K_{22}, the shear stiffness of the section in the second direction. If either value K_{11} or K_{22} is omitted or given as zero, the nonzero value will be used for both.

6. If you are specifying properties for homogeneous shell sections integrated during the analysis, click  at the bottom of the shell section editor to define rebar layers in the shell section, as described in *Defining rebar layers*.
7. Click **OK** to save your changes and to close the shell section editor.

Creating composite shell sections

This section describes how to create a composite shell section.

Shell section behavior is defined in terms of the response of the shell section to stretching, bending, shear, and torsion. For more information, see *Shell Section Behavior*. Composite shell sections are composed of layers made of different materials in different orientations.

When you create shell sections, you must choose a section integration method. You can choose to provide the section property data before the analysis (a pre-integrated shell section) or to have Abaqus calculate (integrate) the cross-sectional behavior from section integration points during the analysis.

Shell sections integrated during analysis allow the cross-sectional behavior to be calculated by numerical integration through the shell thickness, thus providing complete generality in material modeling. Any number of material points can be defined through the thickness, and the material response can vary from point to point. This type of shell section is generally used with nonlinear material behavior in the section. It must be used with shells that provide for heat transfer. For more information, see *Using a Shell Section Integrated during the Analysis to Define the Section Behavior*.

Linear moment-bending and force-membrane strain relationships can be defined using pre-integrated shell sections. In this case all calculations are done in terms of section forces and moments. The section properties are specified by elastic material plies; optionally, you can also apply an idealization based on assumptions about the expected behavior or makeup of the shell. Use a pre-integrated shell section if the response of the shell is linear elastic and its behavior is not dependent on changes in temperature or predefined field variables. For more information, see *Using a General Shell Section to Define the Section Behavior*.

In this section:

- *Creating a composite shell section*
- *Specifying basic properties for composite shell sections*
- *Specifying advanced properties for composite shell sections*

Creating a composite shell section

You can create a composite shell section.

1. From the main menu bar, select **Section->Create**.

   A **Create Section** dialog box appears.

   Tip: You can also click **Create** in the **Section Manager** or select the create section tool  in the Property module toolbox.

2. Enter a section name. For more information on naming objects, see *Using basic dialog box components*.
3. Select **Shell** as the section **Category** and **Composite** as the section **Type**, and click **Continue**.

   The shell section editor appears.
4. Choose the **Section integration** method. Choose **During analysis** to specify properties for a composite shell section integrated during the analysis. Choose **Before analysis** to specify properties for a pre-integrated composite shell section.
5. Enter a layup name. Abaqus/CAE displays this name in a ply stack plot. For more information on naming objects, see *Using basic dialog box components*.
6. Click  at the bottom of the shell section editor to define rebar layers in the shell section, as described in *Defining rebar layers*.
7. Click **OK** to save your changes and to close the shell section editor.

Specifying basic properties for composite shell sections

You can specify basic properties for composite shell sections.

On the **Basic** tabbed page:

1. Enter the layup name. For more information on naming objects, see *Using basic dialog box components*.
2. If you are specifying properties for composite shell sections integrated before the analysis, specify the **Idealization** to apply to the section based on assumptions about the expected behavior or makeup of the shell. For more information, see *Idealizing the Section Response*.
   - Select **No idealization** to account for the complete stiffness of the shell section as determined by the material assignments and layer composition.
   - Select **Smeared properties** if you do not know the exact stacking sequence for the material layers in the composite shell. Contributions from each specified layer are smeared across the entire thickness of the shell, resulting in a general response independent of the stacking sequence.
   - Select **Membrane only** if the predominant response of the shell will be in-plane stretching; bending stiffness terms are eliminated from the shell stiffness calculations.
   - Select **Bending only** if the predominant response of the shell will be pure bending; membrane stiffness terms are eliminated from the shell stiffness calculations.
3. If you are specifying properties for composite shell sections integrated during the analysis, select the **Thickness integration rule**.
   - Choose **Simpson** to use Simpson's rule for the shell section integration.
   - Choose **Gauss** to use Gauss quadrature for the shell section integration.

   See *Defining the Shell Section Integration* for more information.
4. If the layers of material in the section are symmetric about a central core, toggle on **Symmetric layers**. Enter the material layers in the data table, starting with the bottom layer in the first row and ending with the central layer. During the analysis Abaqus appends layers to the section definition by repeating the entered layers (including the central layer) in the reverse order to the top of the section. Each generated layer is labeled in ply stack plots and the output database by adding `Sym_` to the beginning of the repeated layer's original name.
5. Each layer of the composite shell section is represented by a row in the data table. To add rows to the table, click mouse button three on a row and select **Insert Row Before** or **Insert Row After** from the menu that appears. For each layer, enter the following data:

Material

The name of the material forming this layer. Click in the **Material** column, then click the arrow that appears to display the list of available materials, and select the material forming the layer.

Thickness

The layer thickness. For continuum shell elements Abaqus determines the thickness from the element geometry, and the thickness may vary through the model for a given section definition. Hence, the thickness values that you specify are only relative thicknesses for each layer. The actual thickness of a layer is the element thickness times the fraction of the total thickness that is accounted for by each layer. You do not have to use physical units to specify the thickness ratios for the layers, and the sum of the layer relative thicknesses does not have to add to one. Abaqus uses the shell thickness to estimate certain section properties, such as hourglass stiffness, which are later computed from the element geometry.

Orientation Angle

The orientation, either as a reference to a section orientation definition or as an orientation angle in degrees. The orientation angle, ϕ, is measured positive counterclockwise around the normal and relative to the section orientation definition.

If either of the two local directions from the section orientation is not in the surface of the shell, ϕ is applied after the section orientation has been projected onto the shell surface. If no section orientation has been defined, ϕ is measured relative to the default shell local directions.

If you specify an orientation name, Abaqus/CAE assumes a user-defined orientation. You must supply the user subroutine *ORIENT* that contains the definition of the user-defined orientation for the specified orientation name. You cannot define a variable orientation angle using a discrete field; to define ply-by-ply orientation distributions in a composite shell, you must use the composite layup editor (see *Creating and editing composite layups*).

Integration Points

The number of integration points through the thickness, if you are specifying properties for composite shell sections integrated during the analysis.

The default number of integration points is 3 for Simpson's rule integration and 2 for Gauss quadrature integration.

- If you are using the **Simpson** integration rule, you can specify only odd numbers.
- If you are using the **Gauss** integration rule, you can specify numbers less than or equal to 7.

Ply Name

The name of the layer. Abaqus/CAE displays this name when you are viewing the composite plies in the Visualization module and in a ply stack plot.

Specifying advanced properties for composite shell sections

You can specify advanced properties for composite shell sections.

On the **Advanced** tabbed page:

1. Specify the **Shell thickness**.
   - Choose **Use section thickness** to use the thickness calculated from the individual layer thicknesses.
   - Choose **Element distribution**; and select either an analytical field, labeled with an (A), or an element-based discrete field, labeled with a (D), to define a spatially varying element-based shell thickness. Alternatively, you can click $f(x)$ to create a new analytical field or click  to create a new discrete field. See *The Analytical Field toolset* and *The Discrete Field toolset* for more information.
   - Choose **Nodal distribution**; and select either an analytical field, labeled with an (A), or a node-based discrete field, labeled with a (D), to define a spatially varying node-based shell thickness. Alternatively, you can click $f(x)$ to create a new analytical field or click  to create a new discrete field. See *The Analytical Field toolset* and *The Discrete Field toolset* for more information.
2. Specify the **Section Poisson's ratio** to define the shell thickness behavior.
   - In conventional shell elements that permit finite membrane strains in large-deformation analysis, specifying the section Poisson's ratio causes the shell thickness to change as a function of membrane strains:
     - Toggle on **Use analysis default** to use the default value. In Abaqus/Standard the default value is 0.5, which will enforce incompressible behavior of the element for membrane strains. In Abaqus/Explicit the default is to base the change in thickness on the element material definition.
     - Toggle on **Specify value**, and enter a value for the Poisson's ratio. This value must be between −1.0 and 0.5. A value of 0.0 will enforce constant shell thickness, and a negative value will result in an increase in the shell thickness in response to tensile membrane strains.
   - In continuum shell elements specifying the section Poisson's ratio defines the thickness behavior for both small- and large-displacement analysis:
     - Toggle on **Use analysis default** to indicate that the change in thickness is based on the element material definition.
     - Toggle on **Specify value**, and enter a value for the Poisson's ratio to cause the shell thickness to change as a function of membrane strains. This value must be between −1.0 and 0.5. A value of 0.5 cannot be used with continuum shells. A value of 0.0 will enforce constant shell thickness, and a negative value will result in an increase in the shell thickness in response to tensile membrane strains.
3. For continuum shell elements, toggle on **Thickness modulus**, and enter a value for the effective thickness modulus. If you do not specify a thickness modulus, Abaqus will try to compute it based on the initial elastic material properties.
4. If you are specifying properties for composite shell sections integrated during the analysis, select a method for defining the **Temperature variation** through the section:
   - Choose **Linear through thickness** to indicate that the temperature at the reference surface and the temperature gradient or gradients through the section are specified. You can use the Load module to specify these temperatures.

- Choose **Piecewise linear over *n* values** to enter the number of temperature points (values) through the section in the text field provided. You can use the Load module to specify the temperature at each of these points.

5. Toggle on **Density**, and enter a value for the mass per unit surface area of the shell. The mass of the shell includes a contribution from the density in addition to any contribution from the selected material.
6. For most shell sections Abaqus will calculate the transverse shear stiffness values required in the element formulation. If desired, toggle on **Specify values** from the **Transverse Shear Stiffnesses** options to include nondefault transverse shear stiffness effects in the section definition, and enter values for K_{11}, the shear stiffness of the section in the first direction; K_{12}, the coupling term in the shear stiffness of the section; and K_{22}, the shear stiffness of the section in the second direction. If either value K_{11} or K_{22} is omitted or given as zero, the nonzero value will be used for both.

Creating membrane sections

Membrane sections are used to define the section properties of thin surfaces in space that offer strength in the plane of the surface but have no bending stiffness. For more information, see *Membrane Elements*.

1. From the main menu bar, select **Section->Create**.

   A **Create Section** dialog box appears.

   Tip: You can also click **Create** in the **Section Manager** or select the create section tool  in the Property module toolbox.

2. Enter a section name. For more information on naming objects, see *Using basic dialog box components*.
3. Select **Shell** as the section **Category** and **Membrane** as the section **Type**, and click **Continue**.

   The membrane section editor appears.
4. Select a material for the membrane section. If desired, click **Create** to create a material; see *Creating or editing a material*, for more information.
5. Specify the **Membrane thickness**.
   - Choose **Value**, and enter a value for the membrane thickness.
   - Choose **Element distribution**; and select either an analytical field, labeled with an (A), or an element-based discrete field, labeled with a (D), to define a spatially varying element-based membrane thickness. Alternatively, you can click  to create a new analytical field or click  to create a new discrete field. See *The Analytical Field toolset* and *The Discrete Field toolset* for more information.
6. Specify the **Section Poisson's ratio** to define how the membrane thickness will change with deformation.
   - Toggle on **Use analysis default** to use the default value. In Abaqus/Standard the default value is 0.5, which will enforce incompressible behavior of the element. In Abaqus/Explicit the default is to base the change in thickness on the element material definition.
   - Toggle on **Specify value**, and enter a value for the Poisson's ratio. This value must be between −1.0 and 0.5. A value of 0.0 will enforce constant thickness, and a negative value will result in an increase in the thickness in response to tensile membrane strains.
7. Click  at the bottom of the membrane section editor to define rebar layers in the membrane section, as described in *Defining rebar layers*.
8. Click **OK** to save your changes and to close the membrane section editor.

Creating surface sections

Surface sections are used to define the section properties of surfaces in space that have no inherent stiffness and behave like membranes with zero thickness. For more information, see *Surface Elements*.

1. From the main menu bar, select **Section->Create**.

   A **Create Section** dialog box appears.

   Tip: You can also click **Create** in the **Section Manager** or select the create section tool  in the Property module toolbox.

2. Enter a section name. For more information on naming objects, see *Using basic dialog box components*.
3. Select **Shell** as the section **Category** and **Surface** as the section **Type**, and click **Continue**.

   The surface section editor appears.
4. To bring additional mass into the model, toggle on **Density** and enter the mass density per unit area.
5. Click  to define rebar layers in the surface section, as described in *Defining rebar layers*.
6. Click **OK** to save your changes and to close the surface section editor.

Creating general shell stiffness sections

Shell section behavior is defined in terms of the response of the shell section to stretching, bending, shear, and torsion.

General shell stiffness sections allow you to specify shell section properties directly in terms of a stiffness matrix and thermal expansion response. These data completely define the shell section's mechanical response, so no material reference is needed as part of the section definition. General shell stiffness sections provide an efficient and flexible method for defining shell responses when you know the terms of the applicable stiffness and thermal stress matrices. For more information, see *Specifying the Equivalent Section Properties Directly for Conventional Shells*.

General shell stiffness sections cannot be used with variable thickness shells or continuum shells. Like other pre-integrated shell sections, general shell stiffness sections are not integrated through their thickness and do not provide for heat transfer. In an Abaqus/Standard analysis, stresses and strains are not available for output from general shell stiffness sections.

For more information, see *Shell Section Behavior*.

In this section:

- *Creating a general shell stiffness section*
- *Specifying dependencies for general shell stiffness sections*
- *Specifying advanced properties for general shell stiffness sections*

Creating a general shell stiffness section

You can create a general shell stiffness section.

1. From the main menu bar, select **Section->Create**.

   A **Create Section** dialog box appears.

   Tip: You can also click **Create** in the **Section Manager** or select the create section tool  in the Property module toolbox.

2. Enter a section name. For more information on naming objects, see *Using basic dialog box components*.
3. Select **Shell** as the section **Category** and **General shell stiffness** as the section **Type**, and click **Continue**.

   The general shell stiffness section editor appears.

4. On the **Stiffness** tabbed page, enter the symmetric half of the shell stiffness matrix in the data table.

   The first row contains matrix entries D_{11} through D_{16}, the second row contains matrix entries D_{22} through D_{26}, and so on; the last row contains matrix entry D_{66}. See *Entering tabular data*, for more information.

Specifying dependencies for general shell stiffness sections

The **Dependencies** tabbed page allows you to define thermal stresses on the shell section. You can also apply temperature-dependent and field variable–dependent scaling factors to the shell stiffness matrix and thermal stresses. For detailed information on the equations used to define shell stiffness dependencies, refer to *Specifying the Equivalent Section Properties Directly for Conventional Shells*.

On the **Dependencies** tabbed page:

1. If you are defining a thermal expansion coefficient that is a function of temperature, toggle on **Specify reference temperature** and enter the reference temperature, θ^0, in the field provided.
2. To define thermal stresses on the shell section, toggle on **Apply thermal stress** and enter the stress components in the table provided: ε_{11} (**Sigma11**), ε_{22} (**Sigma22**), γ_{12} (**Gamma12**), κ_{11} (**K11**), κ_{22} (**K22**), and κ_{12} (**K12**).
3. To define scaling factors that depend on temperature, toggle on **Use temperature-dependent data**.
   A column labeled **Temp** appears in the **Scaling factors** data table.
4. To define scaling factors that depend on field variables, click the arrows to the right of the **Number of field variables** to increase or decrease the number of field variables.
   Field variable columns appear in the **Scaling factors** data table.
5. In the **Scaling factors** data table, enter the **Scaling modulus** (*Y*) for the stiffness matrix and the **Thermal Expansion Coefficient** (α) for the thermal stresses.

Specifying advanced properties for general shell stiffness sections

You can specify advanced properties for general shell stiffness sections.

On the **Advanced** tabbed page:

1. Specify the **Section Poisson's ratio** to define the shell thickness behavior. Specifying the section Poisson's ratio causes the shell thickness to change as a function of membrane strains.
   - Toggle on **Use analysis default** to use the default value of 0.5, which will enforce incompressible behavior of the element for membrane strains.
   - Toggle on **Specify value**, and enter a value for the Poisson's ratio. This value must be between −1.0 and 0.5. A value of 0.0 will enforce constant shell thickness, and a negative value will result in an increase in the shell thickness in response to tensile membrane strains.
2. Toggle on **Density**, and enter a value for the mass per unit surface area of the shell. The mass of the shell is determined from this density.
3. For most shell sections Abaqus will calculate the transverse shear stiffness values required in the element formulation. If desired, toggle on **Specify values** from the **Transverse Shear Stiffnesses** options to include nondefault transverse shear stiffness effects in the section definition, and enter values for K_{11}, the shear stiffness of the section in the first direction; K_{12}, the coupling term in the shear stiffness of the section; and K_{22}, the shear stiffness of the section in the second direction. If either value K_{11} or K_{22} is omitted or given as zero, the nonzero value will be used for both.
4. Click **OK** to save your changes and to close the general shell stiffness section editor.

Creating beam sections

Beam section behavior is defined in terms of the response of the beam section to stretching, bending, shear, and torsion.
For more information, see *Beam Section Behavior*.

When you create beam sections, you must choose a section integration method. You can choose to provide the section property data before the analysis (a general beam section) or to have Abaqus calculate (integrate) the cross-sectional behavior from section integration points during the analysis.

In this section:

- *Specifying properties for beam sections integrated during analysis*
- *Specifying properties for general beam sections*

Specifying properties for beam sections integrated during analysis

Beam sections integrated during analysis allow the cross-sectional behavior to be calculated by numerical integration of the stress over the cross-section to define the beam's response as the analysis proceeds. The material behavior is evaluated independently at each point on the section. This type of beam section should be used when the section nonlinearity is caused only by nonlinear material response. For more information, see *Using a Beam Section Integrated during the Analysis to Define the Section Behavior*.

1. From the main menu bar, select **Section->Create**.

   A **Create Section** dialog box appears.

   Tip: You can also click **Create** in the **Section Manager** or select the create section tool  in the Property module toolbox.

2. Enter a section name. For more information on naming objects, see *Using basic dialog box components*.
3. Select **Beam** as the section **Category** and **Beam** as the section **Type**, and click **Continue**.

   The beam section editor appears.
4. Choose **During analysis** as the **Section integration** method.
5. Select a profile for the beam section. If desired, click  to create a profile; see *Creating profiles*, for more information.

   The **Profile shape** field is updated to reflect your choice.
6. On the **Basic** tabbed page:

   a. Select a **Material name** to be used with this beam section definition. If desired, click  to create a material; see *Creating and editing materials*, for more information.

   b. Enter a value for the **Section Poisson's ratio** to provide uniform strain in the section due to strain of the beam axis (so that the cross-sectional area changes when the beam is stretched). This value must be between −1.0 and 0.5. A value of 0.5 will enforce incompressible behavior.

   c. Select a method for defining the **Temperature variation** through the section:

      - Choose **Linear by gradients** to indicate that the temperature at the cross-section origin and the temperature gradient or gradients through the section are specified. You can use the Load module to specify these temperatures.
      - Choose **Interpolated from temperature points** to indicate that the shape of the beam section profile determines the number and location of the temperature points. (For more information on temperature points, see *Beam Cross-Section Library*.) You can use the Load module to specify the temperature at each of these points.

7. On the **Stiffness** tabbed page, do the following:

   a. Select **Use consistent mass matrix formulation** to let Abaqus calculate the mass formulation for the beam section using the McCalley-Archer consistent mass matrix based on the cubic interpolation of deflections and quadratic interpolation of rotations. If you toggle off this option, Abaqus performs this calculation using a lumped mass formulation.

   b. Toggle on **Specify transverse shear** to include nondefault transverse shear stiffness effects in the section definition and specify the **Slenderness compensation**:

      - Select **Use analysis product default** to let Abaqus calculate the shear stiffness and the slenderness compensation factor from the elastic material definition for the beam section.

- Select **Value** to specify the transverse shear stiffness effects directly.
  - Enter a slenderness compensation factor in the field provided.
  - Enter values for the K_{23} and K_{13} shear stiffnesses of the section in the fields provided.

8. On the **Fluid Inertia** tabbed page, toggle on **Specify fluid inertia effects** to simulate the inertial effects of the beam being submerged in a fluid. For details, see *Additional Inertia due to Immersion in Fluid*.
   a. Specify whether the beam is **Fully submerged** or **Half submerged** in the fluid. If you select **Half submerged**, the added inertia per unit length is reduced by a factor of one-half.
   b. Specify the **Fluid density**.
   c. Enter the effective radius of the wetted cross-section in the **Section radius** field.
   d. Specify C_A, the added mass coefficient for **Lateral motions of the beam**.
   e. Specify C_{A-E}, the added mass coefficient for **Motions along beam axis**.
   f. If the beam cross-section origin is different than the centroid of the wetted cross-section, specify the centroid's **X** and **Y** coordinates relative to the cross-section origin.
9. Click **OK** to save your changes and to close the beam section editor.

Specifying properties for general beam sections

In general beam sections the cross-section properties are calculated only once, during preprocessing. All section computations during the analysis are performed in terms of the precomputed values. No material definition is needed for a general beam section. Use this type of beam section when the response of the beam is linear or when it is nonlinear and the nonlinearity arises from more than just material nonlinearity, such as in cases when section collapse occurs. For more information, see *Using a General Beam Section to Define the Section Behavior*.

1. From the main menu bar, select **Section->Create**.

   A **Create Section** dialog box appears.

   Tip: You can also click **Create** in the **Section Manager** or select the create section tool  in the Property module toolbox.

2. Enter a section name. For more information on naming objects, see *Using basic dialog box components*.
3. Select **Beam** as the section **Category** and **Beam** as the section **Type**, and click **Continue**.

   The beam section editor appears.
4. Select **Before analysis** as the **Section integration** method.
5. From the **Beam shape along length** options, do one of the following:

   - To maintain the same cross-sectional profile along the entire length of the beam, select **Constant** and select a beam profile from the **Beam Shape** options. If desired, click  to create a profile; see *Creating profiles*, for more information.
   - To define different cross-sectional profiles at each end of the beam, select **Tapered** and select starting and ending profiles from the **Beam Start** and **Beam End** options, respectively. If desired, click  to create a profile; see *Creating profiles*, for more information. The starting and ending profiles must be the same shape.

     Tapered beams are supported for Abaqus/Standard analyses only. Abaqus/CAE scales beam profiles linearly between the starting and ending profiles.

6. From the **Material definition type** options, do one of the following:

   - To specify the material definition of the section using a predefined material name, select **Material name**.
   - To specify the material definition of the section by creating a new material, select **Table**.

7. If you selected a generalized profile, you can offset the beam section from its node by specifying how far and in which direction along the cross-section axes to move the section centroid and/or shear center. Enter the local $\mathbf{x}_1$- and $\mathbf{x}_2$-coordinates for the **Centroid** and/or the **Shear Center** as desired.
8. On the **Basic** tabbed page:

   - If **Table** is selected as the **Material definition type**, do the following:

   a. To define the section thermal expansion coefficient, toggle on **Use thermal expansion data**.

      A column labeled **Thermal Expansion** appears in the data table.

   b. To define section data that depend on temperature, toggle on **Use temperature-dependent data**.

      A column labeled **Temperature** appears in the data table.

c. To define section data that depend on field variables, click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables.

Field variable columns appear in the data table.

d. Enter values for the section **Young's Modulus** and torsional **Shear Modulus** in the data table.

e. Enter a value for the **Section Poisson's ratio** to provide uniform strain in the section due to strain of the beam axis (so that the cross-sectional area changes when the beam is stretched). This value must be between −1.0 and 0.5. A value of 0.5 will enforce incompressible behavior. The default value is 0.

f. To define a density for the beam section, toggle on **Specify section material density** and enter a value in the field provided. This value is required in an Abaqus/Explicit analysis. In an Abaqus/Standard analysis it is needed only when the mass is required, such as in dynamic analysis or gravity loading.

g. If the thermal expansion coefficient is temperature dependent, toggle on **Specify reference temperature** and enter a value for the thermal expansion in the field provided.

- If **Material name** is selected as the **Material definition type**, do the following:

a. Select a **Material name** to be used with this beam section definition.

b. Enter a value for the **Section Poisson's ratio** to provide uniform strain in the section due to strain of the beam axis (so that the cross-sectional area changes when the beam is stretched). This value must be between −1.0 and 0.5. A value of 0.5 will enforce incompressible behavior.

9. On the **Damping** tabbed page, specify damping properties to include mass and stiffness proportional damping in the dynamic response of the section:

a. Enter a value in the **Alpha** field for the α_R factor to create mass proportional damping in direct-integration dynamics. This value is ignored in modal dynamics.

b. Enter a value in the **Beta** field for the β_R factor to create stiffness proportional damping in direct-integration dynamics. This value is ignored in modal dynamics.

c. Enter a value in the **Composite** field for the fraction of critical damping to be used in calculating composite damping factors for the modes (for use in modal dynamics). This value is applicable only to Abaqus/Standard analysis and is ignored in direct-integration dynamics.

10. On the **Stiffness** tabbed page, do the following:

a. Select **Use consistent mass matrix formulation** to let Abaqus calculate the mass formulation for the beam section using the McCalley-Archer consistent mass matrix based on the cubic interpolation of deflections and quadratic interpolation of rotations. If you toggle off this option, Abaqus performs this calculation using a lumped mass formulation.

b. Toggle on **Specify transverse shear** to include nondefault transverse shear stiffness effects in the section definition and specify the **Slenderness compensation**:

- Select **Use analysis product default** to let Abaqus calculate the shear stiffness and the slenderness compensation factor from the elastic material definition for the beam section.
- Select **Value** to specify the transverse shear stiffness effects directly.
  - Enter a slenderness compensation factor in the field provided.
  - Enter values for the K_{23} and K_{13} shear stiffnesses of the section in the fields provided.

11. On the **Fluid Inertia** tabbed page, toggle on **Specify fluid inertia effects** to simulate the inertial effects of the beam being submerged in a fluid. For details, see *Additional Inertia due to Immersion in Fluid*.

a. Specify whether the beam is **Fully submerged** or **Half submerged** in the fluid. If you select **Half submerged**, the added inertia per unit length is reduced by a factor of one-half.

b. Specify the **Fluid density**.

c. Enter the effective radius of the wetted cross-section in the **Section radius** field.

d. Specify C_A, the added mass coefficient for **Lateral motions of the beam**.

e. Specify C_{A-E}, the added mass coefficient for **Motions along beam axis**.

f. If the beam cross-section origin is different than the centroid of the wetted cross-section, specify the centroid's **X** and **Y** coordinates relative to the cross-section origin.

12. On the **Output Points** tabbed page, you can locate points in the beam section for which stress and strain output are required. Enter the local x_1- and x_2-positions of as many section points as needed.

13. Click **OK** to save your changes and to close the beam section editor.

Creating truss sections

Truss sections are used to define the section properties of slender, rod-like structures in two and three dimensions that provide axial strength but no bending stiffness. For more information, see *Truss Elements*.

1. From the main menu bar, select **Section->Create**.

   A **Create Section** dialog box appears.

   Tip: You can also click **Create** in the **Section Manager** or select the create section tool in the Property module toolbox.

2. Enter a section name. For more information on naming objects, see *Using basic dialog box components*.
3. Select **Beam** as the section **Category** and **Truss** as the section **Type**, and click **Continue**.

   The truss section editor appears.

4. Select a material for the truss section. If desired, click to create a material; see *Creating or editing a material*, for more information.
5. Enter a value for the **Cross-sectional area**.
6. Click **OK** to save your changes and to close the truss section editor.

Creating gasket sections

Gasket sections are used to define the section properties of thin sealing components that are positioned between structural components. For more information, see *Defining the Gasket Behavior Directly Using a Gasket Behavior Model*. *Gaskets*," describes the entire modeling process for an analysis involving gaskets.

1. From the main menu bar, select **Section->Create**.

   A **Create Section** dialog box appears.

   Tip: You can also click **Create** in the **Section Manager** or select the create section tool in the Property module toolbox.

2. Enter a section name. For more information on naming objects, see *Using basic dialog box components*.
3. Select **Other** as the section **Category** and **Gasket** as the section **Type**, and click **Continue**.

   The gasket section editor appears.

4. Select a material for the gasket section. If desired, click to create a material; see *Creating or editing a material*, for more information.
5. Specify the **Stabilization stiffness** that is used to stabilize gasket elements that are not supported at all nodes, such as those that extend outside neighboring components.
   - Toggle on **Use default** to use the default value of 10^{-9} times the initial compressive stiffness in the thickness direction. This default value is usually appropriate.
   - Toggle on **Specify**, and enter a value for the desired stabilization stiffness in units of stress (FL^{-2}).
6. Specify the **Initial thickness** of the gasket.
   - Toggle on **Use nodal coordinates** to obtain the initial gasket thickness from the nodal coordinates.
   - Toggle on **Specify**, and enter a value for the initial gasket thickness.
7. Enter a value for the **Initial gap**, which is the gasket closure that is needed to generate a pressure.
8. Enter a value for the **Initial void**, which is the inter-layer spaces in a gasket.
9. Enter a value for the **Cross-sectional area, width, or out-of-plane thickness**, depending on the gasket element type. For two- and three-dimensional link elements the cross-sectional area of the element should be given. For axisymmetric link elements and three-dimensional line elements the width of the element should be given. For general two-dimensional elements the out-of-plane thickness is required. For three-dimensional area elements no additional quantities are needed to define the element geometry.
10. Click **OK** to save your changes and to close the gasket section editor.

Creating cohesive sections

Cohesive sections are used to define the section properties of adhesive layers at the interface between two bonded parts. For more information, see *About Cohesive Elements*. *Adhesive joints and bonded interfaces*," describes the entire modeling process for an analysis involving cohesive sections.

1. From the main menu bar, select **Section->Create**.

   A **Create Section** dialog box appears.

   Tip: You can also click **Create** in the **Section Manager** or select the create section tool  in the Property module toolbox.

2. Enter a section name. For more information on naming objects, see *Using basic dialog box components*.
3. Select **Other** as the section **Category** and **Cohesive** as the section **Type**, and click **Continue**.

   The cohesive section editor appears.

4. Select a material for the cohesive section. If desired, click  to create a material; see *Creating or editing a material*, for more information.
5. Select a **Response** for defining the constitutive behavior of the cohesive section:

   - Select **Traction Separation** if the response is defined directly in terms of traction and separation. Use this option to model a negligibly thin layer of adhesive (debonding).
   - Select **Continuum** to model a strain state involving one direct (opening strain) and two transverse shear components. Use this option to model a finite thickness adhesive layer.
   - Select **Gasket** to specify that the stress state is uniaxial.

6. Specify the **Initial thickness** of the cohesive section.

   - Toggle on **Use analysis default** to use the analysis default value for a **Traction Separation** or **Continuum** response. No default value is available for the **Gasket** response.
   - Toggle on **Use nodal coordinates** to obtain the initial thickness from the nodal coordinates.
   - Toggle on **Specify**, and enter a value for the initial thickness.

7. Enter a value for the section **Out-of-plane thickness**. If the section will be used with a two-dimensional region, you must specify the section thickness. Abaqus/CAE ignores the thickness information if it is not needed for the region type.
8. Click **OK** to save your changes and to close the cohesive section editor.

Creating acoustic infinite sections

Acoustic infinite sections are used to define the section properties of two-dimensional, three-dimensional, and axisymmetric regions that model an acoustic medium undergoing small pressure changes. You use acoustic infinite sections when you want to improve the accuracy of analyses involving exterior domains. You must create a reference point to indicate the reference node required by acoustic infinite elements. For more information, see *Infinite Elements*.

Specify acoustic infinite section properties

1. From the main menu bar, select **Section->Create**.

   A **Create Section** dialog box appears.

   Tip: You can also click **Create** in the **Section Manager** or select the create section tool  in the Property module toolbox.

2. Enter a section name. For more information on naming objects, see *Using basic dialog box components*.
3. Select **Other** as the section **Category** and **Acoustic infinite** as the section **Type**, and click **Continue**.

   The section editor appears.

4. Select an acoustic medium material for the acoustic infinite section. If desired, click  to create a material; see *Creating or editing a material*, for more information.
5. Enter a value for the section **Plane stress/strain thickness**. If the section will be used with a two-dimensional region, you must specify the section thickness. Abaqus/CAE ignores the thickness information if it is not needed for the region type.
6. To define the number of ninth-order polynomials that will be used to resolve the variation of the acoustic field in the infinite direction, click the arrow to the right of the **Order** field to decrease the number of polynomials that will be used (applies only to Abaqus/Explicit analyses). The default value is 10, which is the value always used in Abaqus/Standard.
7. Click **OK** to save your changes and to close the section editor.

Create a reference point for use with acoustic infinite elements

You must create a reference point to be used to determine the “radius” and “node ray” at each node of acoustic infinite elements. You create a reference point associated with a part in the Part module or in the Property module using the procedure described in *Creating a reference point*. For more information, see *Defining the Reference Point and Thickness for Acoustic Infinite Elements*.

Creating acoustic interface sections

Acoustic interface sections are used to define the section properties of two-dimensional, three-dimensional, and axisymmetric regions that model an acoustic medium undergoing small pressure changes. You use acoustic interface sections when you want to couple the acoustic medium to a structural model. For more information, see *Acoustic Interface Elements*.

1. From the main menu bar, select **Section->Create**.

   A **Create Section** dialog box appears.

   Tip: You can also click **Create** in the **Section Manager** or select the create section tool  in the Property module toolbox.

2. Enter a section name. For more information on naming objects, see *Using basic dialog box components*.
3. Select **Other** as the section **Category** and **Acoustic interface** as the section **Type**, and click **Continue**.

   The section editor appears.

4. Select an acoustic medium material for the acoustic interface section. If desired, click  to create a material; see *Creating or editing a material*, for more information.
5. Enter a value for the section **Plane stress/strain thickness**. If the section will be used with a two-dimensional region, you must specify the section thickness. Abaqus/CAE ignores the thickness information if it is not needed for the region type.
6. Click **OK** to save your changes and to close the section editor.

Defining rebar layers

When you create homogeneous shell sections, composite shell sections, membrane sections, or surface sections, you can define one or more layers of reinforcement (rebar) by using the **Rebar Layers** option. You access the **Rebar Layers** dialog box from the section editor. For more information, see *Defining Reinforcement*.

1. From the **Options** field of the shell, membrane, or surface section editor, click .
   The **Rebar Layers** dialog box appears.
2. Specify the type of rebar geometry.
   - Choose **Constant** for a constant rebar spacing.
   - Choose **Angular** if the rebar spacing varies as a function of radial position in a cylindrical coordinate system.
   - Choose **Lift equation–based** if the rebar spacing and orientation are determined by the tire lift equation.
3. In the table, enter a row of data for each rebar layer.
   Each row should contain the following information:
   - The name of the rebar layer.
   - The name of the material forming the rebar layer. Click in the **Material** column, then click the arrow that appears to display the list of available materials, and select the material forming the rebar layer.
   - The cross-sectional area per bar.
   - The rebar spacing in the plane of the section. For angular rebar spacing, specify the spacing angle in degrees. For lift equation–based spacing, specify the spacing in the uncured geometry.
   - The angular orientation of the rebar (in degrees) relative to the 1-direction of the rebar reference orientation. For lift equation–based spacing, specify the angle in the uncured geometry.
     Alternatively, you can specify an orientation name, in which case Abaqus/CAE assumes a user-defined orientation. You must supply the user subroutine *ORIENT* that contains the definition of the user-defined orientation for the specified orientation name.
   - The position of the rebar in the shell thickness direction measured from the middle surface of the shell, positive in the direction of the positive normal to the shell (not applicable for membrane sections or surface sections).
   - The cord extension ratio, e, (applies only for lift equation–based spacing).
   - The radius, r_0, that describes the position of the rebar in the uncured geometry, measured with respect to the axis of rotation in a cylindrical coordinate system (applies only for lift equation–based spacing).
4. Click **OK** to return to the section editor.

Additional information

- *Creating sections*
- *Defining Reinforcement*

Creating profiles

To create a profile you must choose a profile type and enter all of the data necessary to define the profile in the **Edit Profile** dialog box.

In this section:

- *Choosing a profile type*
- *Defining a box profile*
- *Defining a pipe profile*
- *Defining a circular profile*
- *Defining a rectangular profile*
- *Defining a hexagonal profile*
- *Defining a trapezoidal profile*
- *Defining an I-shaped profile*
- *Defining an L-shaped profile*
- *Defining a T-shaped profile*
- *Defining an arbitrary profile*
- *Defining a generalized profile*
- *Defining a channel profile*
- *Defining a hat profile*

Choosing a profile type

The **Create Profile** dialog box allows you to specify which type of profile you want to define. You can define a shape-based profile by providing the geometric data from which Abaqus can calculate the engineering properties of the section. Alternatively, you can define a generalized profile by providing the engineering properties of the section directly.
For more information, see *Beam Section Behavior*.

After you have assigned the beam section and beam orientation to the part, you can use the part display options to view an idealized representation of the shape-based or generalized beam profile. Displaying beam profiles is useful for checking that the correct profile is assigned to a particular region and that the assigned beam orientation results in the expected orientation of the profile. For more information, see *Controlling beam profile display*.

1. From the main menu bar, select **Profile->Create**.

   The **Create Profile** dialog box appears.

   Tip: You can also click **Create** in the **Profile Manager** or select the create profile tool  in the Property module toolbox.

2. Enter a profile name. For more information on naming objects, see *Using basic dialog box components*.
3. Select a profile shape, and click **Continue**.

   The **Edit Profile** dialog box for the profile shape you have chosen appears.
4. In the **Edit Profile** dialog box, enter the required profile data. See the following sections for details:

   - *Defining a box profile*
   - *Defining a pipe profile*
   - *Defining a circular profile*
   - *Defining a rectangular profile*
   - *Defining a hexagonal profile*
   - *Defining a trapezoidal profile*
   - *Defining an I-shaped profile*
   - *Defining an L-shaped profile*
   - *Defining a T-shaped profile*
   - *Defining an arbitrary profile*
   - *Defining a generalized profile*
   - *Defining a channel profile*
   - *Defining a hat profile*

Additional information

- *Defining profiles*
- *Defining sections*
- *Beam Cross-Section Library*
- *Using a General Beam Section to Define the Section Behavior*

Defining a box profile

Define a box profile by providing geometric data for a rectangular, hollow box.

1. Display the **Edit Profile** dialog box, as described in *Choosing a profile type*.
2. In the **Width (a)** field, enter the length of the segments parallel to the local 1-axis.
3. In the **Height (b)** field, enter the length of the segments parallel to the local 2-axis.
4. Click the arrow to the right of the **Thickness** field, and indicate how you want to define the thickness of each segment:
   - Select **Uniform** if each of the four segments of the box have the same thickness. If you select this option, enter the segment thickness in the **Thickness** field below.
   - Select **Individual** to enter a value for each segment individually. If you select this option, enter the following:
     - In the **t1** field, enter the segment thickness labeled t_1 in the diagram.
     - In the **t2** field, enter the segment thickness labeled t_2 in the diagram.
     - In the **t3** field, enter the segment thickness labeled t_3 in the diagram.
     - In the **t4** field, enter the segment thickness labeled t_4 in the diagram.
5. Click **OK** to save the profile and to close the **Edit Profile** dialog box.

Additional information

- *Defining profiles*
- *Defining sections*
- *Beam Cross-Section Library*

Defining a pipe profile

Define a pipe profile by providing geometric data for a hollow circle and by selecting an integration scheme for a thin-walled pipe or a thick-walled pipe.

1. Display the **Edit Profile** dialog box, as described in *Choosing a profile type*.
2. From the **Integration scheme** options, specify a thin-walled pipe or a thick-walled pipe.
3. In the **Radius** field, enter the radius of the circle from the center of the pipe to the outside edge of the pipe wall.
4. In the **Thickness** field, enter the thickness of the pipe wall.
5. Click **OK** to save the profile and to close the **Edit Profile** dialog box.

Additional information

- *Defining profiles*
- *Defining sections*
- *Beam Cross-Section Library*

Defining a circular profile

Define a circular profile by providing geometric data for a solid circle.

1. Display the **Edit Profile** dialog box, as described in *Choosing a profile type*.
2. In the **r** field, enter the radius of the circle.
3. Click **OK** to save the profile and to close the **Edit Profile** dialog box.

Additional information

- *Defining profiles*
- *Defining sections*
- *Beam Cross-Section Library*

Defining a rectangular profile

Define a rectangular profile by providing geometric data for a solid rectangle.

1. Display the **Edit Profile** dialog box, as described in *Choosing a profile type*.
2. In the **a** field, enter the length of the rectangle edges parallel to the local 1-axis.
3. In the **b** field, enter the length of the rectangle edges parallel to the local 2-axis.
4. Click **OK** to save the profile and to close the **Edit Profile** dialog box.

Additional information

- *Defining profiles*
- *Defining sections*
- *Beam Cross-Section Library*

Defining a hexagonal profile

Define a hexagonal profile by providing geometric data for a hollow hexagon.

1. Display the **Edit Profile** dialog box, as described in *Choosing a profile type*.
2. In the **r** field, enter the circumscribing radius.
3. In the **t** field, enter the wall thickness.
4. Click **OK** to save the profile and to close the **Edit Profile** dialog box.

Additional information

- *Defining profiles*
- *Defining sections*
- *Beam Cross-Section Library*

Defining a trapezoidal profile

Define a trapezoidal profile by providing geometric data for a solid trapezoid.

1. Display the **Edit Profile** dialog box, as described in *Choosing a profile type*.
2. In the **a** field, enter the length of the lower edge of the trapezoid parallel to the local 1-axis.
3. In the **b** field, enter the height of the trapezoid parallel to the local 2-axis.
4. In the **c** field, enter the width of the top edge of the trapezoid parallel to the local 1-axis.
5. In the **d** field, enter the distance between the lower edge of the trapezoid and the local cross-section axis.
6. Click **OK** to save the profile and to close the **Edit Profile** dialog box.

Additional information

- *Defining profiles*
- *Defining sections*
- *Beam Cross-Section Library*

Defining an I-shaped profile

Define an I-shaped profile by providing geometric data for an I-beam section.

1. Display the **Edit Profile** dialog box, as described in *Choosing a profile type*.
2. In the **l** field, enter the distance between the lower edge of the bottom flange and the local cross-section axis.
3. In the **h** field, enter the height of the I-shape, from the bottom edge to the top edge.
4. In the **b1** field, enter the width of the lower flange parallel to the 1-axis.
5. In the **b2** field, enter the width of the upper flange parallel to the 1-axis.
6. In the **t1** field, enter the thickness of the lower flange.
7. In the **t2** field, enter the thickness of the upper flange.
8. In the **t3** field, enter the thickness of the segment joining the upper and lower flanges.
9. Click **OK** to save the profile and to close the **Edit Profile** dialog box.

Additional information

- *Defining profiles*
- *Defining sections*
- *Beam Cross-Section Library*

Defining an L-shaped profile

Define an L-shaped profile by providing geometric data for an L-beam section.

1. Display the **Edit Profile** dialog box, as described in *Choosing a profile type*.
2. In the **a** field, enter the length of the flange parallel to the local 1-axis.
3. In the **b** field, enter the length of the flange parallel to the local 2-axis.
4. In the **t1** field, enter the thickness of the flange parallel to the local 1-axis.
5. In the **t2** field, enter the thickness of the flange parallel to the local 2-axis.
6. Click **OK** to save the profile and to close the **Edit Profile** dialog box.

Additional information

- *Defining profiles*
- *Defining sections*
- *Beam Cross-Section Library*

Defining a T-shaped profile

Define a T-shaped profile by providing geometric data for a T-beam section.

1. Display the **Edit Profile** dialog box, as described in *Choosing a profile type*.
2. In the **b** field, enter the length of the segment parallel to the 1-axis.
3. In the **h** field, enter the height of the T-shape, from the bottom edge to the top edge.
4. In the **l** field, enter the distance between the lower edge and the local cross-section axis.
5. In the **tf** field, enter the thickness of the segment parallel to the local 1-axis.
6. In the **tw** field, enter the thickness of the segment parallel to the local 2-axis.
7. Click **OK** to save the profile and to close the **Edit Profile** dialog box.

Additional information

- *Defining profiles*
- *Defining sections*
- *Beam Cross-Section Library*

Defining an arbitrary profile

You can create an arbitrary profile to model the shape of a simple, thin-walled, open or closed section. You define the profile by entering a series of points which are linked by straight line segments.
For more information, see *Arbitrary, Thin-Walled, Open and Closed Sections*.

1. Display the **Edit Profile** dialog box, as described in *Choosing a profile type*.
2. In the data table, enter the local coordinates for **Point 1**.

   For detailed information on how to enter data, see *Entering tabular data*.
3. Enter the local coordinates for **Point 2**. The line joining **Point 1** and **Point 2** is labeled **Segment 1-2** in the data table.
4. Enter a **Thickness** for **Segment 1-2**.
5. Enter the local coordinates for **Point 3**. The line between **Point 2** and **Point 3** is labeled **Segment 2-3** in the data table.
6. Enter a **Thickness** for **Segment 2-3**.

   Note:

   For each individual segment of an arbitrary section there is no bending stiffness about the line joining the end points of the segment. Thus, an arbitrary section must include at least two segments.
7. If necessary, enter local coordinates for additional points, and provide thicknesses for the resulting segments.
8. Click **OK** to save the profile and to close the **Edit Profile** dialog box.

Additional information

- *Defining profiles*
- *Defining sections*
- *Beam Cross-Section Library*

Defining a generalized profile

When you create a generalized profile, you provide the engineering properties of the section directly in the **Edit Profile** dialog box.
For more information, see *Beam Section Behavior*.

1. Display the **Edit Profile** dialog box, as described in *Choosing a profile type*.
2. In the **Area** field, enter the area of the profile shape.
3. In the **I11** field, enter the moment of inertia for bending about the 1-axis of the section.
4. In the **I12** field, enter the moment of inertia for cross-bending.
5. In the **I22** field, enter the moment of inertia for bending about the 2-axis of the section.
6. In the **J** field, enter the torsional constant.
7. If the profile describes an open-section beam, enter the following:
   - In the **Gamma O** field, enter the sectoral moment, Γ_0.
   - In the **Gamma W** field, enter the warping constant, Γ_W.
8. Click **OK** to save the profile and to close the **Edit Profile** dialog box.

Additional information

- *Defining profiles*
- *Defining sections*
- *Using a General Beam Section to Define the Section Behavior*

Defining a channel profile

Define a channel profile by providing geometric data for a channel section.

1. Display the **Edit Profile** dialog box, as described in *Choosing a profile type*.
2. In the **l** field, enter the distance between the lower edge of the bottom flange and the local cross-section 1-axis.
3. In the **h** field, enter the height of the channel section, from the bottom edge to the top edge.
4. In the **b1** field, enter the width of the lower flange of the channel section.
5. In the **b2** field, enter the width of the upper flange of the channel section.
6. In the **t1** field, enter the thickness of the lower flange of the channel section.
7. In the **t2** field, enter the thickness of the upper flange of the channel section.
8. In the **t3** field, enter the thickness of the segment joining the upper and lower flanges of the channel section.
9. In the **o** field, enter the distance between the left edge of the web section and the local cross-section 2-axis of the channel section.
10. Click **OK** to save the profile and to close the **Edit Profile** dialog box.

Additional information

- *Defining profiles*
- *Defining sections*
- *Beam Cross-Section Library*

Defining a hat profile

Define a hat profile by providing geometric data for a hat section.

1. Display the **Edit Profile** dialog box, as described in *Choosing a profile type*.
2. In the **l** field, enter the distance between the lower edge of the bottom flange and the local cross-section 1-axis.
3. In the **h** field, enter the height of the hat section, from the bottom edge to the top edge.
4. In the **b** field, enter the bottom width of the hat section.
5. In the **b1** field, enter the width of the upper flange of the hat section.
6. In the **b2** field, enter the width of the lower flange of the hat section.
7. In the **t1** field, enter the thickness of the upper flange of the hat section.
8. In the **t2** field, enter the thickness of the lower flange of the hat section.
9. In the **t3** field, enter the thickness of the segment joining the upper and lower flanges.
10. Click **OK** to save the profile and to close the **Edit Profile** dialog box.

- *Beam Cross-Section Library*

Creating and editing composite layups

This section describes how you create a composite layup.

In this section:

- *Using the ply table when defining a composite layup*
- *Creating conventional shell composite layups*
- *Creating continuum shell composite layups*
- *Creating solid composite layups*

Using the ply table when defining a composite layup

When you are creating a composite layup (for a shell, continuum shell, or solid), you use a row in the ply table to enter information about a ply in the layup.
The number of rows determines the number of plies in the layup, and the first row of the ply table corresponds with the ply on the bottom of the layup.

Each row of the ply table asks for the following:

- Whether the ply is activated.
- The name of the ply.
- The region to which the ply is assigned.
- The name of the material used in this ply.
- The ply thickness.
- The coordinate system specifying the reference orientation of the ply.
- A rotation angle relative to the reference orientation.
- The number of integration points in the ply, if you are specifying properties for a composite layup integrated during the analysis.

For general information about working with tables in Abaqus/CAE, see *Entering tabular data*.

As you enter ply data in the table, the ply region is highlighted and the ply orientation is displayed on the model in the viewport. You can modify the display to turn off highlighting, to display the layup orientation, or to select the orientation vectors to display.

In cases where Abaqus/CAE attempts to draw coordinate systems for ply orientations in composite layups at singularity points of the system (i.e., points for which the user-selected coordinate system and the geometric normal from either geometry or elements cannot be resolved into a valid orientation for display purposes in Abaqus/CAE), the coordinate system will be drawn collapsed.

If the layup orientation is specified using a discrete field, no display is available for either the layup or ply orientation. For continuum shell elements, Abaqus/CAE does not project the displayed orientations onto the midplane surface. In both of these cases, you can perform a data check and view the output database in the Visualization module to verify the orientations. For more information, see *Performing a data check on a model*.

A number of tools are available for adding or removing plies from the ply table. Most tools appear as icons above the ply table. Certain tools can be accessed only by clicking mouse button 3 on the ply table and selecting an item from the contextual menu that appears. The following tools are available:

Edit

Edit the contents of the selected table cell. For example, you can select a region from the part in the viewport, choose a material, or enter the thickness. In most cases you can select multiple cells, and Abaqus/CAE applies your change to each of the selected cells. You can select a column header to select the entire column.

The **Edit** tool is available from the contextual menu. Alternatively, you can double-click on a cell in the **Region**, **Material**, or **CSYS** columns to edit that cell. You can also double-click on a column header to apply the same edit to all of the cells in the column.

Move Plies Up or Down

Move the selected plies up or down one row in the ply table. Click  to move the selected plies up one row, or click  to move the selected plies down one row.

Copy Plies Before or After

Create new plies by copying the selected plies before or after the selected plies. Click  to copy the selected plies before the selected plies, or click  to copy the selected plies after the selected plies.

Insert Row Before or After

Insert an empty row before or after each of the selected plies. Click  to insert an empty row before the selected plies, or click  to insert an empty row after the selected plies.

Delete Plies

Delete the selected plies. Click  to delete the selected plies.

Pattern Plies

Copy selected plies using a pattern. Click  to pattern the selected plies.

The location to which the patterned plies are copied can be either the first or last ply in the layup or the first or last ply from the selected plies. You can also specify the copy location by selecting the name of the ply below which to copy. If you select the name of the ply below which to copy, you can choose to insert the copied plies into the ply table or to overwrite any existing plies.

The pattern can be one of the following:

N-Copy

A specified number of copies of the selected plies.

Symmetry

A single copy of the selected plies. The plies that are copied are reordered so that the order of the original plies and the order of the copied plies is symmetric about the specified location.

Invert Plies

Invert the order of two or more selected adjacent plies. Click  to invert the order of the selected plies.

Read From File

Read ply data from an ASCII file. The data can be delimited with spaces, tabs, or commas. You can specify into which row and column of the ply table Abaqus/CAE should start to read the data. The first column of the table is the state of the suppression (true or false).

The **Read From File** tool is available only from the contextual menu.

Note:

The data in the **Region** column of the file refers to a named set in your part. The name of the region is case-sensitive. Therefore, the name of the region that you use in the file must be identical to the name of an existing set in your part. The same is also true for the data in the **CSYS** column—the name of the coordinate system that you use in the file must be identical to the name of an existing datum coordinate system in your part.

Write To File

Write the entire ply table to a specified file. Abaqus/CAE uses commas to delimit the data.

