2. On the **Basic**, **Incrementation**, **Fatigue**, and **Other** tabbed pages, configure settings such as the cycle time period, maximum number of increments, increment size, low-cycle fatigue options, and equation solver preferences as described in the following procedures.

*Configure settings on the **Basic** tabbed page*

1. In the **Edit Step** dialog box, display the **Basic** tabbed page.
2. In the **Description** field, enter a short description of the analysis step. Abaqus stores the text that you enter in the output database, and the text is displayed in the state block by the Visualization module.
3. In the **Cycle time period** field, enter the time of a single loading cycle.
4. Toggle on **Use displacement Fourier coefficients from previous direct cyclic step** to indicate that the current step is a continuation of the previous direct cyclic step. See *Direct Cyclic Analysis* for more details.

*Configure settings on the **Incrementation** tabbed page*

1. In the **Edit Step** dialog box, display the **Incrementation** tabbed page.

   (For information on displaying the **Edit Step** dialog box, see *Creating a step* or *Editing a step*.)
2. Choose a **Type** option:
   - Choose **Automatic** to allow Abaqus/Standard to choose the size of the time increments based on computational efficiency.
   - Choose **Fixed** to specify direct user control of the incrementation. Abaqus/Standard uses an increment size that you specify as the constant increment size throughout the step.
3. In the **Maximum number of increments** field, enter the upper limit to the number of increments in a single loading cycle. The analysis stops if this maximum is exceeded before Abaqus/Standard arrives at the complete solution for the step. See *Controlling the Incrementation during the Cyclic Time Period* for more details.
4. If you selected **Automatic** in Step 2, enter values for **Increment size**:
   a. In the **Initial** field, enter the initial time increment. Abaqus/Standard modifies this value as required throughout the step.
   b. In the **Minimum** field, enter the minimum time increment allowed. If Abaqus/Standard needs a smaller time increment than this value, it terminates the analysis.
   c. In the **Maximum** field, enter the maximum time increment allowed.

5. If you selected **Fixed** in Step 2, enter a value for the constant time increment in the **Increment size** field.
6. In the **Maximum number of iterations** field, enter an upper limit for the number of cyclic iterations. See *Controlling the Iterations in the Modified Newton Method* for more details.
7. In the **Number of Fourier terms** fields, enter values for the **Initial** and **Maximum** number of Fourier terms and the **Increment** in the number of terms. The number of Fourier terms required to obtain an accurate solution depends on the variation of the load as well as the variation of the structural response over the period. More Fourier terms usually provide a more accurate solution but at the expense of additional data storage and computational time. Each of these values must be greater than 0 and less than 100. For more information, see *Controlling the Fourier Representations*.
8. If you selected **Automatic** in Step 2, choose one or both of the following options:

   - Toggle on **Max. allowable temperature change per increment** to enter the maximum temperature change to be allowed in an increment. Abaqus/Standard will restrict the time increment to ensure that this value is not exceeded at any node during any increment of the step.
   - Toggle on **Creep/swelling/viscoelastic strain error tolerance** to enter the maximum difference in the creep strain increment calculated from the creep strain rates based on conditions at the beginning and end of the increment, thus controlling the time integration accuracy of the creep integration.

   For more details about these options, see *Automatic Incrementation*.
9. Toggle on **Evaluate structure response at time points** to define specific times at which the response should be evaluated. Click the arrow to the right of this field, and select a set of time points from the list that appears. Otherwise, click  to define a new set of time points. See *Defining time points* and *Defining the Time Points at Which the Response Must Be Evaluated* for more details.

*Configure settings on the **Fatigue** tabbed page*

1. In the **Edit Step** dialog box, display the **Fatigue** tabbed page.

   (For information on displaying the **Edit Step** dialog box, see *Creating a step* or *Editing a step*.)
2. Toggle on **Include low-cycle fatigue analysis** to use the direct cyclic approach to obtain the stabilized response of a structure subjected to periodic loading. Multiple cycles can be included in a single direct cyclic analysis. The analysis models progressive damage and failure on constitutive points in the bulk materials based on a continuum damage approach. It can also be used to model delamination/debonding growth at the interfaces in laminated composites. For more details, see *Low-Cycle Fatigue Analysis Using the Direct Cyclic Approach*.
3. In the **Cycle increment size** fields, enter values for the **Minimum** and **Maximum** increment in the number of cycles over which the damage is extrapolated forward. Each value must be greater than 0. For more details, see *Damage Extrapolation Technique in the Bulk Material*.
4. In the **Maximum number of cycles** field, choose one of the following options to specify the total number of cycles allowed in the step:

   - Choose **Default** to use a value that is equal to one plus half of the maximum increment in number of cycles over which the damage is extrapolated.
   - Choose **Value**, and enter a number.

   See *Low-Cycle Fatigue Analysis in Abaqus/Standard* for more details.
5. In the **Damage extrapolation tolerance** field, enter a value or accept the default of 1.0. The maximum extrapolated damage increment will be limited by this value. See *Controlling the Accuracy of Damage*

Extrapolation in the Bulk Material When Using the Continuum Damage Mechanics Approach for more details.

*Configure settings on the **Other** tabbed page*

1. In the **Edit Step** dialog box, display the **Other** tabbed page.

   (For information on displaying the **Edit Step** dialog box, see *Creating a step* or *Editing a step*.)

2. Choose a **Matrix storage** option for the equation solver:

   - Choose **Use solver default** to allow Abaqus/Standard to decide whether a symmetric or unsymmetric matrix storage and solution scheme is needed.
   - Choose **Unsymmetric** to restrict Abaqus/Standard to the unsymmetric storage and solution scheme.
   - Choose **Symmetric** to restrict Abaqus/Standard to the symmetric storage and solution scheme.

   For more information on matrix storage, see *Matrix Storage and Solution Scheme in Abaqus/Standard*.

3. Click the arrow to the right of the **Convert severe discontinuity iterations** field, and select an option for dealing with severe discontinuities during nonlinear analysis:

   - Select **Off** to force a new iteration if severe discontinuities occur during an iteration, regardless of the magnitude of the penetration and force errors. This option also changes some time incrementation parameters and uses different criteria to determine whether to do another iteration or to make a new attempt with a smaller increment size.
   - Select **On** to use local convergence criteria to determine whether a new iteration is needed. Abaqus/Standard will determine the maximum penetration and estimated force errors associated with severe discontinuities and check whether these errors are within the tolerances. Hence, a solution may converge if the severe discontinuities are small.
   - Select **Propagate from previous step** to use the value specified in the previous general analysis step. This value appears in parentheses to the right of the field.

   For more information on severe discontinuities, see *Severe Discontinuities in Abaqus/Standard*.

4. Click the arrow to the right of the **Extrapolation of previous state at start of each increment** field, and select a method for determining the first guess to the incremental solution:

   - Select **Linear** to indicate that the process is essentially monotonic and Abaqus/Standard should use a 100% linear extrapolation, in time, of the previous incremental solution to begin the nonlinear equation solution for the current increment.
   - Select **Parabolic** to indicate that the process should use a quadratic extrapolation, in time, of the previous two incremental solutions to begin the nonlinear equation solution for the current increment.
   - Select **None** to suppress any extrapolation.

   For more information, see *Extrapolation of the Solution*.

When you have finished configuring settings for the direct cyclic step, click **OK** to close the **Edit Step** dialog box.

Configuring a dynamic fully coupled thermal-stress procedure using explicit integration

You must configure a fully coupled temperature-displacement analysis when the stress analysis is dependent on the temperature distribution and the temperature distribution depends on the stress solution. For such cases the thermal and mechanical solutions must be obtained simultaneously rather than sequentially. In Abaqus/Explicit a fully coupled thermal-stress analysis includes inertia effects and models transient thermal response. For more information, see *Fully Coupled Thermal-Stress Analysis in Abaqus/Explicit*.

Create or edit a coupled temperature-displacement procedure using explicit integration

1. Display the **Edit Step** dialog box following the procedure outlined in *Creating a step* (**Procedure type:** `General; Dynamic, Temp-disp, Explicit`), or *Editing a step*.
2. On the **Basic**, **Incrementation**, **Mass scaling**, and **Other** tabbed pages, configure settings such as the time period for the step, the increment size, mass scaling definitions, and bulk viscosity parameters as described in the following procedures.

*Configure settings on the **Basic** tabbed page*

1. In the **Edit Step** dialog box, display the **Basic** tabbed page.
2. In the **Description** field, enter a short description of the analysis step. Abaqus stores the text that you enter in the output database, and the text is displayed in the state block by the Visualization module.
3. In the **Time period** field, enter the time period of the step.
4. Select an **Nlgeom** option:

   - Toggle **NlgeomOff** to perform a geometrically linear analysis during the current step.
   - Toggle **NlgeomOn** to indicate that Abaqus/Explicit should account for geometric nonlinearity during the step. Once you have toggled **Nlgeom** on, it will be active during all subsequent steps in the analysis.

   For more information, see *Linear and nonlinear procedures*.

*Configure settings on the **Incrementation** tabbed page*

1. In the **Edit Step** dialog box, display the **Incrementation** tabbed page.

   (For information on displaying the **Edit Step** dialog box, see *Creating a step*, or *Editing a step*.)
2. Choose a **Type** option:

   - Choose **Automatic** to allow Abaqus/Explicit to determine the time incrementation automatically. For more information, see *Automatic Time Incrementation*.
   - Choose **Fixed** to use a fixed time incrementation scheme. The fixed time increment size is determined either by the initial element stability estimate for the step or by a user-specified time increment. For more information, see *Fixed Time Incrementation*.

3. If you selected **Automatic** time incrementation, perform the following steps:
   a. Choose a **Stable increment estimator** option:

      - Choose **Global** to allow the global estimator to determine the stability limit as the step proceeds. The adaptive, global estimation algorithm determines the maximum frequency of the entire model using the current dilatational wave speed. This algorithm continuously updates the estimate for the maximum frequency. The global estimator will usually allow time increments that exceed the element-by-element values.

- Choose **Element-by-element** to allow Abaqus/Explicit to determine an element-by-element estimate using the current dilatational wave speed in each element.

  The element-by-element estimate is conservative; it will give a smaller stable time increment than the true stability limit that is based upon the maximum frequency of the entire model. In general, constraints such as boundary conditions and kinematic contact have the effect of compressing the eigenvalue spectrum, and the element-by-element estimates do not take this into account.

b. By default, the "improved" method to estimate the element stable time increment for three-dimensional continuum elements and elements with plane stress formulations is used. This method usually results in a larger element stable time increment than a more traditional method. Toggle off **Improved Dt Method** to deactivate the "improved" method.

c. Choose a **Max. time increment** option:

- Choose **Unlimited** if you do not want to impose an upper limit to time incrementation.
- Choose **Value** to enter a value for the maximum time increment allowed. Enter the value in the field provided.

For more information, see *Automatic Time Incrementation*.

4. If you selected **Fixed** time incrementation, choose an option for determining increment size:

- Choose **User-defined time increment** to specify a time increment size directly. Enter that time increment size in the field provided.
- Choose **Use element-by-element time increment estimator** to use time increments the size of the initial element-by-element stability limit throughout the step. The dilatational wave speed in each element at the beginning of the step is used to compute the fixed time increment size.

For more information, see *Fixed Time Incrementation*.

5. If desired, enter a **Time scaling factor** to adjust the stable time increment computed by Abaqus/Explicit. (This option is unavailable if you have specified a **User-defined time increment** for the **Fixed** time incrementation scheme.) For more information, see *Scaling the Time Increment*.

*Configure settings on the **Mass scaling** tabbed page*

1. In the **Edit Step** dialog box, display the **Mass scaling** tabbed page. For background information on mass scaling, see *Mass Scaling*.

(For information on displaying the **Edit Step** dialog box, see *Creating a step*, or *Editing a step*.)

2. Choose one of the following options for specifying mass scaling:

- Choose **Use scaled mass and "throughout step" definitions from the previous step** if you want mass scaling definitions from the previous step to propagate through the current step. If you choose this option, you can skip the remaining steps in this procedure.
- Choose **Use scaling definitions below** to create one or more new mass scaling definitions for this step. If you choose this option, complete the remaining steps in this procedure.

3. At the bottom of the **Data** table, click **Create**.

An **Edit mass scaling** dialog box appears.

4. Specify which type of mass scaling definition you want to create:

- Choose **Semi-automatic mass scaling** to define mass scaling for any type of analysis except bulk metal rolling.

- Choose **Automatic mass scaling** to define mass scaling for a bulk metal rolling analysis. For more information, see *Automatic Mass Scaling for Analysis of Bulk Metal Rolling*.
- Choose **Reinitialize mass** to reinitialize masses of elements to their original values. This option allows you to prevent the scaled mass from a previous step from being used in the current step. For more information, see *Reverting the Mass Matrix to the Original State*.
- Choose **Disable mass scaling thoughout step** to disable in this step all variable mass scaling definitions from previous steps. For more information, see *Continuous Mass Matrix with No Further Scaling*.

5. If you selected **Semi-automatic mass scaling**, **Automatic mass scaling**, or **Reinitialize mass**, indicate the region to which you want the mass scaling definition applied:
   - Choose **Whole model** to apply the mass scaling definition to all elements in the model.
   - Choose **Set** to apply the mass scaling definition to a particular set of elements. Click the arrow to the right of the **Set** field, and select the set name of interest.

6. If you selected **Semi-automatic mass scaling**, indicate when, during the step, you want Abaqus/Explicit to scale the element masses:
   - Choose **At beginning of step** to perform fixed mass scaling only at the beginning of the step. For more information, see *Fixed Mass Scaling*.
   - Choose **Throughout step** to scale the mass of elements periodically during the step. For more information, see *Variable Mass Scaling*.

7. If you selected **Semi-automatic mass scaling**, indicate how you want Abaqus/Explicit to scale the element masses:
   - Toggle on **Scale by factor** to scale the elements once at the beginning of the step by the value you enter in the field provided. For more information, see *Defining a Scale Factor Directly*.
   - Toggle on **Scale to target time increment of *n*** to enter a desired element stable time increment in the field provided. Click the arrow to the right of the **Scale element mass** field, and select how you want Abaqus/Explicit to apply that target time increment:
     - Select **Uniformly to satisfy target** to scale the masses of the elements equally so that the smallest element stable time increment of the scaled elements equals the target value.
     - Select **If below minimum target** to scale the masses of only the elements whose element stable time increments are less than the target value.
     - Select **Nonuniformly to equal target** to scale the masses of all elements so that they all have the same element stable time increment equal to the target value.

     For more information, see *Defining a Desired Element-by-Element Stable Time Increment*.

   If you toggle on both **Scale by factor** and **Scale to target time increment**, Abaqus/Explicit first scales the masses by the factor value that you enter and then possibly scales them again, depending on the value you enter for target time increment and the option you select for applying that target.

8. If you selected **Automatic mass scaling**, enter the following values:
   a. In the **Feed rate** field, enter the estimated average velocity of the workpiece in the rolling direction at steady-state conditions.
   b. In the **Extruded element length** field, enter the average element length in the rolling direction.
   c. In the **Nodes in cross-section** field, enter the number of nodes in the cross-section of the workpiece. Increasing this value decreases the amount of mass scaling.

For more information, see *Automatic Mass Scaling for Analysis of Bulk Metal Rolling*.

9. If you selected **Semi-automatic mass scaling** throughout the step or **Automatic mass scaling**, specify when, during the step, you want Abaqus/Explicit to perform mass scaling calculations:

   - Choose **Every *n* increments** to specify the frequency, in increments, at which Abaqus/Explicit is to perform mass scaling calculations. Enter the desired frequency in the field provided.

     For example, if you enter a value of 5, Abaqus/Explicit scales the mass at the beginning of the step and at increments 5, 10, 15, etc.

   - Choose **At *n* equal intervals** to specify the number of intervals during the step at which Abaqus/Explicit is to perform mass scaling calculations. Enter the desired value in the field provided.

     For example, if you enter a value of 2, Abaqus/Explicit scales the mass at the beginning of the step, the increment immediately following the half-way point in the step, and the final increment in the step.

10. Click **OK** to close the **Edit mass scaling** dialog box and return to the **Mass scaling** tabbed page of the **Edit Step** dialog box.

    The mass scaling definition that you have just created appears in the **Data** table.

11. If desired, repeat Steps 3 to 10 to create additional mass scaling definitions.
12. Once you have created one or more mass scaling definitions, you can edit or delete them if desired. Select a particular mass scaling definition in the **Data** table, and click **Edit** or **Delete** at the bottom of the **Data** table.

*Configure settings on the **Other** tabbed page*

1. In the **Edit Step** dialog box, display the **Other** tabbed page.

   (For information on displaying the **Edit Step** dialog box, see *Creating a step*, or *Editing a step*.)

2. Enter a value for the **Linear bulk viscosity parameter**. Linear bulk viscosity is included by default in Abaqus/Explicit.
3. Enter a value for the **Quadratic bulk viscosity parameter**. This form of bulk viscosity pressure is found only in solid continuum element and is applied only if the volumetric strain rate is compressive.

   For more information, see *Bulk Viscosity*.

When you have finished configuring settings for the step, click **OK** to close the **Edit Step** dialog box.

Configuring a geostatic stress field procedure

A geostatic stress field procedure allows you to verify that the initial geostatic stress field is in equilibrium with applied loads and boundary conditions. It also allows you to iterate, if necessary, to obtain equilibrium; or you can allow Abaqus to compute equilibrium automatically for cases in which the initial state is unknown. This type of procedure is usually the first step of a geotechnical analysis, followed by a coupled pore fluid diffusion/stress or static analysis procedure. For more information, see *Geostatic Stress State*.

Create or edit a geostatic stress field procedure

1. Display the **Edit Step** dialog box following the procedure outlined in *Creating a step* (**Procedure type:** `General; Geostatic`), or *Editing a step*.
2. On the **Basic** and **Other** tabbed pages, configure settings such as controls to include nonlinear effects of large displacements and equation solver preferences as described in the following procedures.

*Configure settings on the **Basic** tabbed page*

1. In the **Edit Step** dialog box, display the **Basic** tabbed page.
2. In the **Description** field, enter a short description of the analysis step. Abaqus stores the text that you enter in the output database, and the text is displayed in the state block by the Visualization module.
3. Select an **Nlgeom** option:

   - Toggle **NlgeomOff** to perform a geometrically linear analysis during the current step.
   - Toggle **NlgeomOn** to indicate that Abaqus/Standard should account for geometric nonlinearity during the step. Once you have toggled **Nlgeom** on, it will be active during all subsequent steps in the analysis.

   For more information, see *Linear and nonlinear procedures*.

*Configure settings on the **Incrementation** tabbed page*

1. In the **Edit Step** dialog box, display the **Incrementation** tabbed page.

   (For information on displaying the **Edit Step** dialog box, see *Creating a step*, or *Editing a step*.)
2. Choose a **Type** option:

   - Choose **Automatic** if you want Abaqus/Standard to determine suitable time increment sizes.
   - Choose **Fixed** to use a fixed increment size.

     If you select **Fixed**, no further entries are available on the **Incrementation** tabbed page.

3. If you selected **Automatic** incrementation in Step 2, enter values for the **Increment size** and for the **Max. displacement change**:
   a. In the **Initial** field, enter the initial time increment. Abaqus/Standard modifies this value as required throughout the step.
   b. In the **Minimum** field, enter the minimum time increment allowed. If Abaqus/Standard needs a smaller time increment than this value, it terminates the analysis.
   c. In the **Maximum** field, enter the maximum time increment allowed.
   d. In the **Max. displacement change** field, enter the maximum amount of displacement that is acceptable while Abaqus/Standard calculates the equilibrium state for models in which the initial stress state is unknown or an approximation.

*Configure settings on the **Other** tabbed page*

1. In the **Edit Step** dialog box, display the **Other** tabbed page.

   (For information on displaying the **Edit Step** dialog box, see *Creating a step*, or *Editing a step*.)

2. Choose an **Equation Solver Method** option:

   - Choose **Direct** to use the default direct sparse solver.
   - Choose **Iterative** to use the iterative linear equation solver. The iterative solver is typically most useful for blocky structures with millions of degrees of freedom. For more information, see *Iterative Linear Equation Solver*.

3. Choose a **Matrix storage** option:

   - Choose **Use solver default** to allow Abaqus/Standard to decide whether a symmetric or unsymmetric matrix storage and solution scheme is needed.
   - Choose **Unsymmetric** to restrict Abaqus/Standard to the unsymmetric storage and solution scheme.
   - Choose **Symmetric** to restrict Abaqus/Standard to the symmetric storage and solution scheme.

   For more information on matrix storage, see *Matrix Storage and Solution Scheme in Abaqus/Standard*.

4. Choose a **Solution technique**:

   - Choose **Full Newton** to use Newton's method as a numerical technique for solving nonlinear equilibrium equations. For more information, see *Nonlinear solution methods in Abaqus/Standard*.
   - Choose **Quasi-Newton** to use the quasi-Newton technique for solving nonlinear equilibrium equations. This technique can save substantial computational cost in some cases. Generally it is most successful when the system is large and the stiffness matrix is not changing much from iteration to iteration. You can use this technique only for symmetric systems of equations.

     If you choose this technique, enter a value for the **Number of iterations allowed before the kernel matrix is reformed**. The maximum number of iterations allowed is 25. The default number of iterations is 8.

     For more information, see *Quasi-Newton solution technique*.

5. Click the arrow to the right of the **Convert severe discontinuity iterations** field, and select an option for dealing with severe discontinuities during nonlinear analysis:

   - Select **Off** to force a new iteration if severe discontinuities occur during an iteration, regardless of the magnitude of the penetration and force errors. This option also changes some time incrementation parameters and uses different criteria to determine whether to do another iteration or to make a new attempt with a smaller increment size.
   - Select **On** to use local convergence criteria to determine whether a new iteration is needed. Abaqus/Standard will determine the maximum penetration and estimated force errors associated with severe discontinuities and check whether these errors are within the tolerances. Hence, a solution may converge if the severe discontinuities are small.
   - Select **Propagate from previous step** to use the value specified in the previous general analysis step. This value appears in parentheses to the right of the field.

   For more information on severe discontinuities, see *Severe Discontinuities in Abaqus/Standard*.

When you have finished configuring settings for the step, click **OK** to close the **Edit Step** dialog box.

Configuring a mass diffusion procedure

A mass diffusion analysis models the transient or steady-state diffusion of one material through another, such as the diffusion of hydrogen through a metal. The governing equations for mass diffusion are an extension of Fick's equations: they allow for nonuniform solubility of the diffusing substance in the base material and for mass diffusion driven by gradients of temperature and pressure. For more information, see *Mass Diffusion Analysis*.

Create or edit a mass diffusion procedure

1. Display the **Edit Step** dialog box following the procedure outlined in *Creating a step* (**Procedure type:** `General; Mass diffusion`), or *Editing a step*.
2. On the **Basic**, **Incrementation**, and **Other** tabbed pages, configure settings such as steady-state or transient response and automatic or fixed incrementation as described in the following procedures.

*Configure settings on the **Basic** tabbed page*

1. In the **Edit Step** dialog box, display the **Basic** tabbed page.
2. In the **Description** field, enter a short description of the analysis step. Abaqus stores the text that you enter in the output database, and the text is displayed in the state block by the Visualization module.
3. Choose a **Response** option:

   - Choose **Steady-state** to specify that the analysis provide the steady-state solution directly. The rate of change of concentration with respect to time is omitted from the governing diffusion equation in a steady-state analysis. For more information, see *Steady-State Analysis*.
   - Choose **Transient** to perform time integration with the backward Euler method. This method is unconditionally stable for linear problems. For more information, see *Transient Analysis*.

   Note:

   After you have selected a **Response** option, a message appears informing you that Abaqus/Standard has selected the **Default load variation with time** option (located on the **Other** tabbed page) that corresponds to your **Response** selection. Click **Dismiss** to close the message dialog box.

4. In the **Time period** field, enter the time period of the step.

*Configure settings on the **Incrementation** tabbed page*

1. In the **Edit Step** dialog box, display the **Incrementation** tabbed page.

   (For information on displaying the **Edit Step** dialog box, see *Creating a step*, or *Editing a step*.)
2. Choose a **Type** option:

   - Choose **Automatic** if you want Abaqus/Standard to determine suitable time increment sizes.
   - Choose **Fixed** to specify direct user control of the incrementation. Abaqus/Standard uses an increment size that you specify as the constant increment size throughout the step.

3. In the **Maximum number of increments** field, enter the upper limit to the number of increments in the step. The analysis stops if this maximum is exceeded before Abaqus/Standard arrives at the complete solution for the step.
4. If you selected **Automatic** incrementation in Step 2, enter values for **Increment size**:
   a. In the **Initial** field, enter the initial time increment. Abaqus/Standard modifies this value as required throughout the step.

b. In the **Minimum** field, enter the minimum time increment allowed. If Abaqus/Standard needs a smaller time increment than this value, it terminates the analysis.

c. In the **Maximum** field, enter the maximum time increment allowed.