The **Write To File** tool is available only from the contextual menu.

The options that are available are context sensitive; for example, the  icon and the **Move Plies Up** option in the contextual menu do not appear if you are editing the first row of the ply table.

Creating conventional shell composite layups

This section describes how to create a conventional shell composite layup.

Conventional shell composite layups are composed of plies made of different materials in different orientations. A layup can contain a different number of plies in different regions. For more information, see *Composite layups*. Abaqus models a shell composite layup using conventional shell elements that discretize only the reference surface of each ply. Shell section behavior is defined in terms of the response of the shell section to stretching, bending, twist, and transverse shear. For more information, see *Shell Section Behavior*.

When you create conventional shell composite layups, you must choose a section integration method. You can choose to provide the section property data before the analysis (a pre-integrated shell section) or to have Abaqus calculate (integrate) the cross-sectional behavior from section integration points during the analysis.

Conventional shell composite layups integrated during analysis allow the cross-sectional behavior to be calculated by numerical integration through the shell thickness, thus providing complete generality in material modeling. Any number of material points can be defined through the thickness, and the material response can vary from point to point. You generally use shell elements integrated during analysis when the composite layup includes nonlinear material behavior. You must use shell elements integrated during analysis to model heat transfer. For more information, see *Using a Shell Section Integrated during the Analysis to Define the Section Behavior*.

Linear moment-bending and force-membrane strain relationships can be defined using pre-integrated composite layups. In this case all calculations are done in terms of section forces and moments. The section properties are specified by an elastic material; optionally, you can also apply an idealization based on assumptions about the expected behavior or makeup of the layup. You should use pre-integrated composite layups if the response of the layup is linear elastic and its behavior is not dependent on changes in temperature or predefined field variables. For more information, see *Using a General Shell Section to Define the Section Behavior*.

After you have created a conventional shell composite layup, you can use a ply stack plot to view a graphical representation of a core sample through a region of the layup. For more information, see *Viewing a ply stack plot*.

In this section:

- *Creating conventional shell composite layups*
- *Specifying the plies of a conventional shell composite layup*
- *Specifying the offset of a conventional shell composite layup*
- *Specifying the shell parameters of a conventional shell composite layup*
- *Specifying the display of selected plies of a conventional shell composite layup*

Creating conventional shell composite layups

You can define a conventional shell composite layup composed of plies made of one or more materials.
For each ply of the layup, you specify the name, material, thickness, orientation, and the number of integration points.
In addition, you select the region to which the ply is assigned. For more information, see *Shell Section Behavior*.

1. From the main menu bar, select **Composite->Create**.

   A **Create Composite Layup** dialog box appears.

   Tip: You can also click **Create** in the **Composite Layup Manager** or select the create composite layup tool in the Property module toolbox.

2. Enter a composite layup name. Abaqus/CAE displays this name in a ply stack plot. For more information on naming objects, see *Using basic dialog box components*.
3. Specify the initial ply count. When the composite layup editor appears, it will contain a row for each ply; however, you can use the editor to subsequently add or delete plies. The first row of the ply table corresponds to the bottom ply of the layup.
4. Select **Conventional Shell** as the **Element Type**, and click **Continue**.

   The composite layup editor appears.
5. Enter a description of the layup. Abaqus/CAE displays this description in the composite layup manager.
6. Do one of the following to specify the layup orientation:

   - Select **Part global** to use the part's coordinate system, and choose the axis that represents the **Normal direction**.
   - Select **Coordinate system** to select an existing coordinate system (or create a new coordinate system and select it), and do the following:

     1. Choose the axis that represents the **Normal direction**.
     2. Specify an additional rotation. The selected coordinate system is rotated through this angle about the selected axis. You can specify an angle, or you can select an existing scalar discrete field that defines an angle that is varying spatially across the layup. Abaqus/CAE allows you to select only valid discrete fields, which, for an additional rotation, are scalar discrete fields applied to elements. You can also create a new discrete field by clicking . For more information, see *The Discrete Field toolset*.

   - Select **Discrete** to define a discrete orientation, and do the following:

     1. Click .
     2. In the **Edit Discrete Orientation** dialog box that appears, define the normal axis and primary axis using the procedure described in *Using discrete orientations for material orientations and composite layup orientations*.
     3. Specify an additional rotation. The orientation is rotated through this angle about the selected normal axis. You can specify an angle, or you can select or create a scalar discrete field that defines an angle that is varying spatially across the layup. Abaqus/CAE allows you to select only valid discrete fields, which, for an additional rotation, are scalar discrete fields applied to elements. You can also create a new discrete field by clicking . For more information, see *The Discrete Field toolset*.

- Select **User-defined** to define the orientation in user subroutine *ORIENT*. This option is valid only for Abaqus/Standard analyses. See the following sections for more information:
  - *Specifying general job settings*
  - *ORIENT*

- Select the name of an orientation discrete field to specify a coordinate system that is varying spatially across the layup. You can also create a new discrete field by clicking  to the right of the **Definition** field. For more information, see *The Discrete Field toolset*. After selecting the discrete field, you must do the following:

  1. Choose the axis that represents the **Normal direction**.
  2. Specify an additional rotation. The selected coordinate system is rotated through this angle about the selected axis. You can specify an angle, or you can select or create a scalar discrete field that defines an angle that is varying spatially across the layup.

The layup orientation is the reference orientation for any ply that uses the default orientation system (indicated by **<Layup>** in the **CSYS** column of the ply table). This orientation is used for material calculations and stress output in the individual plies, for the section forces output, and for the transverse shear stiffness. You can specify a different orientation for the individual plies of a continuum shell composite layup by specifying a reference orientation and/or a rotation angle. For more information, see *Understanding composite layups and orientations*.

7. Choose one of the following **Section integration** methods:
   - Choose **During analysis** to specify properties for a shell composite layup integrated during the analysis.
   - Choose **Before analysis** to specify properties for a pre-integrated shell composite layup.

8. If you are specifying properties for a composite layup integrated before the analysis, specify the **Idealization** to apply to the shell based on assumptions about the expected behavior or makeup of the layup. For more information, see *Idealizing the Section Response*.
   - Select **No idealization** to account for the complete stiffness of the shell as determined by the material assignments and ply composition.
   - Select **Smear all layers** if you do not know the exact stacking sequence for the plies in the composite layup. Contributions from each specified ply are smeared across the entire thickness of the layup, resulting in a general response independent of the stacking sequence.
   - Select **Membrane only** if the predominant response of the shell will be in-plane stretching; bending stiffness terms are eliminated from the shell stiffness calculations.
   - Select **Bending only** if the predominant response of the shell will be pure bending; membrane stiffness terms are eliminated from the shell stiffness calculations.

9. If you are specifying properties for a composite layup integrated during the analysis, select the **Thickness integration rule**.
   - Choose **Simpson** to use Simpson's rule for the shell section integration.
   - Choose **Gauss** to use Gauss quadrature for the shell section integration.

   See *Defining the Shell Section Integration*, for more information.

10. When you have finished defining the shell composite layup, click **OK** to save your changes and to close the editor.

Specifying the plies of a conventional shell composite layup

A composite layup is composed of a series of plies. You select the region to which a ply is assigned, and you specify the name, material, thickness, orientation, and the number of integration points of each ply.
You must specify ply names that are unique throughout the entire model to ensure the correct display of ply-based results. Use the icons above the ply table or click mouse button 3 on the ply table to see a menu that allows you to edit the contents of the table cell and to manipulate the data in the table; for example, you can add and delete plies, pattern plies, and invert plies. You can also read data into the table from a file or write data from the table into a file. For more information, see *Using the ply table when defining a composite layup*.

1. From the **Composite Layup** editor, click the **Plies** tab.
2. If the plies in the composite layup are symmetric about a central core, toggle on **Make calculated sections symmetric**. Enter the plies in the ply table, starting with the bottom ply in the first row and ending with the central ply. During the analysis Abaqus appends plies to the layup definition by repeating the entered plies (including the central ply) in the reverse order to the top of the layup. Each generated ply is labeled in ply stack plots and the output database by adding `Sym_` to the beginning of the repeated ply's original name.

   This option cannot be used if the thickness or rotation angle for any of the plies in the layup is defined using a discrete field.
3. For each ply, enter the following data in the ply table:

Ply Name

The name of the ply. Abaqus/CAE displays this name when you are viewing the composite layup in the Visualization module and in a ply stack plot.

Region

Select the region to which the ply is assigned. You can choose faces from the viewport, or you can select a set that refers to a face. If you are displaying a meshed dependent part, you can choose shell elements from the viewport or select an element set. To choose elements from the viewport, you must display the native mesh, and you must use the Selection toolbar to enable the selection of **2D Elements**. You can also select shell elements from a mesh part. For more information, see *Displaying a native mesh*, and *Filtering your selection based on the type of object*.

Material

The name of the material for this ply. Click mouse button 3, select **Edit Material** from the menu that appears, and do either of the following:

- Select the desired material from the list of available materials.
- Click  to create a new material.

Thickness

The ply thickness. Enter a uniform thickness directly in the table, or click mouse button 3 and select **Edit Thickness** to do the following:

- Choose **Specify Value** to enter a uniform thickness for the ply.

- Choose **Distribution** and select a scalar discrete field or analytical field to specify a thickness that varies spatially across the ply.

Coordinate system

To define the coordinate system that will be used as the basis for the reference orientation of the ply, do the following:

1. Click mouse button 3, and select **Edit CSYS** from the menu that appears.

   Note:

   If you choose **Edit Orientation** from the menu, you can define both the coordinate system and the rotation angle.

2. Select the base orientation. You can select the base layup orientation, or you can select a coordinate system. If you select a coordinate system, you must select the axis that defines the normal direction.

Rotation Angle

An additional rotation (counterclockwise about the normal direction) for the ply's reference orientation. Enter a uniform rotation directly in the table, or click mouse button 3 and select **Edit Rotation Angle** to do the following:

- Select a predefined angle (0, 45, 90, or –45 degrees) to define a uniform rotation.
- Select **Uniform**, and enter an **Angle** to define a uniform rotation.
- Select a scalar discrete field to define a rotation that varies spatially across the ply. You can also create a new discrete field by clicking .

Integration Points

The number of integration points, if you are specifying properties for a composite layup integrated during the analysis.

Specifying the offset of a conventional shell composite layup

In most cases you can use the midsurface of an element to indicate the reference surface. However, in some cases you need to define the reference surface as offset from the midsurface of the elements.
For example, a model imported from a CAD system might assume that the shell is located at the top or bottom surface of the elements. In addition, you can specify a shell offset that defines a more precise surface geometry for contact problems where shell thickness is important. The offset value is defined as a fraction of the total thickness measured from the midsurface to the reference surface.

Positive values of the offset are in the positive element normal direction. When the offset is set equal to 0.5, the top surface of the element is the reference surface. When the offset is set equal to –0.5, the bottom surface is the reference surface. The default offset is 0, which indicates that the middle surface of the element is the reference surface. *Figure 1* shows an offset to the top surface of the element.

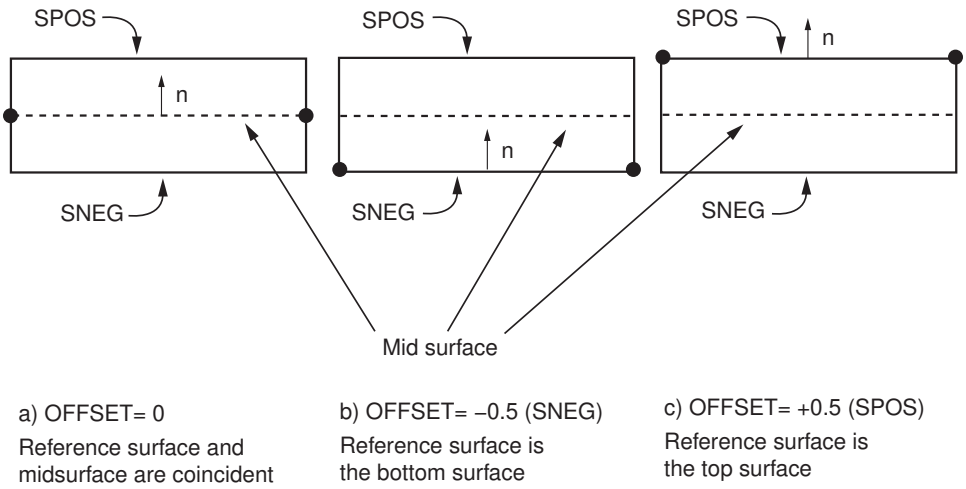

Figure 1: An offset to the top surface of the element.

For more information, see *Defining the Initial Geometry of Conventional Shell Elements*. You can use a discrete field to model elements with continuously varying offsets. For more information, see *The Discrete Field toolset*.

1. From the **Composite Layup** editor, click the **Offset** tab.
2. Do one of the following:
   - Choose the **Middle surface**, **Top surface**, or **Bottom surface** to represent the reference surface.
   - Choose **Specify offset ratio**, and enter a number.
   - Choose **Distribution**, and select an existing scalar discrete field that defines an offset that is varying spatially across the layup. Abaqus/CAE allows you to select only valid discrete fields, which, for an offset, are scalar discrete fields applied to elements. You can also create a new discrete field by clicking . For more information, see *The Discrete Field toolset*.
   - Choose **From Geometry** to use the thickness of the geometric section.

Specifying the shell parameters of a conventional shell composite layup

1. From the **Composite Layup** editor, click the **Shell Parameters** tab.
2. Specify the **Shell thickness**.
   - Choose **Use section thickness** to use the thickness calculated from the individual ply thicknesses.
   - Choose **Element distribution**; and select either an analytical field, labeled with an (A), or an element-based discrete field, labeled with a (D), to define a spatially varying element-based shell thickness. Alternatively, you can click $f(x)$ to create a new analytical field or click  to create a new discrete field. See *The Analytical Field toolset* and *The Discrete Field toolset* for more information.
   - Choose **Nodal distribution**; and select either an analytical field, labeled with an (A), or a node-based discrete field, labeled with a (D), to define a spatially varying node-based shell thickness. Alternatively, you can click $f(x)$ to create a new analytical field or click  to create a new discrete field. See *The Analytical Field toolset* and *The Discrete Field toolset* for more information.
   - Choose **Determine overall thickness from geometry** to have Abaqus/CAE calculate the offset from the thickness defined on the geometry. You must choose **From Geometry** on the **Offset** tabbed page.
3. Specify the **Section Poisson's ratio** to define the shell thickness behavior. In conventional shell elements that permit finite membrane strains in large-deformation analysis, specifying the section Poisson's ratio causes the shell thickness to change as a function of membrane strains.
   - Choose **Use analysis default** to use the default value. In Abaqus/Standard the default value is 0.5, which will enforce incompressible behavior of the element for membrane strains. In Abaqus/Explicit the default is to base the change in thickness on the element material definition.
   - Choose **Specify value**, and enter a value for the Poisson's ratio. This value must be between −1.0 and 0.5. A value of 0.0 will enforce constant shell thickness, and a negative value will result in an increase in the shell thickness in response to tensile membrane strains.
4. If you are specifying properties for a composite layup integrated during the analysis, select a method for defining the **Temperature variation** through the section:
   - Choose **Linear through thickness** to indicate that the temperature at the reference surface and the temperature gradient or gradients through the ply are specified. You can use the Load module to specify these temperatures.
   - Choose **Piecewise linear over *n* values** to enter the number of temperature points (values) through the ply in the text field provided. You can use the Load module to specify the temperature at each of these points.
5. Toggle on **Density**, and enter a value for the density. The mass of the ply includes a contribution from the density in addition to any contribution from the selected material.
6. For most shell sections Abaqus calculates the transverse shear stiffness values required in the element formulation. If desired, toggle on **Specify values** from the **Transverse Shear Stiffnesses** options to include nondefault transverse shear stiffness effects in the section definition, and enter values for K_{11}, the shear stiffness of the section in the first direction; K_{12}, the coupling term in the shear stiffness of the section; and K_{22}, the shear stiffness of the section in the second direction. If either value K_{11} or K_{22} is omitted or given as zero, the nonzero value will be used for both. For more information, see *Defining the Transverse Shear Stiffness*.

Specifying the display of selected plies of a conventional shell composite layup

1. From the **Composite Layup** editor, click the **Display** tab.
2. Choose how Abaqus/CAE highlights the plies that you selected in the ply table:
   - Choose **On** to highlight the selected plies.
   - Choose **Off** to stop highlighting the selected plies. If you have a large number of plies in your model, you may want to turn off highlighting to increase performance.
3. Choose which orientation Abaqus/CAE displays on the selected plies:
   - Choose **Ply** to display the ply orientation on the selected plies.
   - Choose **Layup** to display the layup orientation on the selected plies.
   - Choose **None** to stop displaying an orientation.
4. Specify which orientation vectors you want to display on the selected plies. You can toggle the display of vectors in the 1-direction, the 2-direction, and the 3- (or normal) direction, as well as the reference direction that shows the 1-direction before rotation of the ply's material directions.

Creating continuum shell composite layups

This section describes how to create a continuum shell composite layup.

Abaqus models a continuum shell composite layup using continuum shell elements that fully discretize each ply but have a kinematic behavior that is based on shell theory. Continuum shell composite layups are composed of plies made of different materials in different orientations. A layup can contain a different number of plies in different regions. For more information, see *Composite layups*.

Continuum shell composite layups are expected to have a single element through their thickness, and that single element contains multiple plies that are defined in the ply table. If the region to which you assign your continuum shell composite layup contains multiple elements, each element will contain the plies defined in the ply table, and the analysis results will not be as expected.

You choose the stacking direction of the continuum shell elements in the layup, which allows Abaqus to model the through-thickness response more accurately. In addition, continuum shell composite layups take into account double-sided contact and thickness changes, which provides more accurate contact modeling than conventional shell composite layups. For more information, see *Shell Section Behavior*.

When you create continuum shell composite layups, you must choose a section integration method. You can choose to provide the section property data before the analysis (a pre-integrated continuum shell composite layup) or to have Abaqus calculate (integrate) the cross-sectional behavior from integration points during the analysis.

Continuum shell composite layups integrated during the analysis allow the cross-sectional behavior to be calculated by numerical integration through the continuum shell thickness, thus providing complete generality in material modeling. Any number of material points can be defined through the thickness, and the material response can vary from point to point. You generally use continuum shell elements integrated during analysis when the composite layup includes nonlinear material behavior. You must use continuum shell elements integrated during analysis to model heat transfer. For more information, see *Using a Shell Section Integrated during the Analysis to Define the Section Behavior*.

Linear moment-bending and force-membrane strain relationships can be defined using pre-integrated continuum shell composite layups. In this case all calculations are done in terms of section forces and moments. The section properties are specified by an elastic material; optionally, you can also apply an idealization based on assumptions about the expected behavior or makeup of the layup. You should use pre-integrated continuum shell composite layups if the response of the layup is linear elastic, and its behavior is not dependent on changes in temperature or predefined field variables. For more information, see *Using a General Shell Section to Define the Section Behavior*.

After you have created a continuum shell composite layup, you can use a ply stack plot to view a graphical representation of a core sample through a region of the layup. For more information, see *Viewing a ply stack plot*.

In this section:

- *Creating continuum shell composite layups*
- *Specifying the plies of a continuum shell composite layup*
- *Specifying the shell parameters of a continuum shell composite layup*
- *Specifying the display of selected plies of a continuum shell composite layup*

Creating continuum shell composite layups

You can define a continuum shell composite layup with a specified stacking direction that is composed of plies made of one or more materials. For each ply of the layup, you specify the name, material, relative thickness, orientation, and the number of integration points. In addition, you select the region to which the ply is assigned. For more information, see *Defining a Composite Shell Section*.

1. From the main menu bar, select **Composite->Create**.

   A **Create Composite Layup** dialog box appears.

   Tip: You can also click **Create** in the **Composite Layup Manager** or select the create composite layup tool  in the Property module toolbox.

2. Enter a composite layup name. Abaqus/CAE displays this name in a ply stack plot. For more information on naming objects, see *Using basic dialog box components*.
3. Specify the initial ply count. When the composite layup editor appears, it will contain a row for each ply; however, you can use the editor to subsequently add or delete plies.
4. Select **Continuum Shell** as the **Element Type**, and click **Continue**.

   The composite layup editor appears.
5. Enter a description of the layup. Abaqus/CAE displays this description in the composite layup manager.
6. Do one of the following to specify the layup orientation:

   - Select **Part global** to use the part's coordinate system, and choose the axis that represents the **Normal direction**.
   - Select **Coordinate system** to select an existing coordinate system (or create a new coordinate system and select it), and do the following:

     1. Choose the axis that represents the **Normal direction**.
     2. Specify an additional rotation. The selected coordinate system is rotated through this angle about the selected axis. You can specify an angle, or you can select an existing scalar discrete field that defines an angle that is varying spatially across the layup. Abaqus/CAE allows you to select only valid discrete fields, which, for an additional rotation, are scalar discrete fields applied to elements. You can also create a new discrete field by clicking . For more information, see *The Discrete Field toolset*.

   - Select **Discrete** to define a discrete orientation, and do the following:

     1. Click .
     2. In the **Edit Discrete Orientation** dialog box that appears, define the normal axis and primary axis using the procedure described in *Using discrete orientations for material orientations and composite layup orientations*.
     3. Choose the axis that represents the **Normal direction**.
     4. Specify an additional rotation. The orientation is rotated through this angle about the selected normal axis. You can specify an angle, or you can select or create a scalar discrete field that defines an angle that is varying spatially across the layup. Abaqus/CAE allows you to select only valid discrete fields, which, for an additional rotation, are scalar discrete fields applied to

elements. You can also create a new discrete field by clicking . For more information, see *The Discrete Field toolset*.

- Select **User-defined** to define the orientation in user subroutine *ORIENT*. This option is valid only for Abaqus/Standard analyses. See the following sections for more information:
  - *Specifying general job settings*
  - *ORIENT*
- Select the name of an orientation discrete field to specify a coordinate system that is varying spatially across the layup. You can also create a new discrete field by clicking  to the right of the **Definition** field. For more information, see *The Discrete Field toolset*. After selecting the discrete field, you must do the following:
  1. Choose the axis that represents the **Normal direction**.
  2. Specify an additional rotation. The selected coordinate system is rotated through this angle about the selected axis. You can specify an angle, or you can select or create a scalar discrete field that defines an angle that is varying spatially across the layup.

The layup orientation is the reference orientation for any ply that uses the default orientation system (indicated by **<Layup>** in the **CSYS** column of the ply table). This orientation will be used for material calculations and stress output in the individual plies, for the section forces output, and for the transverse shear stiffness. You can specify a different orientation for the individual plies of a continuum shell composite layup by specifying a reference orientation and/or a rotation angle. For more information, see *Understanding composite layups and orientations*.

7. Choose one of the following to specify the stacking direction of the continuum shell elements:
   - **Element direction 1**
   - **Element direction 2**
   - **Element direction 3**
   - **Layup orientation**. The stacking direction is the normal to the layup orientation.

   You can use the Query toolset to determine the mesh stack orientation. However, the displayed orientations account for only the sweep path; they do not account for changes to the stacking direction as described above. For more information on the Query toolset, see *Using the Query toolset to query the model*. For more information on mesh stack directions, see *Defining the Stacking and Thickness Direction*.
8. Choose one of the following **Section integration** methods:
   - Choose **During analysis** to specify properties for a continuum shell composite layup integrated during the analysis.
   - Choose **Before analysis** to specify properties for a pre-integrated continuum shell composite layup.
9. If you are specifying properties for a composite layup integrated before the analysis, specify the **Idealization** to apply to the shell based on assumptions about the expected behavior or makeup of the layup. For more information, see *Idealizing the Section Response*.
   - Select **No idealization** to account for the complete stiffness of the shell as determined by the material assignments and ply composition.

- Select **Smeared properties** if you do not know the exact stacking sequence for the plies in the composite layup. Contributions from each specified ply are smeared across the entire thickness of the layup, resulting in a general response independent of the stacking sequence.
- Select **Membrane only** if the predominant response of the shell will be in-plane stretching; bending stiffness terms are eliminated from the shell stiffness calculations.
- Select **Bending only** if the predominant response of the shell will be pure bending; membrane stiffness terms are eliminated from the shell stiffness calculations.

10. If you are specifying properties for a composite layup integrated during the analysis, select the **Thickness integration rule**.

- Choose **Simpson** to use Simpson's rule for the shell section integration.
- Choose **Gauss** to use Gauss quadrature for the shell section integration.

See *Defining the Shell Section Integration*, for more information.

11. When you have finished defining the continuum shell composite layup, click **OK** to save your changes and to close the editor.

Specifying the plies of a continuum shell composite layup

A composite layup is composed of a series of plies. You select the region to which a ply is assigned, and you specify the name, material, relative thickness, orientation, and the number of integration points of each ply. You must specify ply names that are unique throughout the entire model to ensure the correct display of ply-based results. Use the icons above the ply table or click mouse button 3 on the ply table to see a menu that allows you to edit the contents of the table cell and to manipulate the data in the table; for example, you can add and delete plies, pattern plies, and invert plies. You can also read data into the table from a file or write data from the table into a file. For more information, see *Using the ply table when defining a composite layup*.

1. From the **Composite Layup** editor, click the **Plies** tab.
2. If the plies in the composite layup are symmetric about a central core, toggle on **Make calculated sections symmetric**. Enter the plies in the ply table, starting with the bottom ply in the first row and ending with the central ply. During the analysis Abaqus appends plies to the layup definition by repeating the entered plies (including the central ply) in the reverse order to the top of the layup. Each generated ply is labeled in ply stack plots and the output database by adding `Sym_` to the beginning of the repeated ply's original name.

   This option cannot be used if the rotation angle for any of the plies in the layup is defined using a discrete field.
3. For each ply, enter the following data in the ply table:

Ply Name

The name of the ply. Abaqus/CAE displays this name when you are viewing the composite layup in the Visualization module and in a ply stack plot.

Region

Select the region to which the ply is assigned. You can choose cells from the viewport, or you can select a set that refers to a cell. If you are displaying a meshed dependent part, you can choose solid elements from the viewport or select an element set. To choose elements from the viewport, you must display the native mesh, and you must use the Selection toolbar to enable the selection of **3D Elements** from the viewport. You can also select solid elements from a mesh part. For more information, see *Displaying a native mesh*, and *Filtering your selection based on the type of object*.

Material

The name of the material for this ply. Click mouse button 3, select **Edit Material** from the menu that appears, and do either of the following:

- Select the desired material from the list of available materials.
- Click  to create a new material.

Element Relative Thickness

The relative ply thickness within each element.

For continuum shell elements Abaqus determines the overall section thickness from the element geometry, which may vary from element to element where the section is defined. Hence, the thickness values that you specify for each ply are relative to the thickness of each element. The

actual thickness of a ply is the element thickness times the fraction of the total thickness that is accounted for by each ply. You do not have to use physical units to specify the thickness ratios for the plies, and the sum of the ply relative thicknesses does not have to add to one. For more information, see *Creating a composite layup*.

Coordinate system

To define the coordinate system that will be used as the basis for the reference orientation of the ply, do the following:

1. Click mouse button 3, and select **Edit CSYS** from the menu that appears.

   Note:

   If you choose **Edit Orientation** from the menu, you can define both the coordinate system and the rotation angle.

2. Select the base orientation. You can select the base layup orientation, or you can select a coordinate system. If you select a coordinate system, you must select the axis that defines the normal direction.

Rotation Angle

An additional rotation (counterclockwise about the normal direction) for the ply's reference orientation. Enter a uniform rotation directly in the table, or click mouse button 3 and select **Edit Rotation Angle** to do the following:

- Select a predefined angle (0, 45, 90, or –45 degrees) to define a uniform rotation.
- Select **Uniform**, and enter an **Angle** to define a uniform rotation.
- Select a scalar discrete field to define a rotation that varies spatially across the ply. You can also create a new discrete field by clicking .

Integration Points

The number of integration points, if you are specifying properties for a composite layup integrated during the analysis.

Specifying the shell parameters of a continuum shell composite layup

You can specify the shell parameters of a continuum shell composite layup.

1. From the **Composite Layup** editor, click the **Shell Parameters** tab.
2. Specify the **Section Poisson's ratio** to define the shell thickness behavior:
   - Toggle on **Use analysis default** to use the default value. In Abaqus/Standard the default value is 0.5, which will enforce incompressible behavior of the element for membrane strains. In Abaqus/Explicit the default is to base the change in thickness on the element material definition.
   - Toggle on **Specify value**, and enter a value for the Poisson's ratio. This value must be between −1.0 and 0.5. A value of 0.0 will enforce constant shell thickness, and a negative value will result in an increase in the shell thickness in response to tensile membrane strains.
3. Toggle on **Thickness modulus**, and enter a value for the thickness modulus. If you do not enter a value, Abaqus assumes the effective thickness modulus is twice the initial in-plane shear modulus based on the material definition.
4. If you are specifying properties for a composite layup integrated during the analysis, select a method for defining the **Temperature variation** through the section:
   - Choose **Linear through thickness** to indicate that the temperature at the reference surface and the temperature gradient or gradients through the ply are specified. You can use the Load module to specify these temperatures.
   - Choose **Piecewise linear over *n* values** to enter the number of temperature points (values) through the ply in the text field provided. You can use the Load module to specify the temperature at each of these points.
5. Toggle on **Density**, and enter a value for the density. The mass of the ply includes a contribution from the density in addition to any contribution from the selected material.
6. For most continuum shell composite layups Abaqus calculates the transverse shear stiffness values required in the element formulation. If desired, toggle on **Specify values** from the **Transverse Shear Stiffnesses** options to include nondefault transverse shear stiffness effects in the composite layup definition, and enter values for K_{11}, the shear stiffness in the first direction; K_{12}, the coupling term in the shear stiffness; and K_{22}, the shear stiffness in the second direction. If either value K_{11} or K_{22} is omitted or given as zero, the nonzero value will be used for both. For more information, see *Defining the Transverse Shear Stiffness*.

Specifying the display of selected plies of a continuum shell composite layup

You can specify the display of selected plies of a continuum shell composite layup.

1. From the **Composite Layup** editor, click the **Display** tab.
2. Choose how Abaqus/CAE highlights the plies that you selected in the ply table:
   - Choose **On** to highlight the selected plies.
   - Choose **Off** to stop highlighting the selected plies. If you have a large number of plies in your model, you may want to turn off highlighting to increase performance.
3. Choose which orientation Abaqus/CAE displays on the selected plies:
   - Choose **Ply** to display the ply orientation on the selected plies.
   - Choose **Layup** to display the layup orientation on the selected plies.
   - Choose **None** to stop displaying an orientation.
4. Specify which orientation vectors you want to display on the selected plies. You can toggle the display of vectors in the 1-direction, the 2-direction, and the 3- (or normal) direction, as well as the reference direction that shows the 1-direction before rotation of the ply's material directions.

Creating solid composite layups

This section describes how to create a solid composite layup.

In most cases, you should model a composite solid as a shell or continuum shell composite layup. However, you should use a solid composite layup for the following cases:

- When the transverse shear effects are predominant.
- When you cannot ignore the normal stress.
- When you require accurate interlaminar stresses, such as near localized regions of complex loading or geometry.

Solid composite layups are expected to have a single element through their thickness, and that single element contains multiple plies that are defined in the ply table. If the region to which you assign your solid composite layup contains multiple elements, each element will contain the plies defined in the ply table, and the analysis results will not be as expected.

In this section:

- *Creating solid composite layups*
- *Specifying the plies of a solid composite layup*
- *Specifying the display of selected plies of a solid composite layup*

Creating solid composite layups

In Abaqus/Standard solid elements can include several layers of different materials for the analysis of laminated composite solids; however, in Abaqus/Explicit solid elements can be composed only of a single homogeneous material. The use of composite solids is limited to three-dimensional brick elements that have only displacement degrees of freedom. Composite solid elements are primarily intended for modeling convenience. They usually do not provide a more accurate solution than composite shell elements. For more information, see *Defining Composite Solid Elements in Abaqus/Standard* and *Modeling Thick Composites with Solid Elements in Abaqus/Standard*.

1. From the main menu bar, select **Composite->Create**.

   A **Create Composite Layup** dialog box appears.

   Tip: You can also click **Create** in the **Composite Layup Manager** or select the create composite layup tool  in the Property module toolbox.

2. Enter a composite layup name. For more information on naming objects, see *Using basic dialog box components*.
3. Specify the initial ply count. When the composite layup editor appears, it will contain a row for each ply; however, you can use the editor to subsequently add or delete plies.
4. Select **Solid** as the **Element Type**, and click **Continue**.

   The composite layup editor appears.
5. Enter a description of the layup. Abaqus/CAE displays this description in the composite layup manager.
6. Do one of the following to specify the layup orientation:

   - Select **Coordinate system** to select an existing coordinate system (or create a new coordinate system and select it), and do the following:

     1. Choose the axis that represents the **Rotation axis**.
     2. Specify an additional rotation. The selected coordinate system is rotated through this angle about the selected axis. You can specify an angle, or you can select an existing scalar discrete field that defines an angle that is varying spatially across the layup. Abaqus/CAE allows you to select only valid discrete fields, which, for an additional rotation, are scalar discrete fields applied to elements. You can also create a new discrete field by clicking . For more information, see *The Discrete Field toolset*.

   - Select **Discrete** to define a discrete orientation, and do the following:

     1. Click .
     2. In the **Edit Discrete Orientation** dialog box that appears, define the normal axis and primary axis using the procedure described in *Using discrete orientations for material orientations and composite layup orientations*.
     3. Choose the axis that represents the **Rotation axis**.
     4. Specify an additional rotation. The orientation is rotated through this angle about the selected normal axis. You can specify an angle, or you can select or create a scalar discrete field that defines an angle that is varying spatially across the layup. Abaqus/CAE allows you to select only valid discrete fields, which, for an additional rotation, are scalar discrete fields applied to

elements. You can also create a new discrete field by clicking . For more information, see *The Discrete Field toolset*.

- Select **User-defined** to define the orientation in user subroutine *ORIENT*. This option is valid only for Abaqus/Standard analyses. See the following sections for more information:
  - *Specifying general job settings*
  - *ORIENT*
- Select the name of an orientation discrete field to specify a coordinate system that is varying spatially across the layup. You can also create a new discrete field by clicking  to the right of the **Definition** field. For more information, see *The Discrete Field toolset*. After selecting the discrete field, you must do the following:
  1. Choose the axis that represents the **Rotation axis**.
  2. Specify an additional rotation. The selected coordinate system is rotated through this angle about the selected axis. You can specify an angle, or you can select or create a scalar discrete field that defines an angle that is varying spatially across the layup.

The layup orientation is the reference orientation for any ply that uses the default orientation system (indicated by **<Layup>** in the **CSYS** column of the ply table). This orientation will be used for material calculations and stress output in the individual plies, for the section forces output, and for the transverse shear stiffness. You can specify a different orientation for the individual plies of a solid composite layup by specifying a reference orientation and/or a rotation angle. For more information, see *Understanding composite layups and orientations*.

7. Choose one of the following to specify the stacking direction of the solid elements with respect to a pair of element faces:
   - **Element direction 1**
   - **Element direction 2**
   - **Element direction 3**

   You can use the Query toolset to determine the mesh stack orientation. However, the displayed orientations account for only the sweep path; they do not account for changes to the stacking direction as described above. For more information on the Query toolset, see *Using the Query toolset to query the model*. For more information on mesh stack directions, see *Defining the Stacking and Thickness Direction*.

Specifying the plies of a solid composite layup

A composite layup is composed of a series of plies. You select the region to which a ply is assigned, and you specify the name, material, thickness, orientation, and the number of integration points of each ply. You must specify ply names that are unique throughout the entire model to ensure the correct display of ply-based results. Use the icons above the ply table or click mouse button 3 on the ply table to see a menu that allows you to edit the contents of the table cell and to manipulate the data in the table; for example, you can add and delete plies, pattern plies, and invert plies. You can also read data into the table from a file or write data from the table into a file. For more information, see *Using the ply table when defining a composite layup*.

1. From the **Composite Layup** editor, click the **Plies** tab.
2. If the plies in the composite layup are symmetric about a central core, toggle on **Make calculated sections symmetric**. Enter the plies in the ply table, starting with the bottom ply in the first row and ending with the central ply. During the analysis Abaqus appends plies to the layup definition by repeating the entered plies (including the central ply) in the reverse order to the top of the layup. Each generated ply is labeled in ply stack plots and the output database by adding `Sym_` to the beginning of the repeated ply's original name.

   This option cannot be used if the rotation angle for any of the plies in the layup is defined using a discrete field.
3. For each ply, enter the following data in the ply table:

Ply Name

The name of the ply. Abaqus/CAE displays this name when you are viewing the composite layup in the Visualization module.

Region

Select the region to which the ply is assigned. You can choose cells from the viewport, or you can select a set that refers to a cell. If you are displaying a meshed dependent part, you can choose solid elements from the viewport or select an element set. To choose elements from the viewport, you must display the native mesh, and you must use the Selection toolbar to enable the selection of **3D Elements** from the viewport. You can also select solid elements from a mesh part. For more information, see *Displaying a native mesh*, and *Filtering your selection based on the type of object*.

Material

The name of the material for this ply. Click mouse button 3, select **Edit Material** from the menu that appears, and do either of the following:

- Select the desired material from the list of available materials.
- Click  to create a new material.

Element Relative Thickness

The relative ply thickness.

For solid elements Abaqus determines the thickness from the part geometry, and the thickness may vary through the model for a given layup. Hence, the thickness values that you specify are only relative thicknesses for each ply. The actual thickness of a ply is the element thickness

times the fraction of the total thickness that is accounted for by each ply. You do not have to use physical units to specify the thickness ratios for the plies, and the sum of the ply relative thicknesses does not have to add to one.

Coordinate system

To define the coordinate system that will be used as the basis for the reference orientation of the ply, do the following:

1. Click mouse button 3, and select **Edit CSYS** from the menu that appears.

   Note:

   If you choose **Edit Orientation** from the menu, you can define both the coordinate system and the rotation angle.

2. Select the base orientation. You can select the base layup orientation, or you can select a coordinate system. If you select a coordinate system, you must select the axis that defines the normal direction.

Rotation Angle

An additional rotation (counterclockwise about the normal direction) for the ply's reference orientation. Enter a uniform rotation directly in the table, or click mouse button 3 and select **Edit Rotation Angle** to do the following:

- Select a predefined angle (0, 45, 90, or −45 degrees) to define a uniform rotation.
- Select **Uniform**, and enter an **Angle** to define a uniform rotation.
- Select a scalar discrete field to define a rotation that varies spatially across the ply. You can also create a new discrete field by clicking .

Integration Points

The number of integration points to be used through the ply. This number must be an odd number.

Specifying the display of selected plies of a solid composite layup

You can specify the display of selected plies of a solid composite layup.

1. From the **Composite Layup** editor, click the **Display** tab.
2. Choose how Abaqus/CAE highlights the plies that you selected in the ply table:
   - Choose **On** to highlight the selected plies.
   - Choose **Off** to stop highlighting the selected plies. If you have a large number of plies in your model, you may want to turn off highlighting to increase performance.
3. Choose which orientation Abaqus/CAE displays on the selected plies:
   - Choose **Ply** to display the ply orientation on the selected plies.
   - Choose **Layup** to display the layup orientation on the selected plies.
   - Choose **None** to stop displaying an orientation.
4. Specify which orientation vectors you want to display on the selected plies. You can toggle the display of vectors in the 1-direction, the 2-direction, and the 3- (or normal) direction, as well as the reference direction that shows the 1-direction before rotation of the ply's material directions.

Assigning sections, orientations, normals, and tangents to a part

This section describes how to use the **Assign** menu to assign properties to a part and how to manage section assignments.

In this section:

- *Assigning a section*
- *Managing section assignments*
- *Assigning a beam orientation*
- *Assigning a material orientation or rebar reference orientation*
- *Assigning shell/membrane normal directions*
- *Assigning beam/truss tangent directions*

Assigning a section

You can assign section properties to a part by first creating a section and then selecting **Assign->Section** to assign the section to a part; a region of a part, including its skins or stringers; or a set of elements.
Section properties that you assign to a part are assigned automatically to all instances of that part in the assembly. Abaqus/CAE colors a region green in the Property module to indicate that the region has a section assignment or colors the region yellow if there are overlapping section assignments. If you delete a section used in a section assignment, Abaqus/CAE colors the region red to indicate that the section is not found.

Note: The order of assignments may be relevant; when section assignments overlap, the last assignment will take precedence.

You can also use the **Section Assignment Manager** to view, create, edit, suppress, resume, and delete section assignments. For more information, see *Managing section assignments*. You can use the Query toolset to verify that you have assigned the correct section to a selected region. For more information, see *Using the Query toolset to obtain assignment information*.

You can create overlapping section assignments anywhere in your model except for a region that contains Eulerian parts. Eulerian parts can be assigned only a single section assignment, and you cannot apply a second section assignment to an Eulerian part, even when its original section assignment is suppressed.

When you import a mesh from an input file, some section properties associated with that mesh may also be imported; in these cases it may be unnecessary to assign section properties to the part. For more information, see *Importing a model from an Abaqus input file*.

1. If the part to which you want to assign a section is not visible in the current viewport, click the name of the desired part in the **Part** list located in the context bar.

   The part that you select appears in the current viewport.

2. From the main menu bar, select **Assign->Section**.

   Tip: You can also click **Create** in the **Section Assignment Manager** or select the  tool in the Property module toolbox.

3. Select the regions of the part from the viewport, and click mouse button 2 to indicate you have finished selecting. (For more information, see *Selecting objects within the viewport*.) If an Eulerian part is in the current viewport, Abaqus/CAE automatically selects the entire part.

   Tip: You can limit the types of objects that you can select in the viewport by using the tools in the **Selection** toolbar. See *Using the selection options* for more information.

   If you select **Skins** as the object type, you can assign the section to the entire skin or to one or more of its faces. From the prompt area, select **(pick entire skin)** or **(pick partial skin)**, then make your selection in the viewport. If the selected part has multiple skins, Abaqus/CAE will display the ambiguous picking options in the prompt area while you make your selection.

   If you select **Stringers** as the object type, you can assign the section to the entire stringer or to one or more of its edges. From the prompt area, select **(pick entire stringer)** or **(pick partial stringer)**, then make your selection in the viewport. If the selected part has multiple stringers, Abaqus/CAE will display the ambiguous picking options in the prompt area while you make your selection.

   If you would rather select from a list of existing sets, do the following:

   a. Click **Sets** on the right side of the prompt area.

Abaqus/CAE displays the **Region Selection** dialog box containing a list of available part sets and element sets.

b. Select the desired set, and click **Continue**.

Note: The default selection method is based on the selection method you most recently employed. To revert to the other method, click the button—**Select in Viewport** or **Sets**—on the right side of the prompt area.

An **Edit Section Assignment** dialog box appears. This dialog box contains a list of existing sections that can be assigned to the selected region or set. For example, if you selected a solid region, any existing solid sections appear in the **Edit Section Assignment** dialog box. In addition, the dialog box contains a **Create Section** button and the section type, material, and region of the displayed section.

4. In the **Edit Section Assignment** dialog box, select the section of interest and click **OK**.

Abaqus/CAE assigns the selected section to the part or set and colors the selected region green to indicate that the region has a section assignment. If there are overlapping section assignments on the region, Abaqus/CAE colors the region yellow.

Note: The order of assignments may be relevant; when section assignments overlap, the last assignment will take precedence.

5. Assign a section thickness:

From section

Use the thickness defined in the section definition.

From geometry

Use the thickness of the geometric section.

6. If you assign a homogeneous or a composite section to a shell, you can define the method used for the **Shell Offset**. Click the arrow to the right of the **Definition** field, and select the option of your choice from the list that appears:

- Select **Middle surface**, **Top surface**, or **Bottom surface** to represent the reference surface.
- Select **Specify value**, and enter a positive or negative distance (as a fraction of the shell thickness) from the midsurface to the reference surface of the shell in the **Offset ratio** field.

  A positive offset will generate nodes and elements closer to the top surface of the shell, and a negative offset will generate them closer to the bottom surface. Offsets greater than `±0.5` will cause the nodes to be beyond the surface of the shell.
- Select an existing scalar discrete field that defines an offset that is varying spatially across the section. Abaqus/CAE allows you to select only valid discrete fields, which, for an offset, are scalar discrete fields applied to elements. This option is valid only for an Abaqus/Standard analysis.

  Alternatively, you can click  to create a new discrete field. (See *The Discrete Field toolset* for more information.)
- Select **From geometry** to have Abaqus/CAE calculate the offset from the thickness defined on the geometry. This option is the default if **From geometry** is selected in the **Thickness** field. You cannot use this option to calculate the offset in an Abaqus/Explicit analysis.

7. If you want to assign sections to additional regions, repeat Steps 3 and 4. When you have finished assigning sections, use one of the following methods to exit the section assignment mode:
   - If you are selecting regions of the part from the viewport, click mouse button 2 or click **Done** in the prompt area.
   - If you are selecting preexisting sets from the **Region Selection** dialog box, click **Cancel** to close the dialog box, then click mouse button 2 or click **Done** in the prompt area.

Additional information

- *Selecting objects within the viewport*
- *Creating and editing sections*
- *Managing section assignments*
- *Assigning thicknesses and offsets*

Managing section assignments

The **Section Assignment Manager** allows you to view, create, edit, suppress, resume, and delete section assignments. The manager lists section assignments in the order of creation and displays the section name, section type, material name, and region associated with each section assignment. In the Property module, Abaqus/CAE colors a region green to indicate that the region has a section assignment or, if there are overlapping section assignments, colors the region yellow.

Note:

The order of assignments may be relevant; when section assignments overlap, the last assignment will take precedence.

1. From the main menu bar, select **Section->Assignment Manager**.
2. From the bottom of the manager, choose from the following:
   - If you want to create a new section assignment, click **Create** and follow the procedure described in *Assigning a section*. The new section assignment appears in the manager.
   - If you want to edit a section assignment, select the section assignment in the manager and click **Edit**. The **Edit Section Assignment** dialog box appears, and the region to which the section is currently assigned is highlighted in the viewport.
     1. If desired, select a different section for the section assignment.
     2. Click  to select a new region for the section assignment.
     3. Select the region from the viewport or from a list of existing sets, and click mouse button 2 to indicate that you have finished selecting.
     4. Click **OK** to close the **Edit Section Assignment** dialog box.
   - If you want to delete a section assignment, select the section assignment in the manager and click **Delete**.
3. In the left column of the manager, click a green check mark to suppress a section assignment or click a red “X” to resume a suppressed section assignment.

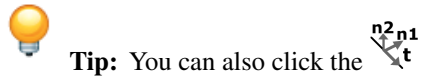
   Note:

   Suppressing and resuming a connector section assignment will suppress or resume the corresponding connector orientation.

   Abaqus/CAE updates the color of the selected part or region to reflect the revised section assignment status.
4. Click **Dismiss** to close the **Section Assignment Manager** dialog box.

Additional information

- *Defining sections*
- *Creating and editing sections*
- *Assigning a section*



Assigning a beam orientation

After you have assigned beam sections to the wire regions of a part or to its stringers, you must assign an orientation to the beam sections by defining the approximate local 1-direction of the cross-section.
The beam orientations that you assign to a part are assigned automatically to all instances of that part in the assembly. You can use the Query toolset to verify that you have assigned the correct beam orientation to a selected region. For more information, see *Using the Query toolset to obtain assignment information*.

1. If the part to which you want to assign an orientation is not visible in the current viewport, click the name of the desired part in the **Part** list located in the context bar.

   The selected part appears in the current viewport.

2. From the main menu bar, select **Assign->Beam Section Orientation**.

   Tip: You can also click the  tool in the Property module toolbox.

3. Select the wire region of the part from the viewport, and click mouse button 2 to indicate that you have finished selecting. (For more information, see *Selecting objects within the viewport*.)

   Tip: You can limit the types of objects that you can select in the viewport by using the tools in the **Selection** toolbar. See *Using the selection options* for more information.

   If you select **Stringers** as the object type, you can assign the beam orientation to the entire stringer or to one or more of its edges. From the prompt area, select **(pick entire stringer)** or **(pick partial stringer)**, then make your selection in the viewport. If the selected part has multiple stringers, Abaqus/CAE will display the ambiguous picking options in the prompt area while you make your selection.

   If you would rather select from a list of existing sets, do the following:

   a. Click **Sets** on the right side of the prompt area.

      Abaqus/CAE displays the **Region Selection** dialog box containing a list of available part sets. Part sets containing only wires appear in the list.

   b. Select the part set of interest, and click **Continue**.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click the button—**Select in Viewport** or **Sets**—on the right side of the prompt area.

4. Abaqus/CAE prompts you to enter the vector representing an approximate $\mathbf{n_1}$-direction (the local 1-direction of the cross-section). For more information on defining the $\mathbf{n_1}$-direction, see *Beam Element Cross-Section Orientation*.

   Note:

   If the part was created in two-dimensional modeling space, the $\mathbf{n_1}$-direction is always normal to the *X*–*Y* plane (0.0, 0.0, −1.0).

   Abaqus/CAE displays the resulting ($\mathbf{n_1}$, $\mathbf{n_2}$, $\mathbf{t}$) axis system on the selected wire regions.

5. If the displayed ($\mathbf{n}_1$, $\mathbf{n}_2$, $\mathbf{t}$) axis system is correct, click **OK** in the prompt area to confirm your choice.

   If you wish to change the beam orientation, click the **Previous** button () and enter a new $\mathbf{n}_1$-direction.
6. If you want to assign beam orientations to additional wire regions, repeat Steps 3 through 5.
7. Click mouse button 2 to indicate you have finished assigning beam orientations.

Additional information

- *Creating and editing sections*
- *Selecting objects within the viewport*
- *Plotting material orientations*
- *Beam Element Cross-Section Orientation*

Assigning a material orientation or rebar reference orientation

You can assign a material orientation or a rebar reference orientation.

In this section:

- *Assigning a material orientation*
- *Assigning a rebar reference orientation*

Assigning a material orientation

The global coordinate system determines the default material orientations. However, you can assign specific material orientations to a shell, solid part, region, skin, or stringer by selecting a datum coordinate system or discrete field or by defining a discrete orientation. For an Abaqus/Standard analysis you can define the local coordinate system in user subroutine *ORIENT*. The datum coordinate systems can be rectangular, cylindrical, or spherical; and you can apply an additional rotation to the coordinate system if required. For more information, see *Orientations*.

In cases where Abaqus/CAE attempts to draw coordinate systems for material orientations at singularity points of the system (i.e., points for which the user-selected coordinate system and the geometric normal from either geometry or elements cannot be resolved into a valid orientation for display purposes in Abaqus/CAE), the coordinate system will be drawn collapsed.

For continuum shell elements, Abaqus/CAE does not project the displayed material orientations onto the midplane surface. You can perform a data check and view the output database in the Visualization module to verify the material orientations. For more information, see *Performing a data check on a model*.

The material orientations that you assign to a part or region are assigned automatically to all instances of that part in the assembly. You can use the Query toolset to verify that you have assigned the correct material orientation to a selected region. For more information, see *Using the Query toolset to obtain assignment information*.

You can edit, suppress, and resume previously defined material orientations by clicking mouse button 3 on the material orientation in the Model Tree and selecting the suppress or resume option from the list that appears. For more information, see *Suppressing and resuming objects*.

1. If the part to which you want to assign a material orientation is not visible in the current viewport, click the name of the desired part in the **Part** list located in the context bar.

   The selected part appears in the current viewport.

2. From the main menu bar, select **Assign->Material Orientation**.

   Tip: You can also click the  tool in the Property module toolbox.

3. Select the shell or solid regions from the viewport, and click mouse button 2 to indicate you have finished selecting. (For more information, see *Selecting objects within the viewport*.)

   Tip: You can limit the types of objects that you can select in the viewport by using the tools in the **Selection** toolbar. See *Using the selection options* for more information.

   If you select **Skins** as the object type, you can assign the material orientation to the entire skin or to one or more of its faces. From the prompt area, select **(pick entire skin)** or **(pick partial skin)**, then make your selection in the viewport. If the selected part has multiple skins, Abaqus/CAE will display the ambiguous picking options in the prompt area while you make your selection.