5. If you selected **Fixed** incrementation in Step 2, enter a value for the constant time increment in the **Increment size** field.

6. If you selected **Automatic** incrementation in Step 2 and **Transient** analysis on the **Basic** tabbed page, do the following:

a. Enter a value in the **End step when normalized concentration change is less than *n*** field. The analysis will end when all nodal normalized concentrations are changing at a rate that is less than the rate that you enter.

b. Enter a value in the **Max. allowable normalized concentration change** field. Abaqus/Standard restricts the time step to ensure that this value is not exceeded at any node (except nodes with boundary conditions) during any increment of the step.

To configure settings on the **Other** tabbed page:

a. In the **Edit Step** dialog box, display the **Other** tabbed page.

(For information on displaying the **Edit Step** dialog box, see *Creating a step*, or *Editing a step*.)

b. Accept the selection of the **Unsymmetric** matrix storage and solution scheme. This scheme is the only **Matrix storage** option that is valid for mass diffusion analyses. For more information on matrix storage, see *Matrix Storage and Solution Scheme in Abaqus/Standard*.

c. Click the arrow to the right of the **Convert severe discontinuity iterations** field, and select an option for dealing with severe discontinuities during nonlinear analysis:

- Select **Off** to force a new iteration if severe discontinuities occur during an iteration, regardless of the magnitude of the penetration and force errors. This option also changes some time incrementation parameters and uses different criteria to determine whether to do another iteration or to make a new attempt with a smaller increment size.
- Select **On** to use local convergence criteria to determine whether a new iteration is needed. Abaqus/Standard will determine the maximum penetration and estimated force errors associated with severe discontinuities and check whether these errors are within the tolerances. Hence, a solution may converge if the severe discontinuities are small.
- Select **Propagate from previous step** to use the value specified in the previous general analysis step. This value appears in parentheses to the right of the field.

For more information on severe discontinuities, see *Severe Discontinuities in Abaqus/Standard*.

d. Abaqus/Standard automatically selects the **Default load variation with time** option that corresponds to your **Response** selection on the **Basic** tabbed page. It is recommended that you leave the **Default load variation with time** selection unchanged.

e. Click the arrow to the right of the **Extrapolation of previous state at start of each increment** field, and select a method for determining the first guess to the incremental solution:

- Select **Linear** to indicate that the process is essentially monotonic and Abaqus/Standard should use a 100% linear extrapolation, in time, of the previous incremental solution to begin the nonlinear equation solution for the current increment.
- Select **Parabolic** to indicate that the process should use a quadratic extrapolation, in time, of the previous two incremental solutions to begin the nonlinear equation solution for the current increment.
- Select **None** to suppress any extrapolation.

For more information, see *Extrapolation of the Solution*.

When you have finished configuring settings for the step, click **OK** to close the **Edit Step** dialog box.

Configuring an effective stress analysis for fluid-filled porous media

A coupled pore fluid diffusion/stress analysis allows you to model single phase, partially or fully saturated fluid flow through porous media. For more information, see *Coupled Pore Fluid Diffusion and Stress Analysis*.

Create or edit a coupled pore fluid diffusion/stress procedure

1. Display the **Edit Step** dialog box following the procedure outlined in *Creating a step* (**Procedure type:** `General; Soils`), or *Editing a step*.
2. On the **Basic**, **Incrementation**, and **Other** tabbed pages, configure settings such as steady-state or transient pore fluid response and automatic or fixed incrementation as described in the following procedures.

*Configure settings on the **Basic** tabbed page*

1. In the **Edit Step** dialog box, display the **Basic** tabbed page.
2. In the **Description** field, enter a short description of the analysis step. Abaqus stores the text that you enter in the output database, and the text is displayed in the state block by the Visualization module.
3. Choose a **Pore fluid response** option:

   - Choose **Steady-state** to specify that there are no transient effects in the wetting liquid continuity equation. The steady-state solution corresponds to constant wetting liquid velocities and constant volume of wetting liquid per unit volume in the continuum. For more information, see *Steady-State Analysis*.
   - Choose **Transient consolidation** to use the backward difference operator to integrate the continuity equation. This operator provides unconditional stability so that the only concern with respect to time integration is accuracy. For more information, see *Transient Analysis*.

   Note:

   After you have selected a **Pore fluid response** option, a message appears informing you that Abaqus/Standard has selected the **Default load variation with time** option and the **Matrix storage** option (both located on the **Other** tabbed page) that correspond to your **Pore fluid response** selection. Click **Dismiss** to close the message dialog box.

4. In the **Time period** field, enter the time period of the step.
5. Select an **Nlgeom** option:

   - Toggle **NlgeomOff** to perform a geometrically linear analysis during the current step.
   - Toggle **NlgeomOn** to indicate that Abaqus/Standard should account for geometric nonlinearity during the step. Once you have toggled **Nlgeom** on, it will be active during all subsequent steps in the analysis.

   For more information, see *Linear and nonlinear procedures*.

6. Select an automatic stabilization method if you expect the problem to have local instabilities such as surface wrinkling, material instability, or local buckling. Abaqus/Standard can stabilize this class of problems by applying damping throughout the model. For more information, see *Unstable Problems*, and *Automatic Stabilization of Static Problems with a Constant Damping Factor*

   Click the arrow to the right of **Automatic stabilization**, and select a method for defining the damping factor:

   - Select **Specify dissipated energy fraction** to allow Abaqus/Standard to calculate the damping factor from a dissipated energy fraction that you provide. Enter a value for the dissipated energy

fraction in the adjacent field (the default is 2.0×10^{-4}). For more information, see *Calculating the Damping Factor Based on the Dissipated Energy Fraction*.

- Select **Specify damping factor** to enter the damping factor directly. Enter a value for the damping factor in the adjacent field. For more information, see *Directly Specifying the Damping Factor*.
- Select **Use damping factors from previous general step** to use the damping factors at the end of the previous step as the initial factors in the current step's variable damping scheme. These factors override any initial damping factors that are calculated or specified directly in the current step. If there are no damping factors associated with the previous general step (for example, if the previous step does not use any stabilization or the current step is the first step of the analysis), Abaqus uses adaptive stabilization to determine the required damping factors.

7. When using automatic stabilization, Abaqus can use the same damping factor over the course of a step, or it can vary the damping factor spatially and temporally during a step based on the convergence history and the ratio of the energy dissipated by damping to the total strain energy. For more information, see *Adaptive Automatic Stabilization Scheme*. If you selected **Specify dissipated energy fraction**, adaptive stabilization is optional and turned on by default. If you selected **Specify damping factor**, adaptive stabilization is optional and turned off by default. If you selected **Use damping factors from previous general step**, adaptive stabilization is required.

   To use adaptive stabilization, toggle on **Use adaptive stabilization with max. ratio of stabilization to strain energy** (if necessary), and enter a value in the adjacent field for the allowable accuracy tolerance for the ratio of energy dissipated by damping to total strain energy in each increment. The default value of 0.05 should be suitable in most cases.

8. If desired, toggle on **Include creep/swelling/viscoelastic behavior**. If you leave this option toggled off, you indicate that there is no creep or viscoelastic response occurring during this step even if creep or viscoelastic material properties have been defined.

*Configure settings on the **Incrementation** tabbed page*

1. In the **Edit Step** dialog box, display the **Incrementation** tabbed page.

   (For information on displaying the **Edit Step** dialog box, see *Creating a step*, or *Editing a step*.)

2. Choose a **Type** option:

   - Choose **Automatic** if you want Abaqus/Standard to determine suitable time increment sizes.
   - Choose **Fixed** to specify direct user control of the incrementation. Abaqus/Standard uses an increment size that you specify as the constant increment size throughout the step.

     Note:

     Fixed incrementation is not generally recommended in this case because the time increments in a typical diffusion analysis can increase over several orders of magnitude during the simulation; automatic incrementation is usually a better choice.

3. In the **Maximum number of increments** field, enter the upper limit to the number of increments in the step. The analysis stops if this maximum is exceeded before Abaqus/Standard arrives at the complete solution for the step.
4. If you selected **Automatic** in Step 2, enter values for **Increment size**:
   a. In the **Initial** field, enter the initial time increment. Abaqus/Standard modifies this value as required throughout the step.
   b. In the **Minimum** field, enter the minimum time increment allowed. If Abaqus/Standard needs a smaller time increment than this value, it terminates the analysis.
   c. In the **Maximum** field, enter the maximum time increment allowed.

5. If you selected **Fixed** in Step 2, enter a value for the constant time increment in the **Increment size** field.
6. If you selected the **Transient consolidation** response on the **Basic** tabbed page, toggle on **End step when pore pressure change rate is less than *n*** to enter a minimum value for the pore pressure change rate. The analysis will end if all pore pressures are changing at a rate that is less than the rate that you enter.
7. If you selected **Automatic** in Step 2, do the following:
   a. If you selected the **Transient consolidation** response on the **Basic** tabbed page, enter a value for the **Max. pore pressure change per increment**. Abaqus/Standard restricts the time step to ensure that this value is not exceeded at any node (except nodes with boundary conditions) during any increment of the step.
   b. If you toggled on **Include creep/swelling/viscoelastic behavior** on the **Basic** tabbed page, toggle on **Creep/swelling/viscoelastic strain error tolerance** to enter the maximum difference in the creep strain increment calculated from the creep strain rates at the beginning and at the end of the increment. This value controls the accuracy of the creep integration. For more information, see *Specifying the Tolerance for Automatic Incrementation*.

*Configure settings on the **Other** tabbed page*

1. In the **Edit Step** dialog box, display the **Other** tabbed page.

   (For information on displaying the **Edit Step** dialog box, see *Creating a step*, or *Editing a step*.)
2. Choose an **Equation Solver Method** option:

   - Choose **Direct** to use the default direct sparse solver.
   - Choose **Iterative** to use the iterative linear equation solver. The iterative solver is typically most useful for blocky structures with millions of degrees of freedom. For more information, see *Iterative Linear Equation Solver*.
3. Choose a **Matrix storage** option:

   - Choose **Use solver default** to allow Abaqus/Standard to decide whether a symmetric or unsymmetric matrix storage and solution scheme is needed.
   - Choose **Unsymmetric** to restrict Abaqus/Standard to the unsymmetric storage and solution scheme.

     Note:

     The steady-state coupled equations are strongly unsymmetric; therefore, the unsymmetric matrix solution and storage scheme is selected automatically for steady-state analysis steps (see *Defining an Analysis*).
   - Choose **Symmetric** to restrict Abaqus/Standard to the symmetric storage and solution scheme.

   For more information on matrix storage, see *Matrix Storage and Solution Scheme in Abaqus/Standard*.
4. Choose a **Solution technique**:

   - Choose **Full Newton** to use Newton's method as a numerical technique for solving nonlinear equilibrium equations. For more information, see *Nonlinear solution methods in Abaqus/Standard*.
   - Choose **Quasi-Newton** to use the quasi-Newton technique for solving nonlinear equilibrium equations. This technique can save substantial computational cost in some cases. Generally it is most successful when the system is large and the stiffness matrix is not changing much from iteration to iteration. You can use this technique only for symmetric systems of equations.

If you choose this technique, enter a value for the **Number of iterations allowed before the kernel matrix is reformed**. The maximum number of iterations allowed is 25. The default number of iterations is 8.

For more information, see *Quasi-Newton solution technique*.

5. Click the arrow to the right of the **Convert severe discontinuity iterations** field, and select an option for dealing with severe discontinuities during nonlinear analysis:

   - Select **Off** to force a new iteration if severe discontinuities occur during an iteration, regardless of the magnitude of the penetration and force errors. This option also changes some time incrementation parameters and uses different criteria to determine whether to do another iteration or to make a new attempt with a smaller increment size.
   - Select **On** to use local convergence criteria to determine whether a new iteration is needed. Abaqus/Standard will determine the maximum penetration and estimated force errors associated with severe discontinuities and check whether these errors are within the tolerances. Hence, a solution may converge if the severe discontinuities are small.
   - Select **Propagate from previous step** to use the value specified in the previous general analysis step. This value appears in parentheses to the right of the field.

   For more information on severe discontinuities, see *Severe Discontinuities in Abaqus/Standard*.

6. Abaqus/Standard automatically selects the **Default load variation with time** option that corresponds to your **Pore fluid response** selection on the **Basic** tabbed page. It is recommended that you leave the **Default load variation with time** selection unchanged.
7. Click the arrow to the right of the **Extrapolation of previous state at start of each increment** field, and select a method for determining the first guess to the incremental solution:

   - Select **Linear** to indicate that the process is essentially monotonic and Abaqus/Standard should use a 100% linear extrapolation, in time, of the previous incremental solution to begin the nonlinear equation solution for the current increment.
   - Select **Parabolic** to indicate that the process should use a quadratic extrapolation, in time, of the previous two incremental solutions to begin the nonlinear equation solution for the current increment.
   - Select **None** to suppress any extrapolation.

   For more information, see *Extrapolation of the Solution*.

When you have finished configuring settings for the step, click **OK** to close the **Edit Step** dialog box.

Configuring a transient, static, stress/displacement analysis with time-dependent material response

You can use a quasi-static stress analysis to analyze problems with time-dependent material response (creep, swelling, viscoelasticity, and two-layer viscoplasticity). This type of analysis is valid when inertial effects can be neglected. It can be linear or nonlinear. For more information, see *Quasi-Static Analysis*.

Create or edit a quasi-static stress analysis procedure

1. Display the **Edit Step** dialog box following the procedure outlined in *Creating a step* (**Procedure type:** `General; Visco`), or *Editing a step*.
2. On the **Basic**, **Incrementation**, and **Other** tabbed pages, configure settings such as the time period, automatic or fixed incrementation, and equation solver preferences as described in the following procedures.

*Configure settings on the **Basic** tabbed page*

1. In the **Edit Step** dialog box, display the **Basic** tabbed page.
2. In the **Description** field, enter a short description of the analysis step. Abaqus stores the text that you enter in the output database, and the text is displayed in the state block by the Visualization module.
3. In the **Time period** field, enter the time period of the step.
4. Select an **Nlgeom** option:

   - Toggle **NlgeomOff** to perform a geometrically linear analysis during the current step.
   - Toggle **NlgeomOn** to indicate that Abaqus/Standard should account for geometric nonlinearity during the step. Once you have toggled **Nlgeom** on, it will be active during all subsequent steps in the analysis.

   For more information, see *Linear and nonlinear procedures*.

5. Select an automatic stabilization method if you expect the problem to have local instabilities such as surface wrinkling, material instability, or local buckling. Abaqus/Standard can stabilize this class of problems by applying damping throughout the model. For more information, see *Unstable Problems*, and *Automatic Stabilization of Static Problems with a Constant Damping Factor*

   Click the arrow to the right of **Automatic stabilization**, and select a method for defining the damping factor:

   - Select **Specify dissipated energy fraction** to allow Abaqus/Standard to calculate the damping factor from a dissipated energy fraction that you provide. Enter a value for the dissipated energy fraction in the adjacent field (the default is 2.0×10^{-4}). For more information, see *Calculating the Damping Factor Based on the Dissipated Energy Fraction*.
   - Select **Specify damping factor** to enter the damping factor directly. Enter a value for the damping factor in the adjacent field. For more information, see *Directly Specifying the Damping Factor*.
   - Select **Use damping factors from previous general step** to use the damping factors at the end of the previous step as the initial factors in the current step's variable damping scheme. These factors override any initial damping factors that are calculated or specified directly in the current step. If there are no damping factors associated with the previous general step (for example, if the previous step does not use any stabilization or the current step is the first step of the analysis), Abaqus uses adaptive stabilization to determine the required damping factors.

6. When using automatic stabilization, Abaqus can use the same damping factor over the course of a step, or it can vary the damping factor spatially and temporally during a step based on the convergence history and the ratio of the energy dissipated by damping to the total strain energy. For more information,

see *Adaptive Automatic Stabilization Scheme*. If you selected **Specify dissipated energy fraction**, adaptive stabilization is optional and turned on by default. If you selected **Specify damping factor**, adaptive stabilization is optional and turned off by default. If you selected **Use damping factors from previous general step**, adaptive stabilization is required.

To use adaptive stabilization, toggle on **Use adaptive stabilization with max. ratio of stabilization to strain energy** (if necessary), and enter a value in the adjacent field for the allowable accuracy tolerance for the ratio of energy dissipated by damping to total strain energy in each increment. The default value of 0.05 should be suitable in most cases.

*Configure settings on the **Incrementation** tabbed page*

1. In the **Edit Step** dialog box, display the **Incrementation** tabbed page.

   (For information on displaying the **Edit Step** dialog box, see *Creating a step*, or *Editing a step*.)

2. Choose a **Type** option:

   - Choose **Automatic** if you want Abaqus/Standard to select time increments automatically based on the accuracy of the integration. A **Creep/swelling/viscoelastic strain error tolerance** parameter that you specify limits the maximum inelastic strain rate change allowed over an increment. **Automatic** incrementation is recommended for almost all cases.
   - Choose **Fixed** to specify direct user control of the incrementation. Abaqus/Standard uses an increment size that you specify as the constant increment size throughout the step.

3. In the **Maximum number of increments** field, enter the upper limit to the number of increments in the step. The analysis stops if this maximum is exceeded before Abaqus/Standard arrives at the complete solution for the step.
4. If you selected **Automatic** in Step 2, do the following:
   a. Enter values for **Increment size**:

      - In the **Initial** field, enter the initial time increment. Abaqus/Standard modifies this value as required throughout the step.
      - In the **Minimum** field, enter the minimum time increment allowed. If Abaqus/Standard needs a smaller time increment than this value, it terminates the analysis.
      - In the **Maximum** field, enter the maximum time increment allowed.

   b. In the **Creep/swelling/viscoelastic strain error tolerance** field, enter the maximum difference in the creep strain increment calculated from the creep strain rates at the beginning and at the end of the increment. This value controls the accuracy of the creep integration. For more information, see *Automatic Incrementation*.
5. If you selected **Fixed** in Step 2, enter a value for the constant time increment in the **Increment size** field.
6. Choose a **Creep/swelling/viscoelastic integration** option:

   - Choose **Explicit/Implicit** if you want to allow Abaqus/Standard to invoke the implicit integration scheme. For creep at very low stress levels the unconditional stability of the backward difference operator (implicit method) is desirable.
   - Choose **Explicit** if you want to restrict Abaqus/Standard to using explicit integration. Explicit integration can be less expensive computationally and simplifies implementation of user-defined creep laws in user subroutine *CREEP*

   For more information, see *Selecting Explicit Creep Integration*.

*Configure settings on the **Other** tabbed page*

1. In the **Edit Step** dialog box, display the **Other** tabbed page.

   (For information on displaying the **Edit Step** dialog box, see *Creating a step*, or *Editing a step*.)

2. Choose an **Equation Solver Method** option:

   - Choose **Direct** to use the default direct sparse solver.
   - Choose **Iterative** to use the iterative linear equation solver. The iterative solver is typically most useful for blocky structures with millions of degrees of freedom. For more information, see *Iterative Linear Equation Solver*.

3. Choose a **Matrix storage** option:

   - Choose **Use solver default** to allow Abaqus/Standard to decide whether a symmetric or unsymmetric matrix storage and solution scheme is needed.
   - Choose **Unsymmetric** to restrict Abaqus/Standard to the unsymmetric storage and solution scheme.
   - Choose **Symmetric** to restrict Abaqus/Standard to the symmetric storage and solution scheme.

   For more information on matrix storage, see *Matrix Storage and Solution Scheme in Abaqus/Standard*.

4. Choose a **Solution technique**:

   - Choose **Full Newton** to use Newton's method as a numerical technique for solving nonlinear equilibrium equations. For more information, see *Nonlinear solution methods in Abaqus/Standard*.
   - Choose **Quasi-Newton** to use the quasi-Newton technique for solving nonlinear equilibrium equations. This technique can save substantial computational cost in some cases. Generally it is most successful when the system is large and the stiffness matrix is not changing much from iteration to iteration. You can use this technique only for symmetric systems of equations.

     If you choose this technique, enter a value for the **Number of iterations allowed before the kernel matrix is reformed**. The maximum number of iterations allowed is 25. The default number of iterations is 8.

     For more information, see *Quasi-Newton solution technique*.

5. Click the arrow to the right of the **Convert severe discontinuity iterations** field, and select an option for dealing with severe discontinuities during nonlinear analysis:

   - Select **Off** to force a new iteration if severe discontinuities occur during an iteration, regardless of the magnitude of the penetration and force errors. This option also changes some time incrementation parameters and uses different criteria to determine whether to do another iteration or to make a new attempt with a smaller increment size.
   - Select **On** to use local convergence criteria to determine whether a new iteration is needed. Abaqus/Standard will determine the maximum penetration and estimated force errors associated with severe discontinuities and check whether these errors are within the tolerances. Hence, a solution may converge if the severe discontinuities are small.
   - Select **Propagate from previous step** to use the value specified in the previous general analysis step. This value appears in parentheses to the right of the field.

   For more information on severe discontinuities, see *Severe Discontinuities in Abaqus/Standard*.

6. Choose an option for **Default load variation with time**:

   - Choose **Instantaneous** if you want loads to be applied instantaneously at the start of the step and remain constant throughout the step.

- Choose **Ramp linearly over step** if the load magnitude is to vary linearly over the step, from the value at the end of the previous step to the full magnitude of the load.

7. Click the arrow to the right of the **Extrapolation of previous state at start of each increment** field, and select a method for determining the first guess to the incremental solution:

   - Select **Linear** to indicate that the process is essentially monotonic and Abaqus/Standard should use a 100% linear extrapolation, in time, of the previous incremental solution to begin the nonlinear equation solution for the current increment.
   - Select **Parabolic** to indicate that the process should use a quadratic extrapolation, in time, of the previous two incremental solutions to begin the nonlinear equation solution for the current increment.
   - Select **None** to suppress any extrapolation.

   For more information, see *Extrapolation of the Solution*.

When you have finished configuring settings for the step, click **OK** to close the **Edit Step** dialog box.

Configuring an annealing procedure

The anneal procedure is intended to simulate the relaxation of stresses and plastic strains that occurs as metals are heated to high temperatures.
Physically, annealing is the process of heating a metal part to a high temperature to allow the microstructure to recrystallize, removing dislocations caused by cold working of the material.

The anneal procedure can be created following a dynamic, explicit procedure or a dynamic fully coupled thermal-stress procedure using explicit integration (see *Configuring a dynamic, explicit procedure* and *Configuring a dynamic fully coupled thermal-stress procedure using explicit integration*.) During the anneal procedure Abaqus/Explicit sets all appropriate state variables to zero. These variables include stresses, backstresses, plastic strains, and velocities. In the case of metal porous plasticity, the void volume fraction is also set to zero, such that the material becomes fully dense.

There is no time scale in an annealing step; therefore, time does not advance. The annealing process occurs instantaneously. No data are required for the anneal procedure.

For more information, see *Annealing*.

1. Display the **Edit Step** dialog box following the procedure outlined in *Creating a step* (**Procedure type:** `General; Anneal`), or *Editing a step*.
2. In the **Description** field, enter a short description of the analysis step. Abaqus stores the text that you enter in the output database, and the text is displayed in the state block by the Visualization module.
3. Choose a **Post-anneal reference temperature** option:
   - Choose **Maintain current** to maintain the current temperature at all nodes in the model after the annealing is complete.
   - Choose **Value** to specify a final temperature to which all nodes in the model will be set after the annealing is complete. Enter the value in the field provided.
4. Click **OK** to close the **Edit Step** dialog box.

Configuring linear perturbation analysis procedures

You can configure linear perturbation procedures to analyze linear problems.
Linear perturbation procedures are available only in Abaqus/Standard. The linear perturbation approach allows general application of linear analysis techniques in cases where the linear response depends on preloading or on the nonlinear response history of the model. For more information, see *General and Perturbation Procedures*.

This section provides instructions for using the step editor to configure different types of linear perturbation procedures.

In this section:

- *Configuring a static, linear perturbation procedure*
- *Configuring a frequency procedure*
- *Configuring a buckling procedure*
- *Configuring a complex frequency procedure*
- *Configuring a modal dynamics procedure*
- *Configuring a random response procedure*
- *Configuring a response spectrum procedure*
- *Configuring a direct-solution steady-state dynamic procedure*
- *Configuring a mode-based steady-state dynamic analysis*
- *Configuring a subspace-based steady-state dynamic analysis*
- *Configuring a substructure generation procedure*
- *Configuring a time-harmonic electromagnetic analysis*

Configuring a static, linear perturbation procedure

The response in a linear analysis step is the linear perturbation response about the *base state*. The base state is the current state of the model at the end of the last general analysis step prior to the linear perturbation step. If the first step of an analysis is a perturbation step, the base state is determined from the initial conditions.

For more information, see *Linear Perturbation Analysis Steps*.

Create or edit a static, linear perturbation procedure

1. Display the **Edit Step** dialog box following the procedure outlined in *Creating a step* (**Procedure type:** `Linear perturbation; Static, Linear perturbation`), or *Editing a step*.
2. On the **Basic** and **Other** tabbed pages, describe the step and enter equation solver preferences as described in the following procedures.

Configure a static, linear perturbation procedure

1. In the **Edit Step** dialog box, display the **Basic** tabbed page.
2. In the **Description** field, enter a short description of the analysis step. Abaqus stores the text that you enter in the output database, and the text is displayed in the state block by the Visualization module.
3. Display the **Other** tabbed page.
4. Choose an **Equation Solver Method** option:
   - Choose **Direct** to use the default direct sparse solver.
   - Choose **Iterative** to use the iterative linear equation solver. The iterative solver is typically most useful for blocky structures with millions of degrees of freedom. For more information, see *Iterative Linear Equation Solver*.
5. Choose a **Matrix storage** option:
   - Choose **Use solver default** to allow Abaqus/Standard to decide whether a symmetric or unsymmetric matrix storage and solution scheme is needed.
   - Choose **Unsymmetric** to restrict Abaqus/Standard to the unsymmetric storage and solution scheme.
   - Choose **Symmetric** to restrict Abaqus/Standard to the symmetric storage and solution scheme.

   For more information on matrix storage, see *Matrix Storage and Solution Scheme in Abaqus/Standard*.
6. Choose a **Solution technique** option:
   - Choose **Full Newton** to use Newton's method as a numerical technique for solving nonlinear equilibrium equations.
   - Choose **LCP Contact** to activate the linearized contact capability to solve for contact status and contact stresses. This option can be specified only within a static perturbation step with small sliding, frictionless contact.

     If you choose this technique, enter a value for the **Gap distance** to specify a zone within which potential contact constraints are exposed to the LCP solver and **Scale factor** for the initial gap distance specified in the **Gap distance** or the internally computed (contact) pair-wise gap distances. The default is 1.0.
7. When you have finished configuring settings for the static, linear perturbation step, click **OK** to close the **Edit Step** dialog box.

Configuring a frequency procedure

This section provides detailed instructions for configuring a frequency extraction procedure.

In this section:

- *Defining frequency extraction procedures*
- *Using the Lanczos eigensolver for a frequency extraction procedure*
- *Using the AMS eigensolver for a frequency extraction procedure*
- *Using the subspace iteration eigensolver for a frequency extraction procedure*

Defining frequency extraction procedures

When you have configured a step for a frequency procedure, Abaqus/Standard performs an eigenvalue extraction procedure during that step to calculate the natural frequencies and the corresponding mode shapes of a system.

When you configure a frequency step, you must choose one of the following eigenvalue extraction methods:

Lanczos

The Lanczos method is the default method because it has general capabilities. However, this method is usually slower than the AMS method. For more information, see *Lanczos Eigensolver* and *Eigenvalue extraction*.

For detailed instructions on configuring settings for the Lanczos eigenvalue extraction method, see *Using the Lanczos eigensolver for a frequency extraction procedure*.

Automatic multi-level substructuring (AMS)

The AMS method is an add-on analysis capability for Abaqus/Standard. The AMS method is faster than the Lanczos method, particularly when you require a large number of eigenmodes for a system with many degrees of freedom. However, the AMS method has several limitations. For more information, see *Automatic Multilevel Substructuring (AMS) Eigensolver*.

For detailed instructions on configuring settings for the AMS extraction method, see *Using the AMS eigensolver for a frequency extraction procedure*.

Subspace iteration

For the subspace iteration procedure you need only specify the number of eigenvalues required; Abaqus/Standard chooses a suitable number of vectors for the iteration. You can also specify the maximum frequency of interest; Abaqus/Standard extracts eigenvalues until either the requested number of eigenvalues has been extracted or the last frequency extracted exceeds the maximum frequency of interest. For more information, see *Eigenvalue extraction*.

For detailed instructions on configuring settings for the subspace iteration extraction method, see *Using the subspace iteration eigensolver for a frequency extraction procedure*.

For background information on frequency extraction procedures, see *Natural Frequency Extraction*.

Using the Lanczos eigensolver for a frequency extraction procedure

The **Edit Step** dialog box provides **Basic** and **Other** tabbed pages on which you can specify settings for the Lanczos eigensolver.

You can display the **Edit Step** dialog box following the procedure outlined in *Creating a step* (**Procedure type:**`Linear perturbation; Frequency`), or *Editing a step*.

Configure settings on the **Basic** tabbed page

1. In the **Edit Step** dialog box, display the **Basic** tabbed page.
2. In the **Description** field, enter a short description of the analysis step. Abaqus stores the text that you enter in the output database, and the text is displayed in the state block by the Visualization module.
3. From the list of **Eigensolver** options, choose **Lanczos**.
4. Choose one of the **Number of eigenvalues requested** options to indicate how many eigenvalues you want calculated:
   - Choose **All in frequency range** if you want Abaqus/Standard to calculate all the eigenvalues within a range determined by a maximum frequency value (and, if desired, a minimum frequency value) that you enter.
   - Choose **Value** if you want a particular number of eigenvalues to be calculated. Enter that value in the field provided.
5. Toggle on **Frequency shift (cycles/time)**2** to specify a positive or negative shifted squared frequency, *S*. If you toggle this option on, enter a value for the frequency shift in the field provided. For more information, see *Frequency Shift*.
6. Toggle on **Minimum frequency of interest (cycles/time)** to specify a lower limit to the frequency range within which Abaqus/Standard will calculate eigenvalues. If you toggle on this option, enter a value for the minimum frequency in the field provided.

   This option is required if you intend to use the Lanczos solver in parallel mode.
7. Toggle on **Maximum frequency of interest (cycles/time)** to specify an upper limit to the frequency range within which Abaqus/Standard will calculate eigenvalues. If you toggle on this option, enter a value for the maximum frequency in the field provided.

   This option is required if you intend to use the Lanczos solver in parallel mode.
8. If the model includes acoustic and structural elements coupled together or ASI-type elements, you can toggle on **Include acoustic-structural coupling where applicable** to include the effect of acoustic-structural coupling during the frequency extraction. (This option is toggled on by default.) For more information, see *Structural-Acoustic Coupling*.
9. Specify your preference for block size:
   - Choose **Default** to use the default block size of 7, which is usually appropriate.
   - Choose **Value** to enter a particular block size. Enter the value in the field provided. In general, the block size for the Lanczos method should be as large as the largest expected multiplicity of eigenvalues.

   For more information, see *Lanczos Eigensolver*.
10. Specify your preference for the **Maximum number of block Lanczos steps**:
    - Choose **Default** to allow Abaqus/Standard to determine the number of block Lanczos steps within each Lanczos run. The default value is usually appropriate.
    - Choose **Value** to enter a limit to the number of Lanczos steps within each Lanczos run. Enter the value in the field provided. In general, if a particular type of eigenproblem converges slowly,

providing more block Lanczos steps will reduce the analysis cost. On the other hand, if you know that a particular type of problem converges quickly, providing fewer block Lanczos steps will reduce the amount of in-core memory used.

11. Toggle on **Use SIM-based linear dynamics procedures** to activate the high performance, mode-based linear dynamics analysis capability. If the eigenmodes that are extracted in this step will be used for subsequent mode-based or subspace-based linear dynamic procedures, the SIM-based capability offers improved efficiency for large models with minimal output requests. For more information, see *Using the SIM Architecture for Modal Superposition Dynamic Analyses*.
12. If you toggled on **Use SIM-based linear dynamics procedures**, Abaqus projects structural and viscous damping operators defined in the model for use in a later, steady-state dynamic step. To deactivate the projection of damping operators, toggle off **Project damping operators**. Deactivating the damping operators may improve the performance of the frequency extraction step; however, structural and viscous material damping will then be ignored in subsequent steady-state dynamic steps. For more information, see *Damping in a Mode-Based Steady-State and Transient Linear Dynamic Analysis Using the SIM Architecture*.
13. Toggle on **Include residual modes** to request that Abaqus/Standard compute residual modes based on the loads specified in the immediately preceding static, linear perturbation step. For more information, see *Residual Modes*.

Configure settings on the **Other** tabbed page

1. In the **Edit Step** dialog box, display the **Other** tabbed page.
2. Accept the default **Matrix storage** setting. Since Abaqus/Standard provides eigenvalue extraction only for symmetric matrices, steps with eigenfrequency extraction or eigenvalue buckling prediction procedures always use the symmetric matrix storage and solution scheme. You cannot change this setting. In such steps Abaqus/Standard will symmetrize all contributions to the stiffness matrix.
3. Choose an option for normalizing eigenvectors:

   - Choose **Displacement** to normalize the eigenvectors so that the largest displacement, rotation, or acoustic pressure entry in each vector is unity.
   - Choose **Mass** to normalize the eigenvectors with respect to the structure's mass matrix (the eigenvectors are scaled so that the generalized mass for each vector is unity).

   If you toggled on **Use SIM-based linear dynamics procedures** on the **Basic** tabbed page, only mass normalization is available. For more information, see *Normalization*.
4. Toggle on **Evaluate dependent properties at frequency** to evaluate frequency-dependent properties for viscoelasticity, springs, and dashpots during the eigenvalue extraction. If you toggle this option on, enter the desired evaluation frequency in the field provided. For more information, see *Evaluating Frequency-Dependent Material Properties*.

When you have finished configuring settings for the frequency step, click **OK** to close the **Edit Step** dialog box.

Using the AMS eigensolver for a frequency extraction procedure

The **Edit Step** dialog box provides **Basic** and **Other** tabbed pages on which you can specify settings for the AMS eigensolver.

You can display the **Edit Step** dialog box following the procedure outlined in *Creating a step* (**Procedure type:**`Linear perturbation; Frequency`), or *Editing a step*.

Configure settings on the **Basic** tabbed page

1. In the **Edit Step** dialog box, display the **Basic** tabbed page.
2. In the **Description** field, enter a short description of the analysis step. Abaqus stores the text that you enter in the output database, and the text is displayed in the state block by the Visualization module.
3. From the list of **Eigensolver** options, choose **AMS**.
4. Coupling of structural and acoustic regions does not affect a frequency extraction procedure that uses the AMS eigensolver: the structural and acoustic modes are computed as if uncoupled. By default, Abaqus projects structural-acoustic coupling operators defined in the model for use in a later, steady-state dynamic step. To deactivate the projection, toggle off **Project acoustic-structural coupling where applicable**. Deactivating the coupling operators may improve the analysis speed, but structural-acoustic coupling will then be ignored in subsequent steady-state dynamic steps.
5. For models that include both structural and acoustic elements, Abaqus by default uses the same frequency range when calculating the acoustic eigenvalues as it does when calculating the structural eigenvalues. To specify different frequency ranges for the two regions, enter an **Acoustic range factor**. Abaqus multiplies this factor by the **Maximum frequency of interest** to determine a different maximum frequency for the acoustic region. The minimum frequency remains the same for both regions.
6. Toggle on **Minimum frequency of interest (cycles/time)** to specify a lower limit to the frequency range within which Abaqus/Standard will calculate eigenvalues. If you toggle on this option, enter a value for the minimum frequency in the field provided.
7. In the **Maximum frequency of interest (cycles/time)** field, enter the upper limit to the frequency range within which Abaqus/Standard will extract all the modes.
8. Toggle on **Limit region of saved eigenvectors** if you want to limit eigenvector computation to only the nodes in a particular region. If you toggle on this option, click the arrow to the right of the field provided to select the region of interest.
9. By default, Abaqus projects any structural or viscous damping operators defined in the model for use in a later, steady-state dynamic step. To deactivate the projection of these operators, toggle off **Project damping operators**. Deactivating the damping operators may improve the performance of the frequency extraction step; however, structural and viscous material damping will then be ignored in subsequent steady-state dynamic steps. For more information, see *Damping in a Mode-Based Steady-State and Transient Linear Dynamic Analysis Using the SIM Architecture*.
10. Toggle on **Include residual modes** to request that Abaqus/Standard compute residual modes based on the static response of the model to a nominal (or unit) load.

    If you toggle on this option, specify the residual mode regions and the degrees of freedom (DOF) for which you want residual modes calculated. Abaqus/Standard computes one residual mode for every requested degree of freedom.

    For more information, see *Residual Modes*.

Configure settings on the **Other** tabbed page

1. In the **Edit Step** dialog box, display the **Other** tabbed page.
2. Accept the default **Matrix storage** setting. Since Abaqus/Standard provides eigenvalue extraction only for symmetric matrices, steps with eigenfrequency extraction or eigenvalue buckling prediction procedures always use the symmetric matrix storage and solution scheme. You cannot change this setting. In such steps Abaqus/Standard will symmetrize all contributions to the stiffness matrix.

3. In the **Cutoff multiplier for substructure eigenproblems** field, enter AMS_{cutoff_1}, the cutoff frequency for substructure eigenproblems, defined as a multiplier of the maximum frequency of interest. The default value is 5.
4. In the **First cutoff multiplier for reduced eigenproblems** field, enter AMS_{cutoff_2}, the first cutoff frequency for a reduced eigenproblem, defined as a multiplier of the maximum frequency of interest.

   The default value is 1.6. $AMS_{\text{cutoff}_2} \leq AMS_{\text{cutoff}_1}$.
5. In the **Second cutoff multiplier for reduced eigenproblems** field, enter AMS_{cutoff_3}, the second cutoff frequency for a reduced eigenproblem, defined as a multiplier of the maximum frequency of interest.

   The default value is 1.3. $\mathbf{1.0} \leq AMS_{\text{cutoff}_3} \leq AMS_{\text{cutoff}_2}$.

   For more information, see *Automatic Multilevel Substructuring (AMS) Eigensolver*.

When you have finished configuring settings for the frequency step, click **OK** to close the **Edit Step** dialog box.

Using the subspace iteration eigensolver for a frequency extraction procedure

The **Edit Step** dialog box provides **Basic** and **Other** tabbed pages on which you can specify settings for the subspace iteration eigensolver.

You can display the **Edit Step** dialog box following the procedure outlined in *Creating a step* (**Procedure type:**`Linear perturbation; Frequency`), or *Editing a step*.

Configure setting on the **Basic** tabbed page

1. In the **Edit Step** dialog box, display the **Basic** tabbed page.
2. In the **Description** field, enter a short description of the analysis step. Abaqus stores the text that you enter in the output database, and the text is displayed in the state block by the Visualization module.
3. From the list of **Eigensolver** options, choose **Subspace**.
4. In the **Number of eigenvalues requested** field, enter the number of eigenvalues that you want Abaqus/Standard to calculate.
5. Toggle on **Frequency shift (cycles/time)******2** to specify a positive or negative shifted squared frequency, *S*. If you toggle this option on, enter a value for the frequency shift in the field provided. For more information, see *Frequency Shift*.
6. Toggle on **Maximum frequency of interest (cycles/time)** to specify an upper limit to the frequency range within which Abaqus/Standard will calculate eigenvalues. If you toggle on this option, enter a value for the maximum frequency in the field provided.

   Abaqus/Standard will extract eigenvalues until either the requested number of eigenvalues has been extracted or the last frequency extracted exceeds the maximum frequency of interest.
7. Enter a value for the number of **Vectors used per iteration**. In general, the convergence is more rapid with more vectors, but the memory requirement is also larger. Thus, if you know that a particular type of eigenproblem converges slowly, providing more vectors by using this option might reduce the analysis cost.
8. Enter a value for the **Maximum number of iterations**. The default is 30.

Configure settings on the **Other** tabbed page

1. In the **Edit Step** dialog box, display the **Other** tabbed page.
2. Accept the default **Matrix storage** setting. Since Abaqus/Standard provides eigenvalue extraction only for symmetric matrices, steps with eigenfrequency extraction or eigenvalue buckling prediction procedures always use the symmetric matrix storage and solution scheme. You cannot change this setting. In such steps Abaqus/Standard will symmetrize all contributions to the stiffness matrix.
3. Choose an option for normalizing eigenvectors:

   - Choose **Displacement** to normalize the eigenvectors so that the largest displacement, rotation, or acoustic pressure entry in each vector is unity.
   - Choose **Mass** to normalize the eigenvectors with respect to the structure's mass matrix (the eigenvectors are scaled so that the generalized mass for each vector is unity).

   For more information, see *Normalization*.
4. Toggle on **Evaluate dependent properties at frequency** to evaluate frequency-dependent properties for viscoelasticity, springs, and dashpots during the eigenvalue extraction. If you toggle on this option, enter the desired evaluation frequency in the field provided. For more information, see *Evaluating Frequency-Dependent Material Properties*.

When you have finished configuring settings for the frequency step, click **OK** to close the **Edit Step** dialog box.

Configuring a buckling procedure

An eigenvalue buckling analysis is generally used to estimate the critical buckling loads of stiff structures (classical eigenvalue buckling). This type of analysis is a linear perturbation procedure, and buckling loads are calculated relative to the base state of the structure. For more information, see *Eigenvalue Buckling Prediction*.

Create or edit a buckling procedure

1. Display the **Edit Step** dialog box following the procedure outlined in *Creating a step* (**Procedure type:** `Linear perturbation; Buckle`), or *Editing a step*.
2. On the **Basic** tabbed page, configure settings such as eigensolver extraction method and maximum number of iterations as described in the following procedures.

   The **Other** tabbed page displays the default matrix storage option. You cannot change this setting because Abaqus/Standard provides eigenvalue extraction for only symmetric matrices. In eigenvalue buckling prediction procedures Abaqus/Standard symmetrizes all contributions to the stiffness matrix.

*Configure settings on the **Basic** tabbed page*

1. In the **Edit Step** dialog box, display the **Basic** tabbed page.
2. In the **Description** field, enter a short description of the analysis step. Abaqus stores the text that you enter in the output database, and the text is displayed in the state block by the Visualization module.
3. Choose either the **Lanczos** eigensolver or the **Subspace** iteration eigensolver.

   The Lanczos method is generally faster when a large number of eigenmodes is required for a system with many degrees of freedom. However, this method does have some limitations (see the warning at the bottom of the **Basic** tabbed page). The subspace iteration method may be faster when only a few (less than 20) eigenmodes are needed. For more information, see *Selecting the Eigenvalue Extraction Method*.
4. In the **Number of eigenvalues requested** field, enter the number of eigenvalues that you want to be estimated. Significant overestimation of the actual number of eigenvalues can create very large files. If you underestimate the actual number of eigenvalues, Abaqus/Standard will issue a corresponding warning message.
5. If you selected the **Lanczos** eigensolver, do the following:
   a. Toggle on **Minimum eigenvalue of interest** to enter a lower limit to the range of eigenvalues Abaqus/Standard will extract. If you toggle on this option, enter the value in the field provided.
   b. Toggle on **Maximum eigenvalue of interest** to enter an upper limit to the range of eigenvalues Abaqus/Standard will extract. If you toggle on this option, enter the value in the field provided.

      If you specify a range of eigenvalues, Abaqus/Standard will extract eigenvalues until either the requested number of eigenvalues has been extracted in the given range or all the eigenvalues in the given range have been extracted.
   c. Choose a **Block size** option:

      - Choose **Default** to use the default block size of 7, which is usually appropriate.
      - Choose **Value** to enter a particular block size in the field provided. In general, the block size for the Lanczos method should be as large as the largest expected multiplicity of eigenvalues.

      For more information, see *Selecting the Eigenvalue Extraction Method*.
   d. Specify your preference for the **Maximum number of block Lanczos steps**:

      - Choose **Default** to allow Abaqus/Standard to determine the number of block Lanczos steps within each Lanczos run. The default value is usually appropriate.

- Choose **Value** to enter a limit to the number of Lanczos steps within each Lanczos run. In general, if a particular type of eigenproblem converges slowly, providing more block Lanczos steps will reduce the analysis cost. On the other hand, if you know that a particular type of problem converges quickly, providing fewer block Lanczos steps will reduce the amount of in-core memory used.

6. If you selected the **Subspace** eigensolver, do the following:
   a. Toggle on **Maximum eigenvalue of interest** to enter an upper limit to the range of eigenvalues Abaqus/Standard will extract. If you toggle on this option, enter the value in the field provided.

      Abaqus/Standard will extract eigenvalues until either the requested number of eigenvalues has been extracted or the last eigenvalue extracted exceeds the maximum eigenvalue of interest.
   b. Enter a value for the number of **Vectors used per iteration**. In general, the convergence is more rapid with more vectors, but the memory requirement is also larger. Thus, if you know that a particular type of eigenproblem converges slowly, providing more vectors by using this option might reduce the analysis cost.
   c. Enter a value for the **Maximum number of iterations**. The default is 30.
7. Click **OK** to save the step and to close the **Edit Step** dialog box.

Configuring a complex frequency procedure

A complex frequency procedure performs eigenvalue extraction to calculate the complex eigenvalues and the corresponding complex mode shapes of a system. It is a linear perturbation procedure and requires that you perform an eigenfrequency extraction procedure (described in *Configuring a frequency procedure*") prior to the complex eigenvalue extraction. For more information, see *Complex Eigenvalue Extraction*.

Create or edit a complex frequency procedure

1. Display the **Edit Step** dialog box following the procedure outlined in *Creating a step* (**Procedure type:** `Linear perturbation; Complex frequency`), or *Editing a step*.
2. On the **Basic** and **Other** tabbed pages, configure settings such as the number of eigenvalues requested and matrix solver preferences as described in the following procedures.

*Configure settings on the **Basic** tabbed page*

1. In the **Edit Step** dialog box, display the **Basic** tabbed page.
2. In the **Description** field, enter a short description of the analysis step. Abaqus stores the text that you enter in the output database, and the text is displayed in the state block by the Visualization module.
3. Choose an option for specifying the **Number of eigenvalues requested**:
   - Choose **All** if you want Abaqus/Standard to report all the eigenmodes available in the projected subspace, formulated on the basis of all eigenmodes computed in the preceding frequency step.
   - Choose **Value** to enter a specific number of eigenmodes that you want Abaqus/Standard to report.
4. Toggle on **Frequency shift (cycles/time)** to specify a shift point, S, for the complex eigenvalue extraction procedure ($S \geq 0$). Abaqus/Standard reports the complex eigenmodes, μ_n, in order of increasing $|Im(\mu_n) - S|$ so that the modes with the imaginary part closest to a given shift point are reported first. This feature is useful when a particular frequency range is of concern. The default is no shift.
5. Toggle on **Minimum frequency of interest (cycles/time)** to specify a lower limit to the frequency range within which Abaqus/Standard reports eigenmodes.
6. Toggle on **Maximum frequency of interest (cycles/time)** to specify an upper limit to the frequency range within which Abaqus/Standard reports eigenmodes.
7. Toggle on **Include friction-induced damping effects** to include friction-induced contributions to the damping matrix. For more information, see *Contact Conditions with Sliding Friction*.

*Configure settings on the **Other** tabbed page*

1. In the **Edit Step** dialog box, display the **Other** tabbed page.
   (For information on displaying the **Edit Step** dialog box, see *Creating a step*, or *Editing a step*.)
2. Choose a **Matrix solver** option:
   - Choose **Use solver default** to allow Abaqus/Standard to decide whether a symmetric or unsymmetric matrix storage and solution scheme is needed.
   - Choose **Unsymmetric** to restrict Abaqus/Standard to the unsymmetric storage and solution scheme.
   - Choose **Symmetric** to restrict Abaqus/Standard to the symmetric storage and solution scheme.

   For more information on matrix storage, see *Matrix Storage and Solution Scheme in Abaqus/Standard*.
3. Toggle on **Evaluate dependent properties at frequency** to enter a frequency at which Abaqus/Standard will evaluate frequency-dependent material properties. For more information, see *Evaluating Frequency-Dependent Material Properties*.

When you have finished configuring settings for the step, click **OK** to close the **Edit Step** dialog box.

Configuring a modal dynamics procedure

A transient model dynamic analysis gives the response of the model as a function of time based on a given time-dependent loading. The structure's response is based on a subset of the modes of the system, which must first be extracted using an eigenfrequency extraction procedure (described in *Configuring a frequency procedure*). For more information, see *Transient Modal Dynamic Analysis*.

Create or edit a modal dynamics procedure

1. Display the **Edit Step** dialog box following the procedure outlined in *Creating a step* (**Procedure type:**`Linear perturbation; Modal dynamics`), or *Editing a step*.
2. On the **Basic** and **Damping** tabbed pages, configure settings such as whether or not to carry over initial conditions from the results of the preceding step and damping at particular modes or frequencies as described in the following procedures.