   If you select **Stringers** as the object type, you can assign the material orientation to the entire stringer or to one or more of its edges. From the prompt area, select **(pick entire stringer)** or **(pick partial stringer)**, then make your selection in the viewport. If the selected part has multiple stringers, Abaqus/CAE will display the ambiguous picking options in the prompt area while you make your selection.

   If you would rather select from a list of existing sets, do the following:

   a. Click **Sets** on the right side of the prompt area.

      Abaqus/CAE displays the **Region Selection** dialog box containing a list of available part sets. Part sets containing only shells or solids appear in the list.

b. Select the part set of interest, and click **Continue**.

Note: The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

4. If you want to specify a material orientation using an existing datum coordinate system, do the following:

a. Select the datum coordinate system.

- Select a coordinate system in the viewport.
- Select a datum coordinate system by name. Click **Datum CSYS List** from the prompt area, select a name from the list, and click **OK**.

Abaqus/CAE displays the resulting material orientation specified for the region, and the **Edit Material Orientation** dialog box appears.

b. Choose **Axis 1**, **Axis 2**, or **Axis 3** to specify the coordinate system axis.

- For a shell region, specify the coordinate system axis that approximates the normal to the shell in the **Normal Direction** portion of the dialog box.
- For a solid region, specify the coordinate system axis about which an optional additional rotation occurs in the **Additional Rotation Direction** portion of the dialog box.

c. If desired, you can provide an additional rotation of the material orientation about the shell normal (for a shell region) or about a local axis of the datum coordinate system (for a solid region) using one of the following methods:

- Choose **Angle**, and enter a value in degrees for the additional rotation.
- Choose **Distribution**, and select an existing scalar discrete field that defines an angle that is spatially varying across the region. Alternatively, you can click  to create a new discrete field. (See *The Discrete Field toolset* for more information.)

Abaqus/CAE applies the additional rotation, if any, and displays the resulting material orientation applied to the region.

5. If you want to use the global coordinate system (default) or specify a material orientation in a discrete orientation, user subroutine, or a discrete field, click **Use Default Orientation or Other Method** from the prompt area. You can also select an existing datum coordinate system or create a new one using this procedure.

a. In the **Edit Material Orientation** dialog box that appears, click the arrow to the right of the **Definition** field, and select one of the following:

- Select **Coordinate system**, and click  to select a coordinate system from the viewport or by name. Alternatively, you can click  to create a new datum coordinate system.
- Select **Global** to use the global coordinate system or to reset a previously assigned material orientation back to the global coordinate system.
- Select **Discrete**, and click  to define a discrete orientation. In the **Edit Discrete Orientation** dialog box that appears, define the normal axis and primary axis using the procedure described in *Using discrete orientations for material orientations and composite layup orientations*.

- Select **User-defined** to define the orientation in user subroutine *ORIENT*. This option is valid only for Abaqus/Standard analyses. See the following sections for more information:
  - *Specifying general job settings*
  - *ORIENT*

- Select a discrete field to define a spatially varying orientation. Alternatively, you can click  to the right of the **Definition** field to create a new discrete field. (See *The Discrete Field toolset* for more information.)

b. Choose **Axis 1**, **Axis 2**, or **Axis 3** to specify the coordinate system axis.

- For a shell region, specify the coordinate system axis that approximates the normal to the shell in the **Normal Direction** portion of the dialog box.
- For a solid region, specify the coordinate system axis about which an optional additional rotation occurs in the **Additional Rotation Direction** portion of the dialog box.

c. If desired, you can provide an additional rotation of the material orientation about the shell normal (for a shell region) or about a local axis of the datum coordinate system (for a solid region) using one of the following methods:

- Choose **Angle**, and enter a value in degrees for the additional rotation.
- Choose **Distribution**, and select an existing scalar discrete field that defines an angle that is spatially varying across the region. Alternatively, you can click  to create a new discrete field. (See *The Discrete Field toolset* for more information.)

Abaqus/CAE applies the additional rotation, if any, and displays the resulting material orientation applied to the region.

d. Choose one of the following to specify the stacking direction of continuum shell elements or solid elements:

- **Element isoparametric direction 1**
- **Element isoparametric direction 2**
- **Element isoparametric direction 3 (bottom to top)**
- **Normal direction of material orientation (Continuum Shells only)**. The stacking direction is the 3-direction of the material orientation.

If the selected regions are meshed, Abaqus/CAE displays the material stacking direction for each element.

6. Click **OK** in the dialog box.

- *About Shell Elements*

Assigning a rebar reference orientation

The angular orientation of a rebar layer is defined relative to the rebar reference orientation. The global coordinate system determines the default rebar reference orientation. However, you can assign a rebar reference orientation to a shell part, region, skin, or stringer by selecting an existing datum coordinate system from the viewport and then selecting an axis on the datum coordinate system that approximates the direction of the shell normal.
The datum coordinate system can be rectangular, cylindrical, or spherical; and you can apply an additional rotation to the coordinate system if required. For more information, see *Orientations*.

The rebar reference orientations that you assign to a part or region are assigned automatically to all instances of that part in the assembly. You can use the Query toolset to verify that you have assigned the correct rebar reference orientation to a selected region. For more information, see *Using the Query toolset to obtain assignment information*.

1. If the part to which you want to assign a rebar reference orientation is not visible in the current viewport, click the name of the desired part in the **Part** list located in the context bar.

   The selected part appears in the current viewport.

2. From the main menu bar, select **Assign->Rebar Reference Orientation**.

   Tip: You can also click the  tool in the Property module toolbox.

3. Select the regions from the viewport, and click mouse button 2 to indicate you have finished selecting. (For more information, see *Selecting objects within the viewport*.)

   Tip: You can limit the types of objects that you can select in the viewport by using the tools in the **Selection** toolbar. See *Using the selection options* for more information.

   If you select **Skins** as the object type, you can assign the rebar reference orientation to the entire skin or to one or more of its faces. From the prompt area, select **(pick entire skin)** or **(pick partial skin)**, then make your selection in the viewport. If the selected part has multiple skins, Abaqus/CAE will display the ambiguous picking options in the prompt area while you make your selection.

   If you select **Stringers** as the object type, you can assign the rebar reference orientation to the entire stringer or to one or more of its edges. From the prompt area, select **(pick entire stringer)** or **(pick partial stringer)**, then make your selection in the viewport. If the selected part has multiple stringers, Abaqus/CAE will display the ambiguous picking options in the prompt area while you make your selection.

   If you would rather select from a list of existing sets, do the following:

   a. Click **Sets** on the right side of the prompt area.

      Abaqus/CAE displays the **Region Selection** dialog box containing a list of available sets.

   b. Select the part set of interest, and click **Continue**.

   Note: The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

4. Specify a local coordinate system in the selected region using one of the following methods:

   - Select a coordinate system in the viewport.
   - Select a datum coordinate system by name. Click **Datum CSYS List** from the prompt area, select a name from the list, and click **OK**.

- Click **Use Default Orientation** to use the global coordinate system.

Abaqus/CAE displays the resulting rebar orientation specified for the region, and the **Edit Rebar Orientation** dialog box appears.

5. Choose **Axis 1**, **Axis 2**, or **Axis 3** to specify the coordinate system axis.

   - For a shell region, specify the coordinate system axis that approximates the normal to the shell in the **Normal Direction** portion of the dialog box.
   - For a solid region, specify the coordinate system axis about which an optional additional rotation occurs in the **Additional Rotation Direction** portion of the dialog box.

6. If desired, you can provide an additional rotation of the rebar reference orientation about the shell normal (for a shell region) or about a local axis of the datum coordinate system (for a solid region). Choose **Angle**, and enter a value in degrees for the additional rotation.

   Abaqus/CAE applies the additional rotation, if any, and displays the resulting rebar reference orientation applied to the region.

7. Click **OK** in the dialog box.

Assigning shell/membrane normal directions

When you create a part with shell regions or an axisymmetric part with wire regions, Abaqus assigns a direction for the normals of the regions. You can reverse the directions of the normals for these regions. In addition, you can reverse the directions for the normals of imported parts or selected orphan elements.

You can also reverse the normals for skin reinforcements; however, if there are multiple skins defined on the surface of a geometric part, you cannot reverse the normal of one of those skins without reversing the normals of every skin defined for that surface. If the surface with multiple skins is a feature of a mesh part, you can reverse the normal of an individual skin without reversing the normals for the other skins defined on that surface.

When you reverse the normal direction of a region, the local normal that defines the material orientation is reversed. You can use the Query toolset to verify that the material orientation is correct for a selected region. For more information, see *Using the Query toolset to obtain assignment information*.

1. If the part to which you want to assign a normal is not visible in the current viewport, click the name of the desired part in the **Part** list located in the context bar.

   The selected part appears in the current viewport.

2. From the main menu bar, select **Assign->Element Normal**.

   Tip: You can also click the 

   tool in the Property module toolbox or select **Mesh->Orientation->Normal** in the Mesh module.

   Abaqus/CAE displays the part using the shaded render style. The side of the shell where the surface normal coincides with the shell normal (top face) is colored brown; the opposite side (bottom face) is colored purple.

3. If the selected part is geometry-based, use one of the following methods to select the regions whose normals you want to reverse:

   - Select the regions from the viewport and click mouse button 2. (For more information, see *Selecting objects within the viewport*.)

     Tip: You can limit the types of objects that you can select in the viewport by using the tools in the **Selection** toolbar. See *Using the selection options*, for more information.

     If you select **Skins** as the object type, you can assign the section to the entire skin or to one or more of its faces. From the prompt area, select **(pick entire skin)** or **(pick partial skin)**, then make your selection in the viewport. If the selected part has multiple skins, Abaqus/CAE will display the ambiguous picking options in the prompt area while you make your selection.

   - To select from a list of existing sets, do the following:

     1. Click **Sets** on the right side of the prompt area.

        Abaqus/CAE displays the **Region Selection** dialog box containing a list of available part sets.

     2. Select the part set of interest, and click **Continue**.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

   Abaqus/CAE reverses the shell/membrane normal directions of the selected regions.

4. If the selected part is a mesh part, use one of the following methods to select the shell elements whose normals you want to reverse:

Selecting individual elements:

1. Click the arrow next to the **Selection method** field in the prompt area, and select **Individually** from the list that appears.
2. Select an element whose normal you want to flip.
3. **[Shift] + Click** on additional elements to add them to your selection.
4. If necessary, **[Ctrl] + Click** on selected elements to unselect them.
5. When you have finished selecting elements, click mouse button 2.

Specifying an existing element set

1. Click **Sets** on the right side of the prompt area.

   Abaqus/CAE displays the **Region Selection** dialog box containing a list of element sets that you have created.
2. Select the set of elements that you want to edit, and click **Continue**.

Note:

The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

Selecting elements using the angle method:

1. From the field in the prompt area, select **by angle**.
2. Enter an angle (from 0° to 90°), and select an element face. Abaqus/CAE selects every adjacent shell element from the selected face until the angle between the element faces is equal to or exceeds the angle that you entered. (See *Using the angle and feature edge method to select multiple objects*, for more information.)
3. After you use the **by angle** method, you can **[Shift] + Click** on additional elements to add them to your selection or **[Ctrl] + Click** on selected elements to remove them from your selection. (See *Combining selection techniques*, for more information.)
4. When you have finished selecting elements, click mouse button 2.

Tip: You can limit the types of objects that you can select in the viewport by using the tools in the **Selection** toolbar. For more information, see *Selecting objects within the viewport*."

5. From the prompt area, select a method for reversing the shell/membrane normal:
   - Click **Flip All** to reverse the normal of all selected elements.
   - Click **Select Normal** to change the normals of the selected elements so that they point in the same direction as the normal of a reference element that you specify.
6. If you chose **Select Normal** in the previous step, do the following:

a. In the viewport, select the reference element.

b. In the prompt area, click **OK**.

Abaqus/CAE changes the normals of the selected elements so that they point in the same direction as the reference element normal.

7. Repeat the previous steps as often as necessary to reverse additional shell/membrane normals. When you have finished assigning normal directions, use one of the following methods to exit the assignment mode:

- If you are selecting regions of the part or elements from the viewport, click mouse button 2 or click **Done** in the prompt area.
- If you are selecting preexisting sets from the **Region Selection** dialog box, click **Cancel** to close the dialog box, then click mouse button 2 or click **Done** in the prompt area.

Abaqus/CAE reverts to the render style that was selected prior to starting the procedure to reverse the shell/membrane normals.

Additional information

• *Creating and editing sections*

• *Selecting objects within the viewport*

Assigning beam/truss tangent directions

When you create a part with wire regions, Abaqus assigns the default tangent directions to the regions. Beam section orientations depend on the tangent directions. You can reverse the direction of a beam or truss tangent to obtain the desired beam section orientation.
You can use the Query toolset to verify that the beam section orientations are correct for a selected region. For more information, see *Using the Query toolset to obtain assignment information*.

You can also reverse the tangent directions for stringer reinforcements; however, if there are multiple stringers defined on the edge of a geometric part, you cannot reverse the tangent of one of those stringers without reversing the tangents of every stringer defined for that edge. If the edge with multiple stringers is a feature of a mesh part, you can reverse the tangent of an individual stringer without reversing the tangents for the other stringers defined for that edge.

1. If the part to which you want to assign a tangent is not visible in the current viewport, click the name of the desired part in the **Part** list located in the context bar.

   The selected part appears in the current viewport.

2. From the main menu bar, select **Assign->Element Tangent**.

   Tip: You can also click the  tool in the Property module toolbox or select **Mesh->Orientation->Tangent** in the Mesh module.

   Abaqus/CAE displays an arrow in the direction of the tangent at the center of each region.

3. Use one of the following methods to select the regions whose tangents you want to reverse:

   - Select the regions from the viewport, and click mouse button 2. (For more information, see *Selecting objects within the viewport*.)

     Tip: You can limit the types of objects that you can select in the viewport by using the tools in the **Selection** toolbar. See *Using the selection options* for more information.

     If you select **Stringers** as the object type, you can assign the beam/truss tangent direction to the entire stringer or to one or more of its edges. From the prompt area, select **(pick entire stringer)** or **(pick partial stringer)**, then make your selection in the viewport. If the selected part has multiple stringers, Abaqus/CAE will display the ambiguous picking options in the prompt area while you make your selection.

   - To select from a list of existing sets, do the following:

     1. Click **Sets** on the right side of the prompt area.

        Abaqus/CAE displays the **Region Selection** dialog box containing a list of available part sets.

     2. Select the part set of interest, and click **Continue**.

   Abaqus/CAE reverses the direction of the tangents for the selected regions.

   Note: The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

4. Repeat the previous step as often as necessary to reverse additional tangent directions. When you have finished assigning tangent directions, use one of the following methods to exit the assignment mode:

- If you are selecting regions of the part from the viewport, click mouse button 2 or click **Done** in the prompt area.
- If you are selecting preexisting sets from the **Region Selection** dialog box, click **Cancel** to close the dialog box, then click mouse button 2 or click **Done** in the prompt area.

Additional information

Using discrete orientations for material orientations and composite layup orientations

A discrete orientation defines a spatially varying orientation at the centroid of each mesh element. The orientation can be based on the topology of the part, allowing you to define a continually varying orientation. You define the normal axis and a primary axis, and Abaqus/CAE uses these axes to construct a right-handed Cartesian coordinate system. For two-dimensional and axisymmetric parts, the normal axis is always the out-of-plane direction and represents the positive 3-axis of the coordinate system. Discrete orientations can be used for material orientations and composite layup orientations.

A variety of selection methods are available to define the desired axes. The datum axis and vector value methods define a constant axis direction, whereas the region selection methods allow for varying orientations. For example, you might want to select a curved surface and allow the normal to follow the shape of the curve.

Abaqus/CAE uses the normal axis and primary axis that you specify and the following algorithm to calculate the discrete orientation:

1. Abaqus/CAE preserves the normal axis direction and uses the specified primary axis direction as a construction direction. If the specified primary axis direction and the normal axis direction form a 90° angle, the final primary axis direction will be the same as the one specified. Otherwise, the primary axis direction will be adjusted to form a Cartesian system.
2. If you define the normal axis by selecting a surface or face, Abaqus/CAE finds the closest point on the surface or face and uses the surface normal at that point as the normal axis direction ($\widehat{N}$).
3. If you define the primary axis by selecting an edge, Abaqus/CAE finds the closest point on the edge and uses the edge tangent at that point as the primary axis construction direction ($\widehat{P_1}$).

   Tip: The accuracy of the projection onto a surface or face or a primary axis edge might depend on the geometry curve refinement setting for the corresponding part when Abaqus/CAE generates the input file. If the orientation normals are insufficiently accurate, you can specify a finer geometry curve refinement before submitting your job or writing the input file from Abaqus/CAE. For more information, see *Controlling curve refinement*.

4. Abaqus/CAE computes the secondary axis direction ($\widehat{S}$) by taking the cross product of the primary axis direction and the normal axis direction ($\widehat{S} = \widehat{P_1} \times \widehat{N}$).
5. Abaqus/CAE computes the final primary axis direction ($\widehat{P}$) by taking the cross product of the secondary axis direction and the normal axis direction ($\widehat{P} = \widehat{S} \times \widehat{N}$).

1. To display the **Edit Discrete Orientation** dialog box, do the following:
   a. Assign a material orientation or create a composite layup.
      - Display the **Edit Material Orientation** dialog box using the procedure described in *Assigning a material orientation or rebar reference orientation*.
      - Display the composite layup editor using one of the procedures described in *Creating and editing composite layups*.

   b. Click the arrow to the right of the **Definition** field, and select **Discrete** from the list that appears.

   c. Click .
2. For three-dimensional parts, choose the coordinate system axis that you want the **Normal axis direction** to represent in the resultant orientation.

3. For three-dimensional parts, define the normal axis of the orientation using one of the following methods:

   - Select **Surface/Faces** to select a region, and do the following:

     1. Click .
     2. From the prompt area, select **individually** or select **by angle** and enter an angle. For more information, see *Using the angle and feature edge method to select multiple objects*.
     3. Identify the regions that define the normal axis of the material orientation by selecting the regions in the viewport or by clicking **Surfaces** or **Sets** in the prompt area and selecting an existing surface or set.

   - Select **Datum axis** to select datum geometry, and do the following:

     1. To create a datum axis, click  and select two points in the viewport that define the axis.
     2. Click .
     3. Select the datum axis that defines the normal axis of the material orientation.

   - Select **Vector (i,j,k)**, and enter the values for the vector components.

   Abaqus/CAE displays arrows in the viewport that indicate your selections and axis direction; for example, arrows labeled `N-3`. If necessary, you can click **Flip Direction** to obtain the desired direction.

4. Choose the coordinate system axis that you want the **Primary axis direction** to represent in the resultant orientation.
5. Define the primary axis of the orientation using one of the following methods:

   - Select **Edges** to select a region, and do the following:

     1. Click .
     2. From the prompt area, select **individually** or select **by edge angle** and enter an angle.
     3. Identify the regions that define the primary axis of the material orientation by selecting the regions in the viewport or by clicking **Sets** in the prompt area and selecting an existing set.

   - Select **Datum axis** to select datum geometry, and do the following:

     1. To create a datum axis, click  and select two points in the viewport that define the axis.
     2. Click .
     3. Select the datum axis that defines the primary axis of the material orientation.

   - Select **Vector (i,j,k)**, and enter the values for the vector components.

   Abaqus/CAE displays arrows in the viewport that indicate your selections and axis direction; for example, arrows labeled `P-1`. If necessary, you can click  to obtain the desired direction.

6. Click **Continue** to save the discrete orientation definition and to close the **Edit Discrete Orientation** dialog box.

Creating material calibrations

This section describes how to import material data into Abaqus, filter and process the data, and use the data to specify Abaqus material behaviors.

In this section:

- *What is material calibration?*
- *Creating and editing data sets for calibration*
- *Processing calibration data*
- *Defining calibration behaviors*

What is material calibration?

Material calibration is the process of deriving Abaqus material behaviors like elasticity and plasticity from sets of material test data. You can create material calibrations in three general steps:

- Create data sets or import data sets into Abaqus/CAE.
- Process these data sets using filters and tools that enable you to scale, smooth, and truncate the data and to convert the data between nominal and true forms.
- Derive material properties such as Young's modulus, Poisson's ratio, or Mullins effect from your data sets.

To begin a new material calibration, double-click **Calibrations** in the Model Tree. In the **Create Calibration** dialog box that appears, enter a calibration name and click **OK**. Abaqus/CAE adds the new calibration to the Model Tree.

Creating and editing data sets for calibration

You can import material data from text (`.txt`) files and customize these data in a data table. You can also specify quantity types to describe the data, such as stress and strain or force and displacement.

1. From the Model Tree, expand **Calibrations** and double-click **Data Sets**.

   The **Create Data Set** dialog box appears.

2. To import a data set from a file, do the following:

   a. Click **Import Data Set**.

      The **Read Data From Text File** dialog box appears.

   b. Navigate to the file you want to import. For more information about file selection, see *Using file selection dialog boxes*.

   c. If the data in your imported file are delimited by a character other than spaces, tabs, or commas, toggle on **other** and enter the delimiting character in the **Delimiter** field.

   d. From the **Data Set Type** options, select the pairing of output variables that describes your imported data. The default type is **Stress/Strain**.

   e. If desired, specify the numbers of the fields from which Abaqus/CAE should import data. By default, Abaqus/CAE reads data from the first and second fields in the data set.

   f. If desired, specify a **Data Set Form** of **True** to import the material data in true form. By default, material data from text files are imported in nominal (or engineering) form.

   Abaqus/CAE displays the imported data and the selected quantity types in the table in the dialog box.

3. If desired, customize the data displayed in the table by adding, deleting, or modifying rows. For more information about tabular data entry, see *Entering tabular data*.

4. Click **OK** to create the new data set and to close the **Create Data Set** dialog box.

   Abaqus/CAE displays the new data set in the **Data Sets** container in the Model Tree and plots the data in the viewport.

Processing calibration data

The calibration data processing options enable you to clean up your material data before using it to define material behaviors.

In this section:

- *Converting calibration data between nominal and true forms*
- *Scaling calibration data*
- *Smoothing calibration data*
- *Truncating and shifting calibration data*

Converting calibration data between nominal and true forms

The **Convert** option enables you to convert the data in a calibration data set from nominal form to true form or vice versa. Abaqus/CAE performs the conversion using the algorithms described in *Stress and Strain Measures*.

1. In the Model Tree, click mouse button 3 on the data set that you want to convert and select **Process** from the menu that appears.

   The **Data Set Processing** dialog box appears.

2. Select **Convert**, and click **Continue**.

   The **Change Data Set Form** dialog box appears.

3. Select the form to which you want to convert the selected data set. Options are **Nominal (Engineering) Form** and **True Form**.
4. If desired, you can retain the original data set and create a new data set when you perform the data conversion. You can also customize the name of the newly created data set.
5. Click **OK**.

   Abaqus/CAE performs the selected form conversion for the data.

Scaling calibration data

The **Scale** option enables you to apply different scaling factors to either column in a calibration data set.

1. In the Model Tree, click mouse button 3 on the data set that you want to convert and select **Process** from the menu that appears.

   The **Data Set Processing** dialog box appears.

2. Select **Scale**, and click **Continue**.

   The **Scale Data Set** dialog box appears.

3. Specify a scaling factor for either column in the data set by editing the values in the **Col 1** or **Col 2** fields.
4. If desired, click **Preview** to review the new data values created by the scaling factor values.

   Abaqus/CAE reflects the new scale factor for each column in the data set.

5. If desired, you can retain the original data set and create a new data set when you perform the data conversion. You can also customize the name of the newly created data set.
6. Click **OK**.

   Abaqus/CAE performs the selected scaling for the data.

Smoothing calibration data

The **Smooth** option enables you to operate on a calibration data set to produce data that has a smoother curve. The resulting data set has the same *X*-coordinate values as the original data set. Abaqus/CAE uses an exponential moving average algorithm to smooth the data; this algorithm is also used by the **smooth2***X–Y* operator. For more information, see *Smoothing an X–Y data object*.

1. In the Model Tree, click mouse button 3 on the data set that you want to convert and select **Process** from the menu that appears.

   The **Data Set Processing** dialog box appears.

2. Select **Smooth**, and click **Continue**.

   The **Smooth Data Set** dialog box appears.

3. In the **Weight** field, specify a value for the smoothing parameter. You can specify a smoothing factor between 0 and 1 for the curve; a smaller value produces a smoother curve. The default smoothing factor is 0.75.
4. If desired, you can retain the original data set and create a new data set when you perform the data conversion. You can also customize the name of the newly created data set.
5. Click **OK**.

   Abaqus/CAE smooths the data set.

Truncating and shifting calibration data

The **Truncate and Shift** option enables you to exclude data points from a calibration data set whose *X*-coordinate values are less than or greater than a user-specified value or to include data points that lie between two specified *X*-coordinate values.

1. In the Model Tree, click mouse button 3 on the data set that you want to convert, and select **Process** from the menu that appears.

   The **Data Set Processing** dialog box appears.

2. Select **Truncate and Shift**, and click **Continue**.

   The **Truncate Data Set** dialog box appears.

3. Specify a truncation point on the left side or the right side of the data set, or specify points on both sides of the data set. You can set a truncation point by dragging a slider in the viewport or by entering a value in the appropriate **X-axis** field.
4. Shift the selected subset of data points using either of the following techniques:

   - Toggle on **Offset first point to (0,0)** to shift the selected subset of data points so that its leftmost point resides at (0,0).
   - Shift the selected subset of data points along either axis by specifying values in the **Offset X-axis** or **Offset Y-axis** fields.

5. If desired, you can retain the original data set and create a new data set when you perform the data conversion. You can also customize the name of the newly created data set.
6. Click **OK**.

   Abaqus/CAE performs the specified truncation or shift.

Defining calibration behaviors

This section describes how to extract material behavior constants from calibration data sets.

You can also add support for custom calibration behaviors, which appear as new options in the **Calibration Behavior** dialog box. For more information, see "Creating custom material calibration plug-ins in Abaqus/CAE" in the Dassault Systèmes Knowledge Base at *http://support.3ds.com/knowledge-base/*.

Abaqus/CAE assumes that the material is fully incompressible when it calculates material properties and plots material response curves from test data other than the volumetric test.

In this section:

- *Calibrating data for isotropic elastic material behavior*
- *Calibrating data for isotropic elastic-plastic material behavior*
- *Calibrating data for hyperelasticity with permanent set*

Calibrating data for isotropic elastic material behavior

The isotropic elastic calibration behavior enables you to derive isotropic elastic data (Young's modulus and Poisson's ratio) from calibration data sets and to apply these material constants to the elastic material properties of a material definition in your model.

1. From the Model Tree, expand the **Calibrations** container and double-click **Behaviors**.

   The **Create Calibration Behavior** dialog box appears.

2. Enter a name for the material calibration behavior, select **Elastic Isotropic**, and click **Continue**.

   The **Edit Behavior** dialog box appears.

3. From the **Parameter Set 1** options, do the following to calculate a value for Young's modulus:

   a. From the **Data set** list, select the data from which you want to calculate Young's modulus.

   b. Click .

      Abaqus/CAE computes Young's modulus and displays its value to the right of the **Young's modulus** label.

4. From the **Parameter Set 2** options, do the following to calculate a value for Poisson's ratio:

   a. From the **Data set** list, select the data from which you want to calculate Poisson's ratio.

   b. Click .

      Abaqus/CAE computes Poisson's ratio and displays its value to the right of the **Poisson's ratio** label.

5. From the **Material** list, select the material definition to which you want to apply this calibration behavior; or click  to create a new material definition for this calibration behavior. For more information about defining a new material model, see *Creating or editing a material*.

6. Click **OK** to save the isotropic elastic behaviors to the selected material model.

   Abaqus/CAE adds the new behavior to the model tree and adds the specified Young's modulus and Poisson's ratio to the **Elastic** material properties for the specified material.

Additional information

• *Creating a linear elastic material model*

Calibrating data for isotropic elastic-plastic material behavior

The isotropic elastic-plastic calibration behavior enables you to derive isotropic elastic and plastic material behaviors.

1. From the Model Tree, expand the **Calibrations** container and double-click **Behaviors**.

   The **Create Calibration Behavior** dialog box appears.

2. Enter a name for the material calibration behavior, select **Elastic Plastic Isotropic**, and click **Continue**.

   The **Edit Behavior** dialog box appears.

3. From the **Elastic-Plastic Data** options, do the following:

   a. Expand the **Data set** list and select the data from which you want to calculate the first set of calibration values.

   b. From the **Ultimate point** options, either click  to calculate the ultimate point automatically or click  and select the ultimate point from the viewport.

   Abaqus/CAE plots the ultimate point in the viewport and displays its coordinates in the dialog box.

   c. From the **Yield point** options, click  and pick the yield point from the viewport.

   Abaqus/CAE plots a line between the origin and the yield point in the viewport, displays the coordinates for the yield point in the dialog box, and calculates the Young's modulus and displays its value to the right of the **Young's modulus** label.

   d. Select the plastic points for this material calibration by doing either of the following:

   - Drag the **Plastic points** slider to the right to calculate a greater number of plastic points or drag the slider to the left to calculate fewer plastic points.
   - Click  to pick plastic points from the viewport.

   Abaqus/CAE adds plastic data points to the table in the dialog box. You can edit any of these data if you want to customize further the plastic data.

4. From the **Poisson's Ratio Data** options, do the following:

   a. From the **Data set** list, select the data from which you want to calculate Poisson's ratio.

   b. Click .

   Abaqus/CAE computes the Poisson's ratio, displays its value in the **Poisson's ratio** field, and plots it in the viewport. If desired, you can adjust the calculated value of Poisson's ratio by changing the value in the field.

5. From the **Material** list, select the material definition to which you want to apply this calibration behavior; or click  to create a new material definition for this calibration behavior. For more information about defining a new material model, see *Creating or editing a material*.

6. Click **OK**.

   Abaqus/CAE updates the new calibration behavior. If you specified a material definition, Abaqus/CAE maps the isotropic elastic-plastic calibration behavior parameters to the **Elastic** and **Plastic** material behaviors of that material definition.

Note:

Any elastic or plastic material behaviors in the selected material are overwritten when you map data from a calibration behavior to the material definition.

- *Defining classical metal plasticity*

Calibrating data for hyperelasticity with permanent set

The hyperelasticity with permanent set calibration behavior enables you to extract plastic and hyperelastic material behaviors and Mullins effect from uniaxial and biaxial data sets of the loading, unloading, and reloading of elastomers and thermoplastics. You can extract data from a uniaxial test, a biaxial test, or from both types of tests. The calibration process includes the following steps:

1. Upload uniaxial and/or biaxial test data files into Abaqus/CAE as new data sets.
2. Extract the loading, unloading, and reloading cycles and the permanent set data from the data files you provide and create separate data sets for the load, unload, and reload phase of every cycle.
3. If desired, select any data cycles that you want to exclude from calculations of material behavior.
4. Select the yield point from the viewport and, if desired, edit individual points on the primary loading data set to create a smoother curve. The permanent set curves are based upon the current yield point, so these curves also change when you select a new yield point.
5. Once you determine the test data sets that you want to use for deriving material behaviors and you specify primary curve options, you can derive material behaviors from the selected data. Abaqus/CAE maps plastic, hyperelastic, and Mullins effect material behaviors to the material you select.

    1. From the Model Tree, expand the **Calibrations** container and double-click **Behaviors**.

       The **Create Calibration Behavior** dialog box appears.
    2. Enter a name for the material calibration behavior, select **Hyperelasticity with permanent set**, and click **Continue**.

       The **Edit Behavior** dialog box appears.
    3. Perform the following steps from the **Uniaxial** or **Biaxial** tabbed page:
        a. Select the cycle from which to extract data to calibrate the Mullins effect. By default, Abaqus/CAE extracts the last unloading and reloading curves.

           - Select **Last cycle found** to extract the last unloading and reloading curves from each strain level in the supplied test data.
           - Select **First cycle found** to extract the first unloading and reloading curves from each strain level in the supplied test data.

        b. Expand the **Data set** list, and select the data from which you want to calculate the calibration values for uniaxial or biaxial data tests.

        c. Click .

           Abaqus/CAE extracts the primary loading curve, the specified unloading and reloading curves for each cyclic strain level, and the permanent set curves, then creates new calibration data sets for each component of each cyclic strain level. Each new data set is available in the **Uniaxial Test Data Sets** or **Biaxial Test Data Sets** options and is plotted in the viewport.

        d. Toggle on the individual loading, unloading, or reloading data sets that you want to include in the material calibration calculations. As you toggle on a data set, Abaqus/CAE displays its corresponding *X*–*Y* curve in the viewport. You can select any of the following:

           - Select **All** to include all the raw data found in the selected test data file.
           - Select **Primary** to include data from the primary loading curve.
           - Select **Unloading** to include data from the unloading curves for each cyclic strain level, or expand this container to select individual unloading curves.

- Select **Reloading** to include data from the reloading curves for each cyclic strain level, or expand this container to select individual reloading curves.
- Select **Permanent Set** to include data from both permanent set curves, or expand this container to select either stress- or strain-related components of permanent set.

e. From the **Yield Point** options, do either of the following:

- Click  , and select the yield point on the primary curve from the viewport.
- Click  , and enter either the **Strain** or **Stress** value; Abaqus/CAE calculates the other value from the primary curve and populates the remaining field.

4. If desired, extract a second data set from the **Uniaxial** or **Biaxial** tabbed page.

5. If you extracted both uniaxial and biaxial test data, Abaqus/CAE applies the data equally by default in the calculations of material behaviors. Perform the following steps from the **Options** tabbed page if you want one data set to have greater weight in these calculations:

a. In the **Material Properties** options, drag the **Weight** slider toward the type of data (uniaxial or biaxial) that you want to assign greater weight in the material behavior calculations.

b. Specify whether the selection of relative weight is based on a linear interpolation or a logarithmic interpolation.

6. From the **Material** list, select the material definition to which you want to apply this calibration behavior; or click  to create a new material definition for this calibration behavior. For more information about defining a new material model, see *Creating or editing a material*.

7. Click **OK**.

Abaqus/CAE updates the new calibration behavior and maps the hyperelasticity with permanent set calibration behavior parameters to the **Hyperelastic**, **Plastic**, and **Mullins Effect** material behaviors of that material definition.

Note:

Any hyperelastic, plastic, or Mullins effect material behaviors in the selected material are overwritten when you map data from a calibration behavior to the material definition.

Using the Special menu in the Property module

You can use the **Special** menu in the Property module to define the following engineering features:

- **Skin**. A skin reinforcement defines a skin that is bonded to the surface of an existing part and specifies its engineering properties. For more information, see *Skin and stringer reinforcements*.
- **Inertia**. You can define lumped mass, rotary inertia, and heat capacitance at a point on a part. You can also define mass and inertia proportional damping. In an Abaqus/Standard analysis, you can define composite damping. For more information, see *Inertia*.
- **Springs/Dashpots**. You can define springs and dashpots that exhibit the same linear behavior independent of field variables. You can also define both spring and dashpot behavior on the same set of points. In an Abaqus/Explicit or an Abaqus/Standard analysis, you can model springs and dashpots that connect two points, following the line of action between the two points. In an Abaqus/Standard analysis, you can also model springs and dashpots that connect two points, acting in a fixed direction, or that connect points to ground. For more information, see *Springs and dashpots*.

Using the Query toolset to obtain assignment information

You can use the Query toolset to display the following:

- A list of all of the regions to which you have assigned sections.
- The name of a section assigned to a selected region.
- Information regarding the regions that require section assignments.
- The beam orientations assigned to selected wire regions.
- The material orientations assigned to selected shell and solid regions.
- A graphic representation of the plies in a composite layup or a composite section.
- The rebar reference orientations assigned to selected shell regions.
- The direction of shell/membrane normals assigned to all shell and axisymmetric wire regions.
- The direction of beam/truss tangents assigned to all wire regions.
- The composite layups and plies that contain disjoint regions.

1. From the main menu bar, select **Tools->Query**.

   Tip: You can also query the model by clicking the tool in the Query toolset.

   Abaqus/CAE displays the **Query** dialog box.

   You can request either a general query or a module-specific query. The **Shell element normals** and **Beam element tangents** queries are general queries. For a discussion of the information displayed by general queries, see *Obtaining general information about the model*. The **Section assignments**, **Regions missing sections**, **Beam orientations**, **Material orientations**, **Rebar orientations**, **Ply stack plot**, and **Disjoint ply regions** queries are specific to the Property module.

2. From the **Property Module Queries** list, select the property of interest.
3. Select the region that you want to query in the viewport.

   Tip: You can limit the types of objects that you can select in the viewport by clicking the selection filter tool in the prompt area and then clicking the selection filter of your choice in the dialog box that appears. See *Using the selection options*, for more information.

4. Once you have selected the region that you want to query, the following information appears:

Section assignment queries

Abaqus/CAE displays the name of the section or sections assigned to the selected region in the message area. If you query a region with a section assignment that has been suppressed, Abaqus/CAE reports no section assignments for that region.

Regions missing sections

If any regions of your part require a section assignment and do not have one, Abaqus/CAE highlights these regions in the viewport and prompts you to save the regions as a set. If you want to save these regions as a named set, toggle on **Save regions in a set** from the dialog box that appears; and, if desired, customize the default set name.

Beam section orientation queries

Abaqus/CAE displays the name of the beam orientation assigned to the selected beam region in the message area. In addition, the $\mathbf{n}_1$-direction for each beam region in the part appears in the message area.

Material orientation queries

Abaqus/CAE displays the type of the material orientation assigned to the selected region in the message area. For the `GLOBAL`, `SYSTEM`, and `DISCRETE` types, Abaqus/CAE displays the material orientation triads in the viewport. In addition, information concerning the material orientation of each region in the part appears in the message area.

Rebar orientation queries

Abaqus/CAE displays the name of the rebar orientation assigned to the selected region in the message area. In addition, information concerning the rebar reference orientation of each region in the part appears in the message area.

Ply stack plot

Abaqus/CAE creates a new viewport and displays a graphical representation of a core sample through a composite layup or a composite section. The image shows the plies in the layup along with details of each ply, such as its fiber orientation, thickness, reference plane, and integration points. For more information, see *Viewing a ply stack plot*."

Disjoint ply regions

Abaqus/CAE displays in the message area the names of the composite layups and the plies within them that contain disjoint regions.

5. To exit the querying procedure, click the cancel button  in the prompt area.

The Assembly module

You use the Assembly module to create and modify the assembly.
A model contains one main assembly, which is composed of instances of parts from the model as well as instances of other models. The tutorial in *Using Additional Techniques to Create and Analyze a Model in Abaqus/CAE* contains examples of how you use the Assembly module to create part instances and position them relative to each other in a global coordinate system.

In this section:

- *Understanding the role of the Assembly module*
- *Entering and exiting the Assembly module*
- *Working with part instances*
- *Working with model instances*
- *Creating the assembly*
- *Creating patterns of instances*
- *Performing Boolean operations on part instances*
- *Understanding toolsets in the Assembly module*
- *Using the Assembly module toolbox*
- *Creating and manipulating part and model instances*
- *Applying constraints to part and model instances*
- *Using the Query toolset to query the assembly*

Understanding the role of the Assembly module

When you create a part, it exists in its own coordinate system, independent of other parts in the model. In contrast, you use the Assembly module to create instances of your parts and to position the instances relative to each other in a global coordinate system, thus creating the assembly. You position part instances by sequentially applying position constraints that align selected faces, edges, or vertices or by applying simple translations and rotations.

You can also create instances of other models in your main model, allowing you to add complete subassemblies in addition to individual parts. Model instances are created in the exact same way as part instances and can be positioned and manipulated in a similar fashion.

An instance maintains its association with the original part or model. If the geometry of a part or model changes, Abaqus/CAE automatically updates all instances of the part or model to reflect these changes. You cannot edit the geometry of an instance directly.

Your main model can contain many parts and model subassemblies, and a part or model can be instanced many times in the main model assembly; however, a model contains only one top-level assembly. Loads, boundary conditions, predefined fields, and meshes are all applied to the complete assembly. Even if your model consists of only a single part, you must still create an assembly that consists of just a single instance of that part.

A part instance can be thought of as a representation of the original part. You can create either independent or dependent part instances. An independent instance is effectively a copy of the part. A dependent instance is only a pointer to the part, partition, or virtual topology; and as a result, you cannot mesh a dependent instance. However, you can mesh the original part from which the instance was derived, in which case Abaqus/CAE applies the same mesh to each dependent instance of the part.

A model instance is always dependent, not independent.

Entering and exiting the Assembly module

You can enter the Assembly module at any time during an Abaqus/CAE session by clicking **Assembly** in the **Module** list located in the context bar. The **Instance**, **Constraint**, **Feature**, and **Tools** menus appear on the main menu bar.

To exit the Assembly module, select any other module from the **Module** list. You need not save your assembly before exiting the module; it will be saved automatically when you save the entire model by selecting **File->Save** or **File->Save As** from the main menu bar.

Working with part instances

This section describes part instances, how they relate to the original part, how you link and exclude part instances, and how you use them to create the assembly.

In this section:

- *Understanding the relationship between models, parts, instances, and assemblies*
- *What is the difference between a dependent and an independent part instance?*
- *How do I decide whether to create a dependent or an independent part instance?*
- *Changing from a dependent to an independent part instance or vice versa*
- *Linking part instances between models*
- *Excluding part instances from an analysis*
- *Sets and part instances*

Understanding the relationship between models, parts, instances, and assemblies

A model can contain many parts; however, it can contain only one top-level assembly. The assembly is composed of instances of the parts positioned relative to each other in a global coordinate system, as described in *What is a part instance?*. The top-level assembly can also contain model instances that effectively create subassemblies from other models.

The concept of parts, part instances, and the assembly is carried throughout the Abaqus/CAE modeling process:

1. You create a part in the Part module; each part is a distinct entity that can be modified and manipulated independently of other parts. Parts exist in their own coordinate system and have no knowledge of other parts.
2. You define section properties in the Property module and also associate a material with a section. You use the Property module to assign these section properties to a part or to a selected region of a part.
3. You create instances of your parts in the Assembly module, and you position those instances relative to each other in a global coordinate system to form the assembly. You can also add instances of other models in the assembly.

   Abaqus/CAE allows you to create either independent or dependent part instances, as described in *What is the difference between a dependent and an independent part instance?*. Both independent and dependent part instances maintain their association with the original part. When you modify the original part in the Part module, Abaqus/CAE updates any instances of that part when you return to the Assembly module. You can instance a part many times and assemble multiple instances of the same part. Each instance of the part is associated with the section properties assigned to the part in the Property module.
4. You use the Interaction and Load modules to complete the definition of the model by, for example, defining contact and applying items such as loads and boundary conditions. The Interaction and Load modules operate on the assembly.
5. You use the Mesh module to mesh the assembly. You can do either of the following:

   - Individually mesh each independent instance of a part in the assembly.
   - Mesh the original part. Abaqus/CAE then associates the mesh with each dependent instance of the part in the assembly.

   The two meshing approaches are described in *What is the difference between a dependent and an independent part instance?*.

Creating a part or model instance, contains detailed instructions on creating part instances.

What is the difference between a dependent and an independent part instance?

When you create a part instance, you can choose to create either a dependent part instance or an independent part instance. You can also edit a part instance and change it from dependent to independent or vice versa. When you create a model instance, it is always dependent.

Dependent part instances

By default, Abaqus/CAE creates a dependent instance of a part. A dependent instance is only a pointer to the original part. In effect, a dependent instance shares the geometry and the mesh of the original part. As a result, you can mesh the original part, but you cannot mesh a dependent instance. When you mesh the original part, Abaqus/CAE applies the same mesh to all dependent instances of the part. Most modifications are not allowed on a dependent part instance; for example, you cannot add partitions or create virtual topology. However, operations that do not modify the geometry of a dependent part instance are still allowed; for example, you can create sets, apply loads and boundary conditions, and define connector section assignments. If you have already meshed a part or added virtual topology to the part, you can create only a dependent instance of the part.

If you apply an adaptive remeshing rule to a dependent part instance in the Mesh module, Abaqus/CAE remeshes the original part and applies the new mesh to each dependent instance of the part.

You cannot change the mesh attributes of an individual dependent part instance; for example, the mesh seeds, mesh controls, and element types. However, you can change the mesh attributes of the original part, and Abaqus/CAE propagates the changes to all dependent instances of the part. Although you have already meshed the original part and applied the same mesh to its dependent instances, the mesh is visible only in the Mesh module. You continue to work with the native Abaqus/CAE geometry in the Assembly, Interaction, and Load modules. In general, you cannot use the Edit Mesh toolset to edit the mesh of a dependent part instance; however, you can use the Edit Mesh toolset to edit and project the nodes of a dependent part instance. Abaqus/CAE moves the nodes of the original meshed part, and your modifications appear on all dependent instances of the part.

The advantages of dependent part instances are that they consume fewer memory resources and you need mesh the part only once. In addition, Abaqus/CAE instances a dependent part instance in the input file by writing a single set of nodal coordinates and element connectivity to define the part along with a transform to define each part instance.

Independent part instances

In contrast, an independent part instance is a copy of the geometry of the original part. You cannot mesh a part from which you created an independent part instance; however, you can mesh the independent instance. In addition to meshing, you can perform most other operations on an independent instance; for example, you can add partitions and create virtual topology. The disadvantages of independent instances are that they consume more memory resources, and you must mesh each independent instance individually. In addition, Abaqus/CAE does not take advantage of instantiation in the input file with independent part instances—sets of nodal coordinates and element connectivity are written to the input file for each independent part instance.

You cannot create both a dependent and an independent instance of the same part. As a result, if you create a dependent instance of a part, all subsequent instances must be dependent. The same argument applies to independent instances. Instances of mesh parts are always dependent.

You can use the Model Tree to determine if an instance is dependent or independent. When you mesh an independent part instance, the mesh appears in the Model Tree under the part instance container, as shown in *Figure 1*. In addition, *Figure 1* also illustrates that as you move the cursor over an instance, the information displayed by the Model Tree indicates whether the instance is dependent or independent.

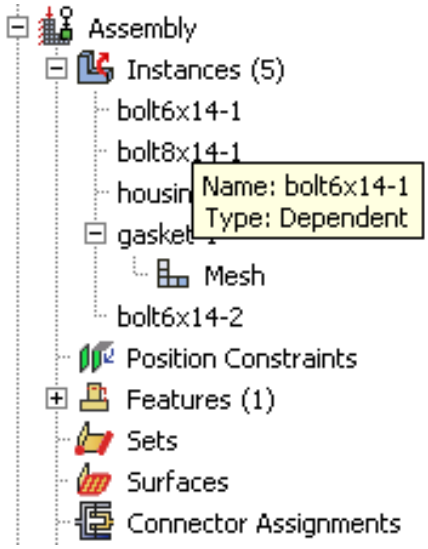

Figure 1: The Model Tree indicates whether a part instance is dependent or independent.

How do I decide whether to create a dependent or an independent part instance?

If your assembly contains a few part instances that are unrelated, dependent instances have little advantage over independent instances. Each part is different, and you must create an instance of each part. In contrast, if your assembly contains identical part instances, you can save time by assembling dependent instances of the part. When you subsequently mesh the original part, Abaqus/CAE applies that mesh to each dependent instance of the part in the assembly. In addition, dependent instances consume fewer memory resources and result in a smaller input file.

For example, *Figure 1* illustrates an assembly of independent and dependent part instances. The pump housing is an independent part instance, and the eight bolts are dependent part instances. The figure on the left shows the assembly in the Assembly module. The figure on the right shows the assembly in the Mesh module. The user has meshed the part representing the bolt, and Abaqus/CAE associated the mesh with each dependent instance of the bolt.

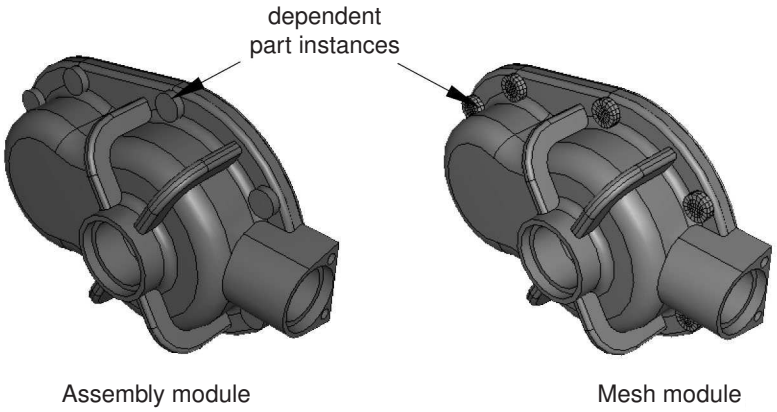

Figure 1: Dependent part instances in the Assembly and Mesh modules.

You will find it more convenient to use dependent part instances when you use the linear or radial pattern tool to create a pattern of identical instances. When you mesh the original part, Abaqus/CAE applies the same mesh to each dependent instance in the pattern. In contrast, if you create a pattern of independent instances, you must mesh each instance individually.

Abaqus/CAE creates dependent instances by default. Unless your assembly contains only a few parts, it is recommended that you work with dependent instances because of the memory savings and the resulting performance gain.

Changing from a dependent to an independent part instance or vice versa

The restrictions on dependent part instances may limit your ability to partition or mesh the assembly, or you may find that you wish to apply virtual topology to an instance. To switch between making a part instance dependent or independent, you can click mouse button 3 on the instance in the Model Tree and select **Make Dependent** or **Make Independent** from the menu that appears.

If you mesh a part and create a dependent instance of the part, Abaqus/CAE associates the mesh with the instance. If you subsequently change the instance from dependent to independent, Abaqus/CAE continues to associate the mesh with the independent instance. However, the reverse is not true. If you create an independent instance, mesh the instance, and subsequently convert the instance to dependent, Abaqus/CAE deletes the mesh from the dependent instance. The same applies to partitions and virtual topology. Abaqus/CAE deletes any partitions or virtual topology applied to an independent part instance when you change it to dependent.

In some cases, you can work around the restrictions on a dependent part instance by creating a copy of the original part and by creating an independent instance of the copy. You can then partition or mesh the new instance or apply virtual topology to it. Similarly, although you cannot create both a dependent and independent instance of the same part, you can create a copy of the part and create either type of instance from the copy.

Linking part instances between models

You can link part instances between models. Linking part instances allows instances and parts to be updated automatically when you modify the instance or part in the original model.

In the Model Tree, select the part instances that you want to link (child instances) to part instances in another model. Click mouse button 3, select **Link Instances**, and specify the parent model and part instances to which you want to link each child instance. Similarly, you can unlink part instances that were previously linked. For detailed instructions, see *Using the Model Tree to manipulate part instances*.

If you select all instances of a part to be linked, the part is also linked automatically. The part and its features, sets, and surfaces are updated using the parent part. Assembly-level features and sets and surfaces are not copied. Instances are updated using the parent instances and retain sets and surfaces defined on them.

If you select only some of the instances of a part to be linked, a new part is created (with `–LinkedCopy` appended to the part name) before linking the instance and the new part to the parent model.

Linked part instances and parts are not editable. The position of the linked child instance is solely determined from the position of the parent instance and cannot be updated.

By default, linked part instances and parts are colored gray in the viewport. Icons are displayed in the Model Tree to indicate the linked status of parts and part instances and to indicate the linked and excluded status of part instances if the part instances are also excluded from the analysis, as shown in *Figure 1*. `Beam-1` is a linked part instance, and `Beam-2` is a linked and excluded part instance. For more information, see *Excluding part instances from an analysis*.

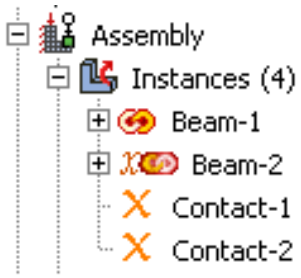

Figure 1: Model Tree icons indicating linked and excluded status of part instances.

Additional information

- *Using the Model Tree to manipulate part instances*

Excluding part instances from an analysis

You can exclude part instances from the analysis so that they are not written to the input file when the analysis job is submitted. An excluded part instance participates in all operations other than the analysis.

In the Model Tree, select the part instances that you want to exclude from the analysis. Click mouse button 3, and select **Exclude from Simulation**. Similarly, you can include part instances that were previously excluded by selecting **Include in Simulation**. Constraints on the part instances are retained if you exclude the instances from the analysis and subsequently include them.