*Configure settings on the **Basic** tabbed page*

1. In the **Edit Step** dialog box, display the **Basic** tabbed page.
2. In the **Description** field, enter a short description of the analysis step. Abaqus stores the text that you enter in the output database, and the text is displayed in the state block by the Visualization module.
3. Indicate whether or not you want to carry over initial conditions from the immediately preceding step:
   - Choose **Use initial conditions (when applicable)** if you want Abaqus/Standard to carry over initial conditions from the immediately preceding step, which must be either another modal dynamic step or a static perturbation step:
     - If the immediately preceding step is a modal dynamic step, both the displacements and velocities are carried over from the end of that step and used as initial conditions for the current step.
     - If the immediately preceding step is a static perturbation step, the displacements are carried over from that step. If initial velocities have been defined (*Initial Conditions*), they will be used; otherwise, the initial velocities will be zero.
   - Choose **Zero initial conditions** If you want the modal dynamic step to begin with zero initial displacements. If you have defined initial velocities Abaqus/Standard will use them; otherwise, the initial velocities will be zero.
4. In the **Time period** field, enter the time period of the step.
5. In the **Time increment** field, enter a value for the desired time increment size.

*Configure settings on the **Damping** tabbed page*

1. In the **Edit Step** dialog box, display the **Damping** tabbed page.
   (For information on displaying the **Edit Step** dialog box, see *Creating a step*, or *Editing a step*.)
2. Indicate how you want to provide damping values:
   - Choose **Specify damping over ranges of Modes** to provide damping values for specific mode ranges.
   - Choose **Specify damping over ranges of Frequencies** to provide damping values at specific frequencies. Abaqus/Standard interpolates the damping coefficient for a mode linearly between the specified frequencies

   If you omit damping data on the **Damping** tabbed page, Abaqus/Standard assumes zero damping values. For more information, see *Specifying Modal Damping*.

3. If you selected **Modes** in Step 2, select one or more of the following options for defining damping:

   - Display the **Direct modal** tabbed page to specify the fraction of critical damping, ξ, for a particular mode range, and do the following:

     1. Toggle on **Use direct damping data**.
     2. Enter the following in the data table:

        - **Start Mode**: the mode number of the lowest mode of a range.
        - **End Mode**: the mode number of the highest mode of a range.
        - **Critical Damping Fraction**: fraction of critical damping, ξ.

   - Display the **Composite modal** tabbed page to select composite modal damping using the damping coefficients calculated in the preceding frequency step. (The damping calculations performed in the frequency step are performed using damping data provided in the material definition). Do the following:

     1. Toggle on **Use composite damping data**.
     2. Enter the following in the data table:

        - **Start Mode**: the mode number of the lowest mode of a range.
        - **End Mode**: the mode number of the highest mode of a range.

   - Display the **Rayleigh** tabbed page to define Rayleigh damping, and do the following:

     1. Toggle on **Use Rayleigh damping data**.
     2. Enter the following in the data table:

        - **Start Mode**: the mode number of the lowest mode of a range.
        - **End Mode**: the mode number of the highest mode of a range.
        - **Alpha**: mass proportional damping, α_M.
        - **Beta**: stiffness proportional damping, β_M.

   For detailed information on how to enter data, see *Entering tabular data*.

4. If you selected **Frequencies** in Step 2, select one or both of the following options for defining damping:

   - Display the **Direct modal** tabbed page to specify the fraction of critical damping, ξ, for a particular frequency range. Do the following:

     1. Toggle on **Use direct damping data**.
     2. Enter the following in the data table:

        - **Frequency**: frequency value in cycles/time.
        - **Critical Damping Fraction**: fraction of critical damping, ξ.

   - Display the **Rayleigh** tabbed page to define Rayleigh damping, and do the following:

     1. Toggle on **Use Rayleigh damping data**.
     2. Enter the following in the data table:

- **Frequency**: frequency value in cycles/time.
- **Alpha**: mass proportional damping, α_M.
- **Beta**: stiffness proportional damping, β_M.

For detailed information on how to enter data, see *Entering tabular data*.

5. If desired, repeat Steps 2–4 to create multiple damping definitions.

Configuring a random response procedure

A random response analysis is a linear perturbation procedure that provides the linearized dynamic response of a model to user-defined random excitation. This type of analysis uses the set of modes extracted in a previous eigenfrequency extraction procedure (described in *Configuring a frequency procedure*") to calculate the power spectral densities of response variables and the corresponding root mean square values. For more information, see *Random Response Analysis*.

Create or edit a random response procedure

1. Display the **Edit Step** dialog box following the procedure outlined in *Creating a step* (**Procedure type:** `Linear perturbation; Random response`), or *Editing a step*.
2. On the **Basic** and **Damping** tabbed pages, configure settings such as frequency range and damping definitions as described in the following procedures.
3. The power spectral density of the Mises equivalent stress and the root mean square of the Mises equivalent stress are computed in the Visualization module. To obtain these data, you must request specific field and history output.
   a. Display the output request editors as described in *Creating an output request*.
   b. For the field output request of the previous frequency step, select the stress component and invariants (S) output variable.
   c. For the history output request of the random response step, do the following:
      - Select **Set** as the **Domain**, and select the desired set from the list.
      - To obtain the power spectral density of the Mises equivalent stress, select the MISES output variable.
      - To obtain the root mean square of the Mises equivalent stress, select the RMISES output variable.
   d. You can view the MISES and RMISES output variables in the Visualization module.
      - To obtain contour plots of the MISES and RMISES output variables, see *Selecting the primary field output variable*.
      - X–Y data plots can be obtained for the MISES and RMISES output variables at element nodal and unique nodal output variable positions. To obtain these plots, see *Reading X–Y data from output database field output*.

*Configure settings on the **Basic** tabbed page*

1. In the **Edit Step** dialog box, display the **Basic** tabbed page.
2. In the **Description** field, enter a short description of the analysis step. Abaqus stores the text that you enter in the output database, and the text is displayed in the state block by the Visualization module.
3. Choose a **Scale** option to indicate whether you want the frequency range(s) of interest to be divided using a **Logarithmic** or **Linear** scale.
4. Enter the following data in the **Data** table:

Lower Frequency

The lower limit of the frequency range or a single frequency, in cycles/time.

Upper Frequency

The upper limit of the frequency range, in cycles/time. If you enter zero, Abaqus/Standard assumes that results are required only at the frequency specified in the **Lower Frequency** column.

Number of Points

The number of points between eigenfrequencies at which the response should be calculated, including the end points, from the lower limit of the frequency range to the first eigenfrequency in the range; in each interval from eigenfrequency to eigenfrequency; and from the highest eigenfrequency in the range to the high limit of the frequency range. If the value given is less than two (or omitted), the default value of 20 points is assumed. Accurate RMS values can be obtained only if enough points are used so that Abaqus/Standard can integrate accurately over the frequency range.

Bias

The bias parameter. This parameter is useful only if you request results at 4 or more frequency points. It is used to bias the results points toward the ends of the intervals so that better resolution is obtained there, since the ends of each interval are the eigenfrequencies where the response amplitudes vary most rapidly. The default bias parameter is 3.0. For more information, see *The Bias Parameter*.

For detailed information on how to enter data, see *Entering tabular data*.

*Configure settings on the **Damping** tabbed page*

1. In the **Edit Step** dialog box, display the **Damping** tabbed page.

   (For information on displaying the **Edit Step** dialog box, see *Creating a step*, or *Editing a step*.)

2. Indicate how you want to provide damping values:

   - Choose **Specify damping over ranges of Modes** to provide damping values for specific mode ranges.
   - Choose **Specify damping over ranges of Frequencies** to provide damping values at specific frequencies. Abaqus/Standard interpolates the damping coefficient for a mode linearly between the specified frequencies

   If you omit damping data on the **Damping** tabbed page, Abaqus/Standard assumes zero damping values. For more information, see *Specifying Damping*.

3. If you selected **Modes** in Step 2, select one or more of the following options for defining damping:

   - Display the **Direct modal** tabbed page to specify the fraction of critical damping, ξ, for a particular mode range, and do the following:

     1. Toggle on **Use direct damping data**.
     2. Enter the following in the data table:

        - **Start Mode**: the mode number of the lowest mode of a range.
        - **End Mode**: the mode number of the highest mode of a range.
        - **Critical Damping Fraction**: fraction of critical damping, ξ.

- Display the **Composite modal** tabbed page to select composite modal damping using the damping coefficients calculated in the preceding frequency step. (The damping calculations performed in the frequency step are performed using damping data provided in the material definition). Do the following:

  1. Toggle on **Use composite damping data**.
  2. Enter the following in the data table:

     - **Start Mode**: the mode number of the lowest mode of a range.
     - **End Mode**: the mode number of the highest mode of a range.

- Display the **Rayleigh** tabbed page to define Rayleigh damping, and do the following:

  1. Toggle on **Use Rayleigh damping data**.
  2. Enter the following in the data table:

     - **Start Mode**: the mode number of the lowest mode of a range.
     - **End Mode**: the mode number of the highest mode of a range.
     - **Alpha**: mass proportional damping, α_M.
     - **Beta**: stiffness proportional damping, β_M.

- Display the **Structural** tabbed page to define damping that is proportional to the internal forces but opposite in direction to the velocity. Do the following:

  1. Toggle on **Use structural damping data**.
  2. Enter the following in the data table:

     - **Start Mode**: the mode number of the lowest mode of a range.
     - **End Mode**: the mode number of the highest mode of a range.
     - **Damping Constant**: Damping factor, *s*.

For detailed information on how to enter data, see *Entering tabular data*.

4. If you selected **Frequencies** in Step 2, select one or more of the following options for defining damping:

- Display the **Direct modal** tabbed page to specify the fraction of critical damping, ξ, for a particular frequency range. Do the following:

  1. Toggle on **Use direct damping data**.
  2. Enter the following in the data table:

     - **Frequency**: frequency value in cycles/time.
     - **Critical Damping Fraction**: fraction of critical damping, ξ.

- Display the **Rayleigh** tabbed page to define Rayleigh damping, and do the following:

  1. Toggle on **Use Rayleigh damping data**.
  2. Enter the following in the data table:

     - **Frequency**: frequency value in cycles/time.

- **Alpha**: mass proportional damping, α_M.
- **Beta**: stiffness proportional damping, β_M.

- Display the **Structural** tabbed page to define damping that is proportional to the internal forces but opposite in direction to the velocity. Do the following:
  1. Toggle on **Use structural damping data**.
  2. Enter the following in the data table:
     - **Frequency**: frequency value in cycles/time.
     - **Damping Constant**: Damping factor, *s*.

For detailed information on how to enter data, see *Entering tabular data*.

5. If desired, repeat Steps 2–4 to create multiple damping definitions.

When you have finished configuring settings for the step, click **OK** to close the **Edit Step** dialog box.

You can view the root mean square of the Mises equivalent stress in the Visualization module, view the RMISES output variable from the **Field Output** dialog box, or create *X–Y* data from **ODB field output**. For more information on viewing field output, see *Selecting the field output to display*, and *Reading X–Y data from output database field output*.

Configuring a response spectrum procedure

You can use a response spectrum analysis to estimate the peak response (displacement, stress, etc.) of a structure to a particular base motion. The method is only approximate, but it is often a useful, inexpensive method for preliminary design studies. The response spectrum procedure is based on using a subset of the modes of the system, which must first be extracted by using the eigenfrequency extraction procedure (described in *Configuring a frequency procedure*"). For more information, see *Response Spectrum Analysis*.

Create or edit a response spectrum procedure

1. Display the **Edit Step** dialog box following the procedure outlined in *Creating a step* (**Procedure type:** `Linear perturbation; Response spectrum`), or *Editing a step*.
2. On the **Basic** and **Damping** tabbed pages, configure settings such as a damping coefficient and the methods for combining multidirectional excitations as described in the following procedures.

*Configure settings on the **Basic** tabbed page*

1. In the **Edit Step** dialog box, display the **Basic** tabbed page.
2. In the **Description** field, enter a short description of the analysis step. Abaqus stores the text that you enter in the output database, and the text is displayed in the state block by the Visualization module.
3. Click the arrow to the right of the **Excitations** field, and select a directional summation method.

   - For the following options, Abaqus/Standard sums the directional excitation components first and then performs the modal summation:

     - Select **Single direction** to sum the directional excitation components for a single direction algebraically.
     - Select **Multiple direction absolute sum** to sum the directional excitation components for multiple directions algebraically.

   - For the following options, Abaqus/Standard performs the modal summation first and then sums the directional excitation components:

     - Select **Multiple direction square root of the sum of squares** to sum the directional excitation components for multiple directions using the square root of the sum of the squares.
     - Select **Multiple direction thirty percent rule** to sum the directional excitation components for multiple directions using the 30% rule.
     - Select **Multiple direction forty percent rule** to sum the directional excitation components for multiple directions using the 40% rule.

   See *Directional Summation Methods*, for more information.
4. Click the arrow to the right of the **Summations** field, and select a modal summation method. For information on each of the methods, see *Modal Summation Methods*.
5. On the **First direction** tabbed page (and on the **Second direction** and **Third direction** tabbed pages if applicable), do the following:
   a. In the **Use response spectrum** field, select the spectrum amplitude to use for calculating the response. Alternatively, you can click  to create a new amplitude. (See *Defining a spectrum*," for more information.)
   b. Enter **Direction cosines X**, **Y**, and **Z**.
   c. In the **Scale factor** field, enter the factor multiplying the magnitudes in the response spectrum.

d. In the **Time duration** field, enter the time duration of the dynamic event from which the spectrum was created. This setting is applicable only when the **Double sum combination** modal summation method is specified.

For multiple direction excitations, you have the option of toggling on **Apply third direction** on the **Third direction** tabbed page to include data for a third direction.

*Configure settings on the **Damping** tabbed page*

1. In the **Edit Step** dialog box, display the **Damping** tabbed page.

   (For information on displaying the **Edit Step** dialog box, see *Creating a step*, or *Editing a step*.)

2. Indicate how you want to provide damping values:

   - Choose **Specify damping over ranges of Modes** to provide damping values for specific mode ranges.
   - Choose **Specify damping over ranges of Frequencies** to provide damping values at specific frequencies. Abaqus/Standard interpolates the damping coefficient for a mode linearly between the specified frequencies

   If you omit damping data on the **Damping** tabbed page, Abaqus/Standard assumes zero damping values. For more information, see *Specifying Damping*.

3. If you selected **Modes** in Step 2, select one or more of the following options for defining damping:

   - Display the **Direct modal** tabbed page to specify the fraction of critical damping, ξ, for a particular mode range. Do the following:

     1. Toggle on **Use direct damping data**.
     2. Enter the following in the data table:

        - **Start Mode**: the mode number of the lowest mode of a range.
        - **End Mode**: the mode number of the highest mode of a range.
        - **Critical Damping Fraction**: fraction of critical damping, ξ.

   - Display the **Composite modal** tabbed page to select composite modal damping using the damping coefficients calculated in the preceding frequency step. (The damping calculations performed in the frequency step are performed using damping data provided in the material definition.) Do the following:

     1. Toggle on **Use composite damping data**.
     2. Enter the following in the data table:

        - **Start Mode**: the mode number of the lowest mode of a range.
        - **End Mode**: the mode number of the highest mode of a range.

   - Display the **Rayleigh** tabbed page to define Rayleigh damping, and do the following:

     1. Toggle on **Use Rayleigh damping data**.
     2. Enter the following in the data table:

        - **Start Mode**: the mode number of the lowest mode of a range.
        - **End Mode**: the mode number of the highest mode of a range.

- **Alpha**: mass proportional damping, α_M.
- **Beta**: stiffness proportional damping, β_M.

For detailed information on how to enter data, see *Entering tabular data*.

4. If you selected **Frequencies** in Step 2, select one or both of the following options for defining damping:

- Display the **Direct modal** tabbed page to specify the fraction of critical damping, ξ, for a particular frequency range. Do the following:
  1. Toggle on **Use direct damping data**.
  2. Enter the following in the data table:
     - **Frequency**: frequency value in cycles/time.
     - **Critical Damping Fraction**: fraction of critical damping, ξ.

- Display the **Rayleigh** tabbed page to define Rayleigh damping, and do the following:
  1. Toggle on **Use Rayleigh damping data**.
  2. Enter the following in the data table:
     - **Frequency**: frequency value in cycles/time.
     - **Alpha**: mass proportional damping, α_M.
     - **Beta**: stiffness proportional damping, β_M.

For detailed information on how to enter data, see *Entering tabular data*.

5. If desired, repeat Steps 2–4 to create multiple damping definitions.

When you have finished configuring settings for the step, click **OK** to close the **Edit Step** dialog box.

Configuring a direct-solution steady-state dynamic procedure

In a direct solution steady-state dynamic procedure, Abaqus/Standard calculates the steady-state harmonic response directly in terms of the physical degrees of freedom of the model, using the mass, damping, and stiffness matrices of the system. For more information, see *Direct-Solution Steady-State Dynamic Analysis*.

Create or edit a direct-solution steady-state dynamic procedure

1. Display the **Edit Step** dialog box following the procedure outlined in *Creating a step* (**Procedure type:** `Linear perturbation; Steady-state dynamics, Direct`), or *Editing a step*.
2. On the **Basic** and **Other** tabbed pages, configure settings such as frequency range and equation solver preferences as described in the following procedures.

*Configure settings on the **Basic** tabbed page*

1. In the **Edit Step** dialog box, display the **Basic** tabbed page.
2. In the **Description** field, enter a short description of the analysis step. Abaqus stores the text that you enter in the output database, and the text is displayed in the state block by the Visualization module.
3. Choose one of the following options:
   - Choose **Compute real response only** if you want Abaqus/Standard to ignore damping terms. This option can significantly reduce computational time.
   - Choose **Compute complex response** if you want to include damping terms and allow a complex system matrix to be factored.

   For more information, see *Damping*.
4. Choose a **Scale** option to indicate whether you want the frequency range(s) of interest to be divided using a **Logarithmic** or **Linear** scale.
5. Toggle on **Use eigenfrequencies to subdivide each frequency range** if you want the frequency range(s) of interest to be subdivided using the system's eigenfrequencies. This option requires a preceding frequency step. For more information, see *Selecting the Type of Frequency Interval for Which Output Is Requested*.
6. Toggle on **Include friction-induced damping effects** to include friction-induced contributions to the damping matrix. For more information, see *Contact Conditions with Sliding Friction*.
7. Enter the following data in the **Data** table:

Lower Frequency

The lower limit of the frequency range or a single frequency, in cycles/time.

Upper Frequency

The upper limit of the frequency range, in cycles/time. If you enter zero, Abaqus/Standard assumes that results are required only at the frequency specified in the **Lower Frequency** column.

Number of Points

The number of points in the frequency range at which results should be given.

If you toggled on **Use eigenfrequencies to subdivide each frequency range**, this is the number of points at which results should be given, including the end points, from the lower limit of the frequency range to the first eigenfrequency in the range; in each interval from eigenfrequency

to eigenfrequency; and from the highest eigenfrequency in the range to the high limit of the frequency range.

If you toggled off **Use eigenfrequencies to subdivide each frequency range**, this is the total number of points in the frequency range, including the end points.

Bias

The bias parameter. This parameter is useful only if you request results at 4 or more frequency points. It is used to bias the results points toward the ends of the intervals so that better resolution is obtained there. This option is recommended if you have toggled on **Use eigenfrequencies to subdivide each frequency range**, since the ends of each interval are the eigenfrequencies where the response amplitudes vary most rapidly.

For more information, see *The Bias Parameter*.

For detailed information on how to enter data, see *Entering tabular data*.

*Configure settings on the **Other** tabbed page*

1. In the **Edit Step** dialog box, display the **Other** tabbed page.
   (For information on displaying the **Edit Step** dialog box, see *Creating a step*, or *Editing a step*.)
2. Choose a **Matrix storage** option:
   - Choose **Use solver default** to allow Abaqus/Standard to decide whether a symmetric or unsymmetric matrix storage and solution scheme is needed.
   - Choose **Unsymmetric** to restrict Abaqus/Standard to the unsymmetric storage and solution scheme.
   - Choose **Symmetric** to restrict Abaqus/Standard to the symmetric storage and solution scheme.

   For more information on matrix storage, see *Matrix Storage and Solution Scheme in Abaqus/Standard*.

When you have finished configuring settings for the step, click **OK** to close the **Edit Step** dialog box.

Configuring a mode-based steady-state dynamic analysis

You can configure a mode-based steady-state dynamic analysis to calculate the steady-state dynamic linearized response of a system to harmonic excitation. Abaqus/Standard calculates the response based on the system's eigenfrequencies and modes, which must first be extracted by using the eigenfrequency extraction procedure (described in *Configuring a frequency procedure*"). This type of procedure is computationally cheaper than direct-solution or subspace-based steady-state analysis, but is less accurate, in particular if significant material damping is present. For more information, see *Mode-Based Steady-State Dynamic Analysis*.

Create or edit a mode-based steady-state dynamic procedure

1. Display the **Edit Step** dialog box following the procedure outlined in *Creating a step* (**Procedure type:** `Linear perturbation; Steady-state dynamics, Modal`), or *Editing a step*.
2. On the **Basic** and **Damping** tabbed pages, configure settings such as frequency range and damping definitions as described in the following procedures.

*Configure settings on the **Basic** tabbed page*

1. In the **Edit Step** dialog box, display the **Basic** tabbed page.
2. In the **Description** field, enter a short description of the analysis step. Abaqus stores the text that you enter in the output database, and the text is displayed in the state block by the Visualization module.
3. Choose a **Scale** option to indicate whether you want the frequency range(s) of interest to be divided using a **Logarithmic** or **Linear** scale.
4. Toggle on **Use eigenfrequencies to subdivide each frequency range** if you want the frequency range(s) of interest to be subdivided using the system's eigenfrequencies. For more information, see *Selecting the Type of Frequency Interval for Which Output Is Requested*.
5. Enter the following data in the **Data** table:

Lower Frequency

The lower limit of the frequency range or a single frequency, in cycles/time.

Upper Frequency

The upper limit of the frequency range, in cycles/time. If you enter zero, Abaqus/Standard assumes that results are required only at the frequency specified in the **Lower Frequency** column.

Number of Points

The number of points in the frequency range at which results should be given.

If you toggled on **Use eigenfrequencies to subdivide each frequency range**, this is the number of points at which results should be given, including the end points, from the lower limit of the frequency range to the first eigenfrequency in the range; in each interval from eigenfrequency to eigenfrequency; and from the highest eigenfrequency in the range to the high limit of the frequency range.

If you toggled off **Use eigenfrequencies to subdivide each frequency range**, this is the total number of points in the frequency range, including the end points.

Bias

The bias parameter. This parameter is useful only if you request results at 4 or more frequency points. It is used to bias the results points toward the ends of the intervals so that better resolution is obtained there. This option is recommended if you have toggled on **Use eigenfrequencies to subdivide each frequency range**, since the ends of each interval are the eigenfrequencies where the response amplitudes vary most rapidly.

For more information, see *The Bias Parameter*.

For detailed information on how to enter data, see *Entering tabular data*.

*Configure settings on the **Damping** tabbed page*

1. In the **Edit Step** dialog box, display the **Damping** tabbed page.
   (For information on displaying the **Edit Step** dialog box, see *Creating a step*, or *Editing a step*.)
2. Indicate how you want to provide damping values:
   - Choose **Specify damping over ranges of Modes** to provide damping values for specific mode ranges.
   - Choose **Specify damping over ranges of Frequencies** to provide damping values at specific frequencies. Abaqus/Standard interpolates the damping coefficient for a mode linearly between the specified frequencies

   If you omit damping data on the **Damping** tabbed page, Abaqus/Standard assumes zero damping values. For more information, see *Specifying Modal Damping*.
3. If you selected **Modes** in Step 2, select one or more of the following options for defining damping:
   - Display the **Direct modal** tabbed page to specify the fraction of critical damping, ξ, for a particular mode range. Do the following:
     1. Toggle on **Use direct damping data**.
     2. Enter the following in the data table:
        - **Start Mode**: the mode number of the lowest mode of a range.
        - **End Mode**: the mode number of the highest mode of a range.
        - **Critical Damping Fraction**: fraction of critical damping, ξ.
   - Display the **Composite modal** tabbed page to select composite modal damping using the damping coefficients calculated in the preceding frequency step. (The damping calculations performed in the frequency step are performed using damping data provided in the material definition). Do the following:
     1. Toggle on **Use composite damping data**.
     2. Enter the following in the data table:
        - **Start Mode**: the mode number of the lowest mode of a range.
        - **End Mode**: the mode number of the highest mode of a range.
   - Display the **Rayleigh** tabbed page to define Rayleigh damping, and do the following:
     1. Toggle on **Use Rayleigh damping data**.

2. Enter the following in the data table:
   - **Start Mode**: the mode number of the lowest mode of a range.
   - **End Mode**: the mode number of the highest mode of a range.
   - **Alpha**: mass proportional damping, α_M.
   - **Beta**: stiffness proportional damping, β_M.

- Display the **Structural** tabbed page to define damping that is proportional to the internal forces but opposite in direction to the velocity. Do the following:
  1. Toggle on **Use structural damping data**.
  2. Enter the following in the data table:
     - **Start Mode**: the mode number of the lowest mode of a range.
     - **End Mode**: the mode number of the highest mode of a range.
     - **Damping Constant**: Damping factor, *s*.

For detailed information on how to enter data, see *Entering tabular data*.

4. If you selected **Frequencies** in Step 2, select one or more of the following options for defining damping:

- Display the **Direct modal** tabbed page to specify the fraction of critical damping, ξ, for a particular frequency range. Do the following:
  1. Toggle on **Use direct damping data**.
  2. Enter the following in the data table:
     - **Frequency**: frequency value in cycles/time.
     - **Critical Damping Fraction**: fraction of critical damping, ξ.

- Display the **Rayleigh** tabbed page to define Rayleigh damping, and do the following:
  1. Toggle on **Use Rayleigh damping data**.
  2. Enter the following in the data table:
     - **Frequency**: frequency value in cycles/time.
     - **Alpha**: mass proportional damping, α_M.
     - **Beta**: stiffness proportional damping, β_M.

- Display the **Structural** tabbed page to define damping that is proportional to the internal forces but opposite in direction to the velocity. Do the following:
  1. Toggle on **Use structural damping data**.
  2. Enter the following in the data table:
     - **Frequency**: frequency value in cycles/time.
     - **Damping Constant**: Damping factor, *s*.

For detailed information on how to enter data, see *Entering tabular data*.

5. If desired, repeat Steps 2–4 to create multiple damping definitions.

When you have finished configuring settings for the step, click **OK** to close the **Edit Step** dialog box.

Configuring a subspace-based steady-state dynamic analysis

You can configure a subspace-based steady-state dynamic analysis to calculate the steady-state dynamic linearized response of a system to harmonic excitation. This type of procedure is based on direct solution of the steady-state dynamic equations projected onto a subspace of modes. You must first extract the modes using the eigenfrequency extraction procedure (described in *Configuring a frequency procedure*"). For more information, see *Subspace-Based Steady-State Dynamic Analysis*.

Create or edit a subspace-based steady-state dynamic procedure

1. Display the **Edit Step** dialog box following the procedure outlined in *Creating a step* (**Procedure type:** `Linear perturbation; Steady-state dynamics, Subspace`), or *Editing a step*.
2. On the **Basic** and **Other** tabbed pages, configure settings such as frequency range and matrix solver preferences as described in the following procedures.

*Configure settings on the **Basic** tabbed page*

1. In the **Edit Step** dialog box, display the **Basic** tabbed page.

   (For information on displaying the **Edit Step** dialog box, see *Creating a step*, or *Editing a step*.)
2. In the **Description** field, enter a short description of the analysis step. Abaqus stores the text that you enter in the output database, and the text is displayed in the state block by the Visualization module.
3. Choose one of the following options:

   - Choose **Compute real response only** if you want Abaqus/Standard to ignore damping terms. This option can reduce computational time.
   - Choose **Compute complex response** if you want to include damping terms and allow a complex system matrix to be factored.

4. Choose a **Scale** option to indicate whether you want the frequency range(s) of interest to be divided using a **Logarithmic** or **Linear** scale.
5. Toggle on **Include friction-induced damping effects** to include friction-induced contributions to the damping matrix. For more information, see *Contact Conditions with Sliding Friction*.
6. Toggle on **Use eigenfrequencies to subdivide each frequency range** if you want the frequency range(s) of interest to be subdivided using the system's eigenfrequencies. For more information, see *Selecting the Type of Frequency Interval for Which Output Is Requested*.
7. Click the arrow to the right of the **Projection** field, and select an option for controlling the frequency of the subspace projections:

   - Select **Evaluate at each frequency** to project the dynamic equations onto the subspace at each frequency you specify. This method is the most computationally expensive.
   - Select **Constant** to perform only one projection using model properties evaluated at the center frequency of all ranges and individual frequency points that you specify. This method is the least expensive. However, you should choose this method only when the material properties do not depend strongly on frequency.
   - Select **Interpolate at eigenfrequencies** to perform the projections at each extracted eigenfrequency in the requested frequency range and at eigenfrequencies immediately outside the range. The projected mass, stiffness, and damping matrices are then interpolated at each frequency point requested.

- Select **As a function of property changes** to select how often subspace projections onto the modal subspace are performed based on material property changes as a function of frequency. If you select this option, do the following:

  1. In the **Max. damping change** field, enter the maximum relative change in damping material properties before a new projection is to be performed.
  2. In the **Max. stiffness change** field, enter the maximum relative change in stiffness material properties before a new projection is to be performed.

- Select **Interpolate at lower and upper frequency limits** to perform projections at the lower and upper limits of the last frequency range. This method can be used only with the SIM architecture.

8. Enter the following data in the **Data** table:

Lower Frequency

The lower limit of the frequency range or a single frequency, in cycles/time.

Upper Frequency

The upper limit of the frequency range, in cycles/time. If you enter zero, Abaqus/Standard assumes that results are required only at the frequency specified in the **Lower Frequency** column.

Number of Points

The number of points in the frequency range at which results should be given.

If you toggled on **Use eigenfrequencies to subdivide each frequency range**, this is the number of points at which results should be given, including the end points, from the lower limit of the frequency range to the first eigenfrequency in the range; in each interval from eigenfrequency to eigenfrequency; and from the highest eigenfrequency in the range to the high limit of the frequency range.

If you toggled off **Use eigenfrequencies to subdivide each frequency range**, this is the total number of points in the frequency range, including the end points.

Bias

The bias parameter. This parameter is useful only if you request results at 4 or more frequency points. It is used to bias the results points toward the ends of the intervals so that better resolution is obtained there. This option is recommended if you have toggled on **Use eigenfrequencies to subdivide each frequency range**, since the ends of each interval are the eigenfrequencies where the response amplitudes vary most rapidly.

For more information, see *The Bias Parameter*.

For detailed information on how to enter data, see *Entering tabular data*.

*Configure settings on the **Other** tabbed page*

1. In the **Edit Step** dialog box, display the **Basic** tabbed page.
   (For information on displaying the **Edit Step** dialog box, see *Creating a step*, or *Editing a step*.)
2. Choose a **Matrix solver** option:

- Choose **Use solver default** to allow Abaqus/Standard to decide whether a symmetric or unsymmetric matrix storage and solution scheme is needed.
- Choose **Unsymmetric** to restrict Abaqus/Standard to the unsymmetric storage and solution scheme.
- Choose **Symmetric** to restrict Abaqus/Standard to the symmetric storage and solution scheme.

For more information on matrix storage, see *Matrix Storage and Solution Scheme in Abaqus/Standard*.

Configuring a substructure generation procedure

You can configure a substructure generation procedure to control the data that are generated for a substructure.

You cannot have a substructure generation step in a model that contains model instances.

Create or edit a substructure generation procedure

1. Display the **Edit Step** dialog box following the procedure outlined in *Creating a step* (**Procedure type:** `Linear perturbation; Substructure generation`), or *Editing a step*.
2. On the **Basic**, **Options**, and **Damping** tabbed pages, configure settings such as substructure generation options and damping specifications.

*Configure settings on the **Basic** tabbed page*

1. In the **Edit Step** dialog box, display the **Basic** tabbed page.

   (For information on displaying the **Edit Step** dialog box, see *Creating a step*, or *Editing a step*.)
2. In the **Description** field, enter a short description of the analysis step. Abaqus stores the text that you enter in the output database, and the text is displayed in the state block by the Visualization module.
3. In the **Substructure identifier** field, enter an integer between 1 and 9999 that uniquely identifies this substructure in your model. Abaqus prepends a "Z" to the number you specify when it stores the substructure identifier in the model database.
4. If desired, toggle on **Evaluate recovery matrix for** to enable selective recovery in your analysis, and do one the following:

   - Select **Whole model** to enable selective recovery for the entire model.
   - Select **Region**, and select a node set or element set from the list to enable selective recovery for a single set in your model.

*Configure settings on the **Options** tabbed page*

1. In the **Edit Step** dialog box, display the **Options** tabbed page.

   (For information on displaying the **Edit Step** dialog box, see *Creating a step*, or *Editing a step*.)
2. From the **Generation Options**, do any of the following:

   - Toggle on **Compute gravity load vectors** to calculate the substructure's gravity load vectors during substructure generation.
   - Toggle on **Compute reduced mass matrix** to generate a reduced mass matrix for the substructure.
   - Toggle on **Compute reduced structural damping matrix** to generate a reduced structural damping matrix for the substructure.
   - Toggle on **Compute reduced viscous damping matrix** to generate a reduced viscous damping matrix for the substructure.
   - Toggle on **Evaluate frequency-dependent properties at frequency** to evaluate frequency-dependent material properties in substructure generation. If you toggle on this option, you can also specify the custom frequency for the frequency-dependent properties.

3. If you want to specify retained eigenmodes for generation of a coupled acoustic-structural substructure, toggle on **Specify retained eigenmodes by**, then select either **Mode range** or **Frequency range**.
4. If you are specifying retained eigenmodes by mode range, enter the following data in the **Data** table to generate the list of eigenmodes:

Start Mode

The first mode number.

End Mode

The end mode number.

Increment

The increment in mode numbers between the start and end modes.

For detailed information on how to enter data, see *Entering tabular data*.

5. If you are specifying retained eigenmodes by frequency range, enter the following data in the **Data** table:

Lower Frequency

The lower limit of the frequency range or a single frequency, in cycles/time.

Upper Frequency

The upper limit of the frequency range, in cycles/time.

For detailed information on how to enter data, see *Entering tabular data*.

*Configure settings on the **Damping** tabbed page*

1. In the **Edit Step** dialog box, display the **Damping** tabbed page.
   (For information on displaying the **Edit Step** dialog box, see *Creating a step*, or *Editing a step*.)
2. From the **Global Damping Ratios** options, specify the **Field** to which global damping will apply in this step:
   - Choose **None** to exclude the effects of global damping.
   - Choose **All** to apply global damping to all of the displacement, rotation, and acoustic fields in a model.
   - Choose **Acoustic** to apply global damping only to the acoustic fields in a model.
   - Choose **Mechanical** to apply global damping only to the displacement and rotation fields in a model.
3. If you selected any **Field** setting other than **None**, do any of the following:
   - For the **Alpha** option, specify a value for the first Rayleigh damping ratio.
   - For the **Beta** option, specify a value for the second Rayleigh damping ratio.
   - For the **Structural** option, specify a value for the structural damping ratio.
4. From the **Viscous damping** options, choose one of the following:
   - Choose **None** to exclude the effects of viscous damping altogether at the usage level.
   - Choose **Element** to activate only the generated condensed viscous damping matrix of the substructure.

- Choose **Factor** to activate only the Rayleigh viscous damping.
- Choose **Combined** to activate the combined generated and Rayleigh viscous damping matrix.

5. From the **Structural damping** options, choose one of the following:
   - Choose **None** to exclude the structural damping matrix.
   - Choose **Element** to activate only the generated condensed structural damping matrix of the substructure.
   - Choose **Factor** to activate only the stiffness proportional structural damping matrix.
   - Choose **Combined** to activate the combined generated and stiffness proportional.
6. When you have finished configuring settings for the substructure generation step, click **OK** to close the **Edit Step** dialog box.

Configuring a time-harmonic electromagnetic analysis

A time-harmonic electromagnetic analysis is valid in an electromagnetic model. In a time-harmonic electromagnetic (or eddy current) analysis, you specify one or more excitation frequencies, one or more frequency ranges, or a combination of excitation frequencies and ranges to obtain the time-harmonic solution directly at a given excitation frequency. For more information, see *Eddy Current Analysis*.

Create or edit a time-harmonic electromagnetic procedure

1. Display the **Edit Step** dialog box following the procedure outlined in *Creating a step* (**Procedure type:** `Linear perturbation; Electromagnetic, Time harmonic`), or *Editing a step*.
2. On the **Basic** and **Other** tabbed pages, configure settings such as frequency range and equation solver preferences as described in the following procedures.

*Configure settings on the **Basic** tabbed page*

1. In the **Edit Step** dialog box, display the **Basic** tabbed page.
2. In the **Description** field, enter a short description of the analysis step. Abaqus stores the text that you enter in the output database, and the text is displayed in the state block by the Visualization module.
3. Enter the following data in the **Data** table:

Lower Frequency

The lower limit of the frequency range or a single frequency, in cycles/time.

Upper Frequency

The upper limit of the frequency range, in cycles/time. If you enter zero, Abaqus/Standard assumes that results are required only at the frequency specified in the **Lower Frequency** column.

Number of Points

The number of points in the frequency range at which results should be given. The minimum value is 2. If the value is omitted, the default value of 20 points is assumed.

For detailed information on how to enter data, see *Entering tabular data*.

*Configure settings on the **Other** tabbed page*

1. In the **Edit Step** dialog box, display the **Other** tabbed page.

   (For information on displaying the **Edit Step** dialog box, see *Creating a step*, or *Editing a step*.)
2. Choose a **Matrix storage** option:
   - Choose **Use solver default** to allow Abaqus/Standard to decide whether a symmetric or unsymmetric matrix storage and solution scheme is needed.
   - Choose **Unsymmetric** to restrict Abaqus/Standard to the unsymmetric storage and solution scheme.
   - Choose **Symmetric** to restrict Abaqus/Standard to the symmetric storage and solution scheme.

   For more information on matrix storage, see *Matrix Storage and Solution Scheme in Abaqus/Standard*.

When you have finished configuring settings for the step, click **OK** to close the **Edit Step** dialog box.

Defining output requests

This section explains how to define and edit output requests.

In this section:

- *Creating an output request*
- *Modifying field output requests*
- *Modifying history output requests*

Creating an output request

When you create the first step in a sequence of steps, Abaqus/CAE generates default field and history output requests based on the analysis procedure that you selected for the step. The output requests are propagated to subsequent steps in the analysis. For more information, see *Propagation of output requests*. You can use the output request editors to edit the default output requests in the step in which they were created. You can also use the output request editors to create new output requests. A new output request overrides any propagated requests.

1. From the main menu bar, select **Output->Field Output Requests->Create** or **Output->History Output Requests->Create**.

   Tip: You can also create field and history output requests using the and tools, located in the module toolbox. For a diagram of the tools in the Step module toolbox, see *Using the Step module toolbox*.

   Abaqus/CAE displays the **Create Field Output** or **Create History Output** dialog box.

2. In the dialog box, do the following:
   a. Type a name for the output request or accept the default name.
   b. Click the arrow next to the **Step** text field, and select the step from the list that appears. Abaqus/CAE creates the output request during the selected step. After you create an output request, you can use the output requests manager to move it to an earlier or later step.
   c. Click **Continue**.

   Abaqus/CAE displays the **Edit Field Output Request** or the **Edit History Output Request** dialog box.

3. In the editor, enter the data necessary to define the output request. For more information on using the editor, see *Modifying field output requests*, or *Modifying history output requests*.
4. When you have finished configuring your output request, click **OK** to save your data and to exit the editor.

Additional information

- *Understanding output requests*
- *Defining output requests*

Modifying field output requests

You can use the field output editor to modify existing field output requests.
If you modify a field output request during a step into which it was propagated, you can modify only the output variables and the output frequency.

1. From the main menu bar, select **Output->Field Output Request->Manager**.

   Abaqus/CAE displays the **Field Output Requests Manager**. The manager indicates in which step the output request was created and into which steps it was propagated.

2. From the list of field output requests in the manager, select the step in which you want to modify the request.
3. From the buttons on the right side of the **Field Output Requests Manager**, click **Edit**.

   Abaqus/CAE displays the **Edit Field Output Request** editor. Information at the top of the editor indicates the following:

   - The name of the output request.
   - The name of the step in which you are editing the output request.
   - The analysis procedure associated with the step.

4. If you edit the output request in the step in which it was created, you can change the region from which variables will be output. From the top of the editor, click the arrow next to the **Domain** text field and select one of the following:

   - Select **Whole model** to request that Abaqus write field data to the output database for the entire model. Toggle on **Exterior only** to request output only on the exterior nodes and elements; this option is applicable only for three-dimensional models in an Abaqus/Standard or Abaqus/Explicit analysis.
   - Select **Set** to request that Abaqus write field data to the output database for only the named region that you specify. Click the arrow, and select the name from the list of sets that appears.
   - Select **Bolt load** to request that Abaqus write field data to the output database for only the bolt load that you specify. Click the arrow, and select the name from the list of bolt loads that appears.
   - Select **Composite layup** to request that Abaqus write field data to the output database for only the plies in the composite layup that you specify. Click the arrow, and select the name from the list of composite layups that appears.
   - Select **Fastener** to request that Abaqus write field data to the output database for only the fastener that you specify. Click the arrow, and select the name from the list of fasteners that appears.
   - Select **Substructure** to request that Abaqus write field data to the output database for only the substructure sets that you specify. Click  to open the **Select Substructure Sets** dialog box, then select the substructure sets for which you want to write field data. Select multiple sets by using the **[Ctrl]** or **[Shift]** keys while clicking on set names. You can use the name filter to show only substructure sets that match a specified pattern, such as belonging to a particular substructure part instance.
   - Select **Interaction** to request that Abaqus write field data to the output database for only the interaction that you specify. Click the arrow, and select the name from the list of surface-to-surface contact and self-contact interactions that appears.
   - Select **Skin** to request that Abaqus write field data to the output database for only the skin reinforcement that you specify. Click the arrow, and select the name from the list of skins that appears.

- Select **Stringer** to request that Abaqus write field data to the output database for only the stringer reinforcements that you specify. Click the arrow, and select the name from the list of stringers that appears.

5. Specify the desired output frequency:
   - Select **Last increment** to request field output for the last increment only. This output frequency is available only when you choose an Abaqus/Standard analysis procedure.
   - Select **Every n increments** to request that Abaqus write field data to the output database in increments. You can then specify the number of increments in the **n** field that appears. If you specify the frequency in increments, Abaqus also writes output after the last increment of the step. This output frequency is available when you choose an Abaqus/Standard analysis procedure.
   - Select **Every time increment** to request that Abaqus write field data to the output database at every time increment. This output frequency is available only when you choose an Abaqus/Explicit analysis procedure.
   - Select **Evenly spaced time intervals** to request that Abaqus write field data to the output database at a number of evenly spaced time intervals. You can then specify the number of intervals in the **Intervals** field that appears.
   - Select **Every x units of time** to request that Abaqus write field data to the output database every time a particular length of time elapses. You can then specify the length of time in the **x** field that appears.
   - Select **From time points** to request that Abaqus write field data to the output database according to a set of time points. You can then select a set of time points from the **Time Points** list that appears or click  to create a new set of time points. See *Defining time points*, for more information about creating a set of time points. This output frequency is available when you choose an Abaqus/Standard or Abaqus/Explicit analysis procedure.
6. If you requested output at **Evenly spaced time intervals**, **Every x units of time**, or **From time points**, you can also select **Output at exact times** from the **Timing** field to alter the time incrementation size to match the time intervals exactly.
7. Specify the desired element output position:
   - Select **Integration points** to request field output at the integration points where they are calculated (this is the default).
   - Select **Centroidal** to request field output at the centroid of each element.
   - Select **Nodes** to request field output at the node of each element.
   - Select **Averaged at nodes** to request field output extrapolated to the nodes of each element and then averaged with the values from surrounding elements that have the same type of properties.
8. In the **Output Variables** section of the editor, choose one of the following variable selection methods:

Select from list below

Choose this method to select the output variables of interest from the list of variable categories below. Use the following techniques to select particular variables:

- Click the arrow next to the desired variable category. From the list of variables that appears, select the variables of your choice.
- Toggle the desired variable category. This action selects or deselects all variables within that category.

The check box next to a variable category becomes completely filled when all variables within that category are selected. The box becomes half filled if only some of the variables within that category are selected.

Preselected defaults

Choose this method to allow Abaqus/CAE to select a preselected (default) set of output variables appropriate for the step's analysis procedure.

All

Choose this method to automatically select all of the allowable output variables within each variable category in the list.

Edit variables

Choose this method to enter or delete output variables in the text field located above the list of variable categories.

Note:

In addition to the current analysis procedure, other aspects of the model may affect the preselected default output variables. For example, if a selected output variable is valid for the analysis procedure but is not valid for the element type used in the mesh, Abaqus will remove that variable during the analysis.

9. If your domain is set to **Whole model**, **Set**, **Skin**, or **Stringer**, do the following:
   a. If your model contains rebar and you edit the output request in the step in which it was created, you can include output for rebar in the field data that Abaqus writes to the output database. From the bottom of the editor, toggle on **Output for rebar** and choose one of the following options that appears:

Include

Choose **Include** to request that Abaqus write output for rebar in addition to output for the underlying material to the output database.

Only

Choose **Only** to request that Abaqus write only output for rebar to the output database.

If you want to view rebar orientations in the Visualization module, you must toggle on **Output for rebar**.

   b. If you edit the output request in the step in which it was created, you can change the section points from which variables will be output. From the bottom of the editor, choose one of the following:

Use defaults

Choose **Use defaults** to request that Abaqus write field data to the output database from the default section points. Abaqus chooses the default section points based on the section selected in the Property module. (The default section points are usually the outer fibers of the section.) For more information see *The Property module*.

Specify

Choose **Specify** to enter the section points for which Abaqus will write field data to the output database. The specified section points are used only during the selected output request; Abaqus reverts to the default section points for subsequent output requests.

c. Toggle off **Include local coordinate directions when available** to reduce the size of the output database by excluding material orientations from the saved data.

10. If your domain is set to **Bolt load** or **Interaction**, toggle off **Include local coordinate directions when available** to reduce the size of the output database by excluding material orientations from the saved data.

Note:

If you exclude local coordinate directions from the output database, Abaqus/CAE displays all analysis results from the output database in the default coordinate system.

11. If your domain is set to **Composite layup**, specify the section points from which variables will be output. For more information, see *Requesting output from a composite layup*.

Note:

By default, Abaqus/CAE writes field output data from only the top and bottom of a composite layup, and no data from the plies are generated. Therefore, if your model contains a composite layup and you want data from individual plies, you must create a new output request or edit the default output request and specify the section points from which variables will be output.

From the bottom of the editor, choose one of the following:

Selected

Choose **Selected points for each ply** to request that Abaqus write field data to the output database from the top, middle, and/or bottom section point of each ply in the selected composite layup.

All

Choose **All section points in all plies** to request that Abaqus write field data to the output database from all of the section points of all of the plies in the selected composite layup.

Specify

Choose **Specify** to enter the section points for which Abaqus will write field data to the output database. Section points are numbered sequentially from the top of the first ply to the bottom of the last ply. The specified section points are used only during the selected output request; Abaqus reverts to the default section points for subsequent output requests.

12. If you edit the output request for an Abaqus/Explicit analysis procedure in the step in which it was created, you can apply a filter to remove high frequency data from the field output.

From the bottom of the editor, toggle on **Apply filter** and choose the default **Antialiasing** filter or select a named filter that was created using the Filter toolset. For more information, see *The Filter toolset*.

13. When you have finished defining the output request, click **OK** to save your changes.

Additional information

- *Understanding output requests*
- *Defining output requests*
- *The Property module*

Modifying history output requests

You can use the history output editor to modify existing history output requests.
If you modify a history output request during a step into which it was propagated, you can modify only the output variables and the output frequency.

1. From the main menu bar, select **Output->History Output Request->Manager**.

   Abaqus/CAE displays the **History Output Requests Manager**. The manager indicates in which step the output request was created and into which steps it was propagated.

2. From the list of history output requests in the manager, select the step in which you want to modify the request.
3. From the buttons on the right side of the **History Output Requests Manager**, click **Edit**.

   Abaqus/CAE displays the **Edit History Output Request** editor. Information at the top of the editor indicates the following:

   - The name of the output request.
   - The name of the step in which you are editing the output request.
   - The analysis procedure associated with the step.

4. If you edit the output request in the step in which it was created, you can change the region from which variables will be output. From the top of the editor, click the arrow next to the **Domain** text field and select one of the following:

   - Select **Whole model** to request that Abaqus write history data to the output database for the entire model.
   - Select **Set** to request that Abaqus write history data to the output database for only the named region that you specify. Click the arrow, and select the name from the list of sets that appears.
   - Select **Bolt load** to request that Abaqus write history data to the output database for only the bolt load that you specify. Click the arrow, and select the name from the list of bolt loads that appears.
   - Select **Composite layup** to request that Abaqus write history data to the output database for only the plies in the composite layup that you specify. Click the arrow, and select the name from the list of composite layups that appears.
   - Select **Contour integral** to request that Abaqus write history data to the output database for only the contour integral that you specify. Click the arrow, and select the name from the list of contour integrals that appears.