By default, part instances that are excluded from the analysis are colored dark gray in the viewport. Icons are displayed in the Model Tree to indicate the excluded status of part instances and to indicate the linked and excluded status of part instances if the part instances are also linked between models, as shown in *Figure 1*. `Contact-1` and `Contact-2` are part instances that are excluded from the analysis, and `Beam-2` is a linked and excluded part instance. For more information, see *Linking part instances between models*.

Additional information

• *Using the Model Tree to manipulate part instances*

Sets and part instances

Part sets are transferred when you create a part instance from a part. For example, you might create a set from a region of a part and use the Property module to assign a section to that set. When you instance the part in the Assembly module, Abaqus creates part instance sets that refer to any part sets that you previously created. Abaqus provides read-only access to these part instance sets in assembly-related modules. You cannot access a part instance set from the **Set Manager**; however, you can select an eligible part instance set during a procedure by clicking the **Set** button and selecting the set from the **Region Selection** dialog box that appears. For more information, see *Understanding sets and surfaces*.

Working with model instances

You can create instances of other models in your main model, allowing you to add complete subassemblies in addition to individual parts.
Model instances are created in the exact same way as part instances and can be positioned and manipulated in a similar fashion.

When you create a new model instance, the main assembly of the referenced model is instantiated in the assembly of the current working model. The instance produces a subassembly from the contents of the other model. Since the referenced model assembly might in turn contain other model instances as children, multiple levels of complex subassemblies are possible.

You must include the external model to be instantiated in the current model database (`.cae`) file to be available. If the model you want to instantiate is contained in a different model database, use **File->Import->Model** to import it into the current model database. A model database file can always contain multiple models.

Renaming model instances is not supported in Abaqus/CAE. You should take care when renaming models because Abaqus/CAE does not update the model instance name in the instantiated models.

Characteristics of model instances

Model instances have the following characteristics:

- A particular model can be instantiated multiple times, and you can instantiate as many different models as desired.
- Model instances are always dependent, not independent.
- You can freely mix model instances with part instances.
- Model instance subassemblies can contain either geometric parts or orphan mesh parts.
- Model instances can be positioned and oriented in the main assembly by using transformations (**Translate**, **Translate To**, **Rotate**) and positioning constraints. The transformations and constraints must be applied to a complete model instance subassembly, not to any of its children. If you select a child instance within a model instance, the transformation or constraint will be applied to the entire parent model instance.
- Linear and radial patterns are not supported and cannot be used with model instances.
- Part instance commands such as **Suppress/Resume**, **Hide/Show**, **Delete**, **Show Parents/Children**, and **Switch Context** can also be used on model instances.

  You cannot use the **Suppress** and **Delete** commands on the child instances of a model instance; you can use them only on the model instance itself. If you suppress a child instance (part or model) in the original (referenced) model assembly, it is also suppressed in the main model. To see that the suppressed instance is correctly suppressed in the main model, you must use the **Model** list in the context bar to switch from the original (referenced) model to the main model. Moving to the main model in the Model Tree will not regenerate the model instance children consistently. (For information about the context bar, see *Components of the main window*.) The child instance must then be resumed in the original model.
- **Replace**, **Exclude from Simulation**, **Merge/Cut**, and **Link Instances** are not supported and cannot be used on model instances.
- The Partition toolset is not supported and cannot be used with model instances.
- The Query toolset is supported and can be used to determine the position and attributes of model instances.
- All sets and surfaces defined in the referenced model are brought into the model instance, maintaining the Model Tree hierarchy of features. These sets and surfaces will be available in the main model.
- Surface-to-surface contact and self-contact interactions defined in the initial step (along with their contact interaction properties) are the only history-level features defined in the referenced model that are brought into the model instance (although they are not visible in the model tree); other history-level features (such as steps, loads, boundary conditions, other interactions, and amplitudes) are not brought into the model instance. Some model-level features (fasteners and other engineering features) defined in the referenced model are not brought into the model instance.

Interactions in the main model depend on the interaction option used. Interaction copies to the main model are restricted based on the following patterns:

- For Abaqus/Explicit model instances, you cannot copy to any main model type.
- For Abaqus/Standard or unknown model type instances, you can copy only to an Abaqus/Standard or an unknown usage main model type.

- Model instances are supported and selectable in **Display Groups** and in the **Instance** tab of the **Assembly Display Options**.
- The Virtual Topology toolset is not supported for model instances.

Any part-level attributes that are needed in your subassembly (referenced) model must be created and assigned in that original model and cannot be created in the main model assembly. For example, materials, sections, orientations, and skin/stringer assignments must be created in the original model. Meshing can be performed on the original independent part instances, and the meshes will appear in the model instance.

When you create a model instance, all the part instances of the referenced model assembly are added to the main model assembly as child part instances. Any suppressed part instances or instances that are excluded from the simulation will retain the same status in the subassembly.

If you modify or delete an existing part instance or model instance subassembly in the main model assembly, Abaqus/CAE automatically regenerates the child instances from all parent instances (parts and models) whenever you switch out of and back into the Assembly module of the main model.

If you try to create a new model instance from another model that in turn contains child model instances, any problems with model referencing circularity will be prevented by Abaqus/CAE.

Abaqus/CAE ensures consistency of the modeling space for model instances; if all instances in the main model are three-dimensional, any other models to be instantiated must also be three-dimensional.

Model instance data saved in input files

When Abaqus/CAE generates the input (`.inp`) file for a model assembly that contains model instances, a single flattened assembly is generated. All model instance subassemblies are written as a flat list of instances under the single assembly block.

Most features from the original model of a model instance are saved in the input file, with some exceptions:

- Surface-to-surface contact and self-contact interactions defined in the initial step are the only history-level features from a model instance subassembly that are saved in the input file. The contact interaction property name and surface names are prepended with the model instance name in the main assembly; for example:

  model-instance-name`#`*contact-property-name*
  model-instance-name`#Surf-1, `*model-instance-name*`#Surf-2`

- Model-level features from a model instance are saved in the input file; for example, materials, section assignments, connector section assignments, skins, stringers, and orientations. Materials and element controls defined in a model instance are prepended with the model name in the main assembly; for example,

  model-name`#`*material-name*

  Connector sections assignments are prepended with the model instance name in the main assembly; for example:

  model-instance-name`#Wire-3-Set-1`

  Other model-level data such as initial conditions and amplitude definitions from a model instance are not saved in the input file.
- Engineering features such as mass and inertia elements, springs, and dashpots defined at the part level in the model instance are saved to the input file, but engineering features defined at the assembly level in the original model are not.

- Sets and surfaces from a model instance are saved in the input file. These set and surface names are also prepended with the model instance name in the main assembly; for example:

  model-instance-name`#Set-1`

- Constraints, reference points, attachment points, attachment lines, and wires from a model instance are saved in the input file.
- For constraints the model instance name will be prepended to the constraint name; for example:

  model-instance-name`#`*constraint-name*

- Attachment points, attachment lines, and wires will be available through sets created in the subassembly.

The following limitations exist:

- Restart analysis is not supported for a model containing model instances.
- Instances of models containing assembled fasteners are not supported.

Creating the assembly

After you create a part instance or a model instance, you apply a succession of position constraints and positioning operations to position it relative to other instances in the global coordinate system. This section describes the tools that Abaqus/CAE provides to position and constrain part and model instances. This section also describes how you can replace a part instance.

In this section:

- *The position tools in the Assembly module*
- *How the position constraint methods differ*
- *How conflicts can arise between position constraints, translations, and rotations*
- *Positioning a part or model instance using the Translate To tool*
- *Replacing an instance*

The position tools in the Assembly module

Each part exists in its own coordinate system in the Part module, and model instances are created in their own coordinate system. You use the Assembly module to position and orient instances of these parts and models relative to each other in a global coordinate system. Abaqus/CAE provides the following tools for positioning part and model instances:

Auto-offset

When you create the first part or model instance in the Assembly module, Abaqus/CAE displays a triad indicating the origin and the orientation of the global coordinate system. Abaqus/CAE positions the first instance so that the origin of the part or model aligns with the origin of the global coordinate system and the axes are aligned. If you create additional instances, Abaqus/CAE continues to position the new instances such that their coordinate system aligns with the global coordinate system. Since this usually results in new instances overlapping existing ones, Abaqus/CAE allows you to apply an offset before it creates the instance. The offset is applied along the *X*-axis for three-dimensional and two-dimensional instances and along the *Y*-axis for axisymmetric instances.

Basic positioning tools

Abaqus/CAE provides the following basic methods for positioning part and model instances:

- You can translate selected instances along a vector by specifying the coordinates of the start point and end point of the translation vector. You can use the following methods to determine the distance moved by the selected instances:
  - The selected instances move along the translation vector from the start point to the end point.
  - The selected instances move along the translation vector from the start point toward the end point and continue to move until a selected face or edge is a specified distance from a face or edge selected from the fixed instances. For more information, see *Positioning a part or model instance using the Translate To tool*.
- You can rotate selected instances about an axis. You specify the *X*-, *Y*-, and *Z*-coordinates of the start point and end point of the axis of rotation and the angle of rotation.

Position constraint tools

A position constraint defines a relationship between two instances. Unlike a simple translation or rotation, you do not specify the position directly. Position constraints define a set of rules that must always be met by the part or model instances in the assembly; for example, a face that must be parallel to another face.

Position constraints defined in the Assembly module create constraints only on the initial positions of instances, whereas constraints defined in the Interaction module define constraints on the analysis degrees of freedom. In the Assembly module constraints are stored as features of the assembly. If you modify a part or move a part or model instance, Abaqus/CAE attempts to apply all existing position constraints when it regenerates the assembly. Each of the position constraints is described in *How the position constraint methods differ*.

Creating the final assembly is an iterative process of creating instances, applying position constraints, and applying translations and rotations. After each repositioning, Abaqus/CAE displays a temporary image indicating the result of the operation. You can accept the new position, cancel the operation, or step back through the repositioning procedure by clicking the **Previous** button  in the prompt area.

You can use the Query toolset to obtain the coordinates of a vertex and to measure the distance between selected vertices. This may help you determine the vector along which you need to translate instances or the angle through

which you need to rotate them. *Using the Query toolset to query the assembly*, contains detailed instructions on how to obtain information about the assembly.

How the position constraint methods differ

A position constraint defines a relationship between two part or model instances—one that will move (the movable instance) and one that will remain stationary (the fixed instance). When you apply a position constraint, Abaqus/CAE computes a position for the movable instance that satisfies this relationship; you do not specify the position directly. You can apply the following position constraints to instances in the Assembly module:

- Parallel face (three-dimensional instances only)
- Face to face (three-dimensional instances only)
- Parallel edge
- Edge to edge
- Coaxial (three-dimensional instances only)
- Coincident point
- Parallel coordinate systems

In general, applying a single position constraint is not sufficient to define the precise location of a movable instance. You must apply several position constraints—usually three for a three-dimensional assembly and two for a two-dimensional assembly—to position an instance in the desired location. Part and model instances can overlap as a result of applying position constraints; Abaqus/CAE does not prevent overclosure between edges, faces, or cells. Similarly, Abaqus/CAE does not prevent you from overconstraining instances or duplicating a constraint.

The definition of a constraint feature includes all the faces and edges that you originally selected. If you subsequently modify a part or move a part or model instance, Abaqus/CAE automatically recalculates the constraint based on your original selection of faces and edges. As a result, one or more instances might move after the assembly is regenerated. For example, different edges might become parallel. For more information on features, see *Manipulating features in the Assembly module* and *The Feature Manipulation toolset*.

The following position constraints are provided by the Assembly module:

Parallel Face

A parallel face position constraint causes a selected face of the movable instance to become parallel with a selected face of the fixed instance. However, the position constraint does not specify the precise location of the movable instance, and the distance between the parallel faces is arbitrary. To apply a parallel face position constraint between two instances, you do the following:

- Select the faces to be constrained to be parallel from the movable instance and the fixed instance, as shown in *Figure 1*.

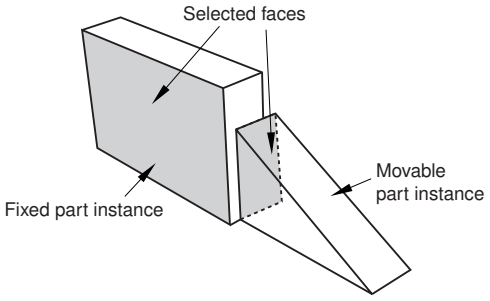

Figure 1: Select the faces to become parallel.

- Abaqus/CAE displays arrows normal to the selected faces. You prescribe the orientation of the movable instance by selecting the direction of the arrow normal to its selected face. *Figure 2* illustrates the result of applying the position constraint and the effect on the movable instance of reversing the direction of the arrow.

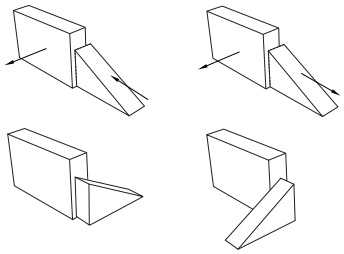

Figure 2: The result of applying a parallel face position constraint and the effect of changing the direction of the arrow normal to the selected face of the movable instance.

Abaqus/CAE rotates the movable instance until the two selected faces are parallel and the arrows are pointing in the same direction.

The faces you select from the movable and fixed instances must be planar. The parallel face position constraint can be applied only to three-dimensional instances.

Face to Face

A face-to-face position constraint is similar to a parallel face position constraint except that you define the clearance between the parallel faces. The clearance is measured between the two selected faces, positive along the normal to the fixed instance. Other than this clearance, the precise location of the movable instance is not constrained. Assuming that you selected the same two faces shown in *Figure 1*, the effect of applying a face-to-face constraint is shown in *Figure 3*. *Figure 3* also illustrates the effect on the movable instance of reversing the direction of the arrow normal to its selected face.

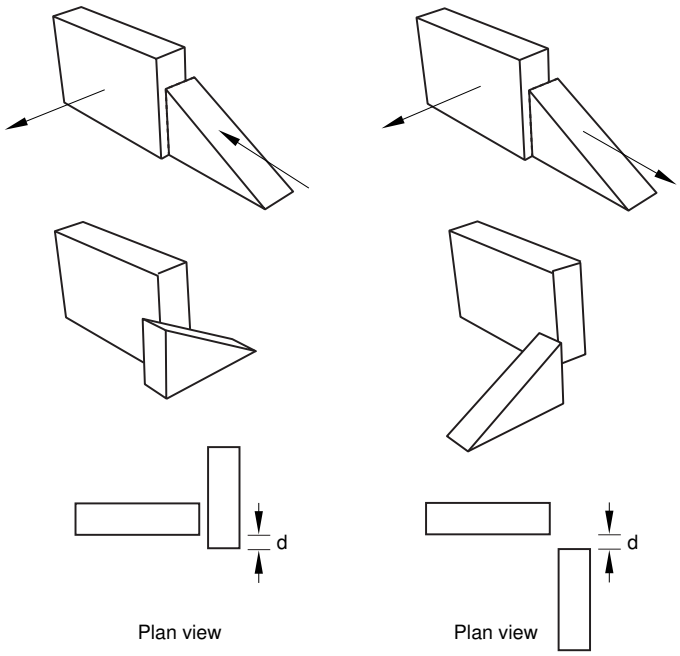

Figure 3: The result of applying a face-to-face constraint and the effect of changing the direction of the arrow normal to the selected face of the movable instance.

Abaqus/CAE rotates the movable instance until the two selected faces are parallel and the arrows point in the same direction. In addition, the movable instance is translated to satisfy the clearance specified. The faces you select from the movable and fixed instances must be planar. The face-to-face position constraint can be applied only to three-dimensional instances.

Parallel Edge

A parallel edge position constraint causes a selected edge of the movable instance to become parallel with a selected edge of the fixed instance. However, the position constraint does not specify the precise location of the movable instance, and the distance between the parallel edges is arbitrary. To apply a parallel edge position constraint between two instances, you do the following:

- Select the edges to be constrained to be parallel from the movable and fixed instance, as shown in *Figure 4*.

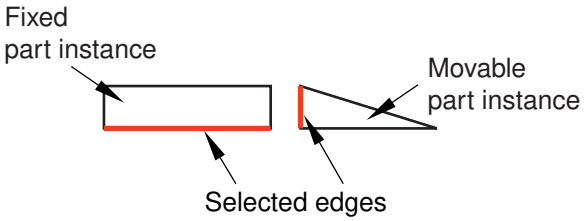

Figure 4: Select the edges to become parallel.

- Abaqus/CAE displays arrows along the selected edges. You prescribe the orientation of the movable instance by selecting the direction of the arrow along its selected edge. *Figure 5* illustrates the result of applying the position constraint and the effect on the movable instance of reversing the direction of the arrow.

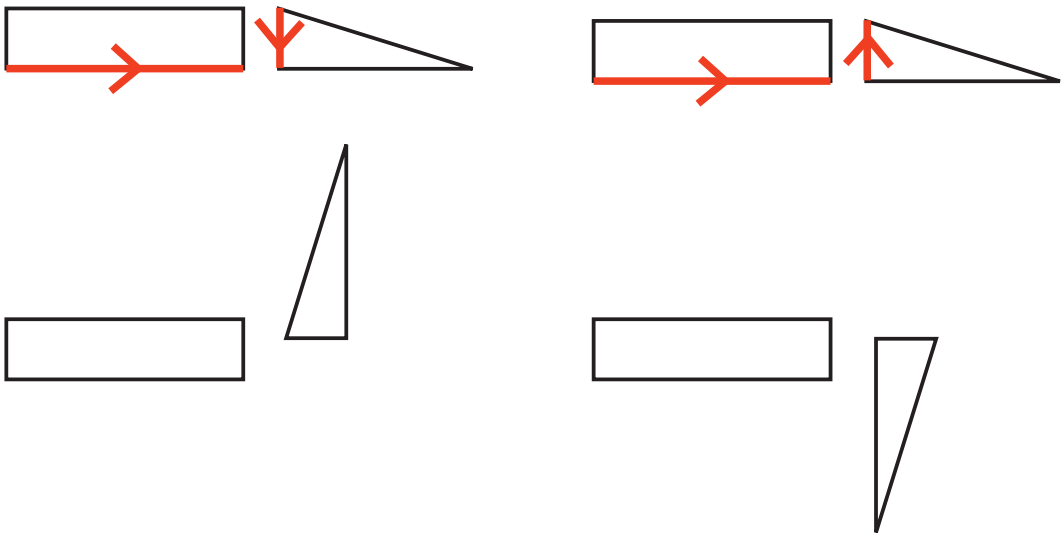

Figure 5: The result of applying a parallel edge constraint and the effect of changing the direction of the arrow along the selected edge of the movable instance.

Abaqus/CAE rotates the movable instance until the two selected edges are parallel and the arrows point in the same direction.

The edges you select from the movable and fixed instances must be straight. You can select an edge from an instance, or you can select a datum axis or one of the axes of a datum coordinate system. The parallel edge position constraint can be applied only to two-dimensional and three-dimensional instances. It has no effect on axisymmetric instances.

Edge to Edge

An edge-to-edge position constraint is similar to a parallel edge position constraint except that the clearance between the parallel edges is defined by the constraint. Assuming that you selected the same two edges shown in *Figure 4*, the effect of applying an edge-to edge position constraint to a two-dimensional assembly is shown in *Figure 6*. *Figure 6* also illustrates the effect on the movable instance of reversing the direction of the arrow along its selected edge.

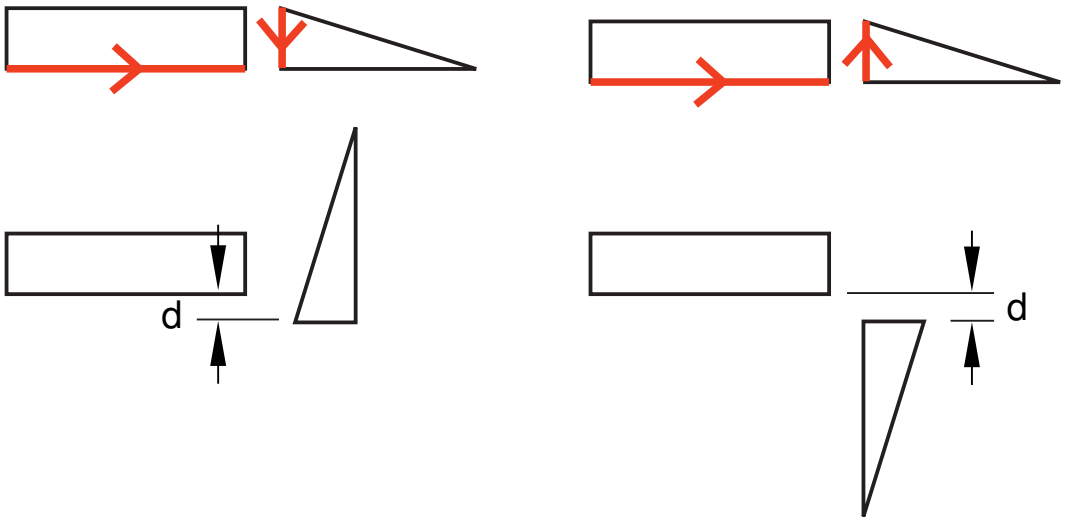

Figure 6: The result of applying an edge-to-edge constraint and the effect of changing the direction of the arrow along the selected edge of the movable instance.

The modeling space of the assembly determines the behavior of Abaqus/CAE after you apply an edge-to-edge position constraint.

- If the assembly is three-dimensional, Abaqus/CAE positions the movable instance so that the edges are coincident.
- If the assembly is two-dimensional, you can specify the clearance between the selected edges. The clearance is measured between the two selected edges, positive along the normal to the fixed instance.

Other than this behavior, the precise location of the movable instance is not constrained. The edge-to-edge position constraint can be applied to two-dimensional, three-dimensional, and axisymmetric instances.

Coaxial

A coaxial position constraint causes a selected cylindrical or conical face of the movable instance to become coaxial with a selected cylindrical or conical face of the fixed instance. However, the coaxial position constraint does not constrain the precise location of the movable instance. To apply a coaxial position constraint between two instances, you do the following:

- Select the cylindrical or conical faces to be constrained to be coaxial from the movable and fixed instance, as shown in *Figure 7*.

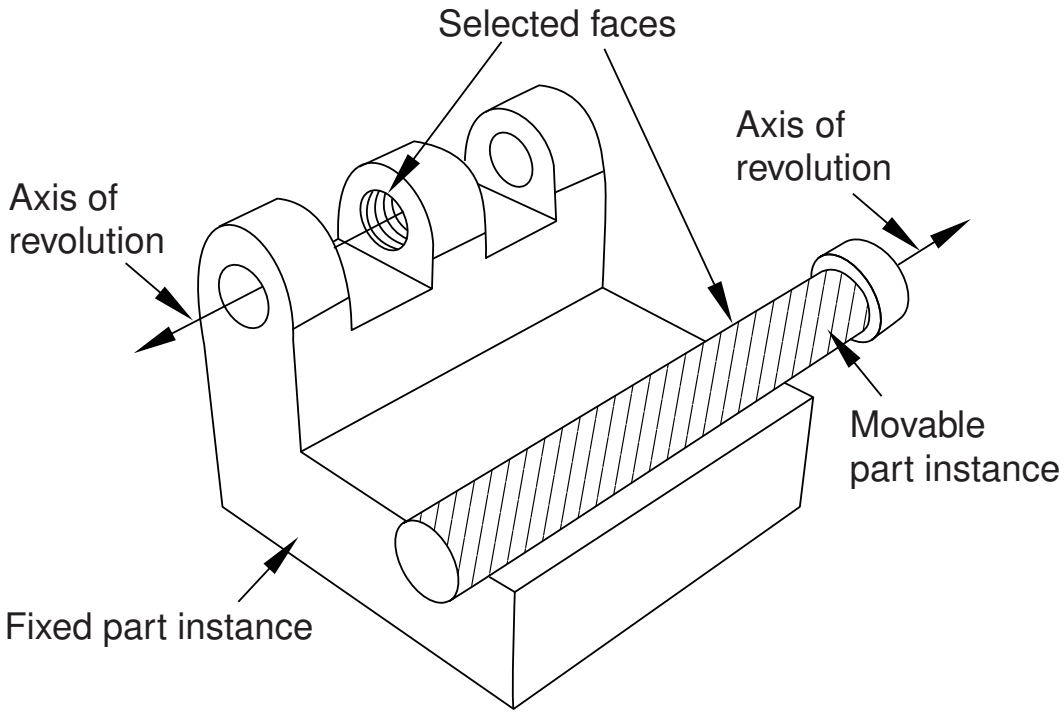

Figure 7: Select the faces to become coaxial.

- Abaqus/CAE displays arrows along the axis of revolution of the selected instances. You prescribe the orientation of the movable instance by selecting the direction of the arrow along its axis of revolution. *Figure 8* illustrates the result of applying the coaxial position constraint.

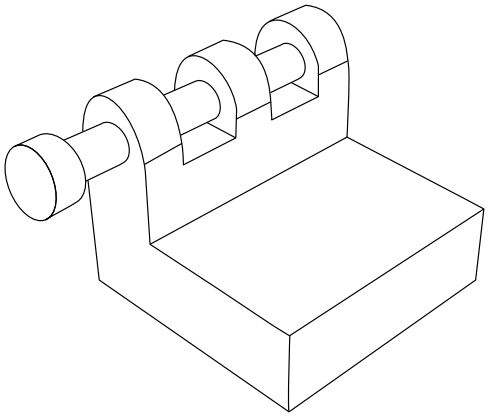

Figure 8: The effect of applying a coaxial constraint.

Abaqus/CAE rotates and translates the movable instance until the two selected faces are coaxial and the arrows are pointing in the same direction. The coaxial position constraint can be applied only to three-dimensional instances.

Coincident Point

A coincident point constraint causes a selected point on the movable instance to coincide with a selected point on the fixed instance. However, the coincident point constraint does not constrain the orientation of the movable

instance. The orientation of the movable instance does not change after the constraint is applied, as shown in *Figure 9*. For detailed instructions, see *Constraining two instances with coincident points*.

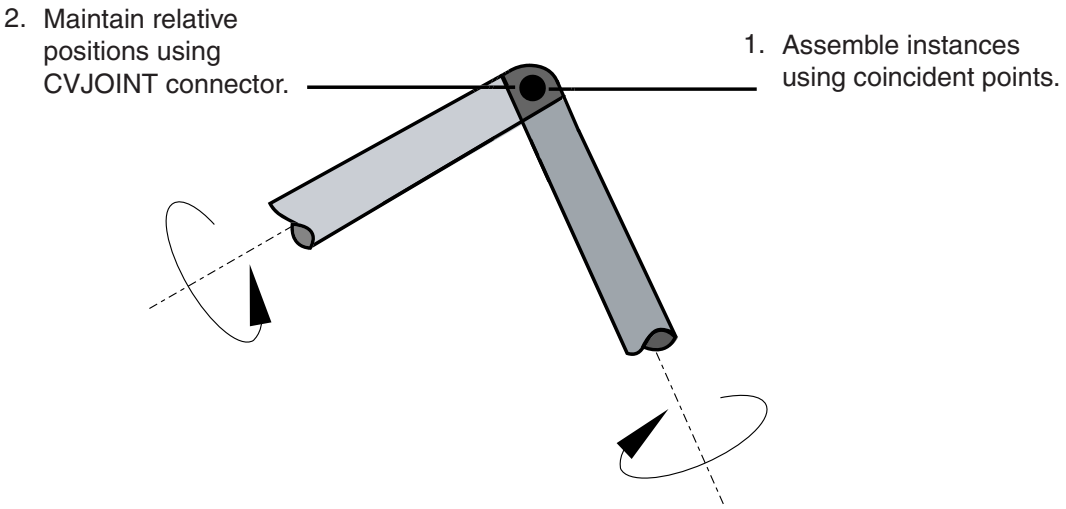

Figure 9: The effect of applying a coincident point constraint.

Parallel CSYS

A parallel coordinate systems constraint causes the axes of a datum coordinate system on the movable instance to become parallel with the axes of a datum coordinate system on the fixed instance. However, the parallel coordinate systems constraint does not specify the precise location of the movable instance. *Figure 10* illustrates the effect of applying a parallel coordinate systems constraint and a coincident point constraint to two instances.

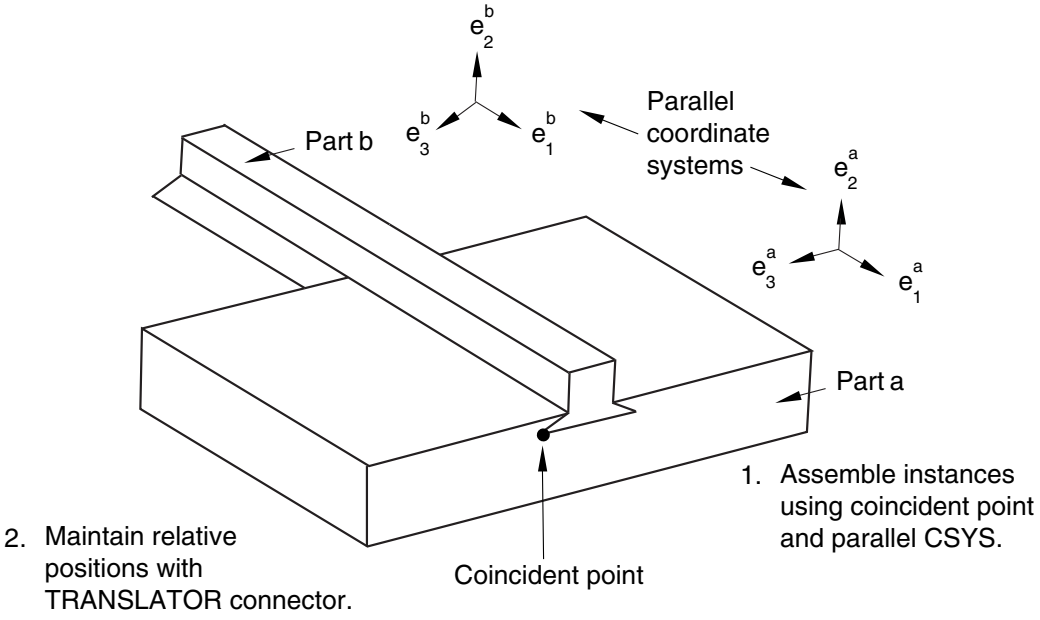

Figure 10: The effect of applying parallel coordinate systems and coincident point constraints.

The coordinate systems can be either rectangular (*X*-, *Y*-, and *Z*-axes), cylindrical (*R*-, θ-, and *Z*-axes), or spherical (*R*-, θ-, and ϕ-axes). For detailed instructions, see *Constraining two instances with parallel coordinate systems*.

You can use datums to position part and model instances. When you are prompted to select a face, you can also select a datum plane. When you are prompted to select an edge, you can also select a datum axis or one of the axes of a datum coordinate system. You can select a datum that you created in the Part module because the datum is associated with an instance of the part and moves with the part instance. However, if the position constraint uses a datum that you created in the Assembly module by selecting from a part instance (such as a face of a part instance), Abaqus/CAE changes its regeneration behavior and regenerates features in the order that you created them. For more information, see *How are position constraints regenerated?*. You cannot select a datum as the movable part instance if you created the datum in the Assembly module and it depends on more than one part instance; for example, a datum axis that runs through vertices of two part instances.

How conflicts can arise between position constraints, translations, and rotations

In some situations attempting to apply a position constraint results in a conflict with existing position constraints. If that is the case, Abaqus/CAE displays an error message, and you can either apply a different position constraint or use the Feature Manipulation toolset to modify the existing position constraints.

Similarly, attempting to translate or rotate a part or model instance may result in a conflict with existing position constraints. If a conflict occurs, Abaqus/CAE does the following:

Translation

Abaqus/CAE applies the components of translation only along the unconstrained degrees of freedom. If all of the degrees of freedom are constrained, Abaqus/CAE displays an error message and the translation fails.

Rotation

Abaqus/CAE displays an error message, and the rotation fails.

If you experience conflicts with an existing position constraint, you can remove all the existing position constraints without changing the position of the instances by using **Instance->Convert Constraints**. You can then apply the new position constraint, translation, or rotation. You cannot restore position constraints that were removed. Alternatively, you can delete a position constraint, and Abaqus/CAE will move the instance back to its original position.

Positioning a part or model instance using the Translate To tool

The **Translate To** tool positions two part or model instances by translating one instance along a user-defined vector defining the direction of motion until selected faces or edges of the movable instance are separated by a specified distance from selected faces or edges of the fixed instance.

When you use the **Translate To** tool to position instances in three-dimensional modeling space, you select faces to come into contact; for instances in two-dimensional or axisymmetric modeling space, you select edges to come into contact. In addition, when you use the **Translate To** tool to position axisymmetric instances, the translation vector must be parallel to the axis of revolution.

When you use the **Translate To** positioning tool, you can select more than one face or edge from both the fixed and the movable instances. Selecting multiple faces or edges is useful if you are not sure what part of the model will come in contact when the movable instance moves along the selected vector. However, for faster processing you should select as few faces or edges as possible.

To translate a movable part or model instance to a fixed instance, you do the following:

- Select faces or edges from the instance that will move and from the instance that will remain stationary.
- Prescribe the motion of the movable instance by defining a translation vector. *Figure 1* illustrates the selected edges and translation vector.

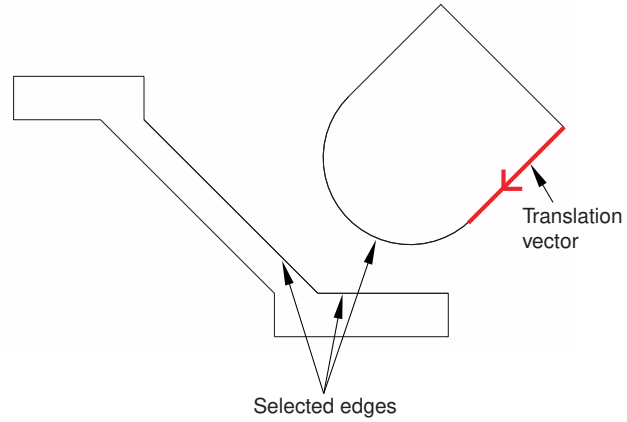

Figure 1: Select the edges to contact, and define the translation vector.

- Define the desired clearance between the selected faces or edges. *Figure 2* shows the effect of the contact constraint after specifying a clearance value of zero and a clearance value of *d*.

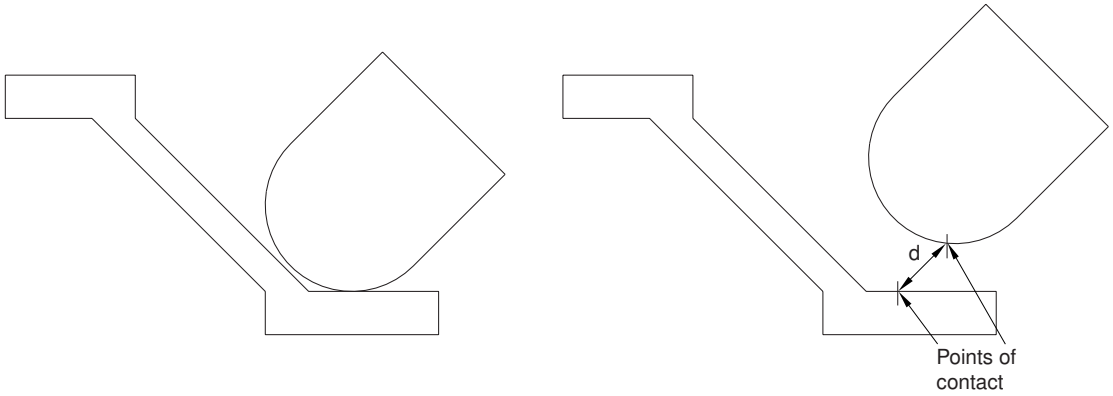

Figure 2: The effect of applying a contact constraint and specifying clearance values of zero and *d*.

To measure the clearance *d*, Abaqus/CAE first moves the instance along the translation vector until any pair of selected faces or edges come into contact. Abaqus/CAE then moves the instance along the translation vector a distance specified by the clearance value. The clearance can be zero or a positive or negative number; a negative value for the clearance results in overclosure between the selected faces or edges. When you use the **Translate To** tool, Abaqus/CAE calculates the position of the movable instance within a tolerance based on its size. If you want to avoid any possibility of overclosure, you should specify a small clearance value, rather than simply specifying zero.

Abaqus/CAE displays an error message and does not move the instance if contact between the selected faces or edges is not possible along the translation vector.

Even though you translate the movable instances until contact occurs with a fixed instance, the physical proximity of the selected surfaces is not enough to indicate any type of interaction between them. You must use the Interaction module to specify mechanical contact between surfaces. The **Translate To** positioning tool is satisfied only within a tolerance based on the size of your model. As a result, contact may not be precise unless it is applied between two planar surfaces.

Abaqus/CAE approximates a curved face with a set of faceted faces. Likewise, Abaqus/CAE approximates a curved edge with a set of faceted edges. The number of facets depends on the degree of curve refinement that you specified when creating the part in the Part module. Use the box zoom tool  to view the faceting applied to curved faces or edges in the assembly. When you are translating curved faces or curved edges, Abaqus/CAE computes the contact position using this faceted representation. You may wish to set the curve refinement to a finer setting based on the curvature of faces or edges that you know will be coming into contact. For more information, see *Controlling curve refinement*.

Replacing an instance

You can replace a part/model instance with an instance of a second part/model. To be precise, you are replacing the part/model from which the part/model instance is created. Abaqus/CAE positions the new instance such that its origin is located at the origin of the original instance and their axes align. In addition, you can choose whether the new instance inherits all the constraints from the instance it replaced.

The replace operation does not change the attributes of the instance. For example, if the original instance is dependent, the instance that replaces it will also be dependent. As a result, if an independent instance of a part exists, you cannot use the replace procedure to create a dependent instance of the same part.

Replacing an instance is useful when you are replacing an instance with one that has similar geometry. For example, the new instance might have additional detail that was not present in the original instance. You can also replace a geometry-based part with a mesh representation of the same part. For example, you could replace a part with the mesh representation of the deformed part imported from an output database.

Creating patterns of instances

You can create multiple copies of a selected instance in either a linear or radial pattern. You can specify the number of instances to create and the structure of the pattern, as described below.

Linear pattern

A linear pattern positions the new instances linearly along a direction; for example, the *X*-direction. The origin of the selected instance and the origins of the new instances lie on the line specified by the direction. You can specify the number of instances and the spacing between the instances. In addition, you can change the orientation of the linear pattern by selecting a line from the assembly that represents the new direction.

You can create a matrix of copied instances by creating copies in a second direction; for example, the *Y*-direction. The options are the same as for the first direction; you can control the number of copies, the spacing, and the orientation. By default, the first direction is the *X*-axis and the second direction is the *Y*-axis. For example, *Figure 1* illustrates how a part instance can be patterned in both the *X*- and *Y*-axes.

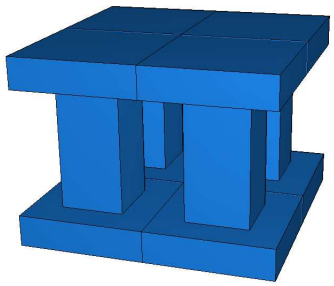

Figure 1: Instances patterned in two linear directions.

Radial pattern

A radial pattern positions the new instances in a circular pattern. You can specify the number of instances, and you can specify the angle between the first and last copy, where a positive angle corresponds to a counterclockwise direction. For example, *Figure 2* illustrates a radial pattern of the same instances that appear in *Figure 1*.

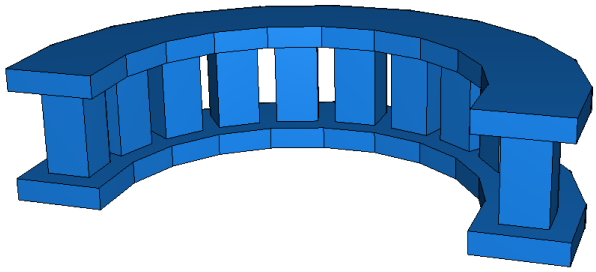

Figure 2: A radial pattern of instances.

By default, Abaqus/CAE creates the radial pattern about the *Z*-axis. Alternatively, you can select a line from the assembly that defines the axis of the circular pattern.

If you create a pattern of instances that are touching and you want to treat the pattern as a single part, you must use the **Merge/Cut** tool to merge all of the part instances in the pattern into a single part instance. For example, the instances

in the radial pattern illustrated in *Figure 2* overlapped each other and have been merged into a single part instance. For more information, see *Performing Boolean operations on part instances*. If you do not merge the part instances, the pattern may include duplicate faces or nodes where the instances touch.

If a part contains part-level sets or surfaces, Abaqus/CAE creates separate assembly-level sets and surfaces for each individual instance in a pattern (see *How do part sets and assembly sets differ?*, for further discussion of part- and assembly-level sets and surfaces). For example, if the top face of the original part in *Figure 1* and *Figure 2* is included in a part-level surface, Abaqus/CAE initially creates individual assembly-level surfaces for the top face of each instance in the patterned assembly. It is often helpful to merge these repeated sets and surfaces into a single set or surface. When you merge patterned part instances, Abaqus/CAE also merges any repeated sets or repeated surfaces into a single set or surface on the merged part and part instance. If you do not merge the patterned part instances, you can still merge sets or surfaces using the **Boolean** option in the Model Tree (see *Performing Boolean operations on sets or surfaces*, for instructions).

You will find it more convenient to use dependent instances when you create a linear or radial pattern of instances. When you mesh the original part, Abaqus/CAE applies the same mesh to each instance in the pattern. In contrast, if you create a pattern of independent instances, you must mesh each instance individually. For more information, see *What is the difference between a dependent and an independent part instance?*.

Performing Boolean operations on part instances

This section describes how you merge and cut part instances.

You can select instances of parts that you created using Abaqus/CAE and merge them into a single instance.In addition, you can cut away the geometric portion of a part instance using the geometric portion of other part instances to make the cut. You can also merge instances of parts containing both geometry and orphan elements.

In this section:

- *Merging and cutting part instances*
- *Merging and cutting independent and dependent part instances*

Merging and cutting part instances

Select **Instance**->**Merge/Cut** from the main menu bar to merge multiple instances of parts. The parts to be merged can contain any combination of geometry and orphan mesh nodes and elements; and there are options for merging the geometry, the mesh (orphan and native), or both. In addition, you can cut the geometric portion of a part instance using the geometric portion of one or more part instances to make the cut. Both merge and cut operations create a new part instance and a new part. When you merge or cut part instances, you can choose to suppress or delete the original part instances. The merge and cut operations are described in more detail below.

Merge

You can select multiple part instances and merge them into a single part instance. For example, *Figure 1* shows two part instances that model a 15-pin connector. The two part instances are positioned along a common face and then merged into a single part instance that can be meshed and analyzed.

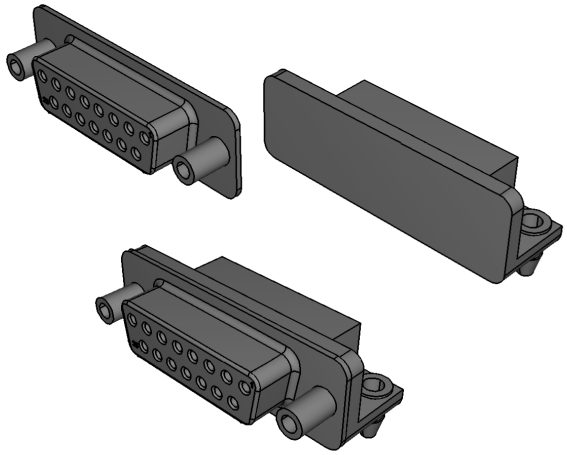

Figure 1: Two part instances merged into a single part instance.

You can merge part instances even if the instances are not touching or overlapping. You can choose whether to remove or retain the intersecting boundaries between the merged part instances, as shown in *Figure 2*. If desired, you can use the **Part Copy** dialog box to create a mirror image of a part about one of the three principal planes. For more information, see *Copying a part*.

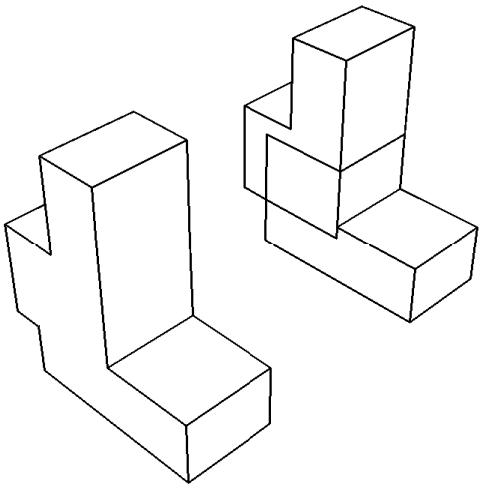

Figure 2: The effect of removing and retaining intersecting boundaries.

If you merge meshes, you can specify the **Node merging tolerance**, which is the maximum distance between nodes that will be merged. Abaqus/CAE creates a compatible mesh by deleting nodes that are closer than the specified distance and replacing them with a single new node. The location of the new node is the average position of the deleted nodes. If the value that you entered for the **Node merging tolerance** is too large, Abaqus/CAE may detect duplicate nodes from the same element. Abaqus/CAE will not merge nodes from the same element. However, the large tolerance can result in a distorted mesh, and Abaqus/CAE asks if you want to continue or end the merging procedure. If no nodes are closer than the specified distance, Abaqus/CAE asks if you want to cancel the procedure or to create a single instance from the selected instances.

When you merge meshed part instances that intersect, you can choose whether to create duplicate elements as well as duplicate nodes. A duplicate element has the same connectivity as another element. By default, Abaqus/CAE deletes duplicate elements, and in most cases you should accept the default behavior. However, you must retain duplicate elements if you want to model a material with a combination of material properties that are not supported by Abaqus, as described in the discussion of stability in *No Compression or No Tension*.

You can choose between the following methods for merging the nodes:

Boundary only

By default, Abaqus/CAE merges the meshed part instances only along their boundaries (defined by free faces for three-dimensional instances and by free edges for two-dimensional instances). Free faces and edges are those faces and edges that belong to only one geometric entity or element. Using this setting, Abaqus/CAE does not check for duplicate nodes in the interior of the parts, which speeds up the merging process. You should retain this default setting if three-dimensional part instances intersect at only a common face or if two-dimensional instances intersect at only a common edge.

All

If the part instances overlap, you may want to merge all the nodes in the selected part instances.

None

Alternatively, you can choose to merge none of the nodes, in which case Abaqus/CAE merges the part instances into a single instance but retains all the original nodes.

In many cases you will be merging part instances that do not intersect but share a common face; for example, the two part instances shown in *Figure 3*.

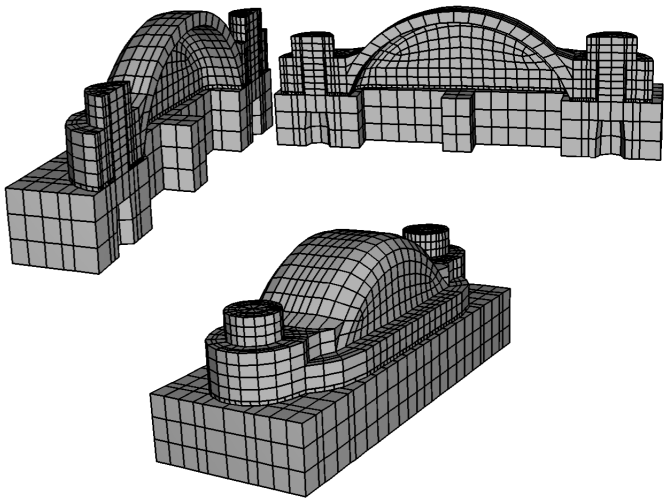

Figure 3: Two meshed part instances merged into a single meshed part instance.

You can also merge selected nodes of a meshed part using the Edit Mesh toolset; for more information, see *Manipulating nodes*.

Although the resulting merged mesh may appear acceptable in the viewport, the mesh may contain small gaps between a node and an element face that are not readily apparent. The mesh may also contain merged faces that have an incompatible mesh pattern. You can use the **Mesh gaps/intersections** tool in the Query toolset to check for small gaps and incompatible faces. For more information, see *Obtaining general information about the model*.

When you merge part instances, any sets or surfaces on the original parts and part instances are mapped to the new part and part instance. If sets or surfaces from different parts have the same name, they are merged into a single set or surface on the merged part and part instance. If you choose to remove intersecting boundaries between the merged part instances, portions of sets or surfaces that lie on those boundary edges and faces are removed from the mapped sets and surfaces.

Section assignments from the original parts are also mapped to the new part. If parts in the original assembly intersect, Abaqus/CAE can map only a single section in the intersecting regions. Similarly, if parts are exactly touching or intersecting and the intersecting boundaries are removed during the merge, Abaqus/CAE maps only a single section to the entire merged part. In these intersecting situations, the section that gets mapped is dependent on a variety of factors and may not match your modeling intent. When merging intersecting regions, you should retain the intersecting boundaries; the boundaries preserve the original section assignments in nonintersecting regions and make it easier to modify mapped section assignments if necessary (for details, see *Managing section assignments*).

Note:

Beam section assignments and rebar reference orientations are not mapped to the merged part. You must recreate them and any associated properties after the merge.

You might want to merge part instances for the following reasons:

- If geometry in separate instances touches or overlaps but you do not merge the instances, Abaqus/CAE creates a separate mesh for each instance and you must apply tie constraints to effectively merge the nodes. In contrast, when you merge part instances, Abaqus/CAE creates a single combined mesh and you do not need to apply computationally expensive tie constraints. In effect, you have created a compatible mesh between

the part instances. If you want to retain the concept of separate part instances, you can create partitions at the common interface of the merged instances.

- Merging part instances allows you to assign material properties to the single part created by the merge operation instead of to each part individually.
- You can apply a display body constraint to a group of merged part instances instead of applying the constraint to each part instance individually.
- When you import a complex assembly, the assembly may appear in Abaqus/CAE as a large number of individual part instances that will be meshed individually. You can merge all the part instances into a single part instance, or you can merge groups of part instances into several separate part instances.

You have the following three options when merging part instances:

Geometry

Merge only the geometry. Any orphan mesh portions of the instances being merged are deleted from the merged part and part instance.

Mesh

Merge all native and orphan mesh components. Any geometry of the instances being merged is deleted from the merged part and part instance. The native mesh portion of the original parts becomes part of the orphan mesh in the new part.

Both

Merge both the geometry and the orphan mesh. Any native meshes are deleted in the process of merging the geometry.

Cut

You can select the geometric portion of a single part instance to be cut, and then you can select the geometry of one or more part instances that are touching or overlapping the part instance to be cut. Abaqus/CAE uses the geometry that will make the cut (the die) to cut away from the geometry of the instance to be cut (the blank). Geometry must touch or overlap to create a cut part and part instance. If the part instance being cut includes orphan mesh elements, they are unaffected by the cut operation.

When you cut a part instance, sets, surfaces, and section assignments from the original part and part instance are mapped to the new part and part instance. Portions of original sets and surfaces that lie within cut portions of the original geometry are removed from the mapped sets and surfaces.

The cut operation is useful if you want to create a mold from a part or vice versa. *Figure 4* shows a bottle and a rectangular blank and how the cut process creates the mold.

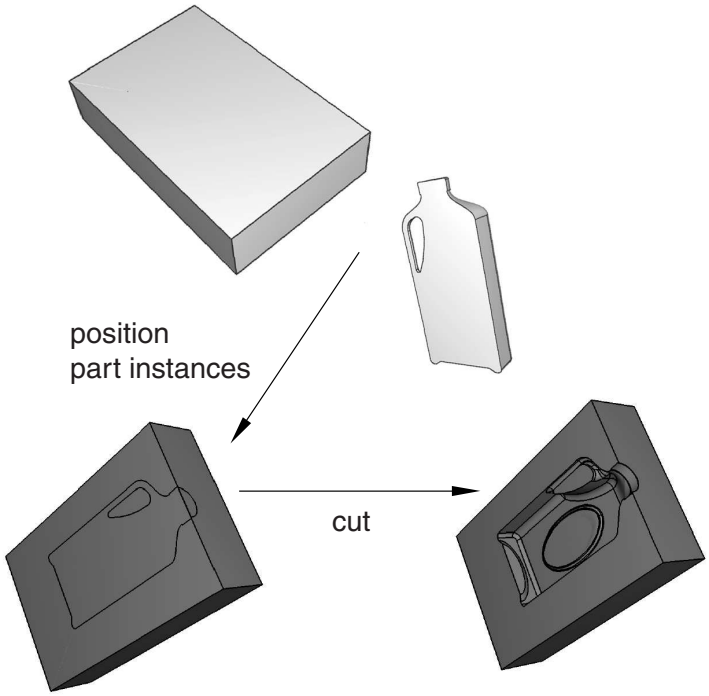

Figure 4: A mold created from a blank and a die using the cut operation.