     When you request output from a contour integral, the **History Output Request** editor allows you to select only the frequency of output, the number of contour integrals, and the type of contour integral calculation. For more information, see *Requesting contour integral output*.
   - Select **Fastener** to request that Abaqus write history data to the output database for only the fastener that you specify. Click the arrow, and select the name from the list of fasteners that appears.
   - Select **General contact surface** to request that Abaqus write history data to the output database for only the general contact surface that you specify (this option is available only for Abaqus/Explicit analyses). Click the arrow, and select the surface from the list of surfaces that appears. History output will be written only for surfaces within the general contact domain.
   - Select **Integrated output section** to request that Abaqus write history data to the output database for only the integrated output section that you specify. Click the arrow, and select the name from the list of sections that appears. See *Defining integrated output sections*, for information on creating an integrated output section.

- Select **Interaction** to request that Abaqus write history data to the output database for only the interaction that you specify. Click the arrow, and select the name from the list of surface-to-surface contact and self-contact interactions that appears.
- Select **Skin** to request that Abaqus write history data to the output database for only the skin reinforcement that you specify. Click the arrow, and select the name from the list of skins that appears.
- Select **Spring/Dashpot** to request that Abaqus write history data to the output database for only the springs/dashpots that you specify. Click the arrow, and select the name from the list of springs/dashpots that appears.
- Select **Stringer** to request that Abaqus write history data to the output database for only the stringer reinforcements that you specify. Click the arrow, and select the name from the list of stringers that appears.

5. Specify the desired output frequency:
   - Select **Last increment** to request history output for the last increment only. This output frequency is available only when you choose an Abaqus/Standard analysis procedure.
   - Select **Every n increments** to request that Abaqus write history data to the output database in increments. You can then specify the number of increments in the **n** field that appears. If you specify the frequency in increments, Abaqus also writes output after the last increment of the step. This output frequency is available when you choose an Abaqus/Standard analysis procedure.
   - Select **Every n time increments** to request that Abaqus write history data to the output database in time increments. You can then specify the number of time increments in the **n** field that appears. This output frequency is available only when you choose an Abaqus/Explicit analysis procedure.
   - Select **Evenly spaced time intervals** to request that Abaqus write history data to the output database at a number of evenly spaced time intervals. You can then specify the number of intervals in the **Intervals** field that appears.
   - Select **Every x units of time** to request that Abaqus write history data to the output database every time a particular length of time elapses. You can then specify the length of time in the **x** field that appears.
   - Select **From time points** to request that Abaqus write history data to the output database according to a set of time points. You can then select a set of time points from the **Time Points** list that appears or click  to create a new set of time points. See *Defining time points*, for more information about creating a set of time points. This output frequency is available only when you choose an Abaqus/Standard analysis procedure.
6. If you selected an Abaqus/Standard analysis procedure and requested output at **Evenly spaced time intervals**, **Every x units of time**, or **From time points**, you can also select **Output at exact times** from the **Timing** field to alter the time incrementation size to match the time intervals exactly.
7. From the **Output Variables** field, choose the variables and variable components to output:

Select from list below

Choose this method to select the output variables of interest from the list of variable categories. Use the following techniques to select particular variables:

- In the top half of the editor, click the arrow next to the desired variable category. From the list of variables that appears, select the variables of your choice. If a variable of interest has components, click the arrow next to the variable and select the components of interest. To select or deselect all components of a variable, toggle the variable itself.

- Toggle the desired variable category to select or deselect all variables and variable components within that category.

The check box next to a variable category name becomes completely filled when all variables within that category are selected as well as all of the components of those variables. The box becomes half filled if only some of the variables or variable components within that category are selected. Likewise, the check box next to a variable name becomes completely filled when all components of that variable are selected. The box becomes half filled if only some of the components of that variable are selected.

Preselected defaults

Choose this method to allow Abaqus/CAE to select a preselected (default) set of output variables and components appropriate for the step's analysis procedure.

All

Choose this method to automatically select all of the allowable output variables and variable components within each variable category in the list.

Edit variables

Choose this method to enter or delete output variables and components in the text field located above the list of variable categories.

Note:

In addition to the current analysis procedure, other aspects of the model may affect the preselected default output variables. For example, if an output variable is valid for the analysis procedure but is not valid for the element type used in the mesh, Abaqus will remove that variable during the analysis.

8. If you want to include sensor output, toggle on **Include sensor when available**. This option is available when the domain **Set** is selected.
9. Toggle **Use global directions for vector-valued output**. This option is available when the domain **Set** is selected.

   When **Use global directions for vector-valued output** is on, nodal history output is requested in the global directions.

   When **Use global directions for vector-valued output** is off, nodal history output is requested in the local directions defined by nodal transformations.
10. If your domain is set to **Whole model**, **Set**, **Skin**, or **Stringer** do the following:
    a. If your model contains rebar and you edit the output request in the step in which it was created, you can include output for rebar in the field data that Abaqus writes to the output database. From the bottom of the editor, toggle on **Output for rebar** and choose one of the following options that appears:

Include

Choose **Include** to request that Abaqus write output for rebar in addition to output for the underlying material to the output database.

Only

Choose **Only** to request that Abaqus write only output for rebar to the output database.

If you want to view rebar orientations in the Visualization module, you must toggle on **Output for rebar**.

b. If you edit the output request in the step in which it was created, you can change the section points from which variables will be output. From the bottom of the editor, choose one of the following:

Use defaults

Choose **Use defaults** to request that Abaqus write field data to the output database from the default section points. Abaqus chooses the default section points based on the section selected in the Property module. (The default section points are usually the outer fibers of the section.) For more information see *The Property module*.

Specify

Choose **Specify** to enter the section points for which Abaqus will write field data to the output database. The specified section points are used only during the selected output request; Abaqus reverts to the default section points for subsequent output requests.

11. If your domain is set to **Composite layup**, specify the section points from which variables will be output.

Note:

By default, Abaqus/CAE writes field output data from only the top and bottom of a composite layup, and no data from the plies are generated. Therefore, if your model contains a composite layup and you want data from individual plies, you must create a new output request or edit the default output request and specify the section points from which variables will be output.

From the bottom of the editor, choose one of the following:

Selected

Choose **Selected points for each ply** to request that Abaqus write field data to the output database from the top, middle, and/or bottom section point of each ply.

All

Choose **All section points in all plies** to request that Abaqus write field data to the output database from all of the section points of all of the plies.

Specify

Choose **Specify** to enter the section points for which Abaqus will write field data to the output database. Section points are numbered sequentially from the top of the first ply to the bottom of the last ply. For example, if you have three plies, each with three section points, and you want output from the middle section point of each ply, you would enter `2,5,8`. The specified section points are used only during the selected output request; Abaqus reverts to the default section points for subsequent output requests.

12. If you edit the output request for an Abaqus/Explicit analysis procedure in the step in which it was created, you can apply a filter to remove high frequency data from the history output.

    From the bottom of the editor, toggle on **Apply filter** and choose the default **Antialiasing** filter or select a named filter that was created using the Filter toolset. For more information, see *The Filter toolset*.

13. When you have finished defining the output request, click **OK** to save your changes.

Additional information

- *Understanding output requests*
- *Defining output requests*
- *The Property module*

Defining step control

This section explains how to define and edit step controls.

In this section:

- *Creating a step control*
- *Modifying step controls*

Creating a step control

You can create the step control using create step control dialog box for any analysis step. The step control is not allowed in the initial step. You can use the step control editors to edit the step control in the step in which they were created. The step control is a non-propagating object.

1. From the main menu bar, select **Step Control->Create**.

   Tip: You can also create a step control using the tools located in the step module toolbox.

   Abaqus/CAE displays the **Create Step Control** dialog box.

2. In the dialog box, do the following:
   a. Type a name for the step control or accept the default name.
   b. Click the arrow next to the **Step** text field, and select the step from the list that appears. Abaqus/CAE creates the step control in the selected step.
   c. Click **Continue**.

   Abaqus/CAE displays the **Edit Step Control** dialog box.

3. In the editor, enter the data necessary to define the step control. For more information on using the editor, see *Modifying step controls*.
4. When you have finished configuring your step control, click **OK** to save your data and to exit the editor.

Additional information

- *Understanding step control*
- *Defining step control*

Modifying step controls

You can use the step control editor to modify existing step controls.

1. From the main menu bar, select **Step Control->Manager**.

   Abaqus/CAE displays the **step control Manager**. The manager shows the list of step controls created in the current step.

2. From the list of step control in the manager, select the one which you want to modify.
3. From the buttons available on the **Step Control Manager**, click **Edit**.

   Abaqus/CAE displays the **Edit Step Control** editor. Information at the top of the editor indicates the following:

   - The name of the step control.
   - The name of the step in which step control is created.
   - The analysis procedure associated with the step.

4. Select the appropriate action from the **Action** drop-down menu. The default value is **Continue**.
5. Select the appropriate refinement criteria from the **DT Refinement** drop-down menu. The default value is **Yes**.
6. Enter the appropriate value for the tolerance in the **Tolerance** text field. The default value is 0.001.
7. Fill the required data in the table. Only the column of the required field will be editable, other column will appear as a grayout or non-editable. The editability of the column is automatically set based on the selected action and refinement criteria.

   - In the first column named **Sensor**, select the appropriate sensor history output which is going to be used as a sensor.
   - In the second column named **Threshold Criteria**, select the appropriate sensor threshold criteria from the drop-down menu.
   - In the third column named **Threshold Value**, enter the appropriate sensor threshold value.
   - In the forth column named **Time Increment**, enter the time increment value to be used, provided that it is lower than the time increment computed by the automatic time-incrementation algorithms in Abaqus/Standard and the condition for time increment refinement is met.
   - In the fifth column named **Sensor Limit Start**, enter the sensor limit value when the time increment refinement starts.
   - In the last column named **Sensor Limit End**, enter the sensor limit value when the time increment refinement ends.

8. When you have finished defining the step control, click **OK** to save your changes.

Additional information

- *Understanding step control*
- *Defining step control*

Requesting specialized output

This section describes how you request and configure specialized output.

In this section:

- *Defining integrated output sections*
- *Configuring restart output requests*
- *Configuring diagnostic printing*
- *Configuring monitor requests*
- *Defining time points*

Defining integrated output sections

Select **Output->Integrated Output Sections** from the main menu bar to create an integrated output section. For more information, see *Integrated Output Section Definition*.

1. From the main menu bar, select **Output->Integrated Output Sections->Create**.

   The **Create Integrated Output Section** dialog box appears.
2. In the dialog box, type a name for the output section or accept the default name.
3. Select the surface on which to define the integrated output section using either of the following methods:

   - Select a surface in the viewport. When you have finished selecting, click mouse button 2.

     If the model contains a combination of mesh and geometry, click one of the following from the prompt area:

     - Click **Geometry** to define the section on geometry.
     - Click **Mesh** to define the section on native or orphan mesh faces.

   - To select from a list of existing surfaces, do the following:

     1. Click **Surfaces** on the right side of the prompt area.

        Abaqus/CAE displays the **Region Selection** dialog box containing a list of available surfaces.
     2. Select the surface of interest, and click **Continue**.

     Note:

     The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Surfaces** on the right side of the prompt area.

   The integrated output section editor appears. The surface on which you are defining the section is highlighted in the viewport.
4. By default, the integrated output section is anchored at the global origin. To define a reference point at which the section will be anchored, select **Anchor at reference point**, and click **Edit** .
5. If the reference point is not physically connected to the model, you can adjust its initial position and specify that it should follow the average motion of the surface associated with the integrated output section. By default, the reference point does not track the average motion of the surface.

   - To reposition the reference point at the center of the surface in the initial configuration, toggle on **Move point to center of surface**.
   - To specify that the reference point should both translate and rotate with the average motion of the surface, select **Average translation and rotation** for the **Point motion**.
   - To specify that the reference point should translate with the average translation of the surface without any rotation, select **Average translation** for the **Point motion**.

6. By default, the coordinate system for the integrated output section is initialized to the global coordinate system. To choose a local coordinate system instead, click  next to the **CSYS** field.
7. If desired, toggle on **Project orientation onto surface** to project the coordinate system (either global or local) onto the section surface.

8. Click **OK** to close the integrated output section editor.

Additional information

• *Integrated output requests*

Configuring restart output requests

Select **Output->Restart Requests** from the main menu bar to configure the information written to the restart files. For more information, see *Restarting an analysis* and *Restarting an Analysis*.

1. From the main menu bar, select **Output->Restart Requests**.

   The **Edit Restart Requests** dialog box appears with a list of the steps in the current model.

2. From the dialog box, select the step and specify the frequency at which Abaqus writes restart information. Do the following:

Abaqus/Standard

For an Abaqus/Standard analysis step, enter the frequency in increments or in time intervals:

- To write restart information after every regular number of increments, enter that number in the **Frequency** column.
- To write restart information at a specific number of equally spaced time intervals during a step, enter that number in the **Intervals** column.

  Restart information is written at the increment ending immediately after the time specified by the time interval. In an Abaqus/Standard analysis, you can toggle on the **Time Marks** column to write restart information at the exact time specified by the time interval.

By default, no restart information is written for an Abaqus/Standard analysis step (i.e., the frequency is set to zero).

Abaqus/Explicit

For an Abaqus/Explicit analysis step, enter the number of equally spaced time **Intervals** at which restart information is written. By default, Abaqus/Explicit writes restart information only at the beginning and end of each step (i.e., **Intervals** is set to one). You cannot avoid writing data to the restart files for an Abaqus/Explicit analysis step; the number of **Intervals** must be set to one or greater.

By default, Abaqus/Explicit writes restart information at the increment ending immediately after the time specified by the time interval. Toggle on the **Time Marks** column to write restart information at the exact time specified by the time interval.

3. For an Abaqus/Standard or Abaqus/Explicit analysis, you can request that information from only one increment per step or from every specified increment be retained.

   - Toggle on the **Overlay** column to request that only information from one increment per step be retained in the restart files, thus minimizing the size of the files. When a step completes, the last increment is retained.
   - Toggle off the **Overlay** column to request that information from every specified increment or time interval be retained in the restart files.

   You can use the **Overlay** column only when the frequency is greater than zero.

4. Repeat Steps 2 and 3 for each step of the analysis.

5. When you have finished configuring your restart output requests, click **OK** to close the **Edit Restart Requests** dialog box.

Additional information

• *Restart output requests*

Configuring diagnostic printing

Select **Output->Diagnostic Print** to configure the diagnostic messages that Abaqus writes to the message file (for Abaqus/Standard) or to the status file (for Abaqus/Explicit) and reports to the Job module during an analysis. If the analysis of your model fails or produces unexpected results, you can examine these messages and look at a description of the analysis. (For more information, see *Diagnostic printing*.)

Abaqus/Standard also writes most diagnostic information to the output database for use in the Visualization module. However, the diagnostic information written to the output database is not affected by the diagnostic print settings. (For more information, see *Viewing diagnostic output*.)

1. From the main menu bar, select **Output->Diagnostic Print**.

   The **Edit Diagnostic Print** dialog box appears with a list of all the steps in the current model.

2. In the **Frequency** column, specify the frequency at which you want diagnostic printing data written for each step. (This option is not available for Abaqus/Explicit analyses.)
3. Click in the other columns to request specific diagnostic information during a particular step.

   A check mark appears indicating that type of diagnostic printing has been enabled during the step. Click in the column again to turn off diagnostic printing.

4. When you have finished configuring your diagnostic printing, click **OK** to exit the **Edit Diagnostic Print** dialog box.

Additional information

- *Diagnostic printing*
- *Requesting specialized output*
- *Viewing diagnostic output*

Configuring monitor requests

Use the **DOF Monitor** dialog box to monitor a degree of freedom at a point during the course of an analysis. Abaqus reports the degree of freedom values for that point to the Job module, to the status file (`jobname.sta`), and, for Abaqus/Standard analyses, to the message file (`jobname.msg`). For more information, see *Degree of freedom monitor requests*.

1. From the main menu bar, select **Output->DOF Monitor**.

   The **DOF Monitor** dialog box appears.

2. In the dialog box, toggle **Monitor a degree of freedom throughout the analysis**.

   If **Monitor a degree of freedom throughout the analysis** is toggled on, the monitoring options become available in the dialog box.

3. Click  next to the **Region** field, and use one of the following methods to select the point to monitor:

   - Use an existing set to define the point. On the right side of the prompt area, click **Points**. Select an existing set from the **Region Selection** dialog box that appears, and click **Continue**. (Abaqus/CAE displays an error message when you click **OK** in the **DOF Monitor** dialog box if you select a set containing more than one vertex or node.)

     Note:

     The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Points** on the right side of the prompt area.

   - Use the mouse to select a point in the viewport. (For more information, see *Selecting objects within the current viewport*.)

   The point that you select becomes highlighted in red in the viewport.

4. In the **Degree of freedom** field, enter the degree of freedom that you want to monitor.
5. If you are performing an Abaqus/Standard analysis, in the **Print to the message file every *n* increments** field, enter how often you want Abaqus to write the degree of freedom values to the message file.

   (There is no option to control the frequency at which values are written to the status file, since this frequency is determined by Abaqus. For more information, see *About Output*.)

6. Click **OK** to save your request and to exit the dialog box.

Additional information

- *Degree of freedom monitor requests*
- *Requesting specialized output*
- *Monitoring the progress of an analysis job*

Defining time points

You can define named sets of time points that describe all of the moments during an analysis when you want to request that Abaqus write field output or history output data. By requesting output at specified time points, you can create an irregular sampling that focuses on gathering data during the critical points in your analysis.

The **Create Time Points** dialog box provides two methods for defining sets of time points. You can specify each time point by entering every value individually on its own line in the table portion of the dialog box. Alternatively, you can select **Specify using delimiters** to define several ranges of time with a different increment that defines the sampling rate in each range. For example, you can create a time point every 0.1 seconds for the time range between 0 and 1, then change the increment to 0.05 for the time range between 1 and 2. The individual and time range definition methods are mutually exclusive; you cannot, for example, add individual time points to a series of time points specified by the time ranges method.

Note:

You can also import a set of time points either individually or using time ranges into a model database from an ASCII file. Once the data are imported, you can edit those time points.

The **Create Time Points** dialog box presents a set of time points data in a tabular format. You can modify these sets by adding, removing, and clearing rows of data or by editing individual data points or time ranges. Once you create a set of time points, you can edit its contents or copy, rename, or delete the set. If you rename or delete a set of time points for which you have requested field or history output, Abaqus/CAE issues an error message.

1. Open the **Create Time Points** dialog box.

   From the main menu bar, select **Output->Time Points->Create**.

2. Enter a name for this set of time points, and click **OK**.

   The **Edit Time Points** dialog box appears.

3. To read time point data from an ASCII file, perform the following steps:

   1. Click mouse button 3 in the table portion of the dialog box; then choose **Read from File** from the list that appears.

      The **Read Data from ASCII File** dialog box appears.

   2. Click , and use the **ASCII File Selection** dialog box to navigate to the file you want to import. Click **OK** when you have the file selected.

   3. If desired, you can modify the starting location in the time points table for the data import. By default, the starting row and column values for the import are both equal to 1; modify either value if you want to customize the imported data with additional rows and columns of values.

   4. Click **OK** to import the values into the time points table.

4. Select one of the two time point definition methods:

   - To define time points individually, enter a time point in row 1, and then add a new row and time point for every additional time point in the set. Individually entered time points must be entered in sequential order.
   - To specify time points using delimiters, select **Specify using delimiters**, and then enter the starting time, ending time, and increment for each series of time points that you want to create. See *Entering tabular data*, for more information about tabular data entry.

5. Click **OK** to save your set of time points.

Additional information

- *Defining output requests*
- *Requesting specialized output*

Customizing ALE adaptive meshing

This section explains how to configure ALE adaptive meshing in particular analysis steps.

In this section:

- *Defining an ALE adaptive mesh region*
- *Specifying ALE adaptive mesh constraints*
- *Specifying controls for ALE adaptive meshing*

Defining an ALE adaptive mesh region

You can define regions of the model where you want ALE adaptive meshing and you can specify the frequency and intensity of adaptive meshing for that domain. For more information, see the following sections:

- *About ALE Adaptive Meshing*
- *Defining ALE Adaptive Mesh Domains in Abaqus/Explicit*
- *Defining ALE Adaptive Mesh Domains in Abaqus/Standard*

Note:

You can define only one adaptive mesh domain for any particular step.

1. From the main menu bar, select **Other->ALE Adaptive Mesh Domain->Manager**.

   Abaqus/CAE displays the **ALE Adaptive Mesh Domain Manager** showing the steps defined in the model and the adaptive meshing controls associated with each step.

2. In the **ALE Adaptive Mesh Domain Manager**, select the step during which you will configure the adaptive meshing, and click **Edit**.

   Abaqus/CAE displays the ALE adaptive mesh domain editor.

3. At the top of the editor, choose **Use the ALE adaptive mesh domain below**.

4. Click  next to the **Region** field, and use one of the following methods to select the region you want to mesh:

   - Use an existing set to define the region. On the right side of the prompt area, click **Sets**. Select an existing set from the **Region Selection** dialog box that appears, and click **Continue**.
   - Use the mouse to select a region in the viewport. (For more information, see *Selecting objects within the current viewport*.) Click mouse button 2 to indicate you have finished selecting.

   Abaqus/CAE highlights the selected regions in red in the viewport.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

5. If you want to specify nondefault adaptive mesh controls, toggle on **ALE Adaptive mesh controls**, and select the name of the adaptive mesh controls to associate with the region.

   If you have not yet created mesh controls, you can click  to the right of the **ALE Adaptive mesh controls** field to define the controls that you want to assign to the adaptive mesh domain. See *Specifying controls for ALE adaptive meshing*.

6. Enter the **Frequency**, in increments, at which Abaqus will mesh the region.
7. Enter the number of **Remeshing sweeps per increment**. An increment in this case is each adaptive mesh increment, as defined by the **Frequency** setting above.
8. For adaptive meshing in Abaqus/Explicit steps, type the number of **Initial remeshing sweeps** that Abaqus/Explicit will apply at the beginning of the step.
9. Click **OK** to save the settings and to close the ALE adaptive mesh domain editor.

The **ALE Adaptive Mesh Domain Manager** displays the adaptive mesh controls associated with the step.

10. Click **Dismiss** to close the **ALE Adaptive Mesh Domain Manager**.

Additional information

- *ALE Adaptive Meshing*
- *The Set and Surface toolsets*

Specifying ALE adaptive mesh constraints

You can define ALE adaptive mesh constraints on the motion of the mesh for an adaptive mesh domain. The ALE adaptive mesh constraint can either prescribe independent mesh motion for nodes in an adaptive mesh domain or specify nodes that must follow the material. For more information, see the following sections:

- *About ALE Adaptive Meshing*
- *Defining ALE Adaptive Mesh Domains in Abaqus/Explicit*
- *Defining ALE Adaptive Mesh Domains in Abaqus/Standard*

1. From the main menu bar, select **Other->ALE Adaptive Mesh Constraint->Create**.

   Abaqus/CAE displays the ALE adaptive mesh constraint editor.
2. Enter a name for the ALE adaptive mesh constraint.
3. Select the step in which you want to create the constraint.
4. Choose the type of mesh motion, **Displacement/Rotation** or **Velocity/Angular velocity**, and click **Continue**.
5. Use one of the following methods to select the region that you want to constrain:

   - Use an existing set to define the region. On the right side of the prompt area, click **Sets**. Select an existing set from the **Region Selection** dialog box that appears, and click **Continue**.
   - Use the mouse to select a region in the viewport. (For more information, see *Selecting objects within the current viewport*.) Click mouse button 2 to indicate you have finished making selections.

   Abaqus/CAE highlights the selected regions in red in the viewport.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

   The **Edit ALE Adaptive Mesh Constraint** dialog box appears.
6. If you are editing an existing mesh constraint you can edit the region to which the constraint is applied by clicking  in the top part of the editor. Use the region selection techniques described in Step 5.
7. If you want to change the coordinate system (**CSYS**) in which to apply the constraint, click  and use one of the following methods:

   - Select an existing datum coordinate system in the viewport.
   - Select an existing datum coordinate system by name.

     1. From the prompt area, click **Datum CSYS List** to display a list of datum coordinate systems.
     2. Select a name from the list, and click **OK**.

   - Click **Use Global CSYS** from the prompt area to revert to the global coordinate system.

   This coordinate system editing option is available only in the step in which the constraint is created.
8. Click the arrow to the right of the **Motion** field, and specify whether you want to prescribe mesh motions that are independent of the underlying material or define nodes that must follow the underlying material.

If you are performing an Abaqus/Standard analysis, you can also choose to define mesh motion in user subroutine *UMESHMOTION*.

9. If you selected **Independent of underlying material** in Step 8, toggle on the degrees of freedom that you want to constrain. The text field becomes available in which you can specify a value for the degree of freedom. Toggle off a degree of freedom to leave the degree of freedom unconstrained.
10. If you selected **Independent of underlying material** in Step 8, click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click **Create** to create a new amplitude. (See *The Amplitude toolset* for more information.)
11. Click **OK** to save the named constraint and to close the editor.

Additional information

• *ALE Adaptive Meshing*

Specifying controls for ALE adaptive meshing

You can specify controls for the adaptive meshing and advection algorithms applied to an adaptive mesh domain. For more information, see *ALE Adaptive Meshing and Remapping in Abaqus/Explicit* and *ALE Adaptive Meshing and Remapping in Abaqus/Standard*.

In this section:

- *Specifying ALE adaptive mesh controls for an Abaqus/Standard analysis*
- *Specifying ALE adaptive mesh controls for an Abaqus/Explicit analysis*

Specifying ALE adaptive mesh controls for an Abaqus/Standard analysis

You use the **Edit ALE Adaptive Mesh Controls** dialog box to customize various aspects of the adaptive meshing and advection algorithms applied to an adaptive mesh domain. For more information, see *ALE Adaptive Meshing and Remapping in Abaqus/Standard*.

1. From the main menu bar, select **Other->ALE Adaptive Mesh Controls->Create**.

   A **Create ALE Adaptive Mesh Controls** dialog box appears.

2. In the dialog box, type a name for the ALE adaptive mesh controls, and click **Continue**.

   The **Edit ALE Adaptive Mesh Controls** dialog box appears.

3. Click the arrow to the right of the **Smoothing algorithm** field, and select a method for calculating adaptive mesh smoothing:

   - Select **Determined by analysis product** to accept the default for the analysis product you are using (in this case, Abaqus/Standard).
   - Select **Enhanced algorithm based on evolving geometry** to use geometrically enhanced forms of the basic smoothing algorithms as a technique to mitigate distortion. These forms are heuristic and based on nodal locations only. Due to their heuristic nature, geometric enhancements may not always improve the mesh smoothing.
   - Select **Conventional smoothing** to use the conventional forms of the smoothing algorithms.

   For more information on adaptive mesh smoothing, see *The ALE Adaptive Mesh Sweeping Algorithm*.

4. Calculation of the new mesh in Abaqus/Standard is based on some combination of two basic smoothing methods: original configuration projection smoothing and volume smoothing. You must specify the weighting factor for each method in the **Volumetric** and **Original configuration projection** fields. For more information, see *Combining Smoothing Methods*.

5. In the **Initial feature angle** field, enter the initial geometric feature angle, θ_I, in degrees ($0° \le \theta_I \le 180°$). This angle is used to detect geometric edges and corners. The default value is $\theta_I = 30°$. Setting $\theta_I = 180°$ will ensure that no geometric edges or corners are detected or enforced.

   For more information, see *Controlling the Detection of Geometric Edges and Corners*.

6. In the **Transition feature angle** field, enter the transition geometric feature angle, θ_T, in degrees ($0° \le \theta_T \le 180°$). This angle is used to determine when geometric edges and corners should be deactivated to allow remeshing across them. The default value is $\theta_T = 30°$. Setting $\theta_T = 0°$ will ensure that no geometric edges or corners are deactivated.

   For more information, see *Controlling the Activation and Deactivation of Geometric Edges and Corners*.

7. Click **OK** to save the named set of controls and to close the editor.

Specifying ALE adaptive mesh controls for an Abaqus/Explicit analysis

You use the **Edit ALE Adaptive Mesh Controls** dialog box to customize various aspects of the adaptive meshing and advection algorithms applied to an adaptive mesh domain. For more information, see *ALE Adaptive Meshing and Remapping in Abaqus/Explicit*.

1. From the main menu bar, select **Other->ALE Adaptive Mesh Controls->Create**.

   A **Create ALE Adaptive Mesh Controls** dialog box appears.

2. In the dialog box, type a name for the ALE adaptive mesh controls, and click **Continue**.

   The **Edit ALE Adaptive Mesh Controls** dialog box appears.

3. Choose a mesh smoothing **Priority**:

   - Choose **Improve aspect ratio** to perform adaptive meshing that minimizes element distortion and improves element aspect ratios at the expense of diffusing initial mesh gradation. This objective is recommended for problems with moderate to large overall deformation. For more information, see *Specifying a Uniform Mesh Smoothing Objective*.
   - Choose **Preserve initial mesh grading** to perform adaptive meshing that attempts to preserve initial mesh gradation while reducing distortions as the analysis evolves. This objective is recommended only for adaptive mesh domains with reasonably structured graded meshes undergoing low to moderate overall deformation. For more information, see *Specifying a Graded Mesh Smoothing Objective*.

4. Click the arrow to the right of the **Smoothing algorithm** field, and select a method for calculating adaptive mesh smoothing:

   - Select **Determined by analysis product** to accept the default for the analysis product you are using (in this case, Abaqus/Explicit).
   - Select **Enhanced algorithm based on evolving geometry** to use geometrically enhanced forms of the basic smoothing algorithms as a technique to mitigate distortion.
   - Select **Conventional smoothing** to use the conventional forms of the smoothing algorithms.

   For more information on adaptive mesh smoothing, see *Mesh Smoothing Methods*.

5. Choose a **Meshing predictor** option:

   - Choose **Current deformed position** to perform adaptive meshing based on current nodal positions. This method is recommended for all Langrangian-like problems and for problems with very large distortions. For more information, see *Positioning Nodes in Lagrangian Domains*.
   - Choose **Position from previous ALE adaptive mesh increment** to perform adaptive meshing based on the positions of the nodes at the end of the previous adaptive mesh increment. This technique is recommended for Eulerian-like problems where material flow is significant compared to the overall deformation. For more information, see *Positioning Nodes in Eulerian Domains*.

6. In the **Curvature refinement** field, enter a value for the curvature refinement weight, α_C. An appropriate value allows you to ensure that there is sufficient mesh refinement near highly curved boundaries. The default, $\alpha_C = 1$, works well on a wide variety of problems. For more information, see *Solution-Dependent Meshing Based on Concave Boundary Curvature*.
7. Calculation of the new mesh in Abaqus/Explicit is based on some combination of three basic smoothing methods: volume smoothing, Laplacian smoothing, and equipotential smoothing. You must specify the weighting factor for each method in the **Volumetric**, **Laplacian**, and **Equipotential** fields. For more information, see *Mesh Smoothing Methods*.

8. In the **Initial feature angle** field, enter the initial geometric feature angle, θ_I, in degrees ($0° \le \theta_I \le 180°$). This angle is used to detect geometric edges and corners. The default value is $\theta_I = 30°$. Setting $\theta_I = 180°$ will ensure that no geometric edges or corners are detected or enforced.
9. In the **Transition feature angle** field, enter the transition geometric feature angle, θ_T, in degrees ($0° \le \theta_T \le 180°$). This angle is used to determine when geometric edges and corners should be deactivated to allow remeshing across them. The default value is $\theta_T = 30°$. Setting $\theta_T = 0°$ will ensure that no geometric edges or corners are deactivated.
10. In the **Mesh constraint angle field**, enter the mesh constraint angle, θ_C, in degrees ($5° \le \theta_C \le 85°$). The default value is $\theta_C = 60°$.

    When adaptive mesh constraints are applied to nodes on Lagrangian or sliding boundary regions, the analysis will terminate if the angle between the normal to the boundary region and the direction of the prescribed constraint becomes less than θ_C. When adaptive mesh constraints are applied to nodes that are part of a Lagrangian or active geometric edge, the analysis will terminate if the angle between the prescribed constraint and the plane perpendicular to the edge becomes less than θ_C.
11. Choose an algorithm for remapping solution variables after adaptive meshing has been performed:
    - Choose **First order** to use a first order method based on donor cell differencing.
    - Choose **Second order** to use a second order method based on the work of Van Leer.

    For more information, see *Advection Methods for Element Variables*.
12. Choose a method for advecting momentum:
    - Choose **Element center projection** for the least expensive method.
    - Choose **Half-index shift** for a method that is more expensive computationally but which may demonstrate better dispersion properties.

    For more information, see *Momentum Advection*.
13. Click **OK** to save the named set of controls and to close the editor.

Customizing the Abaqus analysis controls

This section explains how to customize the Abaqus analysis controls.

In this section:

- *Customizing general solution controls*
- *Customizing solver controls*

Customizing general solution controls

The general solution controls editor allows you to modify the algorithms used for convergence and for time integration accuracy.
For more information, see *Analysis Convergence Controls*.

Note:

This option is available only for general Abaqus/Standard analysis steps.

1. From the main menu bar, select **Other->General Solution Controls->Manager**.
   Abaqus/CAE displays the **General Solution Controls Manager** showing the steps defined in the model and the general solution controls associated with each step.
2. In the **General Solution Controls Manager**, select the analysis step of interest, and click **Edit**.
   The **General Solution Controls Editor** appears.
3. Choose an option for specifying solution controls:
   - Choose **Propagate from previous step** if you want the solution controls settings from the previous step to remain active in the current step.
   - Choose **Reset all parameters to their system-defined defaults** if you want all of the parameters on all of the tabbed pages in the editor to revert to their default values.
   - Choose **Specify** if you want to enter new values for particular parameters for this step.
4. If desired, display the **Field Equations** tabbed page to define tolerances for field equations:
   a. If you want to select a particular type of equation for which the solution control parameters are being defined, choose **Specify individual fields**. Otherwise, choose **Apply to all applicable fields** to apply the values that you enter to all fields.
   b. Enter new values for one or more of the following parameters:
      - R_n^α, convergence criterion for the ratio of the largest residual to the corresponding average flux norm for convergence. Default $R_n^\alpha = 5 \times 10^{-3}$.
      - C_n^α, convergence criterion for the ratio of the largest solution correction to the largest corresponding incremental solution value. Default $C_n^\alpha = 10^{-2}$.
      - $\tilde{q}_0^\alpha$, initial value of the time average flux for this step. The default is the time average flux from previous steps or 10^{-2} if this is Step 1.
      - $\tilde{q}_u^\alpha$, user-defined average flux. When this value is defined, $\tilde{q}^\alpha(t) = \tilde{q}_u^\alpha$ for all t.

      The remaining items rarely need to be reset from their default values:

      - R_P^α, alternative residual convergence criterion to be used after I_P^α iterations. Default $R_P^\alpha = 2 \times 10^{-2}$.
      - ϵ^α, criterion for zero flux compared to $\tilde{q}^\alpha$. Default $\epsilon^\alpha = 10^{-5}$.
      - C_ϵ^α, convergence criterion for the ratio of the largest solution correction to the largest corresponding incremental solution value when there is zero flux in the model. Default $C_\epsilon^\alpha = 10^{-3}$.

- R_l^α, convergence criterion for the ratio of the largest residual to the corresponding average flux norm for convergence to be accepted in one iteration (that is, for a linear case). Default $R_l^\alpha = 10^{-8}$.
- C_f, field conversion ratio used in scaling the relationship between two active fields when one is of negligible magnitude. Default $C_f = 1.0$.
- ϵ_l^α, criterion for zero flux compared to the time averaged value of the largest flux $\tilde{q}_{\max}^\alpha$ in the model during the current step. Default $\epsilon_l^\alpha = 10^{-5}$.
- ϵ_d^α, criterion for zero displacement increment (and/or zero penetration if the **Convert severe discontinuity iterations** setting for the step is **On**) compared to the characteristic element length in the model. This item is used only for the displacement field and warping degree of freedom equilibrium equations. Default $\epsilon_d^\alpha = 10^{-8}$.

At any time you can click **System-defined Defaults for this Page** to return all parameters on this tabbed page to their system-defined default values. For more information, see *Defining Tolerances for Field Equations*.

5. If desired, display the **Time Incrementation** tabbed page to set time incrementation control parameters:
   a. Toggle on **Discontinuous analysis** to set $I_0 = 8$ and $I_R = 10$. These settings can help avoid premature cutbacks of the time increment.
   b. Enter new values for one or more of the following parameters:
      - I_0, number of equilibrium iterations (without severe discontinuities) after which the check is made whether the residuals are increasing in two consecutive iterations. Minimum value is $I_0 = 3$. Default $I_0 = 4$. If you toggled on **Discontinuous analysis**, $I_0 = 8$ and cannot be changed.
      - I_R, number of consecutive equilibrium iterations (without severe discontinuities) at which logarithmic rate of convergence check begins. Default $I_R = 8$. If you toggled on **Discontinuous analysis**, $I_R = 10$ and cannot be changed. The logarithmic rate of convergence is not checked if fixed time incrementation is used.

      The remaining items rarely need to be reset from their default values:

      - I_P, number of consecutive equilibrium iterations (without severe discontinuities) after which the residual tolerance R_p is used instead of R_n. Default $I_P = 9$.
      - I_C, upper limit on the number of consecutive equilibrium iterations (without severe discontinuities), based on prediction of the logarithmic rate of convergence. Default $I_C = 16$.
      - I_L, number of consecutive equilibrium iterations (without severe discontinuities) above which the size of the next increment will be reduced. Default $I_L = 10$.
      - I_G, maximum number of consecutive equilibrium iterations (without severe discontinuities) allowed in consecutive increments for the time increment to be increased. Default $I_G = 4$.

- I_S, maximum number of severe discontinuity iterations allowed in an increment if the **Convert severe discontinuity iterations** setting for the step is **Off**. Default $I_S = 12$. This parameter is not used if the **Convert severe discontinuity iterations** setting for the step is **On**.
- I_A, maximum number of cutbacks allowed for an increment. Default $I_A = 5$.
- I_J, maximum number of severe discontinuity iterations allowed in two consecutive increments for the time increment to be increased if the **Convert severe discontinuity iterations** setting for the step is **Off**. Default $I_J = 5$. This parameter is not used if the **Convert severe discontinuity iterations** setting for the step is **On**.
- I_T, minimum number of consecutive increments in which the time integration accuracy measure must be satisfied without any cutbacks to allow a time increment increase. Default $I_T = 3$. Maximum allowed $I_T = 10$.
- I_S^c, maximum number of severe discontinuity iterations allowed in an increment if the **Convert severe discontinuity iterations** setting for the step is **On**. Default $I_S^c = 50$. This parameter serves only as a protection against failure of the default convergence criteria and should rarely need to be changed. This parameter is not used if the **Convert severe discontinuity iterations** setting for the step is **Off**.
- D_f, cutback factor used when the solution appears to be diverging. Default $D_f = 0.25$.
- D_C, cutback factor used when the logarithmic rate of convergence predicts that too many equilibrium iterations will be needed. Default $D_C = 0.5$.
- D_B, cutback factor for the next increment when too many equilibrium iterations (I_L) are used in the current increment. Default $D_B = 0.75$.
- D_A, cutback factor used when the time integration accuracy tolerance is exceeded. Default $D_A = 0.85$.
- D_S, cutback factor used when too many iterations (I_S) arise because of severe discontinuities. Default $D_S = 0.25$.
- D_H, cutback factor used when element calculations have problems such as excessive distortion in large-displacement problems. Default $D_H = 0.25$.
- D_D, increase factor when two consecutive increments converge in a small number of equilibrium iterations (I_G). Default $D_D = 1.5$.
- W_G, ratio of average time integration accuracy measure over I_T increments to the corresponding tolerance for the next allowable time increment to be increased. Default $W_G = 0.75$.
- D_G, increase factor for the next time increment, as a ratio of the average integration accuracy measure over I_T increments to the corresponding tolerance, when the time integration accuracy measure is less than W_G of the tolerance during I_T consecutive increments. Default $D_G = 0.8$.
- D_M, maximum time increment increase factor for all cases except dynamic stress analysis and diffusion-dominated processes. Default $D_M = 1.5$.

- D_M, dyn, maximum time increment increase factor for dynamic stress analysis. Default $D_M = 1.25$.
- D_M, diff, maximum time increment increase factor for diffusion-dominated processes (creep, transient heat transfer, soils consolidation, transient mass diffusion). Default $D_M = 2.0$.
- D_L, minimum ratio of proposed next time increment to D_M times the current time increment for the proposed time increment to be used in a linear transient problem. This parameter is intended to avoid excessive decomposition of the system matrix and should be less than 1.0. Default $D_L = 0.95$.
- D_E, minimum ratio of proposed next time increment to the last successful time increment for extrapolation of the solution vector to take place. Default $D_E = 0.1$.
- D_R, maximum allowable ratio of time increment to stability limit for conditionally stable time integration procedures. Default is 1.0.
- D_F, fraction of stability limit used as current time increment when the time increment exceeds the above factor times the stability limit. This value cannot exceed 1.0. Default 0.95.
- D_T, increase factor for the time increment directly before a time point or end time of a step is reached. This parameter is used to avoid the small time increment that is sometimes necessary to hit a time point or to complete a step and must be greater than or equal to 1.0. If output or restart data are requested at exact times in a step, the default $D_T = 1.25$; otherwise, the default $D_T = 1.0$.

At any time you can click **System-defined Defaults for this Page** to return all parameters on this tabbed page to their system-defined default values. For more information, see *Controlling the Time Incrementation Scheme*.

6. If desired, display the **Constraint Equations** tabbed page, and enter new values for one or more of the following values:
   - T^{vol}, volumetric strain compatibility tolerance for hybrid solid elements. Default $T^{vol} = 10^{-5}$.
   - T^{axial}, axial strain compatibility tolerance for hybrid beam elements. Default $T^{axial} = 10^{-5}$.
   - T^{tshear}, transverse shear strain compatibility tolerance for hybrid beam elements. Default $T^{tshear} = 10^{-5}$.
   - T^{cont}, contact and slip compatibility tolerance. If the **Convert severe discontinuity iterations** setting for the step is **On**, the ratio of the maximum error in the contact or slip constraints to the maximum displacement increment must be less than this tolerance.

     If the **Convert severe discontinuity iterations** setting for the step is **Off**, this item is used only with softened contact specified in the contact interaction property. The ratio of the error in the soft contact constraint clearance to the user-specified clearance at which the contact pressure is zero must lie below this tolerance for $p > p^0$, where p^0 is the pressure value at zero clearance. Default $T^{cont} = 5 \times 10^{-3}$.
   - T^{soft}, soft contact compatibility tolerance for low pressure. This tolerance, which is used only if the **Convert severe discontinuity iterations** setting for the step is **Off**, is similar to T^{cont} for

softened contact, except that it represents the tolerance when $p = 0.0$. The actual tolerance will be interpolated linearly between T^{cont} and T^{soft} for $0 \le p \le p^0$. Default $T^{soft} = 0.1$.

- T^{disp}, displacement compatibility tolerance for distributing coupling elements. The ratio of the error in the distributing coupling displacement compatibility to a measure of the characteristic length of the coupling arrangement must lie below this tolerance. This characteristic length is twice the average of the coupling node arrangement principal radii of gyration. Default $T^{disp} = 10^{-5}$.
- T^{rot}, rotation compatibility tolerance for distributing coupling elements. Default $T^{rot} = 10^{-5}$.

At any time you can click **System-defined Defaults for this Page** to return all parameters on this tabbed page to their system-defined default values. For more information, see *Defining Tolerances for Constraint Equations*.

7. If desired, display the **Line Search Control** tabbed page, and enter new values for one or more of the following values:

   - N^{ls}, maximum number of line search iterations. Default $N^{ls} = 0$ for steps that use the Newton method and $N^{ls} = 5$ for steps that use the quasi-Newton method. A suggested value for activation of the line search algorithm is $N^{ls} = 5$. Specify $N^{ls} = 0$ to forcibly deactivate the method.
   - s^{ls}_{max}, maximum correction scale factor. Default $s^{ls}_{max} = 1.0$.
   - s^{ls}_{min}, minimum correction scale factor. Default $s^{ls}_{min} = 0.0001$.
   - f^{ls}_{s}, residual reduction factor at which line searching terminates. Default $f^{ls}_{s} = 0.25$.
   - η^{ls}, ratio of new to old correction scale factors below which line searching terminates. Default $\eta^{ls} = 0.10$.

   At any time you can click **System-defined Defaults for this Page** to return all parameters on this tabbed page to their system-defined default values. For more information, see *Activating the "Line Search" Algorithm*.

8. If desired, display the **VCCT Linear Scaling** tabbed page, and enter a value for β. The default is $\beta = 0.9$.

   For most crack propagation simulations using VCCT or the enhanced VCCT criterion, the deformation can be nearly linear up to the point of the onset of crack growth; past this point the analysis becomes very nonlinear. In this case linear scaling can be used to reduce the solution time effectively to reach the onset of crack growth. For more information, see *Linear Scaling to Accelerate Convergence for VCCT in Abaqus/Standard*.

9. If desired, display the **Direct Cyclic** tabbed page, and enter new values for one or more of the following values:

   - I_{PI}, iteration number at which the periodicity condition is first imposed. Default $I_{PI} = 1$.
   - CR^{α}_{n}, stabilized state detection criterion for the ratio of the largest residual coefficient on any terms in the Fourier series to the corresponding average flux norm. Default $CR^{\alpha}_{n} = 5 \times 10^{-3}$.
   - CU^{α}_{n}, stabilized state detection criterion for the ratio of the largest correction to the displacement coefficient on any terms in the Fourier series to the largest displacement coefficient. Default $CU^{\alpha}_{n} = 5 \times 10^{-3}$.

- CR_0^α, plastic ratcheting detection criterion for the ratio of the largest residual coefficient on the constant term in the Fourier series to the corresponding average flux norm. Default $CR_0^\alpha = 5 \times 10^{-3}$.
- CU_0^α, plastic ratcheting detection criterion for the ratio of the largest correction to the displacement coefficient on the constant term in the Fourier series to the largest displacement coefficient. Default $CU_0^\alpha = 5 \times 10^{-3}$.

At any time you can click **System-defined Defaults for this Page** to return all parameters on this tabbed page to their system-defined default values. For more information, see *Controlling the Solution Accuracy in Direct Cyclic Analysis*.

10. Click **OK** to save your customized settings and to close the editor.

Additional information

• *General solution controls*

Customizing solver controls

The solver controls editor allows you to modify the parameters that control the iterative linear equation solver. For more information, see *Iterative Linear Equation Solver*.

Note:

Solver controls are available only for **Static, General**; **Static, Linear perturbation**; **Visco**; **Heat transfer**; **Geostatic**; and **Soils** analysis steps.

1. From the main menu bar, select **Other->Solver Controls->Manager**.

   Abaqus/CAE displays the **Solver Controls Manager** showing the steps defined in the model and the solver controls associated with each step.

2. In the **Solver Controls Manager**, select the analysis step of interest, and click **Edit**.

   The **Edit Solver Controls** dialog box appears.

3. Choose how you want to specify the solver controls:

   - Choose **Propagate from previous step** if you want the solver controls settings from the previous step to remain active in the current step.
   - Choose **Reset all parameters to their system-defined defaults** if you want all of the parameters in the editor to revert to their default values.
   - Choose **Specify** if you want to enter new values for particular parameters in this step.

4. Enter the data necessary to specify the customized solver controls:

   - In the **Relative tolerance** field, enter a value for the relative tolerance of convergence.
   - In the **Max. number of iterations** field, enter a value for the maximum number of linear solver iterations.
   - In the **ILU factorization fill-in level** field, enter a value for the incomplete LU factorization fill-in level (0 *level* 3). This setting is applicable only for **Geostatic** and **Soils** analysis steps.

   For more information on these parameters, see *Setting Controls for the Iterative Linear Solver*.

5. Click **OK** to save your customized settings and to close the editor.

Additional information

- *Solver controls*
- *Configuring analysis procedure settings*

The Interaction module

You can use the Interaction module to define and manage the following objects:

- Mechanical and thermal interactions between regions of a model or between a region of a model and its surroundings.
- The interface region and coupling schemes for an Abaqus/Standard to Abaqus/Explicit co-simulation.
- Analysis constraints between regions of a model.
- Assembly-level wire features, connector sections, and connector section assignments to model connectors.
- Inertia (point mass, rotary inertia, and heat capacitance) on regions of the model.
- Cracks on regions of the model.
- Springs and dashpots between two points of a model or between a point of a model and ground.

In this section:

- *Understanding the role of the Interaction module*
- *Entering and exiting the Interaction module*
- *Understanding interactions*
- *Understanding interaction properties*
- *Understanding constraints*
- *Understanding contact and constraint detection*
- *Understanding connectors*
- *Understanding connector sections and functions*
- *Understanding Interaction module managers and editors*
- *Understanding symbols that represent interactions, constraints, and connectors*
- *Using the Interaction module toolbox*
- *Using the Interaction module*

- *Using the connector section editors*
- *Using the Query toolset to obtain connector assignment information*

Understanding the role of the Interaction module

You can use the Interaction module to define interactions.

You can define the following:

- Contact interactions.
- Elastic foundations.
- Cavity radiation.
- Thermal film conditions.
- Radiation to and from the ambient environment.
- Abaqus/Standard to Abaqus/Explicit co-simulation interaction.
- Pressure penetration.
- Incident waves.
- Acoustic impedance.
- Cyclic symmetry.
- A user-defined actuator/sensor interaction.
- Model change interactions.
- Tie constraints.
- Rigid body constraints.
- Display body constraints.
- Coupling constraints.
- Adjust points constraints.
- MPC constraints.
- Shell-to-solid coupling constraints.
- Embedded region constraints.
- Equation constraints.
- Connector section assignments.
- Inertia.
- Cracks.
- Springs and dashpots.