You cannot make a cut with a shell part instance. Therefore, before the cut operation was performed, the bottle was converted from a shell to a solid part in the Part module. For more information, see *Creating a solid feature from a shell*. In addition, the original part instances (the blank and the die) were suppressed after the cut operation. The cut operation is also useful for modeling a structure and an acoustic medium when you are performing an acoustic or shock analysis.

Note:

You cannot merge or cut part instances that contain virtual topology. When you merge part instances, composite layups and material orientation of the original part are not mapped to the merged part.

For detailed instructions, see *Merging or cutting part instances*.

Merging and cutting independent and dependent part instances

Merging selected part instances results in a new part instance and a new part. If you merge independent part instances, the resulting part instance is also independent. Similarly, if you merge dependent part instances, the resulting part instance is also dependent. Finally, if you merge a combination of independent and dependent part instances, the resulting part instance is dependent.

When you merge the meshes of meshed geometry and/or orphan mesh elements, the resulting part instance is always an orphan mesh part and it is always dependent. When you merge both the meshes and geometry of parts containing geometry and orphan mesh nodes and elements, the resulting part instance is a hybrid containing geometry and orphan nodes and elements, and it is always dependent.

Cutting the geometry of selected part instances also results in a new part instance and a new part. The discussion of merging the geometry of independent and dependent part instances applies to cutting the geometry of independent and dependent part instances; however, orphan mesh elements within a part instance cannot be cut or used to cut the geometry of another instance.

Understanding toolsets in the Assembly module

The Assembly module provides several toolsets that allow you to modify the features that define the assembly. This section describes how these toolsets are used within the Assembly module.

For more detailed information about each toolset, refer to:

- *The Datum toolset*
- *The Feature Manipulation toolset*
- *The Partition toolset*
- *The Query toolset*
- *The Reference Point toolset*
- *The Set and Surface toolsets*

The Display Group toolset is discussed in *Using display groups to display subsets of your model*.

In this section:

- *Using datum geometry in the Assembly module*
- *Manipulating features in the Assembly module*
- *Partitioning the assembly*
- *Querying the assembly*
- *Creating reference points*
- *Using sets and surfaces in the Assembly module*

Using datum geometry in the Assembly module

Within the Assembly module, you use the Datum toolset to provide additional reference geometry (vertices, edges, and surfaces) that is not provided by the assembly. You use the reference geometry to help you define position constraints and to position part or model instances. For example, you can use a datum plane when creating a parallel face or face-to-face constraint if the desired surface does not exist. Similarly, you can use a datum axis when creating a parallel edge or edge-to-edge constraint if the desired edge does not exist. A datum is a parent feature of any constraint in which it was selected. Datums do not modify the geometry of a part or model instance; as a result, you can create datums that refer to both independent and dependent part instances.

Datum geometry that you create in the Part module is transferred along with the rest of the part's geometry when you create a part instance in the Assembly module. In addition, when you translate and rotate a part instance in the Assembly module, a datum created in the Part module is translated and rotated along with the instance. In contrast, a datum created in the Assembly module follows only the reference points that were used to create the datum. As a result if you translate and rotate a part instance, the behavior of the datum may not reflect your design intent. If you know that a datum should be associated with a part, you should create the datum in the Part module.

Figure 1 illustrates a model in which a deformable curved shell will be compressed between two rigid surfaces.

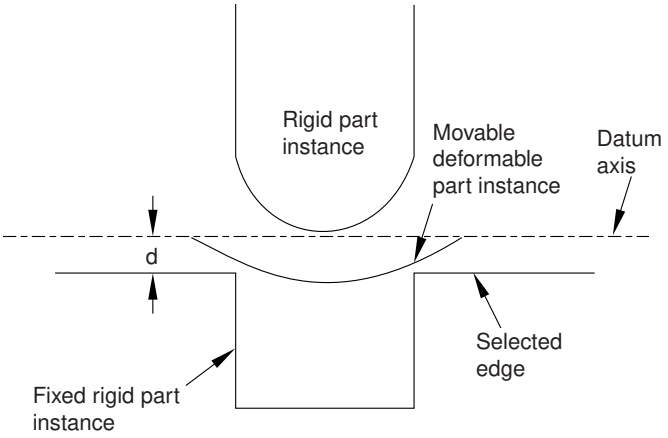

Figure 1: An edge-to-edge constraint applied between a datum axis and a selected edge.

The shell is positioned easily by applying an edge-to-edge position constraint between a selected edge of the lower rigid surface (the fixed part instance) and a datum axis associated with the shell (the movable part instance). The datum axis was created with the deformable part in the Part module and moves along with the movable part instance when the position constraint is applied. In contrast, *Figure 2* illustrates an edge-to-edge position constraint applied between three movable part instances and a fixed datum axis that provides reference geometry. In this example the datum axis was created along the *X*-axis of the assembly and is not associated with any part instance. Applying three edge-to-edge position constraints, one to each of the three part instances shown, would result in alignment of the three instances along the datum axis.

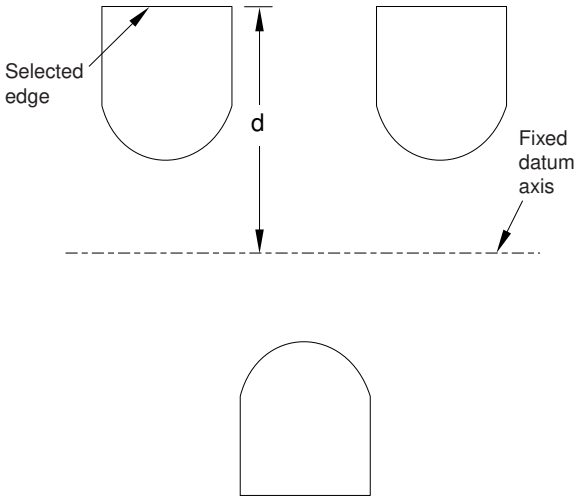

Figure 2: Edge-to-edge constraints applied between multiple parts and a fixed datum axis.

A datum is a feature of the assembly and is regenerated along with the rest of the assembly. You can make datum geometry invisible while still retaining it in the assembly by selecting **View->Assembly Display Options** from the main menu bar. For more information, see *Controlling datum display*.

The triad indicating the origin and the orientation of the global coordinate system is a datum coordinate system created by the Assembly module. You can suppress or delete it, but you cannot modify it.

Additional information

- *Understanding toolsets in the Assembly module*
- *The Datum toolset*

Manipulating features in the Assembly module

Along with datum geometry and partitions, part instances, model instances, and position constraints are considered to be features of the assembly and appear in the list of features in the Model Tree.

Part instances

You can suppress, resume, and delete part instances. You can partition a part instance, but you cannot edit its shape or its features. To modify a part instance, you must edit the original part in the Part module; Abaqus/CAE automatically regenerates instances of a modified part when you return to the Assembly module.

You can make a part instance invisible while still retaining it in the assembly by selecting **View->Assembly Display Options->Instance** from the main menu bar. For more information, see *Controlling instance visibility*. This technique is not the same as suppressing a part instance; a suppressed part instance is removed from the assembly until you resume it. You can also use display groups to make part instances invisible; for more information, see *Using display groups to display subsets of your model*.

You can link part instances, and you can exclude part instances from an analysis; for more information, see *Linking part instances between models* and *Excluding part instances from an analysis*.

Model instances

You can suppress, resume, and delete model instances. To modify a model instance, you must edit the original model's assembly.

You can make a model instance invisible while still retaining it in the assembly by selecting **View->Assembly Display Options->Instance** from the main menu bar. You can also use display groups to make model instances invisible.

Position constraints

You can edit, suppress, resume, and delete position constraints. You can modify the following parameters of a position constraint:

- The direction of the arrow normal to the selected face or along the selected edge of the movable part instance.
- The clearance between the selected face or edge of the movable part instance and the selected face or edge of the fixed part instance. The clearance parameter applies only to face-to-face, edge-to-edge, and contact constraints.

Translations and rotations are not stored as features and cannot be edited, suppressed, resumed, or deleted.

You can use the Feature Manipulation toolset to modify features of the assembly. When you are prompted to select a feature to modify, you can select a visible feature such as a part instance, a datum, or a partition from the viewport. However, to select a position constraint, you must select it from the Model Tree.

The following feature manipulation tools are available from the Feature Manipulation toolset:

Edit

When you edit a feature, Abaqus/CAE displays the **Edit Feature** dialog box and you can modify the feature's parameters or the sketch that defined the feature. You cannot edit part instances; you must return to the Part module to modify the original part.

Regenerate

When you modify features in a complex assembly, it may be convenient to postpone regeneration until you make all your changes, since regeneration can be time consuming. Select **Feature->Regenerate** when you are ready to regenerate the assembly.

Rename

Rename a feature.

Suppress

Suppressing a feature temporarily removes it from the definition of the assembly. A suppressed feature is invisible, cannot be meshed, and is not included in the analysis of the model. Suppressing a parent feature will suppress all of its child features.

Resume

Resuming a feature restores a suppressed feature to the assembly. You can choose to resume all features, the set of features most recently suppressed, or just a selected feature.

Delete

Deleting a feature removes it from the assembly; you cannot restore a deleted feature.

Query

When you query a feature, Abaqus/CAE displays information in the message area and writes the same information to the replay file (*abaqus*`.rpy`) in the form of comments.

Options

The **Feature Options** dialog box allows you to control whether Abaqus/CAE performs self-intersection checks and enables you to prioritize the regeneration of constraint features over other assembly features.

For a more detailed explanation of the Feature Manipulation toolset, see *The Feature Manipulation toolset*.

Additional information

- *Understanding toolsets in the Assembly module*
- *The Feature Manipulation toolset*

Partitioning the assembly

Within the Assembly module, you can use the Partition toolset to partition the assembly into additional regions. You can use vertices, edges, and faces from one part instance to create a partition that divides a second part instance; for example, you might use the **Extend Face** method to partition a cell by extending a face of one part instance into a second part instance. Partitions cannot span part instances.

A partition in the assembly appears in every module that operates on the assembly. Partitions you create in the Part module are transferred along with the rest of the part's geometry when you create a part instance in the Assembly module. Partitions are features of the assembly, and they are regenerated along with the rest of the assembly. You cannot turn off the display of partitions. Partitions modify the geometry of a part instance; as a result, you cannot partition a dependent part instance.

The Partition toolset is not supported and cannot be used with model instances.

Additional information

- *Understanding toolsets in the Assembly module*
- *The Partition toolset*

Querying the assembly

You can use the Query toolset to request either general information or module-specific information. For a discussion of the information displayed by general queries, see *Obtaining general information about the model*.

In addition, you can use the Assembly module-specific queries to determine the following attributes of a part instance or a model instance:

- Name, type, and modeling space
- Origin
- The sum of the translations and rotations applied to the instance

For more information, see *Using the Query toolset to query the assembly*.

Creating reference points

From the main menu bar, select **Tools->Reference Point** to create a reference point on a part instance or a model instance. You can create multiple reference points on the assembly; Abaqus/CAE labels them **RP-1**, **RP-2**, **RP-3**, etc. For more information, see *The Reference Point toolset*.

Abaqus/CAE displays the reference point at the desired location along with its label. You can change the reference point label by clicking mouse button 3 on the feature in the Model Tree and selecting **Rename** from the menu that appears. If desired, you can turn off the display of the reference point symbol and the reference point label; for more information, see *Controlling reference point display*.

Using sets and surfaces in the Assembly module

Sets created by selecting geometry from the assembly are called assembly sets, and you use the Set toolset to create and manage assembly sets. For example, you can select an assembly set to indicate where loads, boundary conditions, and interactions are applied. You can also use assembly sets to define regions of the model from which Abaqus/CAE will generate output during the analysis; for example, selected vertices or faces. Assembly sets can include regions from multiple part instances.

In contrast, part sets are created by selecting geometry from a part in the Part module or the Property module. When you instance a part in the Assembly module, you can refer to any part sets that you previously created; however, Abaqus provides only read-only access to these part sets in assembly-related modules. In addition, you cannot access a part set from the **Set Manager** in assembly-related modules; however, you can select an eligible part set during a procedure by clicking the **Set** button and selecting the set from the **Region Selection** dialog box that appears. For more information, see *Understanding sets and surfaces*.

You create surfaces by selecting faces or edges from the assembly, and you use the Surface toolset to create and manage surfaces. Typically you select a surface when a procedure is expecting a face; for example, when you are applying distributed loads, such as pressure loads, and defining contact interactions. For more information, see *What is a surface?*.

For model instances, any sets or surfaces defined in the original model are brought into the model instances, maintaining the Model Tree hierarchy of features.

Additional information

- *Understanding toolsets in the Assembly module*
- *The Set and Surface toolsets*

Using the Assembly module toolbox

You can access all the Assembly module tools through either the main menu bar or through the Assembly module toolbox. *Figure 1* shows the hidden icons for all the Assembly module tools in the toolbox.

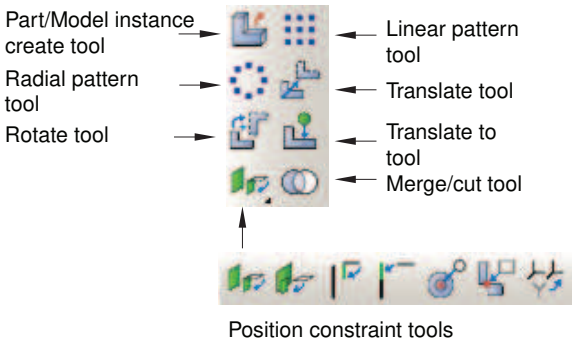

Figure 1: The Assembly module tools.

To see a tooltip containing a brief definition of an Assembly module tool, hold the mouse over the tool for a moment. For information on using toolboxes and selecting hidden icons, see *Using toolboxes and toolbars that contain hidden icons*.

Creating and manipulating part and model instances

This section describes how you use the Assembly module's **Instance** menu to create part and model instances and to position the instances relative to the global coordinate system.
You can also use the **Instance** menu to replace one part instance with another and to convert the constraints applied to a selected part instance to an absolute position. You can access additional functionality using the Model Tree.

In this section:

- *Using the Instance menu*
- *Using the Model Tree to manipulate part instances*
- *Using the Model Tree to switch the context for part or model instances*
- *Creating a part or model instance*
- *Creating a linear pattern of instances*
- *Creating a radial pattern of instances*
- *Translating part or model instances*
- *Translating a part or model instance to another instance*
- *Rotating part or model instances*
- *Replacing an instance*
- *Converting constraints*
- *Merging or cutting part instances*

Using the Instance menu

Use the **Instance** menu to do the following:

- *Create* instances of parts from the current model and add them to the assembly. You can also create instances of other models to add to the current assembly.
- Create a *linear pattern* of part instances.
- Create a *radial pattern* of part instances.
- *Translate* selected part or model instances along a specified vector.
- *Translate* selected part or model instances along a specified vector until they are a specified distance from another instance.
- *Rotate* selected part or model instances through a specified angle about a specified axis.
- *Replace* a part instance with a second part instance.
- *Convert* any position constraints to an absolute position.
- *Merge or cut* part instances.

You may find it more convenient to access the instance tools using the Assembly module toolbox. For a diagram of the tools in the Assembly toolbox, see *Using the Assembly module toolbox*.

Additional information

- *Using the Assembly module toolbox*
- *The Assembly module*

Using the Model Tree to manipulate part instances

You can access additional functionality for manipulating part instances using the Model Tree. After you select a part instance or multiple instances in the Model Tree, you can click mouse button 3 and select from the following options:

- To change a part instance from dependent to independent, select **Make Independent** from the menu that appears. Similarly, you can select **Make Dependent** from the menu to change a part instance from independent to dependent.
- To link part instances, select **Link Instances** from the menu that appears to display the **Link Instances** dialog box and do the following:

  1. For each child part instance, specify the model and part instance to which you want to link. By default, the dialog box displays all models in the model database other than the current model that have part instances with the same names as the selected instances. You can specify other values by clicking in the **Model** or **Instance** column of the table and selecting from the list of names displayed.
  2. If you want the child part instances excluded from the input file that Abaqus/CAE generates when you submit the job for analysis, toggle on **Also exclude child instances from simulation**.
  3. Click **Link**.

     Icons appear in the Model Tree to indicate the linked status of the part instances. By default, linked part instances are colored gray in the viewport.

  Similarly, you can select **Unlink Instances** from the menu to unlink part instances that were previously linked. For more information, see *Linking part instances between models*.
- To exclude part instances from the analysis, select **Exclude from Simulation** from the menu that appears. Icons appear in the Model Tree to indicate the excluded status of the part instance. By default, part instances that are excluded from the analysis are colored dark gray in the viewport. Similarly, you can select **Include in Simulation** from the menu to include a part instance in an analysis for which it was previously excluded. For more information, see *Excluding part instances from an analysis*.
- To ignore the invalid status of a part instance, select **Ignore Invalidity**. For more information, see *Working with invalid parts*.

Additional information

- *What is the difference between a dependent and an independent part instance?*
- *How do I decide whether to create a dependent or an independent part instance?*
- *Changing from a dependent to an independent part instance or vice versa*
- *Linking part instances between models*
- *Excluding part instances from an analysis*

Using the Model Tree to switch the context for part or model instances

You can use the Model Tree in the Assembly module or Mesh module to switch the context for part instances or for model instances and their child part instances.

In the Model Tree, select the instance for which you want to switch the context. If you select multiple instances, the context switches to the part or model for the first instance that you select. Click mouse button 3, and select **Switch to part/model context**. Abaqus/CAE switches the context as follows (depending on your selection):

- In the Assembly module, if you selected a part instance or a child part instance, the context switches to the Part module with the original part from which the instance was created displayed in the viewport.
- In the Mesh module, if you selected a part instance or a child part instance, the context switches to display the original part from which the instance was created in the viewport.
- If you selected a model instance, the context switches to display the original model from which the model instance was created in the viewport.

Additional information

- *Working with part instances*
- *Working with model instances*

Creating a part or model instance

To create a part or model instance, select **Instance->Create** from the main menu bar and select the desired part or model from the **Create Instance** dialog box that appears.
You can select from any of the existing parts in the current model or any of the existing models in the current model database. You can create multiple instances of the same part or model, but you cannot assemble instances of parts or models that were created in different modeling spaces (three-dimensional, two-dimensional, or axisymmetric).

When you create the first instance,Abaqus/CAE displays a graphic symbol indicating the origin and orientation of the assembly's global coordinate system. This symbol is a datum coordinate system. If desired, you can hide it using the assembly display options; for more information, see *Controlling datum display*.

By default, Abaqus/CAE creates dependent part instances. A dependent instance is only a pointer to the geometry of the original part. As a result, many operations are not allowed on a dependent part instance; for example, you cannot add partitions, create virtual topology, or mesh the instance. In contrast, an independent part instance is a copy of the geometry of the original part. You can perform most operations on an independent instance; for example, you can add partitions, create virtual topology, and mesh the instance. You cannot create both an independent and a dependent instance of the same part. You can select a part instance from the Model Tree and change it from independent to dependent or vice versa. For more information, see *What is the difference between a dependent and an independent part instance?*.

When you create an instance, by default Abaqus/CAE positions the instance so that the origin of the original geometry aligns with the origin of the assembly coordinate system. When you create multiple instances, a new instance can be positioned over an existing instance. However, if you toggle on **Auto-offset from other instances** in the **Create Instance** dialog box, Abaqus/CAE translates each new instance along the *X*–axis until it does not overlap any existing instances. If the assembly is axisymmetric, Abaqus/CAE translates the new instance along the axis of revolution instead of along the *X*–axis.

1. From the main menu bar, select **Instance->Create**.

   Abaqus/CAE displays the **Create Instance** dialog box.

   Tip: You can also create an instance using the  tool from the Assembly module toolbox. For a diagram of the tools in the Assembly toolbox, see *Using the Assembly module toolbox*.

2. Choose **Parts** or **Models**.

   Depending on your choice, the **Create Instance** dialog box shows you a list of all the existing parts in the current model or all the other models in the model database.

3. Choose the desired parts or models from the list. You can use a combination of **[Ctrl] + Click** and **[Shift] + Click** to select multiple items.

   A temporary image of the selected instances appears in the current viewport. Abaqus/CAE positions the temporary images so that their origins coincide with the origin of the global coordinate system.

4. By default, Abaqus/CAE creates **Dependent** part instances. If desired, toggle on **Independent** to create an independent part instance.
5. If desired, toggle on **Auto-offset from other instances** to offset the new instances.
6. **Optional:** Use the **Name** text field at the top of the dialog box to name the instance you are creating.

   - If you do not specify a name, a name is generated automatically.
   - If multiple parts are selected, the name you specify is applied to the first selection. The other instance names are appended with the suffix “-1,” “-2,” “-3,” etc.
   - If you enter an existing name, Abaqus/CAE issues a warning in the CLI and generates a name.

7. If you are satisfied that you have selected the correct instances, click **Apply**.

Abaqus/CAE creates the instances and applies an auto-offset if selected.

8. To create additional instances, repeat this procedure from Step 2. When you have finished creating instances, click **OK** to close the **Create Instance** dialog box.

Additional information

- *Using the Instance menu*
- *Working with part instances*
- *Working with model instances*

Creating a linear pattern of instances

To create multiple copies of a selected instance in a linear pattern, select **Instance->Linear Pattern** from the main menu bar. You can create a pattern that extends in one direction (for example, horizontally or vertically), or you can create a pattern that extends in two directions (for example, both horizontally and vertically). You cannot edit a pattern after you create it. You can specify the following:

- The number of instances to create in each direction, including the selected instance. You can create any number of instances.
- The spacing between each instance along the specified direction.
- A line that defines the direction along which Abaqus/CAE generates the instances.

For more information, see *Creating patterns of instances*.

1. From the main menu bar, select **Instance->Linear Pattern**.

   Tip: You can also create a linear pattern of instances using the tool from the Assembly module toolbox. For a diagram of the tools in the Assembly toolbox, see *Using the Assembly module toolbox*.

2. Select the instances that you want to copy.

   Tip: To select more than one instance, hold down the **[Shift]** key as you click each instance or drag a rectangle around the instances. To unselect an instance, use **[Ctrl] + Click**. For more information, see *Selecting objects within the viewport*.

3. Click mouse button 2 to indicate that you have finished selecting instances.

   Abaqus/CAE displays the **Linear Pattern** dialog box.

4. From the **Linear Pattern** dialog box, configure the pattern in **Direction-1** (by default, **Direction-1** is the *X*-direction):

   a. Click the arrows to the right of **Number** to increase or decrease the number of copies to create, including the selected instances. The number of copies in the assembly updates when you click the arrows and provides a preview of the setting.

      Alternatively, you can type in a number and press **[Enter]** to preview the setting. You can enter any number greater than or equal to 1. If you enter a value of 1, Abaqus/CAE displays only the selected instances and does not create any copies of the selected instances; in effect, you are disabling copies in **Direction-1**.

   b. Enter the **Spacing** between each copy along the specified direction.

   c. By default, Abaqus/CAE creates the copies along the *X*-direction. If you want to change the direction in which Abaqus/CAE creates the copies, click and select a line from the assembly to define the new direction. You must pick a straight edge or a datum axis.

   d. By default, Abaqus/CAE creates the copies in the positive direction. Click to reverse the direction in which Abaqus/CAE creates the copies.

5. To create copies in a second direction, enter a **Number** greater than 1 and specify the **Spacing**, the **Direction**, and the **Flip** direction for **Direction-2** (by default, **Direction-2** is the *Y*-direction). You must enter a **Number** greater than 1 for at least one direction.

6. In most cases you will want to preview the linear pattern that Abaqus/CAE will create as you enter values in the **Linear Pattern** dialog box. However, if you choose to create a large number of copies, the preview capability may impact the performance of Abaqus/CAE. In this case you should toggle off the **Preview** button.
7. To copy more instances, repeat the above steps beginning with Step 1.

Additional information

- *Creating patterns of instances*
- *Creating a radial pattern of instances*

Creating a radial pattern of instances

To create multiple copies of a selected instance in a radial pattern, select **Instance->Radial Pattern** from the main menu bar. You cannot edit a pattern after you create it. You can specify the following:

- The number of copies to create in the radial pattern, including the selected instances. You can create any number of instances.
- The total angle between the original instance and the last copy in the pattern.
- The position of the axis of the circular pattern.

For more information, see *Creating patterns of instances*.

1. From the main menu bar, select **Instance->Radial Pattern**.

   Tip: You can also create a radial pattern of instances using the tool from the Assembly module toolbox. For a diagram of the tools in the Assembly toolbox, see *Using the Assembly module toolbox*.

2. Select the instances that you want to copy.

   Tip: To select more than one instance, hold down the **[Shift]** key as you click each instance or drag a rectangle around the instances. To unselect an instance, use **[Ctrl] + Click**. For more information, see *Selecting objects within the viewport*.

3. Click mouse button 2 to indicate that you have finished selecting instances.

   Abaqus/CAE displays the **Radial Pattern** dialog box.

4. From the **Radial Pattern** dialog box, configure the radial pattern:
   a. Click the arrows to the right of **Number** to increase or decrease the number of copies to create, including the selected instances. The number of copies in the assembly updates when you click the arrows and provides a preview of the setting.

      Alternatively, you can type in a number and press **[Enter]** to preview the setting. You can enter any number greater than or equal to 2.

   b. Enter the **Total angle** between the original instances that you selected and the final copy. The angle must be between –360° and +360°. A positive angle corresponds to a counterclockwise direction.
   c. By default, Abaqus/CAE rotates the selected instance about the *Z*-axis to create the pattern. To define a new axis of rotation, click and select a line from the assembly that represents the new axis of rotation. You can also select an axis from the global coordinate system triad.

5. In most cases you will want to preview the radial pattern that Abaqus/CAE will create as you enter values in the **Radial Pattern** dialog box. However, if you choose to create a large number of copies, the preview capability may impact the performance of Abaqus/CAE. In this case you should toggle off the **Preview** button.
6. To copy more instances, repeat the above steps beginning with Step 1.

Additional information

- *Creating patterns of instances*
- *Creating a linear pattern of instances*

Translating part or model instances

Select **Instance->Translate** from the main menu bar to move selected part or model instances along a selected vector.

The direction and magnitude of the vector are arbitrary except that you can translate axisymmetric part instances only along the axis of rotation. If the translation conflicts with a previous position constraint; for example, a constraint that aligns two faces, Abaqus/CAE applies the components of translation only along the unconstrained degrees of freedom. If all of the degrees of freedom are constrained, Abaqus/CAE displays an error message and the translation fails.

When you create the first instance in your assembly, Abaqus/CAE displays a graphic indicating the origin and orientation of the assembly's default coordinate system. You can use this graphic to help you decide how to translate your part instances. In addition, you can use the Query toolset to review the sum of the translations and rotations previously applied to an instance and the distance between selected vertices. Translations and rotations are not considered features of the assembly and cannot be edited or deleted.

1. From the main menu bar, select **Instance->Translate**.

   Tip: You can also translate instances using the tool from the Assembly module toolbox. For a diagram of the tools in the Assembly toolbox, see *Using the Assembly module toolbox*.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

2. Select the part or model instances to translate. You can also click **Instances** on the right of the prompt area and select the instances to translate from the dialog box that appears.

   Tip: If you are unable to select the desired instance, you can use the **Selection** toolbar to change the selection behavior. For more information, see *Using the selection options*.

   You can use a combination of **[Ctrl] + Click** and **[Shift] + Click** to select multiple instances.

   Abaqus/CAE highlights the selected instances.

3. Specify the translation vector using one of the following methods:

   - Select an axis or linear edge from the viewport, and enter a distance for the translation. Abaqus/CAE displays an arrow along the selected axis/edge, and, if needed, you can flip the direction to define the translation vector.
   - Select the start and end points of the translation vector. You can select any existing vertices or datum points, or you can enter the coordinates in the text box in the prompt area. If you want to enter coordinates for a coordinate system other than the global coordinate system, click **Select** on the right side of the prompt area and select a local coordinate system. By default, the coordinate system applied to the start point is also applied to the end point.

   Abaqus/CAE displays a temporary image indicating the translation that will be applied to the selected instance. You cannot edit or delete a translation after it is applied. Attempting to translate an instance may result in a conflict with existing position constraints. Abaqus/CAE applies the components of translation only along the unconstrained degrees of freedom. If all of the degrees of freedom are constrained, Abaqus/CAE displays an error message and the translation fails.

4. Do one of the following:

   - If you are satisfied the translation is correct, click **OK** in the prompt area.

     Abaqus/CAE translates the instance and positions it at the same location as the temporary image of the instance.

- If you are not satisfied with the translation, click the **Previous** button () and specify a new translation vector.
- Click  to cancel the procedure.

Additional information

• *Using the Instance menu*
• *Creating the assembly*

Translating a part or model instance to another instance

Select **Instance->Translate To** from the main menu bar to position two instances by translating one instance along a vector defining the direction of motion until selected faces or edges of the movable instance are separated by a specified distance from selected faces or edges of the fixed instance.

Abaqus/CAE calculates the contact only within a tolerance based on the size of your model. As a result, contact may not be precise unless it is applied between two planar surfaces. If the selected faces or edges never contact when Abaqus/CAE translates the movable instance, the translation is not applied.

1. From the main menu, select **Instance->Translate To**.

   Tip: You can also define a **Translate To** constraint using the  tool in the Assembly module toolbox. For a diagram of the tools in the Assembly toolbox, see *Using the Assembly module toolbox*.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

2. Select the faces (for three-dimensional part instances) or edges (for two-dimensional part instances) from the part or model instance that will move and the instance that will remain fixed. You can select more than one face or edge from both the fixed and the movable instances. Selecting multiple faces or edges is useful if you are not sure what part of the model will come in contact when the movable instance moves along the selected vector. However, for faster processing you should select as few faces or edges as possible. You cannot select a datum plane.
3. Specify the vector that defines the direction of motion using one of the following methods. If the instances are axisymmetric, the translation vector must be parallel to the axis of revolution.
   - Select an axis or linear edge from the viewport. Abaqus/CAE displays an arrow along the selected axis/edge, and, if needed, you can flip the direction to define the translation vector.
   - Select the start and end points of the vector. You can select any existing vertices or datum points, or you can enter the coordinates in the text box in the prompt area. If you want to enter coordinates for a coordinate system other than the global coordinate system, click **Select** on the right side of the prompt area and select a local coordinate system. By default, the coordinate system applied to the start point is also applied to the end point.
4. In the text box that appears in the prompt area, enter a value for the clearance between the two selected faces; a negative value indicates overclosure. A translation is not saved as a feature, and you cannot change the clearance after you have completed the procedure.
5. From the prompt area, click **Preview**.

   Abaqus/CAE moves the movable part or model instance along the translation vector until the selected faces of the movable instance are separated by the specified clearance from the selected faces of the fixed instance.
6. If the new position of the instance is correct, click **Done** in the prompt area.

   Attempting to translate an instance may result in a conflict with existing position constraints. Abaqus/CAE applies the components of translation only along the unconstrained degrees of freedom. If all of the degrees of freedom are constrained, Abaqus/CAE displays an error message and the translation fails. To avoid the conflict, you can try reversing the selection of the instance that will move and the instance that will remain fixed. Alternatively, you can convert the existing constraints to an absolute position and reapply the translation.

Additional information

- *Using the Constraint menu*

- *Creating the assembly*
- *Converting constraints*

Rotating part or model instances

Select **Instance->Rotate** from the main menu bar to rotate selected part or model instances about a selected axis.

To rotate a three-dimensional instance, you must select two points that define the axis about which the instance will rotate. To rotate a two-dimensional instance, you must select a single point about which the instance will rotate. You cannot rotate axisymmetric instances. If the rotation conflicts with a previous position constraint (for example, a constraint that aligns two faces), Abaqus/CAE displays an error message and the rotation fails.

When you create the first instance in the assembly, Abaqus/CAE displays a graphic indicating the origin and orientation of the assembly's global coordinate system. You can use this graphic to help you decide how to rotate your part and model instances. In addition, you can use the Query toolset to review the sum of the translations and rotations previously applied to an instance and the distance between selected vertices. Rotations and translations are not considered features of the assembly and cannot be edited or deleted.

1. From the main menu bar, select **Instance->Rotate**.

   Tip: You can also rotate an instance using the tool from the Assembly module toolbox. For a diagram of the tools in the Assembly toolbox, see *Using the Assembly module toolbox*.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

2. From the assembly, select the part or model instances to rotate. You can also click **Instances** on the right of the prompt area and select the instances to rotate from the dialog box that appears.

   Tip: If you are unable to select the desired instance, you can use the **Selection** toolbar to change the selection behavior. For more information, see *Using the selection options*.

   You can use a combination of **[Ctrl] + Click** and **[Shift] + Click** to select multiple instances.

   Abaqus/CAE highlights the selected instances.

3. Specify the axis of rotation using one of the following methods:

   - Select an axis or linear edge from the viewport.
   - Select the start and end points of the rotation vector. You can select any existing vertices or datum points, or you can enter the coordinates in the text box in the prompt area. If you want to enter coordinates for a coordinate system other than the global coordinate system, click **Select** on the right side of the prompt area and select a local coordinate system. By default, the coordinate system applied to the start point is also applied to the end point.

4. In the text box that appears in the prompt area, enter the angle of rotation. A positive angle indicates a counterclockwise rotation; a negative angle indicates a clockwise rotation.

   Abaqus/CAE displays a temporary image indicating the rotation that will be applied to the selected instances. You cannot edit or delete a rotation after it is applied. Attempting to rotate an instance may result in a conflict with existing position constraints. If a conflict occurs, Abaqus/CAE displays an error message and the rotation fails.

5. Do one of the following:

   a. If you are satisfied that the rotation is correct, click **OK** in the prompt area.

      Abaqus/CAE rotates the instance and positions it at the same location as the temporary image of the instance.

   b. If you are not satisfied with the rotation, click the **Previous** button ( ) and specify a new rotation.

c. Click () to cancel the procedure.

Additional information

- *Using the Constraint menu*
- *Creating the assembly*

Replacing an instance

Select **Instance->Replace** from the main menu bar to replace a selected instance with an instance of another part/model. Abaqus/CAE positions the new instance so that its origin is located at the origin of the original instance and their axes align. In addition, you can choose whether the new instance inherits all the constraints from the instance it replaced.

The replace operation does not change the attributes of the instance. For example, if the original instance is dependent, the instance that replaces it will also be dependent. As a result, if an independent instance of a part exists, you cannot use the replace procedure to create a dependent instance of the same part.

Replacing an instance is most useful when you are replacing an instance with one that has similar geometry. For example, the new instance might have additional detail that was not present in the original instance.

You can only replace a part instance with a part instance and a model instance with a model instance.

1. From the main menu bar, select **Instance->Replace** to replace a selected instance.
2. From the assembly, select the instance to replace. You can also click the **Instance List** button on the right of the prompt area and select the instance from the **Instance List** dialog box that appears.

   Tip: If you are unable to select the desired instance, you can use the **Selection** toolbar to change the selection behavior. For more information, see *Using the selection options*.

   Abaqus/CAE displays the **Replace Instance** dialog box with a list of all the parts/models in the model.
3. From the **Replace Instance** dialog box, select the part/model that will replace the selected part/model instance in the assembly.

   Abaqus/CAE displays a temporary image of the new part instance in the assembly and positions it so that its origin is located at the origin of the original part instance and their axes align.
4. If the correct instance is selected, click **OK** in the **Replace Instance** dialog box.

   If you have not applied any position constraints to the original instance, Abaqus/CAE replaces it with the new instance.
5. If you have applied position constraints to the original instance, you must choose one of the following buttons in the prompt area:

   - Click **OK** to position the new instance in the same location as the instance it is replacing. Abaqus/CAE removes any constraints that were applied to the original instance, while maintaining its position.
   - Click **Apply previous constraints** if you want the new instance to inherit position constraints from the instance being replaced. Abaqus/CAE applies all the previous constraints that can be satisfied by the new instance; any constraints that cannot be satisfied are ignored.

   Abaqus/CAE replaces the original part instance with the new part instance and the original model instance with the new model instance.

Additional information

- *Replacing an instance*
- *Creating a part or model instance*
- *Applying constraints to part and model instances*
- *Working with part instances*

Converting constraints

To remove all the face, edge, coaxial, and contact constraints applied to a selected part or model instance while leaving the instance in its current position, select **Instance->Convert Constraints** from the main menu bar. The conversion is equivalent to applying a single translation and rotation to the instance that moves it from its original position to the current position. Any previous constraints no longer appear in the list of features and cannot be restored.

1. From the main menu bar, select **Instance->Convert Constraints** to convert any existing constraints to the current position.
2. From the assembly, select the part or model instance whose constraints you want to convert. You can also click the **Instance List** button on the right of the prompt area and select the instance from the **Instance List** dialog box that appears.

   Tip: If you are unable to select the desired instance, you can use the **Selection** toolbar to change the selection behavior. For more information, see *Using the selection options*.

   The instance does not move, but Abaqus/CAE converts any existing constraints to the current position. You cannot restore the original face, edge, coaxial, and contact constraints.

Additional information

- *How the position constraint methods differ*
- *How conflicts can arise between position constraints, translations, and rotations*

Merging or cutting part instances

To merge a selected group of part instances, select **Instance->Merge/Cut** from the main menu bar. You can merge the geometry of parts that you created in the Part module, you can merge the meshes of part instances (any native mesh becomes an orphan mesh), or you can merge both geometry and orphan mesh features. You can also merge selected nodes using the Edit Mesh toolset in the Mesh module; for more information, see *Manipulating nodes*. You can cut the geometry of a selected part instance using the geometry of one or more other part instances to make the cut; any orphan mesh nodes or elements within the instance being cut are retained in the new cut part instance.

The merge or cut operation creates both a new part instance in the assembly and a new part. You can choose to suppress the original part instances that you selected, or you can delete them from the assembly. For more information, see *Performing Boolean operations on part instances*.

You cannot use the **Merge/Cut** command on model instances.

1. From the main menu bar, select **Instance->Merge/Cut**.

   Tip: You can also merge or cut part instances using the  tool from the Assembly module toolbox. For a diagram of the tools in the Assembly toolbox, see *Using the Assembly module toolbox*.

   Abaqus/CAE displays the **Merge/Cut Instances** dialog box.
2. Enter the name of the part that will be created by the operation.
3. Select the type of operation:
   - To merge the geometry of part instances, choose **Merge** and **Geometry**. Any native or orphan mesh nodes and elements are not included in the new part.
   - To merge the meshes of part instances, choose **Merge** and **Mesh**. Any geometry is not included in the new part, and any native mesh becomes an orphan mesh.
   - To merge both the geometry and mesh features of part instances, choose **Merge** and **Both**. Geometry is included in the new part, and any native mesh is deleted.
   - To cut part instances, choose **Cut geometry**.
4. Choose how you would like Abaqus/CAE to handle the original instances that are being merged or cut:
   - Choose **Suppress** to suppress the original part instances but retain them in the model database. After you complete the **Merge/Cut** operation, you can resume the original part instances if necessary (see *Suppressing and resuming objects*).
   - Choose **Delete** to delete the original part instances from the model database. You cannot recover deleted part instances.
5. If you chose a **Merge** operation, do the following:
   a. Choose the desired options:

Geometry

By default, Abaqus/CAE removes the boundaries between intersecting part instances. If you want to retain the boundaries between intersecting part instances, choose **Retain** from the bottom of the **Merge/Cut Instances** dialog box. The effect of removing and retaining the boundaries is shown in *Figure 1*.

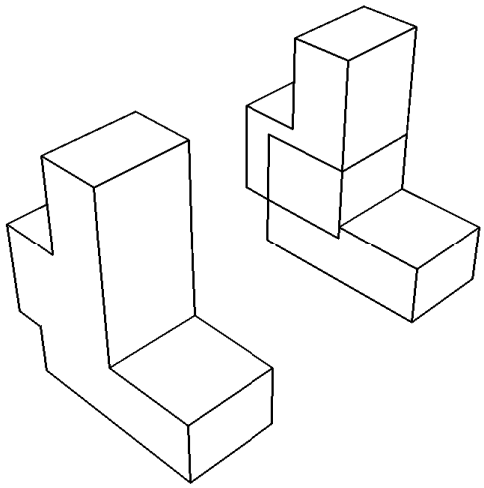

Figure 1: The effect of removing and retaining intersecting boundaries.

Mesh

Choose the method that Abaqus/CAE will use to merge nodes:

- **Boundary only**. By default, Abaqus/CAE merges the meshes only along their boundaries. Therefore, Abaqus/CAE does not check for duplicate nodes in the interior of the parts, which speeds up the merging process. You should retain this default setting if the part instances intersect at only a common face.
- **All**. Merge all the nodes in the selected part instances. By default, Abaqus/CAE removes elements that have the same connectivity as an existing element. Toggle off **Remove duplicate elements** to retain duplicate elements.
- **None**. Merge the part instances into a single part instance but retain the original nodes.

If applicable, enter the **Node merging tolerance**. Abaqus/CAE deletes nodes that are closer than the specified tolerance and replaces them with a single new node. The location of the new node is the average position of the group of nodes that were merged into the new node.

b. Click **Continue**.

c. Select the part instances to merge. You can use a combination of **[Ctrl] + Click** and **[Shift] + Click** to select multiple part instances. You can also click the **Instance List** button on the right of the prompt area and select the instances from the **Instance List** dialog box that appears.

Tip: If you are unable to select the desired part instances, you can use the **Selection** toolbar to change the selection behavior. For more information, see *Using the selection options*.

The part instances do not have to be touching or overlapping.

d. Click mouse button 2 to indicate that you have finished selecting part instances.

e. If you are merging meshes and the value that you entered for the **Node merging tolerance** is too large, Abaqus/CAE may detect duplicate nodes from the same element. Abaqus/CAE will not merge nodes from the same element, but the large tolerance can result in a distorted mesh. If the **Node merging tolerance** is too large, Abaqus/CAE asks if you want to continue merging the part instances.

- Click **Yes** to continue.
- Click **No** to cancel the merging procedure.

f. Abaqus/CAE highlights in magenta any nodes that will be merged and asks if you wish to proceed.

- Click **Yes** to continue.
- Click **No** to cancel the merging procedure.

Abaqus/CAE merges the nodes that are closer than the specified tolerance and replaces them with a single new node. The location of the new node is the average position of the group of nodes that were merged into the new node. If no nodes are closer than the specified tolerance, Abaqus/CAE asks if you want to cancel the procedure or merge the selected instances into a single part instance.

Abaqus/CAE merges the selected instances, creates a new part instance and a new part, and modifies sets and surfaces to include the new part instance.

6. If you chose a **Cut** operation, do the following:

a. Click **Continue**.

b. Select the geometry of the part instance to be cut. You can select only one part instance, and only the geometry is selected, even if the part includes orphan mesh nodes and elements.

c. Select the part instances that will make the cut. The cutting geometry must touch or overlap the geometry of the part instance to be cut.

d. Click mouse button 2 to indicate that you have finished selecting part instances.

Abaqus/CAE cuts the selected instance and creates a new part instance and a new part. Any orphan mesh on the part being cut is copied to the new instance and part.

Additional information

• *How conflicts can arise between position constraints, translations, and rotations*

Applying constraints to part and model instances

This section describes how you use the Assembly module's **Constraint** menu to apply positioning constraints to part and model instances in the assembly.

In this section:

- *Using the Constraint menu*
- *Constraining two instances with parallel planar faces*
- *Constraining two instances with parallel planar faces separated by a specified distance*
- *Constraining two instances with parallel edges*
- *Constraining two instances with parallel edges separated by a specified distance*
- *Constraining two instances with coaxial faces*
- *Constraining two instances with coincident points*
- *Constraining two instances with parallel coordinate systems*

Using the Constraint menu

Use the **Constraint** menu to apply a constraint that does the following:

- ***Parallel Face***. Positions a movable part or model instance so that a selected face is parallel to a selected face of a fixed instance.
- ***Face to Face***. Positions a movable part or model instance so that a selected face is parallel to and a specified distance away from a selected face of a fixed instance.
- ***Parallel Edge***. Positions a movable part or model instance so that a selected edge is parallel to a selected edge of a fixed instance.
- ***Edge to Edge***. Positions a movable part or model instance so that a selected edge is parallel to and a specified distance away from a selected edge of a fixed instance.
- ***Coaxial***. Positions a movable part or model instance so that the axis of revolution of a selected face is coincident with the axis of revolution of a selected face of a fixed instance.
- ***Coincident Point***. Positions a movable part or model instance so that a selected point is coincident with a selected point of a fixed instance.
- ***Parallel CSYS***. Positions a movable part or model instance so that a selected datum coordinate system associated with the instance is parallel to a selected datum system of a fixed instance.

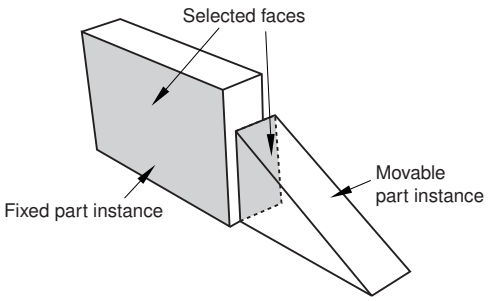
Constraints position one instance relative to another; as a result, constraints cannot be applied until your assembly contains two or more part or model instances.

You may find it more convenient to access the constraint tools using the Assembly module toolbox. For a diagram of the tools in the Assembly toolbox, see *Using the Assembly module toolbox*.

Additional information

- *Creating the assembly*
- *The Assembly module*

Constraining two instances with parallel planar faces



Select **Constraint->Parallel Face** from the main menu bar to apply a constraint that positions a movable instance so that a selected face is parallel to a selected face of a fixed instance. All position constraints are features of the assembly and can be suppressed or deleted using the Feature Manipulation toolset.

1. From the main menu, select **Constraint->Parallel Face**.

   Tip: You can also apply the parallel face constraint using the tool in the Assembly module toolbox. For a diagram of the tools in the Assembly toolbox, see *Using the Assembly module toolbox*.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

2. Select a planar face from the part or model instance that will move and a planar face from the instance that will remain fixed, as shown in the following figure:

   Abaqus/CAE displays arrows normal to the selected faces.

   When Abaqus/CAE prompts you to select the face from the fixed instance, you can select a datum plane that was created in either the Part or Assembly module. In contrast, when you select the face from a movable part instance, you can select a datum plane that was created only in the Part module.

3. From the buttons in the prompt area, do one of the following:

   - Click **OK** to accept the direction of the arrow on the face of the movable instance.
   - Click **Flip** to reverse the direction of the arrow on the face of the movable instance, and click **OK**.

   Abaqus/CAE positions the movable part or model instance so that the two faces are parallel and the arrows point in the same direction. The orientation of the fixed instance remains unchanged. The effect of changing the direction of the arrow is illustrated in the following figure:

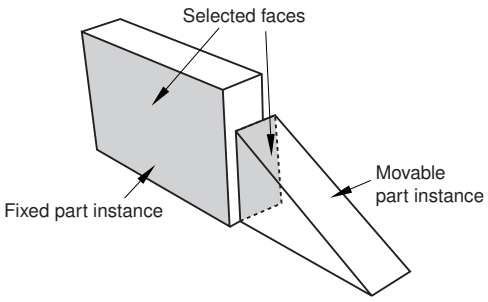
   If the parallel face constraint conflicts with existing constraints, Abaqus/CAE displays an error message and cancels the operation. To avoid the conflict, you can try reversing the selection of the instance that

will move and the instance that will remain fixed. Alternatively, you can delete the existing relative position constraints, apply absolute position constraints, and reapply the parallel face constraint.

Additional information

- *Using the Constraint menu*
- *Creating the assembly*
- *Converting constraints*

Constraining two instances with parallel planar faces separated by a specified distance



Select **Constraint->Face to Face** from the main menu bar to apply a constraint that positions a movable instance so that a selected face is parallel to and a specified distance away from a selected face of a fixed instance. The face-to-face constraint is a feature of the assembly and can be suppressed or deleted using the Feature Manipulation toolset. In addition, you can edit the clearance between the two selected faces.

1. From the main menu, select **Constraint->Face to Face**.

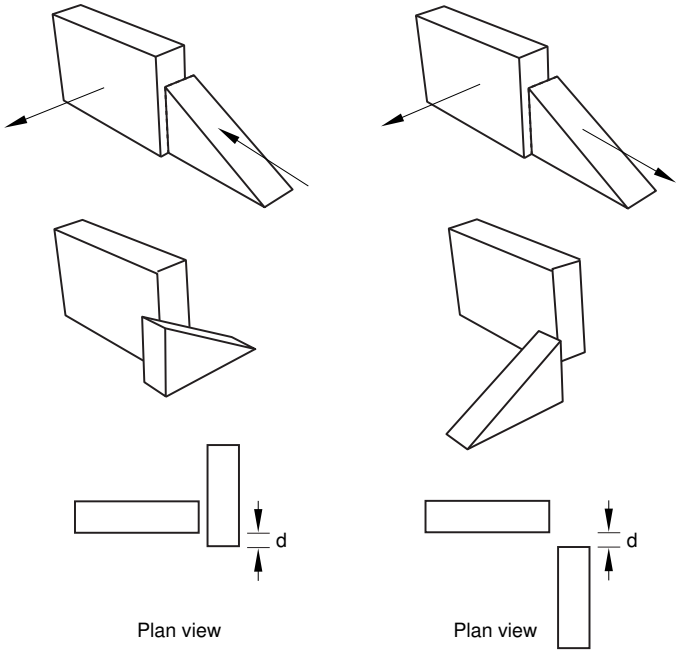
   Tip: You can also apply the face-to-face constraint using the tool in the Assembly module toolbox. For a diagram of the tools in the Assembly toolbox, see *Using the Assembly module toolbox*.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

2. Select a planar face from the part or model instance that will move and a planar face from the instance that will remain fixed, as shown in the following figure:

   Abaqus/CAE displays arrows normal to the selected faces.

   When Abaqus/CAE prompts you to select the face from the fixed instance, you can select a datum plane that was created in either the Part or Assembly module. In contrast, when you select a face from the movable part instance, you can select a datum plane that was created only in the Part module.



3. From the buttons in the prompt area, do one of the following:

   - Click **OK** to accept the direction of the arrow on the face of the movable instance.
   - Click **Flip** to reverse the direction of the arrow on the face of the movable instance, and click **OK**.

   The effect of changing the direction of the arrow is illustrated in the next step.

4. In the text field that appears in the prompt area, enter the distance between the selected faces, positive along the normal to the face of the fixed instance.

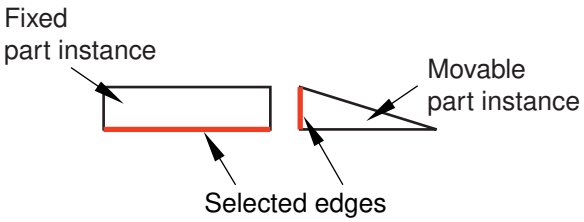
   Abaqus/CAE positions the movable instance so that the two faces are parallel and the arrows point in the same direction. In addition, the movable instance is translated to satisfy the clearance specified. The orientation of the fixed instance remains unchanged. The effect of specifying the distance is illustrated in the following figure:

If the face-to-face constraint conflicts with existing constraints, Abaqus/CAE displays an error message and cancels the operation. To avoid the conflict, you can try reversing the selection of the instance that will move and the instance that will remain fixed. Alternatively, you can convert the existing constraints to an absolute position and reapply the face-to-face constraint.

Additional information

- *Using the Constraint menu*
- *Creating the assembly*
- *Converting constraints*

Constraining two instances with parallel edges



Select **Constraint->Parallel Edge** from the main menu bar to apply a constraint that positions a movable instance so that a selected edge is parallel to a selected edge of a fixed instance. All position constraints are features of the assembly and can be suppressed or deleted using the Feature Manipulation toolset.

1. From the main menu, select **Constraint->Parallel Edge**.

   Tip: You can also apply the parallel edge constraint using the tool in the Assembly module toolbox. For a diagram of the tools in the Assembly toolbox, see *Using the Assembly module toolbox*.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

2. Select a straight edge from the instance that will move and a straight edge from the instance that will remain fixed, as shown in the following figure:

   In addition to selecting an edge or a datum axis, you can also select one of the axes of a datum coordinate system.

   Abaqus/CAE displays arrows along the selected edges.

   When Abaqus/CAE prompts you to select the edge from the fixed instance, you can select a datum axis that was created in either the Part or Assembly module. In contrast, when you select the edge from a movable part instance, you can select a datum axis that was created only in the Part module.

3. From the buttons in the prompt area, do one of the following:

   - Click **OK** to accept the direction of the arrow along the edge of the movable instance.
   - Click **Flip** to reverse the direction of the arrow along the edge of the movable instance, and click **OK**.

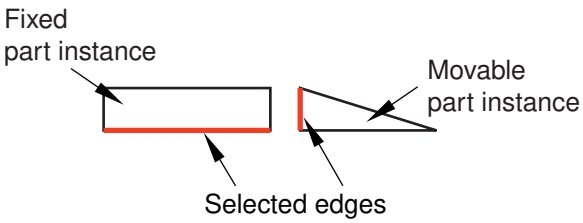
   Abaqus/CAE positions the movable instance so that the two edges are parallel and the arrows point in the same direction. The orientation of the fixed instance remains unchanged. The effect of changing the direction of the arrow is illustrated in the following figure:

If the parallel edge constraint conflicts with existing constraints, Abaqus/CAE displays an error message and cancels the operation. To avoid the conflict, you can try reversing the selection of the instance that will move and the instance that will remain fixed. Alternatively, you can convert the existing constraints to an absolute position and reapply the parallel edge constraint.

Additional information

- *Using the Constraint menu*
- *Creating the assembly*
- *Converting constraints*

Constraining two instances with parallel edges separated by a specified distance



Select **Constraint->Edge to Edge** from the main menu bar to apply a constraint that positions a movable instance so that a selected edge is parallel to a selected edge of a fixed instance. In addition, if the instances are two-dimensional, you must specify the distance between the selected edges; otherwise, Abaqus/CAE makes them coincident. All position constraints are features of the assembly and can be suppressed or deleted using the Feature Manipulation toolset. In addition, you can edit the clearance between the two selected edges, where applicable. For more information, see *How the position constraint methods differ*.

1. From the main menu, select **Constraint->Edge to Edge**.

   Tip: You can also apply the edge-to-edge constraint using the tool in the Assembly module toolbox. For a diagram of the tools in the Assembly toolbox, see *Using the Assembly module toolbox*.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

2. Select a straight edge from the instance that will move and a straight edge from the instance that will remain fixed, as shown in the following figure:

   In addition to selecting an edge or a datum axis, you can also select one of the axes of a datum coordinate system.

   Abaqus/CAE displays arrows along the selected edges.

   When Abaqus/CAE prompts you to select the edge from the fixed instance, you can select a datum axis that was created in either the Part or Assembly module. In contrast, when you select the edge from a movable part instance, you can select a datum axis that was created only in the Part module.

3. From the buttons in the prompt area, do one of the following:

   - Click **OK** to accept the direction of the arrow along the edge of the movable instance.
   - Click **Flip** to reverse the direction of the arrow along the edge of the movable instance and click **OK**.

   The effect of changing the direction of the arrow is illustrated in the next step.

   If the instances are three-dimensional, Abaqus/CAE positions the movable instance so that the selected edges are parallel and coincident.

4. If the instances are two-dimensional, you must specify the clearance between the selected edges. In the text field that appears in the prompt area, enter the distance from the edge of the movable instance to the edge of the fixed instance, positive along the normal to the edge of the fixed instance.

   Abaqus/CAE positions the movable instance so that the two edges are parallel and the arrows point in the same direction. In addition, the movable instance is translated to satisfy the clearance specified. The orientation of the fixed instance remains unchanged. The effect of specifying the distance and changing the direction of the arrow is illustrated with two-dimensional instances in the following figure:

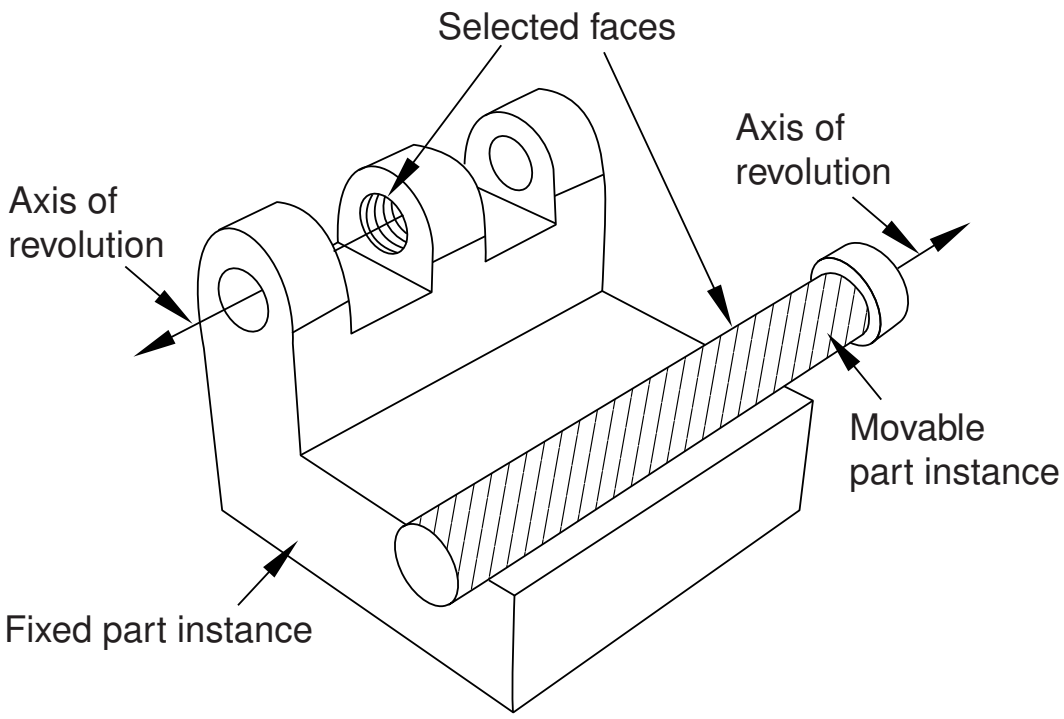
If the edge-to-edge constraint conflicts with existing constraints, Abaqus/CAE displays an error message and cancels the operation. To avoid the conflict, you can try reversing the selection of the instance that will move and the instance that will remain fixed. Alternatively, you can convert the existing constraints to an absolute position and reapply the edge-to-edge constraint.

Additional information

- *Using the Constraint menu*
- *Creating the assembly*
- *Converting constraints*

Constraining two instances with coaxial faces

Select **Constraint->Coaxial** from the main menu bar to apply a constraint that positions a movable instance so that the axis of revolution of a selected face is coincident with the axis of revolution of a selected face of a fixed instance. All position constraints are features of the assembly and can be suppressed or deleted using the Feature Manipulation toolset.



The selected faces of the movable and fixed instances must be either cylindrical or conical. In addition, the coaxial constraint can be applied only to three-dimensional instances. For more information, see *How the position constraint methods differ*.

1. From the main menu, select **Constraint->Coaxial**.

   Tip: You can also apply the coaxial constraint using the tool in the Assembly module toolbox. For a diagram of the tools in the Assembly toolbox, see *Using the Assembly module toolbox*.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

2. Select cylindrical or conical faces from the instance that will move and the instance that will remain fixed, as shown in the following figure:

   Abaqus/CAE displays arrows along the axis of revolution of the selected faces.

3. From the buttons in the prompt area, do one of the following:

   - Click **OK** to accept the direction of the arrow along the axis of revolution of the face of the movable instance.
   - Click **Flip** to reverse the direction of the arrow along the axis of revolution of the face of the movable instance, and click **OK**.

Abaqus/CAE positions the movable instance so that the two axes are coincident and the arrows point in the same direction. The orientation of the fixed instance remains unchanged. The effect of the coaxial constraint with the arrows selected as shown above is illustrated in the following figure:

If the coaxial constraint conflicts with existing constraints, Abaqus/CAE displays an error message and cancels the operation. To avoid the conflict, you can try reversing the selection of the instance that will move and the instance that will remain fixed. Alternatively, you can convert the existing constraints to an absolute position and reapply the coaxial constraint.

Additional information

- *Using the Constraint menu*
- *Creating the assembly*

Constraining two instances with coincident points

Select **Constraint->Coincident Point** from the main menu bar to apply a constraint that positions a movable instance so that a selected point is coincident with a selected point of a fixed instance. All position constraints are features of the assembly and can be suppressed or deleted using the Feature Manipulation toolset.

1. From the main menu, select **Constraint->Coincident Point**.

   Tip: You can also apply the coincident point constraint using the  tool in the Assembly module toolbox. For a diagram of the tools in the Assembly toolbox, see *Using the Assembly module toolbox*.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

2. Select a point from the instance that will move and a point from the instance that will remain fixed. In addition to selecting a vertex or a midpoint, you can select a datum point, a reference point, or the origin of a datum coordinate system.

   Abaqus/CAE moves the movable instance so that the selected points are coincident.

   When Abaqus/CAE prompts you to select the point from the fixed instance, you can select a datum point or a reference point that was created in either the Part or Assembly module. In contrast, when you select the point from a movable part instance, you can only select a datum point or reference point that was created in the Part module.

   If the coincident point constraint conflicts with existing constraints, Abaqus/CAE displays an error message and cancels the operation. To avoid the conflict, you can try reversing the selection of the instance that will move and the instance that will remain fixed. Alternatively, you can convert the existing constraints to an absolute position and reapply the coincident point constraint.

Additional information

- *Using the Constraint menu*
- *Creating the assembly*
- *Converting constraints*

Constraining two instances with parallel coordinate systems

Select **Constraint->Parallel CSYS** from the main menu bar to apply a constraint that positions a movable instance so that a selected datum coordinate system is parallel to a selected datum coordinate system of a fixed instance. All position constraints are features of the assembly and can be suppressed or deleted using the Feature Manipulation toolset.

1. From the main menu, select **Constraint->Parallel CSYS**.

   Tip: You can also apply the parallel coordinate systems constraint using the  tool in the Assembly module toolbox. For a diagram of the tools in the Assembly toolbox, see *Using the Assembly module toolbox*.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

2. Select a datum coordinate system from the movable instance and a datum coordinate system from the fixed instance.

   When Abaqus/CAE prompts you to select the datum coordinate system from the fixed instance, you can select a datum coordinate system that was created in either the Part or Assembly module. In contrast, when you select the datum coordinate system from a movable part instance, you can only select a datum coordinate system that was created in the Part module.

   Abaqus/CAE rotates the movable instance so that the selected coordinate systems are parallel.

   If the parallel coordinate systems constraint conflicts with existing constraints, Abaqus/CAE displays an error message and cancels the operation. To avoid the conflict, you can try reversing the selection of the instance that will move and the instance that will remain fixed. Alternatively, you can convert the existing constraints to an absolute position and reapply the parallel coordinate systems constraint.

Using the Query toolset to query the assembly

Select **Tools->Query** from the main menu bar to start the Query toolset. You can use the Query toolset to request either general information or module-specific information. For a discussion of the information displayed by general queries, see *Obtaining general information about the model*. In addition, you can use the Assembly module-specific tools in the Query toolset to determine the attributes and position of a selected part or model instance.

1. From the main menu bar, select **Tools->Query**.

    **Tip:** You can also select the  tool in the Query toolset.

   Abaqus/CAE displays the **Query** dialog box.

2. From the **Query** dialog box, click on one of the following:

Instance Attributes

Select a part or model instance.

Abaqus/CAE displays the following in the message area:

- The name, modeling space, and type (deformable or rigid, dependent or independent) of the instance

Instance Position

Select a part or model instance.

Abaqus/CAE displays the following in the message area:

- Position of the origin of the instance relative to the global coordinate system
- The sum of the rotations applied to the instance relative to the assembly's global coordinate system
- A list of the constraints applied to the instance

3. Close the **Query** dialog box when you are done querying the assembly.

- *Using the Step Manager*
- *Using the step editor*
- *Configuring analysis procedure settings*
- *Defining output requests*
- *Defining step control*
- *Requesting specialized output*
- *Customizing ALE adaptive meshing*
- *Customizing the Abaqus analysis controls*

Understanding the role of the Step module

You can use the Step module to perform the following tasks:

Create analysis steps

Within a model you define a sequence of one or more analysis steps. The step sequence provides a convenient way to capture changes in the loading and boundary conditions of the model, changes in the way parts of the model interact with each other, the removal or addition of parts, and any other changes that might occur in the model during the course of the analysis. In addition, steps allow you to change the analysis procedure, the data output, and various controls. You can also use steps to define linear perturbation analyses about nonlinear base states. You can use the replace function to change the analysis procedure of an existing step.

Specify output requests

Abaqus writes output from the analysis to the output database; you specify the output by creating output requests that are propagated to subsequent analysis steps. An output request defines which variables will be output during an analysis step, from which region of the model they will be output, and at what rate they will be output. For example, you might request output of the entire model's displacement field at the end of a step and also request the history of a reaction force at a restrained point.

Specify step control

You can define sensor history output based step controls for a step.

Specify adaptive meshing

You can define adaptive mesh regions and specify controls for adaptive meshing in those regions.

Specify analysis controls

You can customize general solution controls and solver controls.

Entering and exiting the Step module

You can enter the Step module at any time during an Abaqus/CAE session by clicking **Step** in the **Module** list located in the context bar. The **Step**, **Output**, **Other**, and **Tools** menus appear on the main menu bar. If the current viewport contains something other than the assembly, the contents of the viewport disappear when you start the Step module.

To exit the Step module, select any other module from the **Module** list. You need not save your steps or output requests before exiting the module; they will be saved automatically when you save the model database by selecting **File**->**Save** or **File**->**Save As** from the main menu bar.

Understanding steps

This section gives an overview of steps.

For more information on steps, see *Defining an Analysis*.

In this section:

- *What is a step?*
- *Linear and nonlinear procedures*
- *Step sequence restrictions*
- *What is step replacement?*
- *Replacing an Abaqus/Standard procedure with an Abaqus/Explicit procedure or vice versa*

What is a step?

An Abaqus/CAE model uses the following two types of steps:

The initial step

Abaqus/CAE creates a special initial step at the beginning of the model's step sequence and names it `Initial`. Abaqus/CAE creates only one initial step for your model, and it cannot be renamed, edited, replaced, copied, or deleted.

The initial step allows you to define boundary conditions, predefined fields, and interactions that are applicable at the very beginning of the analysis. For example, if a boundary condition or interaction is applied throughout the analysis, it is usually convenient to apply such conditions in the initial step. Likewise, when the first analysis step is a linear perturbation step, conditions applied in the initial step form part of the base state for the perturbation.

Analysis steps

The initial step is followed by one or more analysis steps. Each analysis step is associated with a specific procedure that defines the type of analysis to be performed during the step, such as a static stress analysis or a transient heat transfer analysis. You can change the analysis procedure from step to step in any meaningful way, so you have great flexibility in performing analyses. Since the state of the model (stresses, strains, temperatures, etc.) is updated throughout all general analysis steps, the effects of previous history are always included in the response for each new analysis step.

There is no limit to the number of analysis steps you can define, but there are restrictions on the step sequence. (For more information, see *Step sequence restrictions*.)

You use items from the **Step** menu to create a step, to select and define the analysis procedure used during the step, and to manage existing steps. Alternatively, you can select **Step->Manager** from the main menu bar to display the **Step Manager**.

For example, consider the following analysis of a section of a piping system:

Initial Step:

Apply boundary conditions to fix the left end of the pipe and to allow only axial movement at the right end.

Step 1: Compress

Apply a compressive force to the right end of the pipe. This step is a general analysis step.

Step 2: Eigenmodes

Calculate the frequencies and modes of vibration of the pipe in its compressed state. This step is a linear perturbation step.

Figure 1 shows the **Step Manager** after you create these steps.

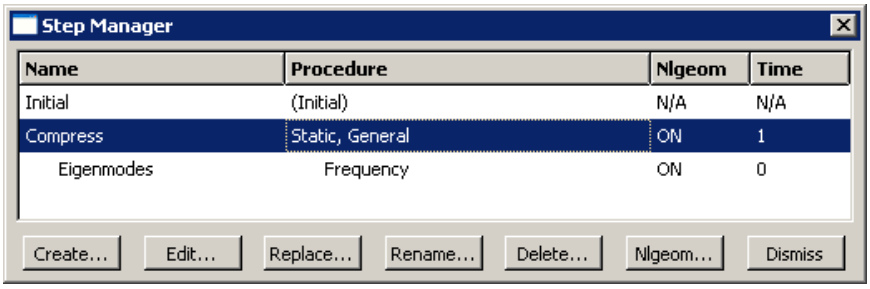

Figure 1: The Step Manager.

The manager lists all of the steps in the analysis as well as a few salient details concerning each step. Step 2, `Eigenmodes`, is indented to show that it is a linear perturbation step based on the state of the model at the end of Step 1, `Compress`.

For detailed information on creating, editing, and replacing steps, see the following sections:

- *Defining an Analysis*

Linear and nonlinear procedures

The **Step Manager** distinguishes between general nonlinear steps and linear perturbation steps by indenting the names and procedure descriptions of linear perturbation steps. General nonlinear analysis steps define sequential events: the state of the model at the end of one general step provides the initial state for the start of the next general step. Linear perturbation analysis steps provide the linear response of the model about the state reached at the end of the last general nonlinear step. You use the **Procedure type** field to choose between **General** and **Linear perturbation** steps when you select the procedure in the **Create Step** dialog box.

For each step in the analysis the **Step Manager** also indicates whether Abaqus will account for nonlinear effects from large displacements and deformations. If the displacements in a model due to loading are relatively small during a step, the effects may be small enough to be ignored. However, in cases where the loads on a model result in large displacements, nonlinear geometric effects can become important. The **Nlgeom** setting for a step determines whether Abaqus will account for geometric nonlinearity in that step.

The **Nlgeom** setting is turned on by default for Abaqus/Explicit steps and turned off by default for Abaqus/Standard steps. The sequence of steps and the current **Nlgeom** setting determine whether you can change the **Nlgeom** setting in a particular step. For example, if Abaqus is already accounting for geometric nonlinearity, the **Nlgeom** setting is toggled on for all subsequent steps, and you cannot toggle it off. Where permissible, the following methods allow you to change the **Nlgeom** setting for a step:

- Click the **Basic** tab in the **Step Editor**, and toggle the **Nlgeom** setting.
- Select **Step->Nlgeom** from the main menu bar.
- Click **Nlgeom** in the **Step Manager**.

For more information, see *Accounting for geometric nonlinearity*, or see *General and Perturbation Procedures*.

Additional information

• *Understanding steps*

Step sequence restrictions

When you select **Step->Create** from the main menu bar, a **Create Step** dialog box appears in which you can specify the procedure type for the step that you are creating. Similarly, when you select **Step->Replace** from the main menu bar, a **Replace Step** dialog box appears in which you can specify a new procedure type for an existing step. The selection of procedure types in the **Create Step** and **Replace Step** dialog boxes depends on the following:

- The model type.
- The procedures that you have already associated with existing steps.
- The position of the new or replaced step in the analysis step sequence.

For example, when you create the first step in an analysis, you can choose from a list of valid procedure types; both Abaqus/Standard and Abaqus/Explicit procedure types appear in the list. However, once you have created the first step, the list of valid procedure types in the **Create Step** dialog box will change to include only those procedures that are compatible with the first step. For example, if the first step is an Abaqus/Standard step, Abaqus/Explicit procedures no longer appear in the list.

What is step replacement?

After you have defined your model and performed an analysis, you may want to run another analysis using a different procedure without having to redefine objects in your model, such as loads, boundary conditions, and interactions. You can use the replace function to replace the analysis procedure for an existing step with any procedure that is allowed by Abaqus/Standard or Abaqus/Explicit; for example, you can change from a **Static, General** procedure to a **Dynamic, Explicit** procedure or from a **Static, General** procedure to a **Static, Riks** procedure. After you select **Step->Replace** from the main menu bar, you select the step that you want to replace and the new analysis procedure for that step. The **Edit Step** dialog box appears with default values for the new analysis procedure. You can modify the default values and specify values for optional settings in the step editor.

When you replace a step, Abaqus/CAE copies all of the compatible step-dependent objects to the new step. If objects are incompatible with the new step, Abaqus/CAE substitutes an equivalent object, if possible, and suppresses or deletes the remaining objects. Therefore, you may want to copy the model before you replace the step. Abaqus/CAE displays a list of the objects that were suppressed or deleted during step replacement in the message area. For example, if you replace a **Static, General** procedure containing an Abaqus/Standard self-contact interaction, a pressure load, and an inertia relief load with a **Dynamic, Explicit** procedure, Abaqus/CAE does the following:

- Substitutes an Abaqus/Explicit self-contact interaction for the Abaqus/Standard self-contact interaction in the **Dynamic, Explicit** procedure.
- Copies the pressure load to the **Dynamic, Explicit** procedure.
- Suppresses the inertia relief load. Inertia relief loads apply only in Abaqus/Standard procedures.

After you replace a step, you should verify that previously defined properties, element types, jobs, and boundary conditions and predefined fields in the initial step remain valid for the model. In the Job module you can click **Write Input** in the **Job Manager** to write the input file and then check the input file for errors.

You can use the replace function to reset step settings to their default values by replacing an existing step with a step of the same procedure type.

Additional information

- *Understanding steps*
- *Step sequence restrictions*
- *Replacing a step*
- *Resetting the default values in the step editor*
- *Writing the input file only*

Replacing an Abaqus/Standard procedure with an Abaqus/Explicit procedure or vice versa

If you want to replace an Abaqus/Standard analysis procedure with an Abaqus/Explicit analysis procedure or vice versa, you must have only one analysis step in the model for the desired procedure type to appear in the **Replace Step** dialog box. If your model contains multiple steps, you can use step-dependent managers to move objects to a single step. You can then delete the other steps and replace the remaining step with the new analysis procedure.

For example, if you want to change a model that contains four **Static, General** procedures from an Abaqus/Standard analysis to an Abaqus/Explicit analysis, you can use the **Load Manager** to move all of the loads into one of the four steps. Similarly, you can use the **Interaction Manager** to move the interactions. You can then delete the other three steps and replace the remaining step with a **Dynamic, Explicit** procedure. If desired, you can create additional Abaqus/Explicit steps and use the step-dependent managers to move objects that were copied during step replacement to the appropriate Abaqus/Explicit procedures.

For more information, see *Modifying the history of a step-dependent object*.

Understanding output requests

This section gives an overview of output requests.

In this section:

- *What is an output request?*
- *What is the difference between field output and history output?*
- *Propagation of output requests*
- *The output request managers*
- *Creating and modifying output requests*

What is an output request?

The Abaqus analysis products compute the values of many variables at every increment of a step. Usually you are interested in only a small subset of all of this computed data. You can specify the data that you want written to the output database by creating output requests. An output request consists of the following information:

- The variables or variable components of interest.
- The region of the model and the integration points from which the values are written to the output database.
- The rate at which the variable or component values are written to the output database.

When you create the first step, Abaqus/CAE selects a default set of output variables corresponding to the step's analysis procedure. By default, output is requested from every node or integration point in the model and from default section points. In addition, Abaqus/CAE selects the default rate at which the variables are written to the output database. You can edit these default output requests or create and edit new ones.

Default output requests and output requests that you modified are propagated to subsequent steps in the analysis. If you have a large model that includes the default output requests and requests output from a large number of frames, the resulting output database will be very large. You can use a C++ program to extract data from a large output database and copy only selected frames to a second output database. For more information, see *Decreasing the amount of data in an output database by retaining data at specific frames*.

When your analysis is complete, you use the Visualization module to read the output database and graphically display the data that were written to it.

For detailed instructions on creating and editing output requests, see the following sections:

- *Creating an output request*
- *Modifying field output requests*
- *Modifying history output requests*

Additional information

- *Understanding output requests*

What is the difference between field output and history output?

When you create an output request, you can choose either field output or history output.

Field output

Abaqus generates field output from data that are spatially distributed over the entire model or over a portion of it. In most cases you use the Visualization module to view field output data using deformed shape, contour, or symbol plots. The amount of field output generated by Abaqus during an analysis is often large. As a result, you typically request that Abaqus write field data to the output database at a low rate; for example, after every step or at the end of the analysis.

When you create a field output request, you can specify the output frequency in equally spaced time intervals or every time a particular length of time elapses. For an Abaqus/Standard analysis procedure, you can alternatively specify the output frequency in increments, request output after the last increment of each step, or request output according to a set of time points. For an Abaqus/Explicit analysis procedure, you can alternatively request field output for every time increment or according to a set of time points.

When you create a field output request, Abaqus writes every component of the selected variables to the output database. For example, if you were using solid elements to model a cantilever beam with a load at the tip, you could request the stress (all six components) and the displacement (all six components) data from the entire model after the last increment of the loading step. You could then use the Visualization module to view a contour plot of stresses and deflections in the final loaded state.

History output

Abaqus generates history output from data at specific points in a model. In most cases you use the Visualization module to display history output using *X*–*Y* plots. The rate of output depends on how you want to use the data that are generated by the analysis, and the rate can be very high. For example, data generated for diagnostic purposes may be written to the output database after every increment. You can also use history output for data that relate to the model or a portion of the model as a whole; for example, whole model energies.

When you create a history output request, you can specify the output frequency in equally spaced time intervals or every time a particular length of time elapses. For an Abaqus/Standard analysis procedure, you can alternatively specify the output frequency in increments, request output after the last increment of each step, or request output according to a set of time points. For an Abaqus/Explicit analysis procedure, you can alternatively request history output in time increments.

When you create a history output request, you can specify the individual components of the variables that Abaqus/CAE will write to the output database. For example, if you model the response of a cantilever beam with a load applied to the tip, you might request the following output after each increment of the loading step:

- The principal stress at a single node at the root of the beam.
- The vertical displacement at a single node at the tip of the beam.

You could then use the Visualization module to view an *X*–*Y* plot of stress at the root versus displacement at the tip with increasing load.

Propagation of output requests

When you create the first step in the analysis, Abaqus/CAE generates default field and history output requests based on the analysis procedure that you selected for the step. These default output requests are propagated to subsequent steps. The **Field Output Requests Manager** and the **History Output Requests Manager** are step-dependent managers that display the propagation and the status of output requests between steps.

The output requested in a general step is independent of the output requested in a linear perturbation step. In addition, the propagation behavior of output requests varies between general steps and linear perturbation steps.

General steps

Abaqus/CAE creates a default field output request for the first general step in your model, and that default output request propagates to all subsequent general steps. Similarly, if you create a new output request or modify the default output request, the new or modified request is propagated to subsequent general steps.

If you insert a new general step into the sequence of steps, the output request from the previous general step propagates to the new step.

Linear perturbation steps

Abaqus/CAE creates a default field output request for the first linear perturbation step in your model, and that default output request propagates to all subsequent linear perturbation steps that use the same analysis procedure; for example, all the frequency analyses. Similarly, if you create a new output request or modify the default output request, the new or modified request is propagated to subsequent steps that use the same analysis procedure.

If you insert a new linear perturbation step into the sequence of steps, the output request from the previous linear perturbation step that uses the same analysis procedure propagates to the new step. If you create a linear perturbation step that uses a different analysis procedure, Abaqus/CAE creates a new default output request. The new default output request propagates to all subsequent linear perturbation steps that use the same analysis procedure.

You should be aware of the following behavior:

- If you insert a new general step at the beginning of a sequence of existing general steps, Abaqus/CAE does not create a default output request for the new step. Similarly, if you insert a new linear perturbation step at the beginning of a sequence of existing linear perturbation steps of the same procedure type, Abaqus/CAE does not create a default output request for the new step. In both cases you must create a new output request for the new step. Alternatively, you can use the output request managers to move the output request from the following step to the new step.
- If you delete a step (general or linear perturbation) that contains a new output request, Abaqus/CAE deletes the output request from all subsequent steps into which the request had propagated.
- If a step does not contain an output request, Abaqus/CAE displays a warning in the Job module when the input file is generated.

The output request managers

Abaqus/CAE provides separate managers for field output requests and history output requests. The output request managers are step-dependent managers, which means that they contain information concerning the status of each output request in each step of the analysis and allow you to control the propagation of requests across the sequence of steps. For more information, see *What are step-dependent managers?*.

The **Field Output Requests Manager** and the **History Output Requests Manager** contain lists of all of the output requests that you have created. For example, the **Field Output Requests Manager** is shown in *Figure 1*.

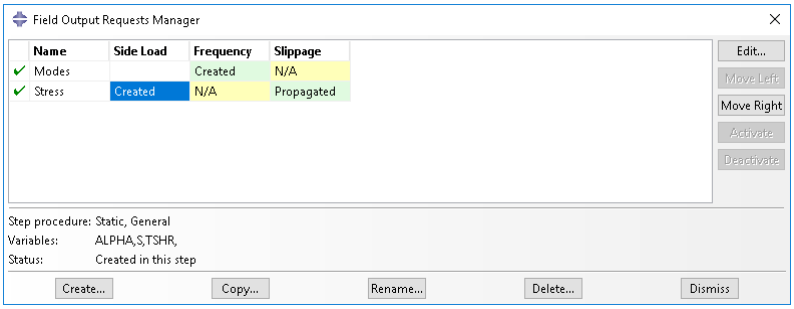

Figure 1: The Field Output Requests Manager.

After you select the step, the **Create** button in the two managers allows you to create a new output request during that step. Similarly, the **Edit**, **Copy**, **Rename**, and **Delete** buttons allow you to edit, copy, rename, and delete the selected output request. You can also initiate the create, edit, copy, rename, and delete procedures using the **Output->Field Output Requests** and **Output->History Output Requests** submenus in the main menu bar.

You can use the **Copy** button in the **Field Output Requests Manager** and the **History Output Requests Manager** (or the corresponding menu commands or Model Tree) to copy an output request. You can copy an output request from any step to any valid step, with some restrictions. For more details, see *Copying step-dependent objects using manager dialog boxes*.

The **Move Left**, **Move Right**, **Activate**, and **Deactivate** buttons allow you to control the propagation of output requests over the course of an analysis. For more information, see *Modifying the history of a step-dependent object*.

You can use the icons in the column along the left side of the managers to suppress output requests or to resume previously suppressed output requests for an analysis. The suppress and resume procedures are also available from the **Output->Field Output Requests** and **Output->History Output Requests** submenus in the main menu bar. For more information, see *Suppressing and resuming objects*.

Additional information

- *What are step-dependent managers?*
- *What is the difference between field output and history output?*

Creating and modifying output requests

To create an output request, select **Output->Field Output Requests->Create** or **Output->History Output Requests->Create** from the main menu bar.
An editor appears in which you can enter all of the information necessary to define the output request. The top of the editor displays the following:

- The name of the output request.
- The name of the step in which you are creating or modifying the output request.
- The name of the analysis procedure associated with the step.

For example, the **Field Output Request** editor is shown in *Figure 1*.

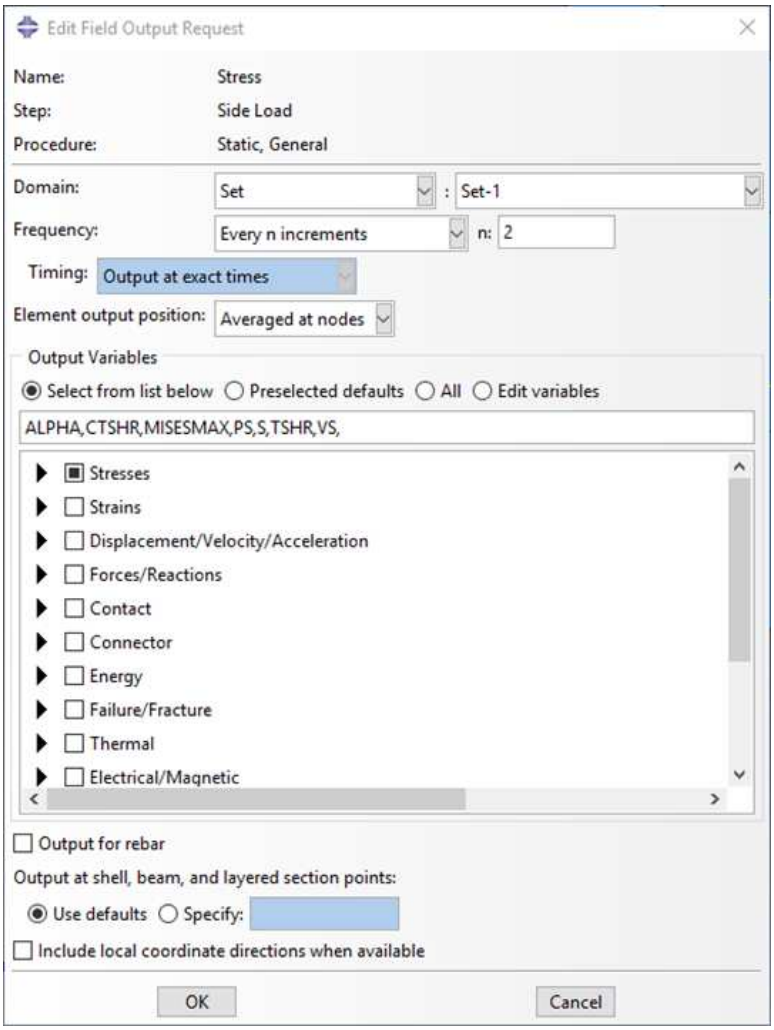

Figure 1: The Field Output Request editor.

The **Domain** section of the editor allows you to choose the region from which output will be generated. You can request that Abaqus write field data to the output database for the following:

- Whole model
- Whole model, only exterior nodes and elements (three-dimensional models in Abaqus/Standard or Abaqus/Explicit analyses)

- A set
- A bolt load
- A skin
- A stringer
- A fastener
- An assembled fastener set
- An interaction
- A composite layup
- A substructure

Similarly, you can request that Abaqus write history data to the output database for the following:

- Whole model
- A set
- A bolt load
- A skin
- A stringer
- A fastener
- An assembled fastener set
- A contour integral
- A general contact surface (Abaqus/Explicit steps only)
- An integrated output section (Abaqus/Explicit steps only)
- An interaction
- Springs/dashpots
- A composite layup

The **Frequency** section of the editor allows you to specify the frequency at which the output is written to the output database. Choose one of the following:

- **Last increment** to request output only after the last increment of the step. This output frequency is available only when you choose an Abaqus/Standard analysis procedure.
- **Every *n* increments** to request output after a specified number of increments. If you specify the frequency in increments, Abaqus also writes output after the last increment of the step. This output frequency is available when you choose an Abaqus/Standard analysis procedure.
- **Every time increment** to request output at every time increment. This output frequency is available for field output when you choose an Abaqus/Explicit analysis procedure.
- **Every *n* time increments** to request output at a specified number of time increments. This output frequency is available for history output when you choose an Abaqus/Explicit analysis procedure.
- **Evenly spaced time intervals** to request output at a number of evenly spaced time intervals.
- **Every *x* units of time** to request output after a particular length of time elapses.
- **From time points** to request output according to a set of time points that you specify. This output frequency is available for field and history output when you choose an Abaqus/Standard analysis procedure and for field output when you choose an Abaqus/Explicit analysis procedure.

The **Element output position** section of the editor allows you to choose the position where selected field output values are written. Choose one of the following:

- **Averaged at nodes** (Abaqus/Standard steps only)
- **Centroidal**
- **Integration points** (default)
- **Nodes**

The **Output Variables** section of the editor contains a list of the variable categories that are applicable to the step procedure and the selected domain. Choose one of the following:

- **Select from list below** to request the variables from the list of check boxes below. You can click the check box next to a category name to select all of the variables within that category, or you can click the arrow next to a category name to display the list of variables in that category and then select individual variables.
- **Preselected defaults** to request the default output variables for the procedure.
- **All** to request all output variables for the procedure.
- **Edit variables** to request variables from the text field below. You can manually edit this field and type or delete variable names.

Note:

In addition to the current analysis procedure, other aspects of the model such as the region specified might affect the output variables. For example, if an output variable is valid for the analysis procedure but is not valid for the element type used in the mesh, Abaqus will remove that variable during the analysis.

If you use the **Field Output Request** editor to select a vector or tensor variable to be included in a field output request, Abaqus automatically writes all components of that variable to the output database during the step. For example, if you select the vector U in a three-dimensional model, Abaqus outputs the three displacement components U1, U2, and U3 to the output database along with the three rotation components UR1, UR2, and UR3.

In contrast, if you use the **History Output Request** editor to select a vector or tensor variable to be included in a history output request, the **History Output Request** editor allows you to select individual components of the variable. It is useful to specify individual components in a history output request because these variables are typically output very frequently—possibly as often as every increment.

If your model contains rebar, you must toggle on **Output for rebar** to include rebar output in the data that Abaqus writes to the output database and to view plots of the rebar orientations in the Visualization module. For more information, see *Understanding rebar in shell sections*.

The editor also allows you to specify the section points from which output will be obtained. If you request output from a composite layup, you can specify the section points from which output will be obtained for each ply of the layup. For more information, see *Requesting output from a composite layup*.

For example, in *Figure 1* the user is editing a field output request that is associated with a **Static, General** analysis procedure. The user has selected all of the variables in the **Stresses** category. These variables will be included in the output request during the step named `Side Load`. Abaqus will write output from the default section points at every increment.

For detailed instructions on selecting output variables and components, see the following sections:

- *Modifying field output requests*
- *Modifying history output requests*

Once you have created an output request, you can modify it in the following ways:

- Select **Output->Field Output Requests->Edit** or **Output->History Output Requests->Edit** to display the field or history output request editor.
- Select **Output->Field Output Requests->Manager** or **Output->History Output Requests->Manager** to display the field or history output requests manager. Use the manager to modify the stepwise history of the output request. (See *What are step-dependent managers?*, for more information.)

If you modify an output request during the step in which you created the request, you can modify the domain, the output variables, the output for rebar option, the section points, and the output frequency. However, if you modify an output request during a step into which it was propagated, you can modify only the output variables and the output frequency.

When you request output from a contour integral, the **History Output Request** editor allows you to select only the frequency of output, the number of contour integrals, and the type of contour integral calculation. For more information, see *Requesting contour integral output*.

Additional information

• *Understanding output requests*

Understanding step control

You can monitor one or more simulation states with sensors during the analysis and take an action, such as terminating the current step or the entire analysis, when the sensor value reaches a specified threshold criterion. (See *Defining Sensors* for more information.) In addition, you can choose to modify the time increment as the simulation state approaches the threshold value or when the simulation state is within a predefined range of values. For this purpose you must define the step control in the particular step.

You can define the step control by selecting **Step Control->Create** from the main menu bar.

For detailed information on adaptive meshing, see *Controlling the Analysis Based on the Simulation State in Abaqus/Standard*.

For detailed instructions on defining step control, see *Defining step control*.

Understanding ALE adaptive meshing

Arbitrary Lagrangian-Eulerian (ALE) adaptive meshing allows you to maintain a high-quality mesh throughout an analysis, even when large deformations or losses of material occur, by allowing the mesh to move independently of the material. Adaptive meshing moves only nodes; the mesh topology remains unchanged. Adaptive meshing is available only for **Coupled temp-displacement**; **Dynamic, Explicit**; **Dynamic, Temp-disp, Explicit**; **Soils**; and **Static, General** steps.

You can define regions of the model where you want adaptive meshing by selecting **Other->ALE Adaptive Mesh Domain** from the main menu bar. If necessary, you can select **Other->ALE Adaptive Mesh Controls** or **Other->ALE Adaptive Mesh Constraint** to customize the adaptive mesh controls or to add regional adaptive mesh constraints, respectively. Currently, you can define only one ALE adaptive mesh domain for any particular step.

For detailed information on adaptive meshing, see *ALE Adaptive Meshing*.

For detailed instructions on defining adaptive mesh regions, see the following sections:

- *Defining an ALE adaptive mesh region*
- *Specifying ALE adaptive mesh constraints*
- *Specifying controls for ALE adaptive meshing*

Understanding integrated, restart, diagnostic, and monitor output

This section explains the additional output controls available in the Step module.

In this section:

- *Integrated output requests*
- *Restart output requests*
- *Diagnostic printing*
- *Degree of freedom monitor requests*

Integrated output requests

To obtain history output of variables such as the forces summed over an exterior surface in contact or transmitted through a tie constraint between surfaces, you must refer to an integrated output section to identify the surface where output is needed.
(See *Integrated Output*.) In addition, the integrated output section definition can provide a local coordinate system in which to express the vector output quantities and/or a reference node as an anchor point about which the total moment across the surface is computed.

By default, an integrated output section is anchored at the global origin and does not follow the motion of the surface on which it is defined. You can define a reference point at which the output section is anchored and specify how this reference point tracks with the average motion of the surface. The reference point must not be connected to any other part of the finite element model.

Integrated output sections associated with a coordinate system and/or a reference node can be used independent of integrated output requests to track the average motion of a surface.

You define integrated output sections by selecting **Output->Integrated Output Sections->Create** from the main menu bar. For detailed instructions, see *Defining integrated output sections*. For information on requesting output for an integrated output section, see *Modifying history output requests*.

Additional information

- *Defining integrated output sections*
- *Understanding output requests*
- *Understanding integrated, restart, diagnostic, and monitor output*

Restart output requests

You can use the restart files created by Abaqus to continue an analysis from a specified step of a previous analysis. This section describes how you control the output of restart data.
For a discussion of how you use the restart data in a subsequent job, see *Restarting an analysis*, and *What are the model attributes?*.

By default, no restart information is written for an Abaqus/Standard analysis and restart information is written only at the beginning and end of each step for an Abaqus/Explicit analysis. However, default restart requests are created automatically for every step in an analysis. The **Edit Restart Requests** dialog box, invoked by selecting **Output->Restart Requests** from the main menu bar in the Step module, allows you to specify how often you want the restart information to be written.

You can specify the frequency at which Abaqus writes data to the restart files; however, the behavior of restart differs between analysis products.

Abaqus/Standard

You can request the frequency in increments or in time intervals. For an Abaqus/Standard step, you can choose whether the output is written at the exact time interval or at the closest approximation.

Abaqus/Explicit

For an Abaqus/Explicit analysis, you specify the number of equally spaced time intervals at which Abaqus writes data to the restart files. In addition, for an Abaqus/Explicit step you can choose whether the output is written at the exact time interval or at the closest approximation. However, you cannot avoid writing information to the restart files for Abaqus/Explicit steps; the number of time intervals must be set to one or greater.

For an Abaqus/Standard or an Abaqus/Explicit analysis, you can request that data written to the restart files overlay data from the previous increment. If you select this option, Abaqus retains the information from only one increment of each step in the restart files, thus minimizing the size of the files. By default, Abaqus does not overlay data.

For more information, see *Restarting an analysis*, and *Restarting an Analysis*. For detailed instructions on requesting restart output, see *Configuring restart output requests*.

You can use the **abaqus restartjoin** execution procedure to extract data from the output database created by a restart analysis and append the data to a second output database. For more information, see *Joining Output Database (.odb) Files from Restarted Analyses*.

Additional information

- *Understanding output requests*
- *Understanding integrated, restart, diagnostic, and monitor output*

Diagnostic printing

If the analysis of your model fails or produces unexpected results, you can examine its iteration-by-iteration progress by looking at selected diagnostic information that is written to the following files:

For Abaqus/Standard analyses:

Diagnostic information is written to the message (`.msg`) file, and a subset of the information is written to the output database (`.odb`) file. You can view the diagnostic information in the output database in the Visualization module (for more information, see *Viewing diagnostic output*). By default, the information is written during every iteration; you can request that Abaqus discontinue writing diagnostic information to the message file by specifying an output frequency of zero.

For Abaqus/Explicit analyses:

Diagnostic information is written to the status (`.sta`) file. For information on the frequency at which this information is written, see *About Output*.

You display the **Edit Diagnostic Print** dialog box by selecting **Output->Diagnostic Print** from the main menu bar.

For detailed instructions on requesting diagnostic printing, see *Configuring diagnostic printing*.

Note:

Changes to the diagnostic print requests do not affect the diagnostic information written to the output database during Abaqus/Standard analyses.

Additional information

- *Understanding output requests*
- *Understanding integrated, restart, diagnostic, and monitor output*
- *Viewing diagnostic output*

Degree of freedom monitor requests

You can request that Abaqus write the values of a degree of freedom at one selected point to the status (`.sta`) file and, for Abaqus/Standard analyses, to the message (`.msg`) file at specific increments during the course of an analysis. In addition, a plot of the degree of freedom value over time appears in a new viewport that is generated automatically when you submit the analysis. (For more information, see *Monitoring the progress of an analysis job*.) You can use this information to monitor the progress of the solution.

You must specify the vertex or node you want to monitor by selecting an existing geometry or node set or by selecting a point in the viewport. Once you have specified the point, you must indicate which degree of freedom you want to monitor at that vertex or node, how often you want the information displayed in a viewport, and how often you want it printed to the status and message files.

For detailed instructions on monitoring a degree of freedom, see *Configuring monitor requests*.

Additional information

- *Configuring monitor requests*
- *Understanding output requests*
- *Understanding integrated, restart, diagnostic, and monitor output*

How can I customize the Abaqus analysis controls?

This section explains how you can adjust the parameters that control the Abaqus analysis.

In this section:

- *General solution controls*
- *Solver controls*

General solution controls

You can customize the numerous variables that control the convergence and time integration accuracy algorithms in Abaqus. The default solution controls usually work well, but customizing these controls may result in a more cost-effective solution or help you to obtain a solution for particularly difficult analyses.

Note:

These options are available only for general Abaqus/Standard analysis steps.

You can access the solution controls by selecting **Other->General Solution Controls** from the main menu bar. For more information, see *Analysis Convergence Controls*.

Warning:

Solution controls are intended for experienced analysts and should be used with great care. The default settings of these controls are appropriate for most nonlinear analyses. Changing these values inappropriately may greatly increase the computational time of your analysis or produce inaccurate results.

For detailed instructions on setting general solution controls, see *Customizing general solution controls*.

Solver controls

You can customize the variables that control the iterative linear equation solver.

Note:

You can use the iterative linear equation solver only for **Static, General**; **Static, Linear perturbation**; **Visco**; **Heat transfer**; **Geostatic**; and **Soils** analysis steps.

You can access the solver controls by selecting **Other->Solver Controls** from the main menu bar. For more information, see *Iterative Linear Equation Solver*.

For detailed instructions on setting solver controls, see *Customizing solver controls*.

Using the Step module toolbox

You can access all the Step module tools through the main menu bar; in addition, you can also access the tools through the Step module toolbox. *Figure 1* shows the icons for the tools in the Step module toolbox.

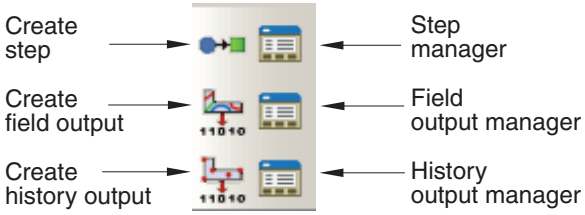

Figure 1: The Step module toolbox.

Using the Step Manager

This section describes how you can use the **Step Manager** to create, edit, and manipulate steps. (For general information on managers, see *Managing objects*.)

In this section:

- *The Step Manager*
- *Creating a step*
- *Editing a step*
- *Replacing a step*
- *Resetting the default values in the step editor*
- *Accounting for geometric nonlinearity*

The Step Manager

You use the **Step Manager** to create, edit, and manipulate the analysis steps associated with the current model. To start the **Step Manager**, select **Step->Manager** from the main menu bar. Columns in the **Step Manager** dialog box display the following information about each step:

Name

The name of the step. Names of linear perturbation steps are indented relative to names of general steps.

Procedure

The analysis procedure that you selected for this step when the step was created. You can change the analysis procedure after creating a step. Click **Replace** to select a new procedure type for the selected step. The **Procedure** column also indicates whether thermal and soils steps assume steady-state or transient conditions or if neither is applicable.

Nlgeom

Whether the analysis step accounts for geometric nonlinearities. You use the **Nlgeom** button to control the **Nlgeom** setting for a particular step. Once you have set the **Nlgeom** option for a step, your setting remains in effect for all subsequent steps.

Time

The time period for the step. The default value for the time period is 1.0 time unit. Click **Edit** to display the step editor so that you can modify the time period.

You use the buttons across the bottom of the **Step Manager** dialog box to create a step that follows the selected step or to manipulate the selected step. You use the **Dismiss** button to close the **Step Manager** dialog box. You can perform the same tasks using the pull-down menus available from the **Step** menu, located in the main menu bar.

You can suppress an analysis step to exclude the procedure from the analysis. The suppressed step is removed from the context bar, the restart request dialog box, and the diagnostic print dialog box. Any step-dependent or propagating attributes created in the step are automatically suppressed and ignored during the analysis. Upon resuming the step, the status of each attribute will return to the original state. For example, suppressing and resuming a step will not resume an associated load that was previously suppressed. You can suppress or resume a step as long as the step sequence remains valid.

Warning:

If you use the **Step Manager** or the **Step** menu to delete a step, objects associated with that step, such as prescribed conditions or output requests, are also deleted. If you use the **Step Manager** or the **Step** menu to replace a step, objects that are incompatible with the new analysis procedure are substituted with an equivalent object, if possible, or deleted.

Additional information

- *Suppressing and resuming objects*
- *Understanding steps*
- *Using the Step Manager*

Creating a step

You can create any sequence of procedures that is allowed by the Abaqus analysis products; the procedure list in the **Create Step** dialog box is updated to show only the available procedures for the new step. For example, if your first step contains a static stress/displacement procedure, you cannot follow it with a new step containing a heat transfer procedure.

1. From the main menu bar, select **Step->Create**.

   The **Create Step** dialog box appears.

   Tip: You can initiate the **Create** procedure in two other ways:

   - Click **Create** in the **Step Manager**. (You can display the **Step Manager** by selecting **Step->Manager** from the main menu bar.)
   - Click the tool in the Step module toolbox.

2. If desired, use the **Name** text field to change the name of the new step.

   All steps must have unique names, and you cannot name a step “Initial”.

3. From the list of existing steps, select the step after which the new step will be inserted.
4. Click the arrow next to the **Procedure type** field, and select either **General** or **Linear perturbation** from the list that appears.

   The lower half of the dialog box displays a list of available procedures.

5. Select the desired procedure and click **Continue**.

   The **Edit Step** dialog box appears.

6. Use the **Edit Step** dialog box to modify the settings from their default values and to provide values for optional settings. (For detailed help on a particular editor feature, select **Help->On Context** from the main menu bar and then click the feature of interest.)
7. Click **OK**.

   Abaqus/CAE closes the **Edit Step** dialog box, and the new step appears in the **Step Manager**.

Additional information

- *Understanding steps*
- *General and Perturbation Procedures*

Editing a step

You can use the step editor to edit the analysis procedure settings associated with an existing step.

1. From the main menu bar, select **Step->Edit->*step name***.

   The step editor appears.

   Tip: You can also select the step name in the **Step Manager** and click **Edit**.

2. Use the tabs within the step editor to modify the settings. (For detailed help on a particular editor feature, select **Help->On Context** from the main menu bar and then click the feature of interest.)
3. Click **OK** to close the step editor and save the new settings.

Additional information

- *Understanding steps*

Replacing a step

You can replace an existing procedure with any procedure that is allowed by the Abaqus analysis products; the procedure list in the **Replace Step** dialog box is updated to show only the available procedures for the revised step. For example, you can change from a **Static, General** procedure to a **Static, Riks** procedure. Abaqus/CAE copies compatible step-dependent objects to the new step, substitutes equivalent objects, if possible, and deletes the remaining objects.

After you replace a step, you should verify that previously defined properties, element types, jobs, and boundary conditions and fields in the inital step remain valid for the model. For more information, see *What is step replacement?*.

1. From the main menu bar, select **Step->Replace->*step name***.

   The **Replace Step** dialog box appears.

   Tip: You can also select the step name in the **Step Manager** and click **Replace**.

2. Click the arrow next to the **New procedure type** field, and select either **General** or **Linear perturbation** from the list that appears.

   The lower half of the dialog box displays a list of available procedures.

3. Select the new procedure, and click **Continue**.

   The **Edit Step** dialog box appears.

4. Use the **Edit Step** dialog box to modify the settings from their default values and to provide values for optional settings. (For detailed help on a particular editor feature, select **Help->On Context** from the main menu bar and then click the feature of interest.)

5. Click **OK**.

   If step-dependent objects are not compatible with the new step, Abaqus/CAE displays a list of the objects that were deleted during step replacement in the message area and closes the **Edit Step** dialog box.

Additional information

- *Understanding steps*

Resetting the default values in the step editor

When you create, edit, or replace a step, you use the step editor to configure the analysis procedure settings. You can use the replace function to reset the settings in the step editor to their default values by replacing an existing step with a step of the same procedure type.

1. From the main menu bar, select **Step->Replace->*step name***.

   The **Replace Step** dialog box appears with the current procedure highlighted in the list of available procedures.

   Tip: You can also select the step name in the **Step Manager** and click **Replace**.

2. Click **Continue**.

   The **Edit Step** dialog box appears with default values for the procedure settings.

3. Use the **Edit Step** dialog box to modify the settings from their default values and to provide values for optional settings. (For detailed help on a particular editor feature, select **Help->On Context** from the main menu bar and then click the feature of interest.)

4. Click **OK**.

   Abaqus/CAE copies step-dependent objects to the new step and closes the **Edit Step** dialog box.

Accounting for geometric nonlinearity

The **Nlgeom** setting for a step determines whether Abaqus will account for geometric nonlinearity in that step. The **Nlgeom** setting is turned on by default for Abaqus/Explicit steps and turned off by default for Abaqus/Standard steps.

The sequence of steps and the current **Nlgeom** setting determine whether you can change the **Nlgeom** setting in a particular step. For example, if Abaqus is already accounting for geometric nonlinearity, the **Nlgeom** setting is toggled on for all subsequent steps, and you cannot toggle it off. Similarly, you cannot change the **Nlgeom** setting during a linear perturbation step. For more information, see *Linear and nonlinear procedures*.

Note:

When you create a step, you can click the **Basic** tab in the **Step Editor** and select **On** or **Off** as the **Nlgeom** setting.

1. To display the **Edit Nlgeom** dialog box and to change the setting where applicable, do one of the following:
   - From the main menu bar, select **Step->Nlgeom**.
   - From the main menu bar, select **Step->Edit->*step name***.

     The **Step Editor** appears. From the **Nlgeom** field on the **Basic** tabbed page, click .
   - From the main menu bar, select **Step->Manager**.

     The **Step manager** appears. From the buttons along the bottom of the manager, click **Nlgeom**.
2. From the **Edit Nlgeom** dialog box, click the step name of interest to turn **Nlgeom** on or off for that step.

   If **Nlgeom** is turned on for a step, a check mark appears in the **Nlgeom** column. If **Nlgeom** is turned off for a step, no tickmark appears.
3. Click **OK** to close the **Edit Nlgeom** dialog box.

Additional information

- *Understanding steps*

Using the step editor

This section describes the step editor and the options that appear in the step editor.

In this section:

- *The step editor*
- *The Incrementation tab*

The step editor

When you create, edit, or replace a step, the step editor displays a set of tabbed pages that allow you to configure the settings for the procedure you selected. The pages are unique for each procedure; for example, when you configure a **Static, General** procedure, the step editor displays the **Basic**, **Incrementation**, and **Other** tabs. Settings you can configure with these tabbed pages include the time period for the step, the maximum number of increments, the increment size, the default load variation with time, and whether to account for geometric nonlinearity.

Abaqus stores the text that you enter in the **Description** field on the **Basic** tabbed page in the output database, and it is displayed in the state block by the Visualization module.

If you want to reset the procedure settings to their default values, you can replace an existing step with a step of the same procedure type. For more information, see *Resetting the default values in the step editor*.

For detailed help on a specific feature of the editor, select **Help->On Context** and then click the feature of interest.

Additional information

- *Understanding steps*
- *Using the step editor*

The Incrementation tab

When you configure general procedures, you use the **Basic** tab in the step editor to enter the total time period for the step. You use the **Incrementation** tab to configure the approach that Abaqus will use to divide the total time period for the step into increments. For a general, static step as well as for many other kinds of steps you can set the following options on the **Incrementation** tabbed page:

Time incrementation

- When you choose **Automatic** time incrementation, Abaqus starts the incrementation using the value entered for the initial increment size. The size of subsequent time increments are adjusted based on how quickly the solution converges. This option is the default selection.
- When you choose **Fixed** time incrementation, Abaqus uses the value entered for the initial increment size throughout the step.

Warning:

Choosing **Fixed** time incrementation may prevent the solution from converging and is not recommended.

Maximum number of increments

Abaqus limits the number of increments in a step to the value that you enter for the maximum number of increments. If the step exceeds this number of increments, the analysis stops, and diagnostic information is reported to the Job module and written to the message file. By default, Abaqus/CAE sets the maximum number of increments to 100.

Initial increment size

Abaqus starts the step using the value entered for the initial increment size.

Minimum increment size

Abaqus checks for the minimum increment size only when you analyze your model using automatic time incrementation. If Abaqus needs a smaller time increment than this value to reach a convergent solution, it terminates the analysis, reports to the Job module, and writes diagnostic information to the message file. If you do not enter a minimum increment size, Abaqus uses 10^{-5} times the total time period.

Maximum increment size

Abaqus checks for the maximum increment size only when you analyze your model using automatic time incrementation. Abaqus will not increase the increment size beyond this value during the analysis. If you do not specify this value, Abaqus/CAE sets the value to that of the total time period (with the exception of dynamic, implicit procedures, in which the default maximum increment size depends on a variety of analysis settings; see *Configuring a dynamic, implicit procedure*).

Note:

A value must be entered for each of the incrementation options described above. Abaqus/CAE does not allow you to create the step if you delete the default value for an incrementation option but fail to provide another.

For detailed information on other items in the **Incrementation** tabbed page, click **Help->On Context** and then click the item of interest.

Additional information

- *Understanding steps*
- *Using the step editor*

Configuring analysis procedure settings

The **Edit Step** dialog box allows you to configure the analysis procedure settings for a particular step. This section provides instructions for each analysis procedure.

In this section:

- *Configuring general analysis procedures*
- *Configuring linear perturbation analysis procedures*

Configuring general analysis procedures

You can configure general analysis procedures to analyze linear or nonlinear response. You can include general analysis procedures in Abaqus/Standard or Abaqus/Explicit analyses.
For more information, see *General and Perturbation Procedures*.

This section provides instructions for using the step editor to configure different types of general analysis procedures.

In this section:

- *Configuring a static, general procedure*
- *Configuring a static, Riks procedure*
- *Configuring a dynamic, explicit procedure*
- *Configuring a heat transfer procedure*
- *Configuring a dynamic, implicit procedure*
- *Configuring a fully coupled, simultaneous heat transfer and stress procedure*
- *Configuring a fully coupled, simultaneous heat transfer and electrical procedure*
- *Configuring a fully coupled, simultaneous heat transfer, electrical, and structural procedure*
- *Configuring a coupled, thermal electrochemical procedure*
- *Configuring a fully coupled, thermal electrochemical structural procedure*
- *Configuring a fully coupled, thermal electrochemical structural pore pressure procedure*
- *Configuring a direct cyclic procedure*
- *Configuring a dynamic fully coupled thermal-stress procedure using explicit integration*
- *Configuring a geostatic stress field procedure*
- *Configuring a mass diffusion procedure*
- *Configuring an effective stress analysis for fluid-filled porous media*
- *Configuring a transient, static, stress/displacement analysis with time-dependent material response*
- *Configuring an annealing procedure*

Configuring a static, general procedure

A static stress procedure is one in which inertia effects are neglected. The analysis can be linear or nonlinear and ignores time-dependent material effects. For more information, see *Static Stress Analysis*.

Create or edit a static, general procedure

1. Display the **Edit Step** dialog box following the procedure outlined in *Creating a step* (**Procedure type:** `General; Static, General`), or *Editing a step*.
2. On the **Basic**, **Incrementation**, and **Other** tabbed pages, configure settings such as the time period for the step, the maximum number of increments, the increment size, the default load variation with time, and whether to account for geometric nonlinearity as described in the following procedures.

*Configure settings on the **Basic** tabbed page*

1. In the **Edit Step** dialog box, display the **Basic** tabbed page.
2. In the **Description** field, enter a short description of the analysis step. Abaqus stores the text that you enter in the output database, and the text is displayed in the state block by the Visualization module.
3. In the **Time period** field, enter the time period of the step. For more information, see *Time Period*.
4. Select an **Nlgeom** option:

   - Toggle **NlgeomOff** to perform a geometrically linear analysis during the current step.
   - Toggle **NlgeomOn** to indicate that Abaqus/Standard should account for geometric nonlinearity during the step. Once you have toggled **Nlgeom** on, it will be active during all subsequent steps in the analysis.

   For more information, see *Linear and nonlinear procedures*.

5. Select an automatic stabilization method if you expect the problem to have local instabilities such as surface wrinkling, material instability, or local buckling. Abaqus/Standard can stabilize this class of problems by applying damping throughout the model. For more information, see *Unstable Problems*, and *Automatic Stabilization of Static Problems with a Constant Damping Factor*

   Click the arrow to the right of **Automatic stabilization**, and select a method for defining the damping factor:

   - Select **Specify dissipated energy fraction** to allow Abaqus/Standard to calculate the damping factor from a dissipated energy fraction that you provide. Enter a value for the dissipated energy fraction in the adjacent field (the default is 2.0×10^{-4}). For more information, see *Calculating the Damping Factor Based on the Dissipated Energy Fraction*.
   - Select **Specify damping factor** to enter the damping factor directly. Enter a value for the damping factor in the adjacent field. For more information, see *Directly Specifying the Damping Factor*.
   - Select **Use damping factors from previous general step** to use the damping factors at the end of the previous step as the initial factors in the current step's variable damping scheme. These factors override any initial damping factors that are calculated or specified directly in the current step. If there are no damping factors associated with the previous general step (for example, if the previous step does not use any stabilization or the current step is the first step of the analysis), Abaqus uses adaptive stabilization to determine the required damping factors.

6. When using automatic stabilization, Abaqus can use the same damping factor over the course of a step, or it can vary the damping factor spatially and temporally during a step based on the convergence history and the ratio of the energy dissipated by damping to the total strain energy. For more information, see *Adaptive Automatic Stabilization Scheme*. If you selected **Specify dissipated energy fraction**, adaptive stabilization is optional and turned on by default. If you selected **Specify damping factor**,

adaptive stabilization is optional and turned off by default. If you selected **Use damping factors from previous general step**, adaptive stabilization is required.

To use adaptive stabilization, toggle on **Use adaptive stabilization with max. ratio of stabilization to strain energy** (if necessary), and enter a value in the adjacent field for the allowable accuracy tolerance for the ratio of energy dissipated by damping to total strain energy in each increment. The default value of 0.05 should be suitable in most cases.

7. Toggle on **Include adiabatic heating effects** if you are performing an adiabatic stress analysis. This option is relevant only for isotropic metal plasticity materials with a Mises yield surface. For more information, see *Adiabatic Analysis*.
8. When you have finished configuring settings for the static, general step, click **OK** to close the **Edit Step** dialog box.

*Configure settings on the **Incrementation** tabbed page*

1. In the **Edit Step** dialog box, display the **Incrementation** tabbed page.

   (For information on displaying the **Edit Step** dialog box, see *Creating a step*, or *Editing a step*.)
2. Choose a **Type** option:
   - Choose **Automatic** to allow Abaqus/Standard to choose the size of the time increments based on computational efficiency.
   - Choose **Fixed** to specify direct user control of the incrementation. Abaqus/Standard uses an increment size that you specify as the constant increment size throughout the step.
3. In the **Maximum number of increments** field, enter the upper limit to the number of increments in the step. The analysis stops if this maximum is exceeded before Abaqus/Standard arrives at the complete solution for the step.
4. If you selected **Automatic** in Step 2, enter values for **Increment size**:
   a. In the **Initial** field, enter the initial time increment. Abaqus/Standard modifies this value as required throughout the step.
   b. In the **Minimum** field, enter the minimum time increment allowed. If Abaqus/Standard needs a smaller time increment than this value, it terminates the analysis.
   c. In the **Maximum** field, enter the maximum time increment allowed.
5. If you selected **Fixed** in Step 2, enter a value for the constant time increment in the **Increment size** field.
6. When you have finished configuring settings for the static, general step, click **OK** to close the **Edit Step** dialog box.

*Configure settings on the **Other** tabbed page*

1. In the **Edit Step** dialog box, display the **Other** tabbed page.

   (For information on displaying the **Edit Step** dialog box, see *Creating a step*, or *Editing a step*.)
2. Choose an **Equation Solver Method** option:
   - Choose **Direct** to use the default direct sparse solver.
   - Choose **Iterative** to use the iterative linear equation solver. The iterative solver is typically most useful for blocky structures with millions of degrees of freedom. For more information, see *Iterative Linear Equation Solver*.
3. Choose a **Matrix storage** option:

- Choose **Use solver default** to allow Abaqus/Standard to decide whether a symmetric or unsymmetric matrix storage and solution scheme is needed.
- Choose **Unsymmetric** to restrict Abaqus/Standard to the unsymmetric storage and solution scheme.
- Choose **Symmetric** to restrict Abaqus/Standard to the symmetric storage and solution scheme.

For more information on matrix storage, see *Matrix Storage and Solution Scheme in Abaqus/Standard*.

4. Choose a **Solution technique**:

   - Choose **Full Newton** to use Newton's method as a numerical technique for solving nonlinear equilibrium equations. For more information, see *Nonlinear solution methods in Abaqus/Standard*.
   - Choose **Quasi-Newton** to use the quasi-Newton technique for solving nonlinear equilibrium equations. This technique can save substantial computational cost in some cases. Generally it is most successful when the system is large and the stiffness matrix is not changing much from iteration to iteration. You can use this technique only for symmetric systems of equations.

     If you choose this technique, enter a value for the **Number of iterations allowed before the kernel matrix is reformed**. The maximum number of iterations allowed is 25. The default number of iterations is 8.

     For more information, see *Quasi-Newton solution technique*.

5. Click the arrow to the right of the **Convert severe discontinuity iterations** field, and select an option for dealing with severe discontinuities during nonlinear analysis:

   - Select **Off** to force a new iteration if severe discontinuities occur during an iteration, regardless of the magnitude of the penetration and force errors. This option also changes some time incrementation parameters and uses different criteria to determine whether to do another iteration or to make a new attempt with a smaller increment size.
   - Select **On** to use local convergence criteria to determine whether a new iteration is needed. Abaqus/Standard will determine the maximum penetration and estimated force errors associated with severe discontinuities and check whether these errors are within the tolerances. Hence, a solution may converge if the severe discontinuities are small.
   - Select **Propagate from previous step** to use the value specified in the previous general analysis step. This value appears in parentheses to the right of the field.

   For more information on severe discontinuities, see *Severe Discontinuities in Abaqus/Standard*.

6. Choose an option for **Default load variation with time**:

   - Choose **Instantaneous** if you want loads to be applied instantaneously at the start of the step and remain constant throughout the step.
   - Choose **Ramp linearly over step** if the load magnitude is to vary linearly over the step, from the value at the end of the previous step to the full magnitude of the load.

7. Click the arrow to the right of the **Extrapolation of previous state at start of each increment** field, and select a method for determining the first guess to the incremental solution:

   - Select **Linear** to indicate that the process is essentially monotonic and Abaqus/Standard should use a 100% linear extrapolation, in time, of the previous incremental solution to begin the nonlinear equation solution for the current increment.
   - Select **Parabolic** to indicate that the process should use a quadratic extrapolation, in time, of the previous two incremental solutions to begin the nonlinear equation solution for the current increment.
   - Select **None** to suppress any extrapolation.

For more information, see *Extrapolation of the Solution*.

8. Toggle on **Stop when region *region name* is fully plastic** if "fully plastic" analysis is required with deformation theory plasticity. If you toggle on this option, enter the name of the region being monitored for fully plastic behavior.

   The step ends when the solutions at all constitutive calculation points in the element set are fully plastic (defined by the equivalent strain being 10 times the offset yield strain). However, the step can end before this point if either the maximum number of increments that you specified on the **Incrementation** tabbed page or the time period that you specified on the **Basic** tabbed page is exceeded.

9. If you selected **Fixed** time incrementation on the **Incrementation** tabbed page, you can toggle on **Accept solution after reaching maximum number of iterations**. This option directs Abaqus/Standard to accept the solution to an increment after the maximum number of iterations allowed has been completed, even if the equilibrium tolerances are not satisfied. Very small increments and a minimum of two iterations are usually necessary if you use this option.

   Warning:

   This approach is not recommended; you should use it only in special cases when you have a thorough understanding of how to interpret results obtained in this way.

10. Toggle on **Obtain long-term solution with time-domain material properties** to obtain the fully relaxed long-term elastic solution with time-domain viscoelasticity or the long-term elastic-plastic solution for two-layer viscoplasticity. This parameter is relevant only for time-domain viscoelastic and two-layer viscoplastic materials.
11. When you have finished configuring settings for the static, general step, click **OK** to close the **Edit Step** dialog box.

Configuring a static, Riks procedure

Geometrically nonlinear static problems sometimes involve buckling or collapse behavior, where the load-displacement response shows a negative stiffness, and the structure must release strain energy to remain in equilibrium. The modified Riks method allows you to find static equilibrium states during the unstable phase of the response.

You can use this method for cases where the load magnitudes are governed by a single scalar parameter. It is also useful for solving ill-conditioned problems such as limit load problems or almost unstable problems that exhibit softening. For more information, see *Unstable Collapse and Postbuckling Analysis*.

Create or edit a static, Riks procedure

1. Display the **Edit Step** dialog box following the procedure outlined in *Creating a step* (**Procedure type:** `General; Static, Riks`), or *Editing a step*.
2. On the **Basic**, **Incrementation**, and **Other** tabbed pages, configure settings such as stopping criteria, the maximum number of increments, the arc increment length, and whether to account for geometric nonlinearity as described in the following procedures.

*Configure settings on the **Basic** tabbed page*

1. In the **Edit Step** dialog box, display the **Basic** tabbed page.
2. In the **Description** field, enter a short description of the analysis step. Abaqus stores the text that you enter in the output database, and the text is displayed in the state block by the Visualization module.
3. Select an **Nlgeom** option:
   - Toggle **NlgeomOff** to perform a geometrically linear analysis during the current step.
   - Toggle **NlgeomOn** to indicate that Abaqus/Standard should account for geometric nonlinearity during the step. Once you have toggled **Nlgeom** on, it will be active during all subsequent steps in the analysis.

   For more information, see *Linear and nonlinear procedures*.
4. Toggle on **Include adiabatic heating effects** if you are performing an adiabatic stress analysis. This option is relevant only for isotropic metal plasticity materials with a Mises yield surface. For more information, see *Adiabatic Analysis*.
5. Since the loading magnitude is part of the solution, you need a method to specify when the step is completed. Choose one or both of the following options:
   - Toggle on **Maximum load proportionality factor** to enter a maximum value for the load proportionality factor, λ_{end}. Abaqus/Standard uses this value to terminate the step when the load exceeds a certain magnitude. For more information, see *Proportional Loading*
   - Toggle on **Maximum displacement** to enter a maximum displacement value at a specific degree of freedom (**DOF**). You must also specify the **Node Region** that Abaqus/Standard will monitor for finishing displacement. If this maximum displacement is exceeded, Abaqus/Standard terminates the step.

   If you leave both of these finishing conditions unspecified, the analysis continues for the number of increments that you specify on the **Incrementation** tabbed page.

*Configure settings on the **Incrementation** tabbed page*

1. In the **Edit Step** dialog box, display the **Incrementation** tabbed page.
   (For information on displaying the **Edit Step** dialog box, see *Creating a step*, or *Editing a step*.)
2. Choose a **Type** option:

- Choose **Automatic** to allow Abaqus/Standard to choose the size of the arc length increments based on computational efficiency.
- Choose **Fixed** to specify direct user control of the incrementation. Abaqus/Standard uses an arc length increment that you specify as the constant increment size throughout the step. This method is not recommended for a Riks analysis since it prevents Abaqus/Standard from reducing the arc length when a severe nonlinearity is encountered.

For more information, see *Incrementation*.

3. In the **Maximum number of increments** field, enter the upper limit to the number of increments in the step. The analysis stops if this maximum is exceeded before Abaqus/Standard arrives at the complete solution for the step.
4. If you selected **Automatic** in Step 2, enter values for **Arc length increment**:
   a. In the **Initial** field, enter the initial increment in arc length along the static equilibrium path in scaled load-displacement space, Δl_{in}.
   b. In the **Minimum** field, enter the minimum arc length increment, Δl_{min}. If you enter zero, Abaqus assumes a default value of the smaller of the suggested initial arc length or 10^{-5} times the total arc length.
   c. In the **Maximum** field, enter the maximum arc length increment, Δl_{max}. If this value is not specified, no upper limit is imposed.
   d. In the **Estimated total arc length** field, enter the total arc length scale factor associated with this step, l_{period}. If this entry is zero or is unspecified, Abaqus/Standard assumes a default value of **1.0**.
5. If you selected **Fixed** in Step 2, enter a value for the constant arc length increment in the **Arc length increment** field.

*Configure settings on the **Other** tabbed page*

1. In the **Edit Step** dialog box, display the **Other** tabbed page.
   (For information on displaying the **Edit Step** dialog box, see *Creating a step*, or *Editing a step*.)
2. Choose a **Matrix storage** option:
   - Choose **Use solver default** to allow Abaqus/Standard to decide whether a symmetric or unsymmetric matrix storage and solution scheme is needed.
   - Choose **Unsymmetric** to restrict Abaqus/Standard to the unsymmetric storage and solution scheme.
   - Choose **Symmetric** to restrict Abaqus/Standard to the symmetric storage and solution scheme.

   For more information on matrix storage, see *Matrix Storage and Solution Scheme in Abaqus/Standard*.
3. Click the arrow to the right of the **Convert severe discontinuity iterations** field, and select an option for dealing with severe discontinuities during nonlinear analysis:
   - Select **Off** to force a new iteration if severe discontinuities occur during an iteration, regardless of the magnitude of the penetration and force errors. This option also changes some time incrementation parameters and uses different criteria to determine whether to do another iteration or to make a new attempt with a smaller increment size.
   - Select **On** to use local convergence criteria to determine whether a new iteration is needed. Abaqus/Standard will determine the maximum penetration and estimated force errors associated with severe discontinuities and check whether these errors are within the tolerances. Hence, a solution may converge if the severe discontinuities are small.
   - Select **Propagate from previous step** to use the value specified in the previous general analysis step. This value appears in parentheses to the right of the field.

For more information on severe discontinuities, see *Severe Discontinuities in Abaqus/Standard*.

4. Click the arrow to the right of the **Extrapolation of previous state at start of each increment** field, and select a method for determining the first guess to the incremental solution:

   - Select **Linear** to indicate that the process is essentially monotonic, and Abaqus/Standard should use a 1% linear extrapolation of the previous incremental solution to begin the nonlinear equation solution for the current increment.
   - Select **None** to suppress any extrapolation.

   (The **Parabolic** option is not relevant for Riks analyses.) For more information, see *Extrapolation of the Solution*.

5. Toggle on **Stop when region *region name* is fully plastic** if "fully plastic" analysis is required with deformation theory plasticity. If you toggle on this option, enter the name of the region being monitored for fully plastic behavior.

   The step ends when the solutions at all constitutive calculation points in the element set are fully plastic (defined by the equivalent strain being 10 times the offset yield strain). However, the step can end before this point if the maximum number of increments that you specified on the **Incrementation** tabbed page is exceeded.

6. If you selected **Fixed** time incrementation on the **Incrementation** tabbed page, you can toggle on **Accept solution after reaching maximum number of iterations**. This option directs Abaqus/Standard to accept the solution to an increment after the maximum number of iterations allowed has been completed, even if the equilibrium tolerances are not satisfied. Very small increments and a minimum of two iterations are usually necessary if you use this option.

   Warning:

   This approach is not recommended; you should use it only in special cases when you have a thorough understanding of how to interpret results obtained in this way.

7. Toggle on **Obtain long-term solution with time-domain material properties** to obtain the fully relaxed long-term elastic solution with time-domain viscoelasticity or the long-term elastic-plastic solution for two-layer viscoplasticity. This parameter is relevant only for time-domain viscoelastic and two-layer viscoplastic materials.

When you have finished configuring settings for the static, Riks step, click **OK** to close the **Edit Step** dialog box.

Configuring a dynamic, explicit procedure

An explicit, dynamic analysis is computationally efficient for the analysis of large models with relatively short dynamic response times and for the analysis of extremely discontinuous events or processes. This type of analysis allows for the definition of very general contact conditions and uses a consistent, large-deformation theory. For more information, see *Explicit Dynamic Analysis*.

Create or edit a dynamic, explicit procedure

1. Display the **Edit Step** dialog box following the procedure outlined in *Creating a step* (**Procedure type:** `General; Dynamic, Explicit`), or *Editing a step*.
2. On the **Basic**, **Incrementation**, **Mass scaling**, and **Other** tabbed pages, configure settings such as the time period for the step, the maximum time increment, the increment size, mass scaling definitions, and bulk viscosity parameters as described in the following procedures.

*Configure settings on the **Basic** tabbed page*

1. In the **Edit Step** dialog box, display the **Basic** tabbed page.
2. In the **Description** field, enter a short description of the analysis step. Abaqus stores the text that you enter in the output database, and the text is displayed in the state block by the Visualization module.
3. In the **Time period** field, enter the time period of the step.
4. Select an **Nlgeom** option:
   - Toggle **NlgeomOff** to perform a geometrically linear analysis during the current step.
   - Toggle **NlgeomOn** to indicate that Abaqus/Explicit should account for geometric nonlinearity during the step. Once you have toggled **Nlgeom** on, it will be active during all subsequent steps in the analysis.

   For more information, see *Linear and nonlinear procedures*.
5. Toggle on **Include adiabatic heating effects** if you are performing an adiabatic stress analysis. This option is relevant only for metal plasticity. For more information, see *Adiabatic Analysis*.

*Configure settings on the **Incrementation** tabbed page*

1. In the **Edit Step** dialog box, display the **Incrementation** tabbed page.

   (For information on displaying the **Edit Step** dialog box, see *Creating a step*, or *Editing a step*.)
2. Choose a **Type** option:
   - Choose **Automatic** to allow Abaqus/Explicit to determine the time incrementation automatically. For more information, see *Automatic Time Incrementation*.
   - Choose **Fixed** to use a fixed time incrementation scheme. The fixed time increment size is determined either by the initial element stability estimate for the step or by a user-specified time increment. For more information, see *Fixed Time Incrementation*.
3. If you selected **Automatic** time incrementation, perform the following steps:
   a. Choose a **Stable increment estimator** option:
      - Choose **Global** to allow the global estimator to determine the stability limit as the step proceeds. The adaptive, global estimation algorithm determines the maximum frequency of the entire model using the current dilatational wave speed. This algorithm continuously updates the estimate for the maximum frequency. The global estimator will usually allow time increments that exceed the element-by-element values.

- Choose **Element-by-element** to allow Abaqus/Explicit to determine an element-by-element estimate using the current dilatational wave speed in each element.

  The element-by-element estimate is conservative; it will give a smaller stable time increment than the true stability limit that is based upon the maximum frequency of the entire model. In general, constraints such as boundary conditions and kinematic contact have the effect of compressing the eigenvalue spectrum, and the element-by-element estimates do not take this into account.

b. By default, the "improved" method to estimate the element stable time increment for three-dimensional continuum elements and elements with plane stress formulations is used. This method usually results in a larger element stable time increment than a more traditional method. Toggle off **Improved Dt Method** to deactivate the "improved" method.

c. Choose a **Max. time increment** option:

- Choose **Unlimited** if you do not want to impose an upper limit to time incrementation.
- Choose **Value** to enter a value for the maximum time increment allowed. Enter the value in the field provided.

For more information, see *Automatic Time Incrementation*.

4. If you selected **Fixed** time incrementation, choose an option for determining increment size:

- Choose **User-defined time increment** to specify a time increment size directly. Enter that time increment size in the field provided.
- Choose **Use element-by-element time increment estimator** to use time increments the size of the initial element-by-element stability limit throughout the step. The dilatational wave speed in each element at the beginning of the step is used to compute the fixed time increment size.

For more information, see *Fixed Time Incrementation*.

5. If desired, enter a **Time scaling factor** to adjust the stable time increment computed by Abaqus/Explicit. (This option is unavailable if you have specified a **User-defined time increment** for the **Fixed** time incrementation scheme.) For more information, see *Scaling the Time Increment*.

*Configure settings on the **Mass scaling** tabbed page*

1. In the **Edit Step** dialog box, display the **Mass scaling** tabbed page. For background information on mass scaling, see *Mass Scaling*.

(For information on displaying the **Edit Step** dialog box, see *Creating a step*, or *Editing a step*.)

2. Choose one of the following options for specifying mass scaling:

- Choose **Use scaled mass and “throughout step” definitions from the previous step** if you want mass scaling definitions from the previous step to propagate through the current step. If you choose this option, you can skip the remaining steps in this procedure.
- Choose **Use scaling definitions below** to create one or more new mass scaling definitions for this step. If you choose this option, complete the remaining steps in this procedure.

3. At the bottom of the **Data** table, click **Create**.

An **Edit mass scaling** dialog box appears.

4. Specify which type of mass scaling definition you want to create:

- Choose **Semi-automatic mass scaling** to define mass scaling for any type of analysis except bulk metal rolling.

- Choose **Automatic mass scaling** to define mass scaling for a bulk metal rolling analysis. For more information, see *Automatic Mass Scaling for Analysis of Bulk Metal Rolling*.
- Choose **Reinitialize mass** to reinitialize masses of elements to their original values. This option allows you to prevent the scaled mass from a previous step from being used in the current step. For more information, see *Reverting the Mass Matrix to the Original State*.
- Choose **Disable mass scaling thoughout step** to disable in this step all variable mass scaling definitions from previous steps. For more information, see *Continuous Mass Matrix with No Further Scaling*.

5. If you selected **Semi-automatic mass scaling**, **Automatic mass scaling**, or **Reinitialize mass**, indicate the region to which you want the mass scaling definition applied:
   - Choose **Whole model** to apply the mass scaling definition to all elements in the model.
   - Choose **Set** to apply the mass scaling definition to a particular set of elements. Enter the set name in the field provided.

6. If you selected **Semi-automatic mass scaling**, indicate when, during the step, you want Abaqus/Explicit to scale the element masses:
   - Choose **At beginning of step** to perform fixed mass scaling only at the beginning of the step. For more information, see *Fixed Mass Scaling*.
   - Choose **Throughout step** to scale the mass of elements periodically during the step. For more information, see *Variable Mass Scaling*.

7. If you selected **Semi-automatic mass scaling**, indicate how you want Abaqus/Explicit to scale the element masses:
   - Toggle on **Scale by factor** to scale the elements once at the beginning of the step by the value you enter in the field provided. For more information, see *Defining a Scale Factor Directly*.
   - Toggle on **Scale to target time increment of *n*** to enter a desired element stable time increment in the field provided. Click the arrow to the right of the **Scale element mass** field, and select how you want Abaqus/Explicit to apply that target time increment:
     - Select **Uniformly to satisfy target** to scale the masses of the elements equally so that the smallest element stable time increment of the scaled elements equals the target value.
     - Select **If below minimum target** to scale the masses of only the elements whose element stable time increments are less than the target value.
     - Select **Nonuniformly to equal target** to scale the masses of all elements so that they all have the same element stable time increment equal to the target value.

     For more information, see *Defining a Desired Element-by-Element Stable Time Increment*.

   If you toggle on both **Scale by factor** and **Scale to target time increment**, Abaqus/Explicit first scales the masses by the factor value that you enter and then possibly scales them again, depending on the value you enter for target time increment and the option you select for applying that target.

8. If you selected **Automatic mass scaling**, enter the following values:
   - In the **Feed rate** field, enter the estimated average velocity of the workpiece in the rolling direction at steady-state conditions.
   - In the **Extruded element length** field, enter the average element length in the rolling direction.
   - In the **Nodes in cross-section** field, enter the number of nodes in the cross-section of the workpiece. Increasing this value decreases the amount of mass scaling.

For more information, see *Automatic Mass Scaling for Analysis of Bulk Metal Rolling*.

9. If you selected **Semi-automatic mass scaling** throughout the step or **Automatic mass scaling**, specify when, during the step, you want Abaqus/Explicit to perform mass scaling calculations:

   - Choose **Every *n* increments** to specify the frequency, in increments, at which Abaqus/Explicit is to perform mass scaling calculations. Enter the desired frequency in the field provided.

     For example, if you enter a value of 5, Abaqus/Explicit scales the mass at the beginning of the step and at increments 5, 10, 15, etc.

   - Choose **At *n* equal intervals** to specify the number of intervals during the step at which Abaqus/Explicit is to perform mass scaling calculations. Enter the desired value in the field provided.

     For example, if you enter a value of 2, Abaqus/Explicit scales the mass at the beginning of the step, the increment immediately following the half-way point in the step, and the final increment in the step.

10. Click **OK** to close the **Edit mass scaling** dialog box and return to the **Mass scaling** tabbed page of the **Edit Step** dialog box.

    The mass scaling definition that you have just created appears in the **Data** table.

11. If desired, repeat Steps 3 to 10 to create additional mass scaling definitions.
12. Once you have created one or more mass scaling definitions, you can edit or delete them if desired. Select a particular mass scaling definition in the **Data** table, and click **Edit** or **Delete** at the bottom of the **Data** table.

*Configure settings on the **Other** tabbed page*

1. In the **Edit Step** dialog box, display the **Other** tabbed page.

   (For information on displaying the **Edit Step** dialog box, see *Creating a step*, or *Editing a step*.)

2. Enter a value for the **Linear bulk viscosity parameter**. Linear bulk viscosity is included by default in Abaqus/Explicit.
3. Enter a value for the **Quadratic bulk viscosity parameter**. This form of bulk viscosity pressure is found only in solid continuum element and is applied only if the volumetric strain rate is compressive.

   For more information, see *Bulk Viscosity*.

When you have finished configuring settings for the dynamic, explicit step, click **OK** to close the **Edit Step** dialog box.

Configuring a heat transfer procedure

You can perform an uncoupled heat transfer analysis to model solid body heat conduction with general, temperature-dependent conductivity, internal energy (including latent heat effects), and general convection and radiation boundary conditions, including cavity radiation. For more information, see *Uncoupled Heat Transfer Analysis*.

Create or edit a heat transfer procedure

1. Display the **Edit Step** dialog box following the procedure outlined in *Creating a step* (**Procedure type:** `General; Heat transfer`), or *Editing a step*.
2. On the **Basic**, **Incrementation**, and **Other** tabbed pages, configure settings such as the time period for the step, the maximum allowable temperature change per increment, and equation solver preferences as described in the following procedures.

*Configure settings on the **Basic** tabbed page*

1. In the **Edit Step** dialog box, display the **Basic** tabbed page.
2. In the **Description** field, enter a short description of the analysis step. Abaqus stores the text that you enter in the output database, and the text is displayed in the state block by the Visualization module.
3. Choose a **Response** option:
   - Choose **Steady-state** to omit the internal energy term (the specific heat term) in the governing heat transfer equation. For more information, see *Steady-State Analysis*.
   - Choose **Transient** to perform time integration with the backward Euler method in the pure conduction elements. This method is unconditionally stable for linear problems. For more information, see *Transient Analysis*.

   Note:

   After you have selected a **Response** option, a message appears informing you that Abaqus/Standard has selected the **Default load variation with time** option (located on the **Other** tabbed page) that corresponds to your **Response** selection. Click **Dismiss** to close the message dialog box.

4. In the **Time period** field, enter the time period of the step.

*Configure settings on the **Incrementation** tabbed page*

1. In the **Edit Step** dialog box, display the **Incrementation** tabbed page.

   (For information on displaying the **Edit Step** dialog box, see *Creating a step*, or *Editing a step*.)
2. Choose a **Type** option:
   - Choose **Automatic** if you want Abaqus/Standard to determine suitable time increment sizes.
   - Choose **Fixed** to specify direct user control of the incrementation. Abaqus/Standard uses an increment size that you specify as the constant increment size throughout the step.
3. In the **Maximum number of increments** field, enter the upper limit to the number of increments in the step. The analysis stops if this maximum is exceeded before Abaqus/Standard arrives at the complete solution for the step.
4. If you selected **Automatic** in Step 2, enter values for **Increment size**:
   a. In the **Initial** field, enter the initial time increment. Abaqus/Standard modifies this value as required throughout the step.

b. In the **Minimum** field, enter the minimum time increment allowed. If Abaqus/Standard needs a smaller time increment than this value, it terminates the analysis.

c. In the **Maximum** field, enter the maximum time increment allowed.

5. If you selected **Fixed** in Step 2, enter a value for the constant time increment in the **Increment size** field.
6. If you selected **Transient** analysis on the **Basic** tabbed page, do the following:

   a. Toggle on **End step when temperature change is less than *n*** if you want the analysis to end when the temperature at every temperature degree of freedom changes at a rate that is less than a rate that you specify. If you toggle on this option, enter the desired temperature change rate in the field provided.

   b. If you selected **Automatic** in Step 2, enter a value for the **Max. allowable temperature change per increment**. Abaqus/Standard restricts the time step to ensure that this value is not exceeded at any node (except nodes whose temperature degree of freedom is constrained via boundary conditions, MPCs, etc.) during any increment of the step.
7. If you selected **Automatic** in Step 2 and you are performing a cavity radiation analysis, enter a value for **Max. allowable emissivity change per increment** or accept the default of 0.1. If this value is exceeded, Abaqus/Standard cuts back the increment until the maximum change in emissivity is less than the specified value. See *Cavity Radiation in Abaqus/Standard*, for more information.

*Configure settings on the **Other** tabbed page*

1. In the **Edit Step** dialog box, display the **Other** tabbed page.

   (For information on displaying the **Edit Step** dialog box, see *Creating a step*, or *Editing a step*.)
2. Choose an **Equation Solver Method** option:

   - Choose **Direct** to use the default direct sparse solver.
   - Choose **Iterative** to use the iterative linear equation solver. The iterative solver is typically most useful for blocky structures with millions of degrees of freedom. For more information, see *Iterative Linear Equation Solver*.
3. Choose a **Matrix storage** option:

   - Choose **Use solver default** to allow Abaqus/Standard to decide whether a symmetric or unsymmetric matrix storage and solution scheme is needed.
   - Choose **Unsymmetric** to restrict Abaqus/Standard to the unsymmetric storage and solution scheme.
   - Choose **Symmetric** to restrict Abaqus/Standard to the symmetric storage and solution scheme.

   For more information on matrix storage, see *Matrix Storage and Solution Scheme in Abaqus/Standard*.
4. Choose a **Solution technique** option:

   - Choose **Full Newton** to use Newton's method as a numerical technique for solving nonlinear equilibrium equations. For more information, see *Nonlinear solution methods in Abaqus/Standard*.
   - Choose **Quasi-Newton** to use the quasi-Newton technique for solving nonlinear equilibrium equations. This technique can save substantial computational cost in some cases. Generally it is most successful when the system is large and the stiffness matrix is not changing much from iteration to iteration. You can use this technique only for symmetric systems of equations.

     If you choose this technique, enter a value for the **Number of iterations allowed before the kernel matrix is reformed**. The maximum number of iterations allowed is 25. The default number of iterations is 8.

     For more information, see *Quasi-Newton solution technique*.

5. Click the arrow to the right of the **Convert severe discontinuity iterations** field, and select an option for dealing with severe discontinuities during nonlinear analysis:

   - Select **Off** to force a new iteration if severe discontinuities occur during an iteration, regardless of the magnitude of the penetration and force errors. This option also changes some time incrementation parameters and uses different criteria to determine whether to do another iteration or to make a new attempt with a smaller increment size.
   - Select **On** to use local convergence criteria to determine whether a new iteration is needed. Abaqus/Standard will determine the maximum penetration and estimated force errors associated with severe discontinuities and check whether these errors are within the tolerances. Hence, a solution may converge if the severe discontinuities are small.
   - Select **Propagate from previous step** to use the value specified in the previous general analysis step. This value appears in parentheses to the right of the field.

   For more information on severe discontinuities, see *Severe Discontinuities in Abaqus/Standard*.

6. Abaqus/Standard automatically selects the **Default load variation with time** option that corresponds to your **Response** selection on the **Basic** tabbed page. It is recommended that you leave the **Default load variation with time** selection unchanged.
7. Click the arrow to the right of the **Extrapolation of previous state at start of each increment** field, and select a method for determining the first guess to the incremental solution:

   - Select **Linear** to indicate that the process is essentially monotonic and Abaqus/Standard should use a 100% linear extrapolation, in time, of the previous incremental solution to begin the nonlinear equation solution for the current increment.
   - Select **Parabolic** to indicate that the process should use a quadratic extrapolation, in time, of the previous two incremental solutions to begin the nonlinear equation solution for the current increment.
   - Select **None** to suppress any extrapolation.

   For more information, see *Extrapolation of the Solution*.

When you have finished configuring settings for the heat transfer step, click **OK** to close the **Edit Step** dialog box.

Configuring a dynamic, implicit procedure

General linear or nonlinear dynamic analysis in Abaqus/Standard uses implicit time integration to calculate the transient dynamic response of a system. See *Implicit Dynamic Analysis Using Direct Integration*, or *Implicit dynamic analysis*, for details on implicit dynamic analysis.

Create or edit a dynamic, implicit procedure

1. Display the **Edit Step** dialog box following the procedure outlined in *Creating a step* (**Procedure type:** `General; Dynamic, Implicit`), or *Editing a step*.
2. On the **Basic**, **Incrementation**, and **Other** tabbed pages, configure settings such as the time period for the step, increment size, and equation solver preferences as described in the following procedures.

*Configure settings on the **Basic** tabbed page*

1. In the **Edit Step** dialog box, display the **Basic** tabbed page.
2. In the **Description** field, enter a short description of the analysis step. Abaqus stores the text that you enter in the output database, and the text is displayed in the state block by the Visualization module.
3. In the **Time period** field, enter the time period of the step.
4. Select an **Nlgeom** option:

   - Toggle **NlgeomOff** to perform a geometrically linear analysis during the current step.
   - Toggle **NlgeomOn** to indicate that Abaqus/Standard should account for geometric nonlinearity during the step. Once you have toggled **Nlgeom** on, it will be active during all subsequent steps in the analysis.

   For more information, see *Linear and nonlinear procedures*.
5. Select an **Application** option. The application setting adjusts various numerical settings (such as damping and time incrementation) to most efficiently and accurately capture the intended behavior of your analysis.

   - **Transient fidelity** applications—such as an analysis of satellite systems—use small time increments to accurately resolve the vibrational response of the structure, and numerical energy dissipation is kept at a minimum.
   - **Moderate dissipation** applications—including various insertion, impact, and forming analyses—use some energy dissipation (via plasticity, viscous damping, or numerical effects) to reduce solution noise and improve convergence behavior without significantly degrading solution accuracy.
   - **Quasi-static** applications introduce inertia effects primarily to regularize unstable behavior in analyses whose main focus is a final static response. Large time increments are taken when possible to minimize computational cost, and considerable numerical dissipation may be used to obtain convergence during certain stages of the loading history.
   - The **Analysis product default** depends on the presence of contact in the model: analyses involving contact are treated as moderate dissipation applications; analyses without contact are treated as transient fidelity applications.
6. Toggle on **Include adiabatic heating effects** if you are performing an adiabatic stress analysis. This option is relevant only for isotropic metal plasticity materials with a Mises yield surface. For more information, see *Adiabatic Analysis*.

*Configure settings on the **Incrementation** tabbed page*

1. In the **Edit Step** dialog box, display the **Incrementation** tabbed page.

(For information on displaying the **Edit Step** dialog box, see *Creating a step*, or *Editing a step*.)

2. Choose a **Type** option:
   - Choose **Automatic** to allow Abaqus/Standard to choose the size of the increments based on computational efficiency.
   - Choose **Fixed** to specify direct user control of the incrementation. Abaqus/Standard uses an increment size that you specify as the constant increment size throughout the step.

     Warning:

     Fixed incrementation is not generally recommended; it should be used only in special cases when you have a thorough understanding of how to interpret results obtained in this way. Impact events are particularly difficult to solve using fixed time increments.

3. In the **Maximum number of increments** field, enter the upper limit to the number of increments in the step. The analysis stops if this maximum is exceeded before Abaqus/Standard arrives at the complete solution for the step.
4. If you selected **Automatic** in Step 2, do the following:
   a. Enter values for **Increment size**:
      - In the **Initial** field, enter the initial time increment. Abaqus/Standard modifies this value as required throughout the step.
      - In the **Minimum** field, enter the minimum time increment allowed. If Abaqus/Standard needs a smaller time increment than this value, it terminates the analysis.

   b. Specify the **Maximum increment size**:
      - Choose **Specify** to enter the maximum increment size directly.
      - Choose **Analysis application default** to set the maximum increment size automatically based on the application setting:
        - For transient fidelity applications, the default maximum increment is the time period of the step divided by 100.
        - For moderate dissipation applications, the default maximum increment is the time period of the step divided by 10.
        - For quasi-static applications, the default maximum increment is the time period of the step.

   c. The half-increment residual tolerance represents the equilibrium residual error (out-of-balance forces) halfway through a time increment. If the half-increment residual is small, it indicates that the accuracy of the solution is high and that the time step can be increased safely; conversely, if the half-increment residual is large, the time step used in the solution should be reduced. For more information, see *Numerical Details*.

      You must specify an appropriate **Half-increment Residual**:
      - Toggle on **Suppress calculation** to reduce the solution cost by skipping half-increment residual tolerance checks.
      - Choose **Analysis product default** to set a half-increment residual tolerance automatically based on the application setting:
        - For transient fidelity applications involving contact, the default half-increment residual tolerance is 10,000 times the time average force and moment values.

- For transient fidelity applications without contact, the default half-increment residual tolerance is 1000 times the time average force and moment values.
- For moderate dissipation and quasi-static applications, the half-increment residual tolerance checks are suppressed.

- Choose **Specify scale factor** to enter the half-increment residual tolerance as a scale factor applied to the time average force and moment values.
- Choose **Specify value** to enter the half-increment residual tolerance value directly.

5. If you selected **Fixed** in Step 2, do the following:
   a. Enter a value for the constant time increment in the **Increment size** field.
   b. If desired, toggle on **Suppress calculation** to skip half-increment residual tolerance checks and reduce the solution cost.

*Configure settings on the **Other** tabbed page*

1. In the **Edit Step** dialog box, display the **Other** tabbed page.
   (For information on displaying the **Edit Step** dialog box, see *Creating a step*, or *Editing a step*.)
2. Choose a **Matrix storage** option:
   - Choose **Use solver default** to allow Abaqus/Standard to decide whether a symmetric or unsymmetric matrix storage and solution scheme is needed.
   - Choose **Unsymmetric** to restrict Abaqus/Standard to the unsymmetric storage and solution scheme.
   - Choose **Symmetric** to restrict Abaqus/Standard to the symmetric storage and solution scheme.

   For more information on matrix storage, see *Matrix Storage and Solution Scheme in Abaqus/Standard*.
3. Choose a **Solution technique**:
   - Choose **Full Newton** to use Newton's method as a numerical technique for solving nonlinear equilibrium equations. For more information, see *Nonlinear solution methods in Abaqus/Standard*.
   - Choose **Quasi-Newton** to use the quasi-Newton technique for solving nonlinear equilibrium equations. This technique can save substantial computational cost in some cases. Generally it is most successful when the system is large and the stiffness matrix is not changing much from iteration to iteration. You can use this technique only for symmetric systems of equations.

     If you choose this technique, enter a value for the **Number of iterations allowed before the kernel matrix is reformed**. The maximum number of iterations allowed is 25. The default number of iterations is 8.

     For more information, see *Quasi-Newton solution technique*.
4. Click the arrow to the right of the **Convert severe discontinuity iterations** field, and select an option for dealing with severe discontinuities during nonlinear analysis:
   - Select **Off** to force a new iteration if severe discontinuities occur during an iteration, regardless of the magnitude of the penetration and force errors. This option also changes some time incrementation parameters and uses different criteria to determine whether to do another iteration or to make a new attempt with a smaller increment size.
   - Select **On** to use local convergence criteria to determine whether a new iteration is needed. Abaqus/Standard will determine the maximum penetration and estimated force errors associated with severe discontinuities and check whether these errors are within the tolerances. Hence, a solution may converge if the severe discontinuities are small.

- Select **Propagate from previous step** to use the value specified in the previous general analysis step. This value appears in parentheses to the right of the field.

For more information on severe discontinuities, see *Severe Discontinuities in Abaqus/Standard*.

5. Choose an option for **Default load variation with time**:
   - Choose **Instantaneous** if you want loads to be applied instantaneously at the start of the step and remain constant throughout the step.
   - Choose **Ramp linearly over step** if the load magnitude is to vary linearly over the step, from the value at the end of the previous step to the full magnitude of the load.
6. Click the arrow to the right of the **Extrapolation of previous state at start of each increment** field, and select a method for determining the first guess to the incremental solution:
   - Select **None** to suppress any extrapolation.
   - Select **Linear** to indicate that the process is essentially monotonic and Abaqus/Standard should use a 100% linear extrapolation, in time, of the previous incremental solution to begin the nonlinear equation solution for the current increment.
   - Select **Parabolic** to indicate that the process should use a quadratic displacement-based extrapolation, in time, of the previous two incremental solutions to begin the nonlinear equation solution for the current increment.
   - Select **Velocity parabolic** to indicate that the process should use a quadratic velocity-based extrapolation, in time, of the previous incremental solutions to begin the nonlinear equation solution for the current increment.
   - Select **Analysis product default** to select the extrapolation method automatically based on the application setting:
     - For transient fidelity applications, Abaqus/Standard uses the velocity-based parabolic extrapolation method.
     - For moderate dissipation and quasi-static applications, Abaqus/Standard uses the linear extrapolation method.

   For more information, see *Extrapolation of the Solution*.
7. For transient fidelity applications, indicate **Alpha**, the numerical (artificial) damping control parameter in the implicit operator:
   - Choose **Analysis product default** to set $\alpha = -0.05$ for slight numerical damping.
   - Choose **Specify** to enter a nondefault value for α. Allowable values are zero (no damping) to -0.5 ($\alpha = -0.333$ provides maximum damping).

   For moderate dissipation applications, α cannot be modified from the default value of -0.41421. The α parameter is not used in quasi-static applications.
8. Indicate how Abaqus/Standard should handle **Initial acceleration calculations at beginning of step**:
   - Choose **Allow** to calculate the actual accelerations in a model at the beginning of the dynamic step.
   - Choose **Bypass** to set the initial accelerations based on the following criteria:
     - If the current step is the first dynamic step, Abaqus/Standard assumes that the initial accelerations for the current step are zero.
     - If the immediately preceding step was also a dynamic step, Abaqus/Standard uses the accelerations from the end of the previous step to continue the new step.

This approach is appropriate only if the loading does not change suddenly at the start of the new step. For more information, see *Controlling Calculation of Accelerations at the Beginning of a Dynamic Step*.

- Choose **Analysis product default** to determine the initial accelerations based on the application setting used for the step (this option is available only if the **Application** option on the **Basic** tabbed page is also set to **Analysis product default**):
  - For transient fidelity applications, the actual initial accelerations are calculated.
  - For moderate dissipation applications, the actual initial accelerations are set based on the criteria described above for the **Bypass** option.

9. If you selected **Fixed** time incrementation on the **Incrementation** tabbed page, you can toggle on **Accept solution after reaching maximum number of iterations**. This option directs Abaqus/Standard to accept the solution to an increment after the maximum number of iterations allowed has been completed, even if the equilibrium tolerances are not satisfied. Very small increments and a minimum of two iterations are usually necessary if you use this option.

   Warning:

   This approach is not recommended; you should use it only in special cases when you have a thorough understanding of how to interpret results obtained in this way.

When you have finished configuring settings for the step, click **OK** to close the **Edit Step** dialog box.

Configuring a fully coupled, simultaneous heat transfer and stress procedure

You must configure a fully coupled temperature-displacement analysis when the stress analysis is dependent on the temperature distribution and the temperature distribution depends on the stress solution. For example, metalworking problems may include significant heating due to inelastic deformation of the material which, in turn, changes the material properties. For such cases the thermal and mechanical solutions must be obtained simultaneously rather than sequentially. For more information, see *Fully Coupled Thermal-Stress Analysis*.

Create or edit a coupled temperature-displacement procedure

1. Display the **Edit Step** dialog box following the procedure outlined in *Creating a step* (**Procedure type:** `General; Coupled temp-displacement`), or *Editing a step*.
2. On the **Basic**, **Incrementation**, and **Other** tabbed pages, configure settings such as the time period for the step, increment size, and solution technique preferences as described in the following procedures.

*Configure settings on the **Basic** tabbed page*

1. In the **Edit Step** dialog box, display the **Basic** tabbed page.
2. In the **Description** field, enter a short description of the analysis step. Abaqus stores the text that you enter in the output database, and the text is displayed in the state block by the Visualization module.
3. Indicate whether you want **Steady-state** or **Transient** response. See the following sections for more information:
   - *Steady-State Analysis*
   - *Transient Analysis*

   Note:

   After you have selected a **Response** option, a message appears informing you that Abaqus/Standard has selected the **Default load variation with time** option (located on the **Other** tabbed page) that corresponds to your **Response** selection. Click **Dismiss** to close the message dialog box.

4. In the **Time period** field, enter the time period of the step.
5. Choose an **Nlgeom** option:
   - Toggle **NlgeomOff** to perform a geometrically linear analysis during the current step.
   - Toggle **NlgeomOn** to indicate that Abaqus/Standard should account for geometric nonlinearity during the step. Once you have toggled **Nlgeom** on, it will be active during all subsequent steps in the analysis.

   For more information, see *Linear and nonlinear procedures*.
6. Select an automatic stabilization method if you expect the problem to have local instabilities such as surface wrinkling, material instability, or local buckling. Abaqus/Standard can stabilize this class of problems by applying damping throughout the model. For more information, see *Unstable Problems*, and *Automatic Stabilization of Static Problems with a Constant Damping Factor*.

   Click the arrow to the right of **Automatic stabilization**, and select a method for defining the damping factor:
   - Select **Specify dissipated energy fraction** to allow Abaqus/Standard to calculate the damping factor from a dissipated energy fraction that you provide. Enter a value for the dissipated energy fraction in the adjacent field (the default is 2.0×10^{-4}). For more information, see *Calculating the Damping Factor Based on the Dissipated Energy Fraction*.

- Select **Specify damping factor** to enter the damping factor directly. Enter a value for the damping factor in the adjacent field. For more information, see *Directly Specifying the Damping Factor*.
- Select **Use damping factors from previous general step** to use the damping factors at the end of the previous step as the initial factors in the current step's variable damping scheme. These factors override any initial damping factors that are calculated or specified directly in the current step. If there are no damping factors associated with the previous general step (for example, if the previous step does not use any stabilization or the current step is the first step of the analysis), Abaqus uses adaptive stabilization to determine the required damping factors.

7. When using automatic stabilization, Abaqus can use the same damping factor over the course of a step, or it can vary the damping factor spatially and temporally during a step based on the convergence history and the ratio of the energy dissipated by damping to the total strain energy. For more information, see *Adaptive Automatic Stabilization Scheme*. If you selected **Specify dissipated energy fraction**, adaptive stabilization is optional and turned on by default. If you selected **Specify damping factor**, adaptive stabilization is optional and turned off by default. If you selected **Use damping factors from previous general step**, adaptive stabilization is required.

   To use adaptive stabilization, toggle on **Use adaptive stabilization with max. ratio of stabilization to strain energy** (if necessary), and enter a value in the adjacent field for the allowable accuracy tolerance for the ratio of energy dissipated by damping to total strain energy in each increment. The default value of 0.05 should be suitable in most cases.

8. If desired, toggle on **Include creep/swelling/viscoelastic behavior**. If you leave this option toggled off, you indicate that there is no creep or viscoelastic response occurring during this step even if creep or viscoelastic material properties have been defined.

*Configure settings on the **Incrementation** tabbed page*

1. In the **Edit Step** dialog box, display the **Incrementation** tabbed page.

   (For information on displaying the **Edit Step** dialog box, see *Creating a step*, or *Editing a step*.)

2. Choose a **Type** option:

   - Choose **Automatic** if you want Abaqus/Standard to determine suitable time increment sizes.
   - Choose **Fixed** to specify direct user control of the incrementation. Abaqus/Standard uses an increment size that you specify as the constant increment size throughout the step.

3. In the **Maximum number of increments** field, enter the upper limit to the number of increments in the step. The analysis stops if this maximum is exceeded before Abaqus/Standard arrives at the complete solution for the step.
4. If you selected **Automatic** in Step 2, enter values for **Increment size**:
   a. In the **Initial** field, enter the initial time increment. Abaqus/Standard modifies this value as required throughout the step.
   b. In the **Minimum** field, enter the minimum time increment allowed. If Abaqus/Standard needs a smaller time increment than this value, it terminates the analysis.
   c. In the **Maximum** field, enter the maximum time increment allowed.
5. If you selected **Fixed** in Step 2, enter a value for the constant time increment in the **Increment size** field.
6. If you selected **Automatic** in Step 2 and if you selected **Transient** response on the **Basic** tabbed page, do the following:
   a. Enter a value for the **Max. allowable temperature change per increment**. Abaqus/Standard restricts the time step to ensure that this value is not exceeded at any node during any increment of the step.

b. If you toggled on **Include creep/swelling/viscoelastic behavior** on the **Basic** tabbed page, toggle on **Creep/swelling/viscoelastic strain error tolerance** to enter the maximum difference in the creep strain increment calculated from the creep strain rates at the beginning and at the end of the increment. This value controls the accuracy of the creep integration. For more information, see *Automatic Incrementation Controlled by the Creep Response*.

7. If you toggled on **Include creep/swelling/viscoelastic behavior** on the **Basic** tabbed page, choose a **Creep/swelling/viscoelastic integration** option:

- Choose **Explicit/Implicit** if you want to allow Abaqus/Standard to invoke the implicit integration scheme. For most coupled thermal-stress analyses, the unconditional stability of the backward difference operator (implicit method) is desirable.
- Choose **Explicit** if you want to restrict Abaqus/Standard to using explicit integration. Explicit integration can be less expensive computationally and simplifies implementation of user-defined creep laws in user subroutine *CREEP*.

For more information, see *Automatic Incrementation Controlled by the Creep Response*.

*Configure settings on the **Other** tabbed page*

1. In the **Edit Step** dialog box, display the **Other** tabbed page.

(For information on displaying the **Edit Step** dialog box, see *Creating a step*, or *Editing a step*.)

2. Choose a **Matrix storage** option:

- Choose **Use solver default** to allow Abaqus/Standard to decide whether a symmetric or unsymmetric matrix storage and solution scheme is needed.
- Choose **Unsymmetric** to restrict Abaqus/Standard to the unsymmetric storage and solution scheme. (This is the only matrix storage option available if you choose the **Full Newton** solution technique.)
- Choose **Symmetric** to restrict Abaqus/Standard to the symmetric storage and solution scheme.

For more information on matrix storage, see *Matrix Storage and Solution Scheme in Abaqus/Standard*.

3. Choose a **Solution technique**:

- Choose **Full Newton** to use Newton's method as a numerical technique for solving nonlinear equilibrium equations. For more information, see *Nonlinear solution methods in Abaqus/Standard*.
- Choose **Separated** to specify that linearized equations for the individual fields in the fully coupled procedure are to be decoupled and solved separately for each field. This option provides a less costly solution for an analysis that is fully coupled in the sense that the mechanical and thermal solutions evolve simultaneously, but with a weak coupling between the two solutions. For more information, see *Approximate Implementation*.

4. Click the arrow to the right of the **Convert severe discontinuity iterations** field, and select an option for dealing with severe discontinuities during nonlinear analysis:

- Select **Off** to force a new iteration if severe discontinuities occur during an iteration, regardless of the magnitude of the penetration and force errors. This option also changes some time incrementation parameters and uses different criteria to determine whether to do another iteration or to make a new attempt with a smaller increment size.
- Select **On** to use local convergence criteria to determine whether a new iteration is needed. Abaqus/Standard will determine the maximum penetration and estimated force errors associated with severe discontinuities and check whether these errors are within the tolerances. Hence, a solution may converge if the severe discontinuities are small.

- Select **Propagate from previous step** to use the value specified in the previous general analysis step. This value appears in parentheses to the right of the field.

For more information on severe discontinuities, see *Severe Discontinuities in Abaqus/Standard*.

5. Abaqus/Standard automatically selects the **Default load variation with time** option that corresponds to your **Response** selection on the **Basic** tabbed page. It is recommended that you leave the **Default load variation with time** selection unchanged.
6. Click the arrow to the right of the **Extrapolation of previous state at start of each increment** field, and select a method for determining the first guess to the incremental solution:

   - Select **Linear** to indicate that the process is essentially monotonic and Abaqus/Standard should use a 100% linear extrapolation, in time, of the previous incremental solution to begin the nonlinear equation solution for the current increment.
   - Select **Parabolic** to indicate that the process should use a quadratic extrapolation, in time, of the previous two incremental solutions to begin the nonlinear equation solution for the current increment.
   - Select **None** to suppress any extrapolation.

   For more information, see *Extrapolation of the Solution*.

When you have finished configuring settings for the step, click **OK** to close the **Edit Step** dialog box.

Configuring a fully coupled, simultaneous heat transfer and electrical procedure

Joule heating arises when the energy dissipated by an electrical current flowing through a conductor is converted into thermal energy. Abaqus/Standard provides a fully coupled thermal-electrical procedure for analyzing this type of problem; the coupled thermal-electrical equations are solved simultaneously for both temperature and electrical potential at the nodes. For more information, see *Coupled Thermal-Electrical Analysis*.

Create or edit a coupled thermal-electrical procedure

1. Display the **Edit Step** dialog box following the procedure outlined in *Creating a step* (**Procedure type:** `General; Coupled thermal-electric`), or *Editing a step*.
2. On the **Basic**, **Incrementation**, and **Other** tabbed pages, configure settings such as the time period for the step, increment size, and solution technique preferences as described in the following procedures.

*Configure settings on the **Basic** tabbed page*

1. In the **Edit Step** dialog box, display the **Basic** tabbed page.
2. In the **Description** field, enter a short description of the analysis step. Abaqus stores the text that you enter in the output database, and the text is displayed in the state block by the Visualization module.
3. Choose a **Response** option:
   - Choose **Steady-state** to omit the internal energy term (the specific heat term) in the governing heat transfer equation. Only direct current is considered in the electrical problem, and it is assumed that the system has negligible capacitance. (Electrical transient effects are so rapid that they can be neglected.) For more information, see *Steady-State Analysis*.
   - Choose **Transient** to perform time integration with the same backward Euler method used in uncoupled heat transfer analyses. This method is unconditionally stable for linear problems. For more information, see *Transient Analysis*.

   Note:

   After you have selected a **Response** option, a message appears informing you that Abaqus/Standard has selected the **Default load variation with time** option (located on the **Other** tabbed page) that corresponds to your **Response** selection. Click **Dismiss** to close the message dialog box.

4. In the **Time period** field, enter the time period of the step.

*Configure settings on the **Incrementation** tabbed page*

1. In the **Edit Step** dialog box, display the **Incrementation** tabbed page.

   (For information on displaying the **Edit Step** dialog box, see *Creating a step*, or *Editing a step*.)
2. Choose a **Type** option:
   - Choose **Automatic** if you want Abaqus/Standard to determine suitable time increment sizes.
   - Choose **Fixed** to specify direct user control of the incrementation. Abaqus/Standard uses an increment size that you specify as the constant increment size throughout the step.
3. In the **Maximum number of increments** field, enter the upper limit to the number of increments in the step. The analysis stops if this maximum is exceeded before Abaqus/Standard arrives at the complete solution for the step.
4. If you selected **Automatic** in Step 2, enter values for **Increment size**:

a. In the **Initial** field, enter the initial time increment. Abaqus/Standard modifies this value as required throughout the step.
b. In the **Minimum** field, enter the minimum time increment allowed. If Abaqus/Standard needs a smaller time increment than this value, it terminates the analysis.
c. In the **Maximum** field, enter the maximum time increment allowed.

5. If you selected **Fixed** in Step 2, enter a value for the constant time increment in the **Increment size** field.
6. If you selected **Transient** analysis on the **Basic** tabbed page, do the following:

   - Toggle on **End step when temperature change is less than *n*** if you want the analysis to end when the temperature at every temperature degree of freedom changes at a rate that is less than a rate that you specify. If you toggle on this option, enter the desired temperature change rate in the field provided.
   - If you selected **Automatic** in Step 2, enter a value for the **Max. allowable temperature change per increment**. Abaqus/Standard restricts the time step to ensure that this value is not exceeded at any node (except nodes with boundary conditions) during any increment of the step.

7. If you selected **Automatic** in Step 2 and you are performing a cavity radiation analysis, enter a value for **Max. allowable emissivity change per increment**, or accept the default of 0.1. If this value is exceeded, Abaqus/Standard cuts back the increment until the maximum change in emissivity is less than the specified value. See *Cavity Radiation in Abaqus/Standard*, for more information.

*Configure settings on the **Other** tabbed page*

1. In the **Edit Step** dialog box, display the **Other** tabbed page.

   (For information on displaying the **Edit Step** dialog box, see *Creating a step*, or *Editing a step*.)
2. Choose a **Matrix storage** option:

   - Choose **Use solver default** to allow Abaqus/Standard to decide whether a symmetric or unsymmetric matrix storage and solution scheme is needed.
   - Choose **Unsymmetric** to restrict Abaqus/Standard to the unsymmetric storage and solution scheme. (This is the only matrix storage option available if you choose the **Full Newton** solution technique.)
   - Choose **Symmetric** to restrict Abaqus/Standard to the symmetric storage and solution scheme.

   For more information on matrix storage, see *Matrix Storage and Solution Scheme in Abaqus/Standard*.
3. Choose a **Solution technique**:

   - Choose **Full Newton** to use Newton's method as a numerical technique for solving nonlinear equilibrium equations. For more information, see *Nonlinear solution methods in Abaqus/Standard*.
   - Choose **Separated** to specify that linearized equations for the individual fields in the fully coupled procedure are to be decoupled and solved separately for each field. This option provides a less costly solution for an analysis that is fully coupled in the sense that the electrical and thermal solutions evolve simultaneously, but with a weak coupling between the two solutions. For more information, see *Approximate Implementation*.

4. Click the arrow to the right of the **Convert severe discontinuity iterations** field, and select an option for dealing with severe discontinuities during nonlinear analysis:

   - Select **Off** to force a new iteration if severe discontinuities occur during an iteration, regardless of the magnitude of the penetration and force errors. This option also changes some time incrementation parameters and uses different criteria to determine whether to do another iteration or to make a new attempt with a smaller increment size.

- Select **On** to use local convergence criteria to determine whether a new iteration is needed. Abaqus/Standard will determine the maximum penetration and estimated force errors associated with severe discontinuities and check whether these errors are within the tolerances. Hence, a solution may converge if the severe discontinuities are small.
- Select **Propagate from previous step** to use the value specified in the previous general analysis step. This value appears in parentheses to the right of the field.

For more information on severe discontinuities, see *Severe Discontinuities in Abaqus/Standard*.

5. Abaqus/Standard automatically selects the **Default load variation with time** option that corresponds to your **Response** selection on the **Basic** tabbed page. It is recommended that you leave the **Default load variation with time** selection unchanged.
6. Click the arrow to the right of the **Extrapolation of previous state at start of each increment** field, and select a method for determining the first guess to the incremental solution:

   - Select **Linear** to indicate that the process is essentially monotonic and Abaqus/Standard should use a 100% linear extrapolation, in time, of the previous incremental solution to begin the nonlinear equation solution for the current increment.
   - Select **Parabolic** to indicate that the process should use a quadratic extrapolation, in time, of the previous two incremental solutions to begin the nonlinear equation solution for the current increment.
   - Select **None** to suppress any extrapolation.

   For more information, see *Extrapolation of the Solution*.

When you have finished configuring settings for the step, click **OK** to close the **Edit Step** dialog box.

Configuring a fully coupled, simultaneous heat transfer, electrical, and structural procedure

A fully coupled thermal-electrical-structural analysis is the union of a coupled thermal-displacement analysis and a coupled thermal-electrical analysis. Coupling between the temperature and electrical degrees of freedom arises from temperature-dependent electrical conductivity and internal heat generation (Joule heating), which is a function of the electrical current density. Coupling between the temperature and displacement degrees of freedom arises from temperature-dependent material properties, thermal expansion, and internal heat generation, which is a function of inelastic deformation of the material. Coupling between the electrical and displacement degrees of freedom arises in problems where electricity flows between contact surfaces.

For more information, see *Fully Coupled Thermal-Electrical-Structural Analysis*.

Create or edit a coupled thermal-electrical-structural procedure

1. Display the **Edit Step** dialog box following the procedure outlined in *Creating a step* (**Procedure type:** `General; Coupled thermal-electric-structural`), or *Editing a step*.
2. On the **Basic**, **Incrementation**, and **Other** tabbed pages, configure settings such as the time period for the step, type of incrementation, and solution technique preferences as described in the following procedures.

*Configure settings on the **Basic** tabbed page*

1. In the **Edit Step** dialog box, display the **Basic** tabbed page.
2. In the **Description** field, enter a short description of the analysis step. Abaqus stores the text that you enter in the output database, and the text is displayed in the state block by the Visualization module.
3. Choose a **Response** option:
   - Choose **Steady-state** to omit the internal energy term (the specific heat term) in the governing heat transfer equation. A static displacement solution is assumed. Only direct current is considered in the electrical problem, and it is assumed that the system has negligible capacitance. (Electrical transient effects are so rapid that they can be neglected.) For more information, see *Steady-State Analysis*.
   - Choose **Transient** to perform a transient analysis. As with the steady-state response, electrical transient effects are neglected and a static displacement solution is assumed. You can control the time incrementation in a transient analysis directly, or Abaqus/Standard can control it automatically. Automatic time incrementation is generally preferred. For more information, see *Transient Analysis*.
4. In the **Time period** field, enter the time period of the step.
5. Choose an **Nlgeom** option:
   - Toggle **NlgeomOff** to perform a geometrically linear analysis during the current step.
   - Toggle **NlgeomOn** to indicate that Abaqus/Standard should account for geometric nonlinearity during the step. Once you have toggled **Nlgeom** on, it will be active during all subsequent steps in the analysis.

   For more information, see *Linear and nonlinear procedures*.
6. Select an automatic stabilization method if you expect the problem to have local instabilities such as surface wrinkling, material instability, or local buckling. Abaqus/Standard can stabilize this class of problems by applying damping throughout the model. For more information, see *Unstable Problems*, and *Automatic Stabilization of Static Problems with a Constant Damping Factor*.

   Click the arrow to the right of **Automatic stabilization**, and select a method for defining the damping factor:

- Select **Specify dissipated energy fraction** to allow Abaqus/Standard to calculate the damping factor from a dissipated energy fraction that you provide. Enter a value for the dissipated energy fraction in the adjacent field (the default is 2.0×10^{-4}). For more information, see *Calculating the Damping Factor Based on the Dissipated Energy Fraction*.
- Select **Specify damping factor** to enter the damping factor directly. Enter a value for the damping factor in the adjacent field. For more information, see *Directly Specifying the Damping Factor*.
- Select **Use damping factors from previous general step** to use the damping factors at the end of the previous step as the initial factors in the current step's variable damping scheme. These factors override any initial damping factors that are calculated or specified directly in the current step. If there are no damping factors associated with the previous general step (for example, if the previous step does not use any stabilization or the current step is the first step of the analysis), Abaqus uses adaptive stabilization to determine the required damping factors.

7. When using automatic stabilization, Abaqus can use the same damping factor over the course of a step, or it can vary the damping factor spatially and temporally during a step based on the convergence history and the ratio of the energy dissipated by damping to the total strain energy. For more information, see *Adaptive Automatic Stabilization Scheme*. If you selected **Specify dissipated energy fraction**, adaptive stabilization is optional and turned on by default. If you selected **Specify damping factor**, adaptive stabilization is optional and turned off by default. If you selected **Use damping factors from previous general step**, adaptive stabilization is required.

   To use adaptive stabilization, toggle on **Use adaptive stabilization with max. ratio of stabilization to strain energy** (if necessary), and enter a value in the adjacent field for the allowable accuracy tolerance for the ratio of energy dissipated by damping to total strain energy in each increment. The default value of 0.05 should be suitable in most cases.

8. If desired, toggle on **Include creep/swelling/viscoelastic behavior**. If you leave this option toggled off, you indicate that there is no creep or viscoelastic response occurring during this step even if creep or viscoelastic material properties have been defined.

*Configure settings on the **Incrementation** tabbed page*

1. In the **Edit Step** dialog box, display the **Incrementation** tabbed page.

   (For information on displaying the **Edit Step** dialog box, see *Creating a step*, or *Editing a step*.)

2. Choose a **Type** option:

   - Choose **Automatic** if you want Abaqus/Standard to determine suitable time increment sizes.
   - Choose **Fixed** to specify direct user control of the incrementation. Abaqus/Standard uses an increment size that you specify as the constant increment size throughout the step.

3. In the **Maximum number of increments** field, enter the upper limit to the number of increments in the step. The analysis stops if this maximum is exceeded before Abaqus/Standard arrives at the complete solution for the step.
4. If you selected **Automatic** in Step 2, enter values for **Increment size**:
   a. In the **Initial** field, enter the initial time increment. Abaqus/Standard modifies this value as required throughout the step.
   b. In the **Minimum** field, enter the minimum time increment allowed. If Abaqus/Standard needs a smaller time increment than this value, it terminates the analysis.
   c. In the **Maximum** field, enter the maximum time increment allowed.
5. If you selected **Fixed** in Step 2, enter a value for the constant time increment in the **Increment size** field.

6. If you selected **Automatic** in Step 2 and you selected **Transient** response on the **Basic** tabbed page, do the following:
   a. Enter a value for the **Max. allowable temperature change per increment**. Abaqus/Standard restricts the time step to ensure that this value is not exceeded at any node (except nodes with boundary conditions) during any increment of the step.
   b. If you toggled on **Include creep/swelling/viscoelastic behavior** on the **Basic** tabbed page, toggle on **Creep/swelling/viscoelastic strain error tolerance** to enter the maximum difference in the creep strain increment calculated from the creep strain rates at the beginning and at the end of the increment. This value controls the accuracy of the creep integration. For more information, see *Automatic Incrementation Controlled by the Creep Response*.
7. If you toggled on **Include creep/swelling/viscoelastic behavior** on the **Basic** tabbed page, choose a **Creep/swelling/viscoelastic integration** option:
   - Choose **Explicit/Implicit** if you want to allow Abaqus/Standard to invoke the implicit integration scheme. For most coupled thermal-stress analyses, the unconditional stability of the backward difference operator (implicit method) is desirable.
   - Choose **Explicit** if you want to restrict Abaqus/Standard to using explicit integration. Explicit integration can be less expensive computationally and simplifies implementation of user-defined creep laws in user subroutine *CREEP*.

   For more information, see *Automatic Incrementation Controlled by the Creep Response*.

*Configure settings on the **Other** tabbed page*

1. In the **Edit Step** dialog box, display the **Other** tabbed page.
   (For information on displaying the **Edit Step** dialog box, see *Creating a step*, or *Editing a step*.)
2. Choose a **Matrix storage** option:
   - Choose **Use solver default** to allow Abaqus/Standard to decide whether a symmetric or unsymmetric matrix storage and solution scheme is needed.
   - Choose **Unsymmetric** to restrict Abaqus/Standard to the unsymmetric storage and solution scheme.
   - Choose **Symmetric** to restrict Abaqus/Standard to the symmetric storage and solution scheme.

   For more information on matrix storage, see *Matrix Storage and Solution Scheme in Abaqus/Standard*.
3. Click the arrow to the right of the **Convert severe discontinuity iterations** field, and select an option for dealing with severe discontinuities during nonlinear analysis:
   - Select **Off** to force a new iteration if severe discontinuities occur during an iteration, regardless of the magnitude of the penetration and force errors. This option also changes some time incrementation parameters and uses different criteria to determine whether to do another iteration or to make a new attempt with a smaller increment size.
   - Select **On** to use local convergence criteria to determine whether a new iteration is needed. Abaqus/Standard will determine the maximum penetration and estimated force errors associated with severe discontinuities and check whether these errors are within the tolerances. Hence, a solution may converge if the severe discontinuities are small.
   - Select **Propagate from previous step** to use the value specified in the previous general analysis step. This value appears in parentheses to the right of the field.

   For more information on severe discontinuities, see *Severe Discontinuities in Abaqus/Standard*.

4. Abaqus/Standard automatically selects the **Default load variation with time** option that corresponds to your **Response** selection on the **Basic** tabbed page. It is recommended that you leave the **Default load variation with time** selection unchanged.
5. Click the arrow to the right of the **Extrapolation of previous state at start of each increment** field, and select a method for determining the first guess to the incremental solution:

   - Select **Linear** to indicate that the process is essentially monotonic and Abaqus/Standard should use a 100% linear extrapolation, in time, of the previous incremental solution to begin the nonlinear equation solution for the current increment.
   - Select **Parabolic** to indicate that the process should use a quadratic extrapolation, in time, of the previous two incremental solutions to begin the nonlinear equation solution for the current increment.
   - Select **None** to suppress any extrapolation.

   For more information, see *Extrapolation of the Solution*.

When you have finished configuring settings for the step, click **OK** to close the **Edit Step** dialog box.

Configuring a coupled, thermal electrochemical procedure

You must configure a coupled thermal-electrochemical analysis when the thermal, electrical, and ion concentration fields strongly affect each other. The coupled thermal-electrochemical procedure is intended for the analysis of battery electrochemistry applications that require solving simultaneous for temperature, electric potentials in the solid electrodes, electric potential in the electrolyte, concentration of ions in the electrolyte, and concentration in the solid particles used in the electrodes.
For more information, see *Coupled Thermal-Electrochemical Analysis*.

Create or edit a coupled thermal-electrochemical procedure

1. Display the **Edit Step** dialog box following the procedure outlined in *Creating a step* (**Procedure type:** `General; Coupled thermal-electrochemical`), or *Editing a step*.
2. On the **Basic**, **Incrementation**, and **Other** tabbed pages, configure settings such as the time period for the step, increment size, and solution technique preferences as described in the following procedures.

*Configure settings on the **Basic** tabbed page*

1. In the **Edit Step** dialog box, display the **Basic** tabbed page.
2. In the **Description** field, enter a short description of the analysis step.

   Abaqus stores the text that you enter in the output database, and the text is displayed in the state block by the Visualization module.

3. Indicate whether you want a **Steady-state** or **Transient** response.

   For more information, see:

   - *Steady-State Analysis*
   - *Transient Analysis*

   Note: After you select a **Response** option, a message indicates that Abaqus/Standard has selected the **Default load variation with time** option (located on the **Other** tabbed page) that corresponds to your **Response** selection. Click **Dismiss** to close the dialog box.

4. In the **Time period** field, enter the time period of the step.

*Configure settings on the **Incrementation** tabbed page*

1. In the **Edit Step** dialog box, display the **Incrementation** tabbed page.

   For information on displaying the **Edit Step** dialog box, see *Creating a step* or *Editing a step*.

2. Choose a **Type** option:

   - Choose **Automatic** if you want Abaqus/Standard to determine suitable time increment sizes.
   - Choose **Fixed** to specify direct user control of the incrementation. Abaqus/Standard uses an increment size that you specify as the constant increment size throughout the step.

3. In the **Maximum number of increments** field, enter the upper limit to the number of increments in the step.

   The analysis stops if this maximum is exceeded before Abaqus/Standard arrives at the complete solution for the step.

4. If you selected **Automatic** in Step 2, enter values for **Increment size**:

   a. In the **Initial** field, enter the initial time increment.

      Abaqus/Standard modifies this value as required throughout the step.

b. In the **Minimum** field, enter the minimum time increment allowed.

If Abaqus/Standard needs a smaller time increment than this value, it terminates the analysis.

c. In the **Maximum** field, enter the maximum time increment allowed.

5. If you selected **Fixed** in Step 2, enter a value for the constant time increment in the **Increment size** field.
6. If you selected **Automatic** in Step 2 and if you selected **Transient** response on the **Basic** tabbed page, enter a value for the **Max. allowable temperature change per increment**.

   Abaqus/Standard restricts the time step to ensure that this value is not exceeded at any node during any increment of the step.

*Configure settings on the **Other** tabbed page*

1. In the **Edit Step** dialog box, display the **Other** tabbed page.

   For information on displaying the **Edit Step** dialog box, see *Creating a step*, or *Editing a step*.
2. Choose a **Matrix storage** option:

   - Choose **Use solver default** to allow Abaqus/Standard to decide whether a symmetric or unsymmetric matrix storage and solution scheme is needed.
   - Choose **Unsymmetric** to restrict Abaqus/Standard to the unsymmetric storage and solution scheme. (This is the only matrix storage option available if you choose the **Full Newton** solution technique.)
   - Choose **Symmetric** to restrict Abaqus/Standard to the symmetric storage and solution scheme.

   For more information on matrix storage, see *Matrix Storage and Solution Scheme in Abaqus/Standard*.
3. Choose a **Solution technique**:

   - Choose **Full Newton** to use Newton's method as a numerical technique for solving nonlinear equilibrium equations. For more information, see *Nonlinear solution methods in Abaqus/Standard*.
   - Choose **Separated** to specify that linearized equations for the individual fields in the fully coupled procedure are to be decoupled and solved separately for each field. This option provides a less costly solution for an analysis that is fully coupled in the sense that the mechanical and thermal solutions evolve simultaneously, but with a weak coupling between the two solutions. For more information, see *Approximate Implementation*.
4. Click the arrow to the right of the **Convert severe discontinuity iterations** field, and select an option for dealing with severe discontinuities during nonlinear analysis:

   - Select **Off** to force a new iteration if severe discontinuities occur during an iteration, regardless of the magnitude of the penetration and force errors. This option also changes some time incrementation parameters and uses different criteria to determine whether to do another iteration or to make a new attempt with a smaller increment size.
   - Select **On** to use local convergence criteria to determine whether a new iteration is needed. Abaqus/Standard will determine the maximum penetration and estimated force errors associated with severe discontinuities and check whether these errors are within the tolerances. Hence, a solution might converge if the severe discontinuities are small.
   - Select **Propagate from previous step** to use the value specified in the previous general analysis step. This value appears in parentheses to the right of the field.

   For more information on severe discontinuities, see *Severe Discontinuities in Abaqus/Standard*.
5. Abaqus/Standard automatically selects the **Default load variation with time** option that corresponds to your **Response** selection on the **Basic** tabbed page. It is recommended that you leave the **Default load variation with time** selection unchanged.

6. Click the arrow to the right of the **Extrapolation of previous state at start of each increment** field, and select a method for determining the first guess to the incremental solution:

   - Select **Linear** to indicate that the process is essentially monotonic and Abaqus/Standard should use a 100% linear extrapolation, in time, of the previous incremental solution to begin the nonlinear equation solution for the current increment.
   - Select **Parabolic** to indicate that the process should use a quadratic extrapolation, in time, of the previous two incremental solutions to begin the nonlinear equation solution for the current increment.
   - Select **None** to suppress any extrapolation.

   For more information, see *Extrapolation of the Solution*.

When you have finished configuring settings for the step, click **OK** to close the **Edit Step** dialog box.

Configuring a fully coupled, thermal electrochemical structural procedure

You must configure a fully coupled thermal electrochemical structural analysis when the mechanical, thermal, electrical, and ion concentration fields strongly affect each other. This analysis is intended for the analysis of battery electrochemistry applications that require solving simultaneously for displacement, temperature, electric potential in the solid electrodes, electric potential in the electrolyte, concentration of ions in the electrolyte, and concentration in the solid particles used in the electrodes.
For more information, see *Fully Coupled Thermal-Electrochemical-Structural Analysis*.

Create or edit a fully coupled thermal-electrochemical structural procedure

1. Display the **Edit Step** dialog box following the procedure outlined in *Creating a step* (**Procedure type:** `General; Coupled thermal-electrochemical-structural`), or *Editing a step*.
2. On the **Basic**, **Incrementation**, and **Other** tabbed pages, configure settings such as the time period for the step, increment size, and solution technique preferences as described in the following procedures.

*Configure settings on the **Basic** tabbed page*

1. In the **Edit Step** dialog box, display the **Basic** tabbed page.
2. In the **Description** field, enter a short description of the analysis step.

   Abaqus stores the text that you enter in the output database, and the text is displayed in the state block by the Visualization module.
3. Indicate whether you want **Steady-state** or **Transient** response.

   See the following sections for more information:

   - *Steady-State Analysis*
   - *Transient Analysis*

   Note:

   After you have selected a **Response** option, a message appears informing you that Abaqus/Standard has selected the **Default load variation with time** option (located on the **Other** tabbed page) that corresponds to your **Response** selection. Click **Dismiss** to close the message dialog box.
4. In the **Time period** field, enter the time period of the step.
5. Choose an **Nlgeom** option:

   - Toggle **Nlgeom Off** to perform a geometrically linear analysis during the current step.
   - Toggle **Nlgeom On** to indicate that Abaqus/Standard should account for geometric nonlinearity during the step. Once you have toggled **Nlgeom** on, it will be active during all subsequent steps in the analysis.

   For more information, see *Linear and nonlinear procedures*.
6. Select an automatic stabilization method if you expect the problem to have local instabilities such as surface wrinkling, material instability, or local buckling. Abaqus/Standard can stabilize this class of problems by applying damping throughout the model. For more information, see *Unstable Problems*, and *Automatic Stabilization of Static Problems with a Constant Damping Factor*. Click the arrow to the right of **Automatic stabilization**, and select a method for defining the damping factor:

   - Select **Specify dissipated energy fraction** to allow Abaqus/Standard to calculate the damping factor from a dissipated energy fraction that you provide. Enter a value for the dissipated energy fraction in the adjacent field (the default is 2.0×10^{-4}). For more information, see *Calculating the Damping Factor Based on the Dissipated Energy Fraction*.

- Select **Specify damping factor** to enter the damping factor directly. Enter a value for the damping factor in the adjacent field. For more information, see *Directly Specifying the Damping Factor*.
- Select **Use damping factors from previous general step** to use the damping factors at the end of the previous step as the initial factors in the current step's variable damping scheme. These factors override any initial damping factors that are calculated or specified directly in the current step. If there are no damping factors associated with the previous general step (for example, if the previous step does not use any stabilization or the current step is the first step of the analysis), Abaqus uses adaptive stabilization to determine the required damping factors.

7. When using automatic stabilization, Abaqus can use the same damping factor over the course of a step, or it can vary the damping factor spatially and temporally during a step based on the convergence history and the ratio of the energy dissipated by damping to the total strain energy. For more information, see *Adaptive Automatic Stabilization Scheme*. If you selected **Specify dissipated energy fraction**, adaptive stabilization is optional and turned on by default. If you selected **Specify damping factor**, adaptive stabilization is optional and turned off by default. If you selected **Use damping factors from previous general step**, adaptive stabilization is required.

   To use adaptive stabilization, toggle on **Use adaptive stabilization with max. ratio of stabilization to strain energy** (if necessary), and enter a value in the adjacent field for the allowable accuracy tolerance for the ratio of energy dissipated by damping to total strain energy in each increment. The default value of 0.05 should be suitable in most cases.

8. **Optional:** If desired, toggle on **Include creep/swelling/viscoelastic behavior**. If you leave this option toggled off, you indicate that there is no creep or viscoelastic response occurring during this step even if creep or viscoelastic material properties have been defined.

*Configure settings on the **Incrementation** tabbed page*

1. In the **Edit Step** dialog box, display the **Incrementation** tabbed page.

   For information on displaying the **Edit Step** dialog box, see *Creating a step*, or *Editing a step*.

2. Choose a **Type** option:

   - Choose **Automatic** if you want Abaqus/Standard to determine suitable time increment sizes.
   - Choose **Fixed** to specify direct user control of the incrementation. Abaqus/Standard uses an increment size that you specify as the constant increment size throughout the step.

3. In the **Maximum number of increments** field, enter the upper limit to the number of increments in the step. The analysis stops if this maximum is exceeded before Abaqus/Standard arrives at the complete solution for the step.
4. If you selected **Automatic** in Step 2, enter values for **Increment size**:
   a. In the **Initial** field, enter the initial time increment. Abaqus/Standard modifies this value as required throughout the step.
   b. In the **Minimum** field, enter the minimum time increment allowed. If Abaqus/Standard needs a smaller time increment than this value, it terminates the analysis.
   c. In the **Maximum** field, enter the maximum time increment allowed.
5. If you selected **Fixed** in Step 2, enter a value for the constant time increment in the **Increment size** field.
6. If you selected **Automatic** in Step 2 and if you selected **Transient** response on the **Basic** tabbed page, do the following:
   a. Enter a value for the **Max. allowable temperature change per increment**. Abaqus/Standard restricts the time step to ensure that this value is not exceeded at any node during any increment of the step.

b. If you toggled on **Include creep/swelling/viscoelastic behavior** on the **Basic** tabbed page, toggle on **Creep/swelling/viscoelastic strain error tolerance** to enter the maximum difference in the creep strain increment calculated from the creep strain rates at the beginning and at the end of the increment. This value controls the accuracy of the creep integration.

7. If you toggled on **Include creep/swelling/viscoelastic behavior** on the **Basic** tabbed page, choose a **Creep/swelling/viscoelastic integration** option:

- Choose **Explicit/Implicit** if you want to allow Abaqus/Standard to invoke the implicit integration scheme. For most coupled thermal-stress analyses, the unconditional stability of the backward difference operator (implicit method) is desirable.
- Choose **Explicit** if you want to restrict Abaqus/Standard to using explicit integration. Explicit integration can be less expensive computationally and simplifies implementation of user-defined creep laws in user subroutine *CREEP*.

*Configure settings on the **Other** tabbed page*

1. In the **Edit Step** dialog box, display the **Other** tabbed page.

For information on displaying the **Edit Step** dialog box, see *Creating a step*, or *Editing a step*.

2. Choose a **Matrix storage** option:

- Choose **Use solver default** to allow Abaqus/Standard to decide whether a symmetric or unsymmetric matrix storage and solution scheme is needed.
- Choose **Unsymmetric** to restrict Abaqus/Standard to the unsymmetric storage and solution scheme. (This is the only matrix storage option available if you choose the **Full Newton** solution technique.)
- Choose **Symmetric** to restrict Abaqus/Standard to the symmetric storage and solution scheme.

For more information on matrix storage, see *Matrix Storage and Solution Scheme in Abaqus/Standard*.

3. Choose a **Solution technique**:

- Choose **Full Newton** to use Newton's method as a numerical technique for solving nonlinear equilibrium equations. For more information, see *Nonlinear solution methods in Abaqus/Standard*.
- Choose **Separated** to specify that linearized equations for the individual fields in the fully coupled procedure are to be decoupled and solved separately for each field. This option provides a less costly solution for an analysis that is fully coupled in the sense that the mechanical and thermal solutions evolve simultaneously, but with a weak coupling between the two solutions. For more information, see *Approximate Implementation*.

4. Click the arrow to the right of the **Convert severe discontinuity iterations** field, and select an option for dealing with severe discontinuities during nonlinear analysis:

- Select **Off** to force a new iteration if severe discontinuities occur during an iteration, regardless of the magnitude of the penetration and force errors. This option also changes some time incrementation parameters and uses different criteria to determine whether to do another iteration or to make a new attempt with a smaller increment size.
- Select **On** to use local convergence criteria to determine whether a new iteration is needed. Abaqus/Standard will determine the maximum penetration and estimated force errors associated with severe discontinuities and check whether these errors are within the tolerances. Hence, a solution might converge if the severe discontinuities are small.
- Select **Propagate from previous step** to use the value specified in the previous general analysis step. This value appears in parentheses to the right of the field.

For more information on severe discontinuities, see *Severe Discontinuities in Abaqus/Standard*.

5. Abaqus/Standard automatically selects the **Default load variation with time** option that corresponds to your **Response** selection on the **Basic** tabbed page. It is recommended that you leave the **Default load variation with time** selection unchanged.
6. Click the arrow to the right of the **Extrapolation of previous state at start of each increment** field, and select a method for determining the first guess to the incremental solution:

   - Select **Linear** to indicate that the process is essentially monotonic and Abaqus/Standard should use a 100% linear extrapolation, in time, of the previous incremental solution to begin the nonlinear equation solution for the current increment.
   -
   - Select **Parabolic** to indicate that the process should use a quadratic extrapolation, in time, of the previous two incremental solutions to begin the nonlinear equation solution for the current increment.
   - Select **None** to suppress any extrapolation.

   For more information, see *Extrapolation of the Solution*.

When you have finished configuring settings for the step, click **OK** to close the **Edit Step** dialog box.

Configuring a fully coupled, thermal electrochemical structural pore pressure procedure

You must configure a fully coupled temperature-displacement analysis when the stress analysis is dependent on the temperature distribution and the temperature distribution depends on the stress solution.

For example, metalworking problems can include significant heating due to inelastic deformation of the material which, in turn, changes the material properties. For such cases the thermal and mechanical solutions must be obtained simultaneously rather than sequentially. For more information, see *Fully Coupled Thermal-Electrochemical-Structural–Pore Pressure Analysis*.

Create or edit a fully coupled thermal-electrochemical structural pore pressure procedure

1. Display the **Edit Step** dialog box following the procedure outlined in *Creating a step* (**Procedure type:** `General; Coupled temp-displacement`), or *Editing a step*.
2. On the **Basic**, **Incrementation**, and **Other** tabbed pages, configure settings such as the time period for the step, increment size, and solution technique preferences as described in the following procedures.

*Configure settings on the **Basic** tabbed page*

1. In the **Edit Step** dialog box, display the **Basic** tabbed page.
2. In the **Description** field, enter a short description of the analysis step.

   Abaqus stores the text that you enter in the output database, and the text is displayed in the state block by the Visualization module.
3. Indicate whether you want **Steady-state** or **Transient** response.

   See the following sections for more information:

   - *Steady-State Analysis*
   - *Transient Analysis*

   Note: After you have selected a **Response** option, a message appears informing you that Abaqus/Standard has selected the **Default load variation with time** option (located on the **Other** tabbed page) that corresponds to your **Response** selection. Click **Dismiss** to close the message dialog box.
4. In the **Time period** field, enter the time period of the step.
5. Choose an **Nlgeom** option:

   - Toggle **Nlgeom Off** to perform a geometrically linear analysis during the current step.
   - Toggle **Nlgeom On** to indicate that Abaqus/Standard should account for geometric nonlinearity during the step. Once you have toggled **Nlgeom** on, it will be active during all subsequent steps in the analysis.

   For more information, see *Linear and nonlinear procedures*.
6. Select an automatic stabilization method if you expect the problem to have local instabilities such as surface wrinkling, material instability, or local buckling. Abaqus/Standard can stabilize this class of problems by applying damping throughout the model. For more information, see *Unstable Problems*, and *Automatic Stabilization of Static Problems with a Constant Damping Factor*.

   Click the arrow to the right of **Automatic stabilization**, and select a method for defining the damping factor:

   - Select **Specify dissipated energy fraction** to allow Abaqus/Standard to calculate the damping factor from a dissipated energy fraction that you provide. Enter a value for the dissipated energy

fraction in the adjacent field (the default is 2.0×10^{-4}). For more information, see *Calculating the Damping Factor Based on the Dissipated Energy Fraction*.

- Select **Specify damping factor** to enter the damping factor directly. Enter a value for the damping factor in the adjacent field. For more information, see *Directly Specifying the Damping Factor*.
- Select **Use damping factors from previous general step** to use the damping factors at the end of the previous step as the initial factors in the current step's variable damping scheme. These factors override any initial damping factors that are calculated or specified directly in the current step. If there are no damping factors associated with the previous general step (for example, if the previous step does not use any stabilization or the current step is the first step of the analysis), Abaqus uses adaptive stabilization to determine the required damping factors.

7. When using automatic stabilization, Abaqus can use the same damping factor over the course of a step, or it can vary the damping factor spatially and temporally during a step based on the convergence history and the ratio of the energy dissipated by damping to the total strain energy. For more information, see *Adaptive Automatic Stabilization Scheme*. If you selected **Specify dissipated energy fraction**, adaptive stabilization is optional and turned on by default. If you selected **Specify damping factor**, adaptive stabilization is optional and turned off by default. If you selected **Use damping factors from previous general step**, adaptive stabilization is required.

   To use adaptive stabilization, toggle on **Use adaptive stabilization with max. ratio of stabilization to strain energy** (if necessary), and enter a value in the adjacent field for the allowable accuracy tolerance for the ratio of energy dissipated by damping to total strain energy in each increment. The default value of 0.05 should be suitable in most cases.

8. **Optional:** If desired, toggle on **Include creep/swelling/viscoelastic behavior**. If you leave this option toggled off, you indicate that there is no creep or viscoelastic response occurring during this step even if creep or viscoelastic material properties have been defined.
9. **Optional:** If desired, toggle on **Include advection for fluid velocity effect**. It adds an advection contribution to the ion flux equation.

*Configure settings on the **Incrementation** tabbed page*

1. In the **Edit Step** dialog box, display the **Incrementation** tabbed page.

   For information on displaying the **Edit Step** dialog box, see *Creating a step*, or *Editing a step*.

2. Choose a **Type** option:

   - Choose **Automatic** if you want Abaqus/Standard to determine suitable time increment sizes.
   - Choose **Fixed** to specify direct user control of the incrementation. Abaqus/Standard uses an increment size that you specify as the constant increment size throughout the step.

3. In the **Maximum number of increments** field, enter the upper limit to the number of increments in the step.

   The analysis stops if this maximum is exceeded before Abaqus/Standard arrives at the complete solution for the step.

4. If you selected **Automatic** in Step 2, enter values for **Increment size**:

   a. In the **Initial** field, enter the initial time increment.

      Abaqus/Standard modifies this value as required throughout the step.

   b. In the **Minimum** field, enter the minimum time increment allowed.

      If Abaqus/Standard needs a smaller time increment than this value, it terminates the analysis.

   c. In the **Maximum** field, enter the maximum time increment allowed.

5. If you selected **Fixed** in Step 2, enter a value for the constant time increment in the **Increment size** field.

6. If you selected **Automatic** in Step 2 and if you selected **Transient** response on the **Basic** tabbed page, do the following:
   a. Enter a value for the **Max. allowable temperature change per increment**.

      Abaqus/Standard restricts the time step to ensure that this value is not exceeded at any node during any increment of the step.

   b. Enter a value for the **Max. allowable pore pressure change per increment**.

      Abaqus/Standard restricts the time step to ensure that this value is not exceeded at any node during any increment of the step.

   c. If you toggled on **Include creep/swelling/viscoelastic behavior** on the **Basic** tabbed page, toggle on **Creep/swelling/viscoelastic strain error tolerance** to enter the maximum difference in the creep strain increment calculated from the creep strain rates at the beginning and at the end of the increment.

      This value controls the accuracy of the creep integration.

7. If you toggled on **Include advection for fluid velocity effect** on the **Basic** tabbed page, toggle on **Ion concentration of the external electrolyte reservoir** to enter the ion concentration of the external electrolyte reservoir.
8. If you toggled on **Include creep/swelling/viscoelastic behavior** on the **Basic** tabbed page, choose a **Creep/swelling/viscoelastic integration** option:

   - Choose **Explicit/Implicit** if you want to allow Abaqus/Standard to invoke the implicit integration scheme. For most coupled thermal-stress analyses, the unconditional stability of the backward difference operator (implicit method) is desirable.
   - Choose **Explicit** if you want to restrict Abaqus/Standard to using explicit integration. Explicit integration can be less expensive computationally and simplifies implementation of user-defined creep laws in user subroutine *CREEP*.

*Configure settings on the **Other** tabbed page*

1. In the **Edit Step** dialog box, display the **Other** tabbed page.

   For information on displaying the **Edit Step** dialog box, see *Creating a step*, or *Editing a step*.
2. Choose a **Matrix storage** option:

   - Choose **Use solver default** to allow Abaqus/Standard to decide whether a symmetric or unsymmetric matrix storage and solution scheme is needed.
   - Choose **Unsymmetric** to restrict Abaqus/Standard to the unsymmetric storage and solution scheme. (This is the only matrix storage option available if you choose the **Full Newton** solution technique.)
   - Choose **Symmetric** to restrict Abaqus/Standard to the symmetric storage and solution scheme.

   For more information on matrix storage, see *Matrix Storage and Solution Scheme in Abaqus/Standard*.
3. Choose a **Solution technique**:

   - Choose **Full Newton** to use Newton's method as a numerical technique for solving nonlinear equilibrium equations. For more information, see *Nonlinear solution methods in Abaqus/Standard*.
   - Choose **Separated** to specify that linearized equations for the individual fields in the fully coupled procedure are to be decoupled and solved separately for each field. This option provides a less costly solution for an analysis that is fully coupled in the sense that the mechanical and thermal solutions evolve simultaneously, but with a weak coupling between the two solutions. For more information, see *Approximate Implementation*.

4. Click the arrow to the right of the **Convert severe discontinuity iterations** field, and select an option for dealing with severe discontinuities during nonlinear analysis:

   - Select **Off** to force a new iteration if severe discontinuities occur during an iteration, regardless of the magnitude of the penetration and force errors. This option also changes some time incrementation parameters and uses different criteria to determine whether to do another iteration or to make a new attempt with a smaller increment size.
   - Select **On** to use local convergence criteria to determine whether a new iteration is needed. Abaqus/Standard will determine the maximum penetration and estimated force errors associated with severe discontinuities and check whether these errors are within the tolerances. Hence, a solution might converge if the severe discontinuities are small.
   - Select **Propagate from previous step** to use the value specified in the previous general analysis step. This value appears in parentheses to the right of the field.

   For more information on severe discontinuities, see *Severe Discontinuities in Abaqus/Standard*.

5. Abaqus/Standard automatically selects the **Default load variation with time** option that corresponds to your **Response** selection on the **Basic** tabbed page. It is recommended that you leave the **Default load variation with time** selection unchanged.
6. Click the arrow to the right of the **Extrapolation of previous state at start of each increment** field, and select a method for determining the first guess to the incremental solution:

   - Select **Linear** to indicate that the process is essentially monotonic and Abaqus/Standard should use a 100% linear extrapolation, in time, of the previous incremental solution to begin the nonlinear equation solution for the current increment.
   - Select **Parabolic** to indicate that the process should use a quadratic extrapolation, in time, of the previous two incremental solutions to begin the nonlinear equation solution for the current increment.
   - Select **None** to suppress any extrapolation.

   For more information, see *Extrapolation of the Solution*.

When you have finished configuring settings for the step, click **OK** to close the **Edit Step** dialog box.

Configuring a direct cyclic procedure

A direct cyclic procedure is a quasi-static analysis that uses a combination of Fourier series and time integration of the nonlinear material behavior to obtain the stabilized cyclic response of the structure iteratively. To avoid the considerable numerical expense associated with a transient analysis, a direct cyclic procedure can be used to calculate the cyclic response of a structure directly. The basis of this method is to construct a displacement function $\overline{u}(t)$ that describes the response of the structure at all times t during a load cycle with period T. For more information, see *Direct Cyclic Analysis*.

Abaqus/Standard assumes geometrically linear behavior for a direct cyclic procedure. For more information, see *Linear and nonlinear procedures*.

Create or edit a direct cyclic procedure

1. Display the **Edit Step** dialog box following the procedure outlined in *Creating a step* (**Procedure type:** `General; Direct cyclic`) or *Editing a step*.