Interactions are step-dependent objects, which means that when you define them, you must indicate in which steps of the analysis they are active. (For more information about step-dependent objects, see *Understanding the status of an object in a step*.) For example, you can define film and radiation conditions on a surface only during a heat transfer, coupled temperature-displacement, or coupled thermal-electrical step. Similarly, you can define an interaction with a user-defined actuator/sensor only during the initial step.

The Set and Surface toolsets in the Interaction module allow you to define and name regions of your model to which you would like interactions and constraints applied. You can use the Amplitude toolset to define variations in some interaction attributes over the course of the analysis. The Analytical Field toolset allows you to create analytical fields that you can use to define spatially varying parameters for selected interactions. The Reference Point toolset allows you to define reference points that are used in constraints and creating assembly-level wire features.

Abaqus/CAE does not recognize mechanical contact between part instances or regions of an assembly unless that contact is specified in the Interaction module; the mere physical proximity of two surfaces in an assembly is not enough to indicate any type of interaction between the surfaces.

For information on defining cracks to study their initiation and propagation, see *Fracture mechanics*. For information on defining inertia, see *Inertia*. For information on defining springs and dashpots, see *Springs and dashpots*.

Additional information

- *About Contact Interactions*
- *The Amplitude toolset*
- *The Analytical Field toolset*
- *The Reference Point toolset*
- *The Set and Surface toolsets*

Entering and exiting the Interaction module

You can enter the Interaction module at any time during an Abaqus/CAE session by clicking **Interaction** in the **Module** list located in the context bar. **Interaction**, **Constraint**, **Connector**, **Special**, **Feature**, and **Tools** menus appear on the main menu bar; and a **Step** list appears under the context bar.

To exit the Interaction module, click another module in the **Module** list. You need not take any specific action to save objects created in the Interaction module before exiting the module; they are saved automatically when you save the entire model by selecting **File->Save** or **File->Save As** from the main menu bar.

Additional information

• *Using the Special menu in the Interaction module*

Understanding interactions

You can use the Interaction module to define several types of interactions.

You can define the following types of interactions:

General contact

General contact interactions allow you to define contact between many or all regions of the model with a single interaction. General contact is also used to define contact between Lagrangian bodies and Eulerian materials in a coupled Eulerian-Lagrangian analysis (see *Defining contact in Eulerian-Lagrangian models*). Typically, general contact interactions are defined for an all-inclusive surface that contains all exterior faces; feature edges; and—in Abaqus/Explicit—analytical rigid surfaces, edges based on beams and trusses, and Eulerian material boundaries. To refine the contact domain, you can include or exclude specific surface pairs. Surfaces used in general contact interactions can span many disconnected regions of the model. Attributes, such as contact properties, surface properties, and contact formulation, are assigned as part of the contact interaction definition but independently of the contact domain definition, which allows you to use one set of surfaces for the domain definition and another set of surfaces for the attribute assignments. For detailed instructions on creating this type of interaction, see *Defining general contact*.

General contact interactions and surface-to-surface or self-contact interactions can be used together in the same analysis. Only one general contact interaction can be active in a step during an analysis.

For more information, see *About Contact Interactions*, *About General Contact in Abaqus/Standard*, *About General Contact in Abaqus/Explicit*, and *Eulerian Analysis*. The assignment of a penalty stiffness scale factor is not supported in Abaqus/CAE. In addition, node-based surfaces cannot be used in a general contact interaction in Abaqus/CAE.

Surface-to-surface contact, self-contact, and pressure penetration

Surface-to-surface contact interactions describe contact between two deformable surfaces or between a deformable surface and a rigid surface. Self-contact interactions describe contact between different areas on a single surface. For detailed instructions on creating these types of interactions, see *Defining surface-to-surface contact*, *Defining self-contact*, and *Using contact and constraint detection*. For more information, see *About Contact Pairs in Abaqus/Standard* and *About Contact Pairs in Abaqus/Explicit*.

If your model includes complex geometries and numerous contact interactions, you may want to customize the variables that control the contact algorithms to obtain cost-effective solutions. These controls are intended for advanced users and should be used with great care. For more information, see *Contact controls editors*.

A pressure penetration interaction allows you to simulate the pressure of a fluid penetrating between two surfaces involved in surface-to-surface contact. The fluid pressure is applied normal to the surfaces. You must create a surface-to-surface contact interaction to specify the main and secondary surfaces for the pressure penetration. The bodies forming the joint can both be deformable, as is the case with threaded connectors; or one can be rigid, as occurs when a soft gasket is used as a seal between stiffer structures. A pressure penetration interaction can be used only in an Abaqus/Standard analysis. For detailed instructions on creating pressure penetration interactions, see *Defining pressure penetration*. For more information, see *Fluid Pressure Penetration Loads*.

Fluid cavity

A fluid cavity interaction allows you to select and assign properties to a liquid- or gas-filled fluid cavity in the model. Fluid cavity selection includes a reference point and the surface that encloses the cavity. The properties are defined in a fluid cavity interaction property (for more information, see *Understanding interaction properties*). You can define fluid cavity interactions in the initial step of an Abaqus/Standard or an Abaqus/Explicit analysis. The fluid cavity interaction remains constant throughout all steps of an analysis; you cannot modify or deactivate

it after the initial step. For detailed instructions on creating fluid cavity interactions, see *Defining a fluid cavity interaction*.

Fluid exchange

A fluid exchange interaction allows you to define movement of fluid between a cavity and the environment or between two cavities. To create a fluid exchange interaction, you must first select an existing fluid cavity interaction for each cavity (one for exchange to environment or two for exchange between cavities). Then you can select or create a fluid exchange interaction property (for more information, see *Understanding interaction properties*) and set the effective exchange area. For detailed instructions on creating fluid exchange interactions, see *Defining a fluid exchange interaction*.

Fluid inflator

A fluid inflator interaction allows you to inflate a fluid cavity to model the flow characteristics of inflators used for airbag systems. To create a fluid inflator interaction, you must first select an existing fluid cavity interaction. Then you can select or create a fluid inflator interaction property (for more information, see *Understanding interaction properties*). For detailed instructions on creating fluid inflator interactions, see *Defining a fluid inflator interaction*.

XFEM crack growth

An XFEM crack growth interaction allows you to activate or deactivate growth of a crack created using the extended finite element method. For detailed instructions on creating this type of interaction, see *Deactivating and activating an XFEM crack growth*.

Model change

A model change interaction allows you to remove and reactivate elements during an analysis. You can use model change interactions in all Abaqus/Standard analysis procedures except for the static, Riks procedure and linear perturbation procedures. For detailed instructions on creating this type of interaction, see *Defining a model change interaction*. For more information on removing and reactivating elements, see *Element and Contact Pair Removal and Reactivation*.

Cyclic symmetry

Cyclic symmetry enables you to model an entire 360° structure at considerably reduced computational expense by analyzing only a single repetitive sector of a model. You can create cyclic symmetry interactions only in the initial step. Once a cyclic symmetry interaction is created, cyclic symmetry applies to the entire analysis history. If you deactivate a cyclic symmetry interaction in a frequency step, Abaqus/CAE evaluates all possible nodal diameters being evaluated for that step. For detailed instructions on creating this type of interaction, see *Defining cyclic symmetry*. For more information about cyclic symmetry in Abaqus, see *Analysis of Models that Exhibit Cyclic Symmetry*.

Elastic foundation (Abaqus/Standard only)

Elastic foundations allow you to model the stiffness effects of a distributed support on a surface without actually modeling the details of the support. You can create elastic foundation interactions only in the initial step. Once an elastic foundation is activated, you cannot deactivate it in later analysis steps. For detailed instructions on creating this type of interaction, see *Defining foundations*. For more information, see *Element Foundations*.

Cavity radiation (Abaqus/Standard only)

Cavity radiation interactions describe heat transfer due to radiation in enclosures. Two cavity radiation models are available in Abaqus/CAE: a fully implicit definition and an approximation. The full version can be used for heat transfer without deformation in two-dimensional, three-dimensional, and axisymmetric models. It can include open or closed cavities and accounts for symmetries and surface blocking, but it does not support surface motion within cavities. For detailed instructions on creating this type of interaction, see *Defining a cavity radiation interaction*.

The cavity radiation approximation is defined using a surface radiation interaction. You can approximate cavity radiation in any heat transfer analysis, with or without deformation. However, approximate cavity radiation can be used only for closed cavities in three-dimensional models. The approximation treats the cavity as a black body enclosure with a temperature equal to the average temperature of the entire surface. Under these limited conditions, approximate cavity radiation can save considerable computational expense. For detailed instructions on creating this type of interaction, see *Defining a surface radiative interaction*.

For more information on both types of cavity radiation, see *Cavity Radiation in Abaqus/Standard*.

Thermal film conditions

Film condition interactions define heating or cooling due to convection by surrounding fluids. Two types of film condition interaction are available in Abaqus/CAE: surface film conditions define convection from model surfaces, and concentrated film conditions define convection from nodes or vertices. You can define film condition interactions only during a heat transfer, fully coupled thermal-stress, or coupled thermal-electrical step. For detailed instructions on defining these types of interactions, see *Defining a surface film condition interaction*, and *Defining a concentrated film condition interaction*, respectively. For more information, see *Thermal Loads*.

Radiation to and from the ambient environment

Radiation interactions describe heat transfer to a nonreflecting environment due to radiation. Two types of radiation interactions are available in Abaqus/CAE: surface radiation interactions describe heat transfer with a nonconcave surface, and concentrated radiation interactions describe radiation from nodes or vertices. You can define radiation interactions only during a heat transfer, fully coupled thermal-stress, or coupled thermal-electrical step. For detailed instructions on creating these types of interactions, see *Defining a surface radiative interaction*, and *Defining a concentrated radiative interaction*, respectively. For more information, see *Thermal Loads*.

Abaqus/Standard to Abaqus/Explicit co-simulation

For an Abaqus/Standard to Abaqus/Explicit co-simulation, you must specify the interface region (region for exchanging data) and coupling schemes (time incrementation process and frequency of data exchange) for the co-simulation. In each model, you create a Standard-Explicit co-simulation interaction to define the co-simulation behavior; only one Standard-Explicit co-simulation interaction can be active in a model. The settings in each co-simulation interaction must be the same in the Abaqus/Standard model and the Abaqus/Explicit model.

A Standard-Explicit co-simulation interaction can be created only in a general static, implicit dynamic, or explicit dynamic step. The interaction is valid only in the step in which it is created and is not propagated to subsequent steps. For detailed instructions on creating this type of interaction, see *Defining a Standard-Explicit co-simulation interaction*. For more information, see *Structural-to-Structural Co-Simulation*.

Incident waves

Incident wave interactions model incident wave loading due to external acoustic wave sources. For detailed instructions on creating this type of interaction, see *Defining incident waves*. For more information, see *Acoustic and Shock Loads*.

Acoustic impedance

An acoustic impedance specifies the relationship between the pressure of an acoustic medium and the normal motion at an acoustic-structural interface. For detailed instructions on creating this type of interaction, see *Defining acoustic impedance*. For more information, see *Acoustic and Shock Loads*.

Actuator/sensor (Abaqus/Standard only)

An actuator/sensor interaction models a combination of sensors and actuators and, therefore, allows for modeling control system components. Currently, this type of interaction allows sensing and actuation at just one point. For detailed instructions on creating this type of interaction, see *Defining an actuator/sensor interaction*.

The interaction definition and its optional associated property are used to define the basic aspects of the interaction, but the user must provide user subroutine *UEL* to supply the specific formulae for how actuation depends on sensor readings. You specify the name of the file containing the user subroutine when you create the analysis job in the Job module.

Warning:

This feature is intended for advanced users only. Its use in all but the simplest test examples will require considerable coding by the user/developer. *User-Defined Elements*, should be read before proceeding.

Actuator/sensor interactions are available only for Abaqus/Standard analyses. For more information, see *About User Subroutines and Utilities*.

Additional information

• *Defining Contact Interactions*

Understanding interaction properties

You can define a set of data that is referred to by an interaction but is independent of the interaction; for example, the coefficients that define friction during contact. This set of data is called an interaction property.
One interaction property can be referred to by many different interactions.

You can create the following types of interaction properties:

Contact

A contact interaction property can define tangential behavior (friction and elastic slip) and normal behavior (hard, soft, or damped contact and separation). In addition, a contact property can contain information about damping, thermal conductance, thermal radiation, and heat generation due to friction. A contact interaction property can be referred to by a general contact, surface-to-surface contact, or self-contact interaction. For detailed instructions on defining this type of interaction property, see *Defining a contact interaction property*.

Film condition

A film condition interaction property defines a film coefficient as a function of temperature and field variables. A film condition interaction property can be referred to only by a film condition interaction. For detailed instructions on defining this type of interaction property, see *Defining a film condition interaction property*.

Cavity radiation

A cavity radiation interaction property defines emissivity for a cavity as a function of temperature and field variables. A cavity radiation interaction property can be referred to only by a cavity radiation interaction. For detailed instructions on defining this type of interaction property, see *Defining a cavity radiation interaction property*.

Fluid cavity

A fluid cavity interaction property defines the type of fluid occupying the cavity and the fluid properties. You can choose either a hydraulic fluid or a pneumatic fluid. Hydraulic fluids must include a fluid density; and they might include a fluid bulk modulus, thermal expansion coefficients, and other temperature-dependent data. Pneumatic fluids must include an ideal gas molecular weight, and they might include a molar heat capacity (Abaqus/Explicit only). For detailed instructions on defining this type of interaction property, see *Defining a fluid cavity interaction property*.

Fluid exchange

A fluid exchange interaction property defines the fluid flow between a cavity and the environment or from one cavity to another. You can define a fluid exchange based on bulk viscosity, mass flux, mass rate leakage, volume flux, or volume rate leakage. For detailed instructions on defining this type of interaction property, see *Defining a fluid exchange interaction property*.

Fluid inflator

A fluid inflator interaction property defines the mass flow rate and temperature as a function of inflation time either directly or by entering tank test data. It also defines the mixture of gases entering the fluid cavity. For detailed instructions on defining this type of interaction property, see *Defining a fluid inflator interaction property*.

Acoustic impedance

An acoustic impedance interaction property defines surface impedance or the proportionality factors between the pressure and the normal components of surface displacement and velocity in an acoustic analysis. An acoustic impedance interaction property can be referred to only by an acoustic impedance interaction. For detailed instructions on defining this type of interaction property, see *Defining an acoustic impedance interaction property*.

Incident wave

An incident wave interaction property defines the speed of the incident wave and other characteristics of the wave loading. An incident wave interaction property can be referred to only by an incident wave interaction. For detailed instructions on defining this type of interaction property, see *Defining an incident wave interaction property*.

Actuator/sensor

An actuator/sensor interaction property provides the `PROPS`, `JPROPS`, `NPROPS`, and `NJPROPS` variables that are passed into a *UEL* user subroutine used with an actuator/sensor interaction. For detailed instructions on defining this type of interaction property, see *Defining an actuator/sensor interaction property*.

Wear

A wear interaction property defines the contact wear properties based on Archard's wear rate model (see *Contact Wear*). For detailed instructions on defining this type of interaction property, see *Defining a wear interaction property*.

Understanding constraints

Constraints defined in the Interaction module define constraints on the analysis degrees of freedom, whereas constraints defined in the Assembly module define constraints only on the initial positions of instances. In the Interaction module you can constrain the degrees of freedom between regions of a model, and you can suppress and resume constraints to vary the analysis model. Currently, you can create the following types of constraints:

Tie

A tie constraint allows you to fuse together two regions even though the meshes created on the surfaces of the regions may be dissimilar. For detailed instructions on creating this type of constraint, see *Defining tie constraints*, and *Using contact and constraint detection*. For more information, see *Mesh Tie Constraints*.

Rigid body

A rigid body constraint allows you to constrain the motion of regions of the assembly to the motion of a reference point. The relative positions of the regions that are part of the rigid body remain constant throughout the analysis. For detailed instructions on creating this type of constraint, see *Defining rigid body constraints*. For more information on reference points, see *The Reference Point toolset*. For more information, see *Rigid Body Definition*.

Display body

A display body constraint allows you to select a part instance that will be used for display only. You do not have to mesh the part instance, and it is not included in the analysis; however, when you view the results of the analysis, the Visualization module displays the selected part instance. You can constrain the part instance to be fixed in space, or you can constrain it to follow selected nodes. You can apply a display body constraint to an instance of an Abaqus native part or to an instance of an orphan mesh part. For detailed instructions on creating this type of constraint, see *Defining display body constraints*. You can customize the appearance of display bodies in the Visualization module; for more information, see *Customizing the appearance of display bodies*.

A display body constraint is especially useful for mechanism or multibody dynamic problems where rigid parts interact with each other via connectors. In such cases you can create a simple rigid part, such as a point part, and a display body that is more representative of the physical part. For an example of a model that includes a display body constraint combined with connectors, see *Display bodies*. You can also use display bodies to model stationary objects that are not involved in the analysis but that help you to visualize the results.

For more information, see *Display Body Definition*.

Coupling

A coupling constraint allows you to constrain the motion of a surface to the motion of a single point. For detailed instructions on creating this type of constraint, see *Defining coupling constraints*. For more information, see *Coupling Constraints*.

Adjust points

An adjust points constraint allows you to move a point or points onto a specified surface. For detailed instructions on creating this type of constraint, see *Defining adjust points constraints*. For more information, see *Adjusting Nodal Coordinates*. This adjustment may be useful in assembled fasteners and other applications; see *About assembled fasteners*, and *Creating assembled fasteners*.

MPC constraint

An MPC constraint allows you to constrain the motion of the secondary nodes of a region to the motion of a single point. For detailed instructions on creating this type of constraint, see *Defining MPC constraints*. A multi-point constraint between two points is defined using connectors. For detailed instructions, see *Connectors*. For more information, see *General Multi-Point Constraints*.

Shell-to-solid coupling

A shell-to-solid coupling constraint allows you to couple the motion of a shell edge to the motion of an adjacent solid face. For detailed instructions on creating this type of constraint, see *Defining shell-to-solid coupling constraints*. For more information, see *Shell-to-Solid Coupling*.

Embedded region

An embedded region constraint allows you to embed a region of the model within a “host” region of the model or within the whole model. For detailed instructions on creating this type of constraint, see *Defining embedded region constraints*. For more information, see *Embedded Elements*.

Equation

Equations are linear, multi-point equation constraints that allow you to describe linear constraints between individual degrees of freedom. For detailed instructions on creating this type of constraint, see *Defining equation constraints*. For more information, see *Linear Constraint Equations*.

Understanding contact and constraint detection

The contact detection tool in Abaqus/CAE provides a fast and easy way to define contact interactions and tie constraints in a three-dimensional model.
Instead of individually selecting surfaces and defining the interactions between them, you can instruct Abaqus/CAE to automatically locate all surfaces in a model that are likely to interact based on initial proximity. You can tune the proximity settings and specify a variety of options that control the active search domain, the definitions of surfaces, and the default interaction or constraint settings. The search works for both geometry and meshed models.

Each detected interaction or constraint involves two identified surfaces, also known as a contact pair candidate. The contact detection dialog box lists each contact pair candidate and its default parameters in a tabular format. The default contact pair candidate parameters are slightly different than the default parameters used in the traditional Abaqus/CAE interaction editors; in particular, the contact detection tool initially assigns surface-to-surface discretization to each contact pair candidate instead of node-to-surface discretization.

Using the tabular interface, you can review the contact pair candidates to ensure that the surface definitions are comprehensive, the main and secondary assignments are appropriate, and the parameters are correct. If necessary, you can modify parameters or surface assignments in the table, and you can create new contact pairs where appropriate. Once the contact pair candidates are configured to your specifications, Abaqus/CAE defines all of the contact interactions and tie constraints simultaneously.

For step-by-step instructions on using the contact detection dialog box, see *Using contact and constraint detection*.

In this section:

- *The contact detection dialog box*
- *Use of the contact detection algorithm*
- *Default interaction and constraint parameters*
- *Tips for using the contact detection tool*

The contact detection dialog box

To use contact detection, select **Interaction->Find contact pairs** or **Constraint->Find contact pairs** from the main menu bar. The contact detection dialog box appears as shown in *Figure 1*. Initially there are no identified contact pairs.

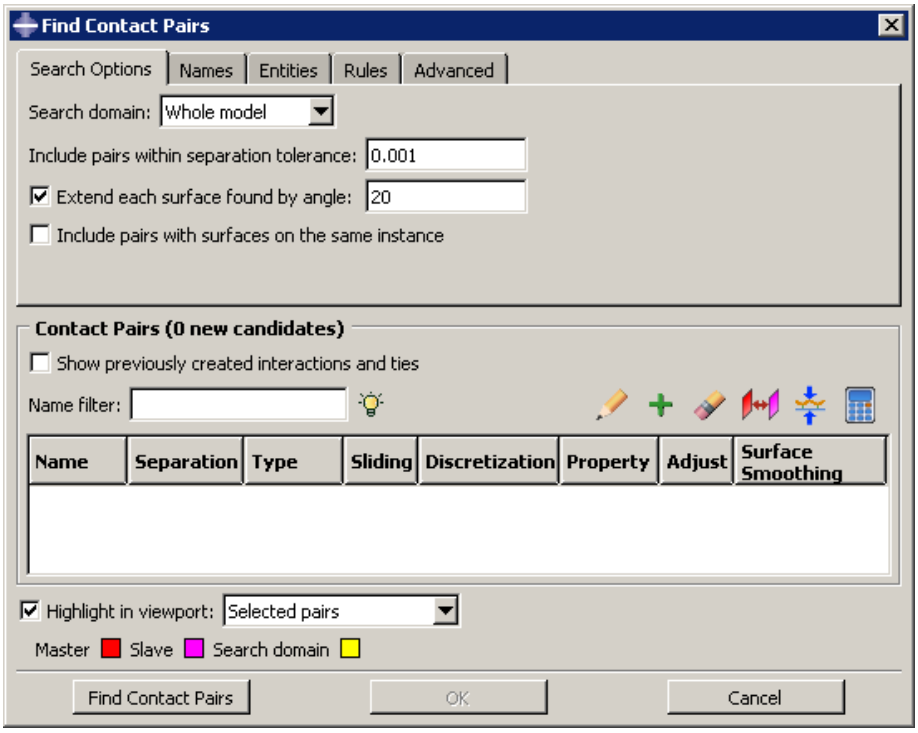

Figure 1: Initial view of the contact detection tool.

Using the contact detection tool is a two-step process: first Abaqus/CAE searches for surfaces in the model that are likely to interact; then you have a chance to review the identified surfaces and modify the default contact pair parameters before creating interactions and constraints. You provide some basic criteria to guide the search. These criteria include the search domain and the distance between surfaces that will likely be in contact.

After entering the necessary search criteria, click **Find Contact Pairs** to begin the search. Abaqus/CAE updates the contact pair candidates table, as illustrated in *Figure 2*.

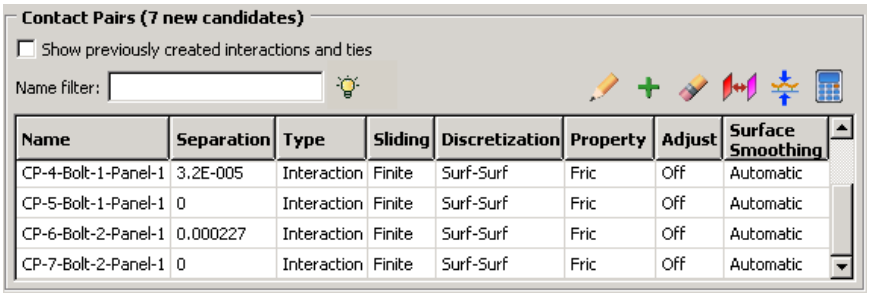

Figure 2: The contact pair candidates table.

You can create either a contact interaction or a tie constraint for each contact pair candidate in the table. You can also modify the parameters of the interaction or constraint definition by clicking on the appropriate table cell (see *Figure 3*).

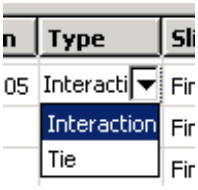

Figure 3: Changing cell values in the contact pair candidates table.

Clicking mouse button 3 on the table displays a menu of extended options and allows you to manually add contact pairs to the table. When you toggle on **Show previously created interactions and ties**, any pre-existing surface-to-surface interactions and tie constraints are added to the contact pair candidates table; you can modify existing contact pairs in the same manner as newly detected contact pair candidates.

The interactions and constraints shown in the contact pair candidates table do not become part of the model until you click **OK**. When you have finished setting parameters for the contact pairs, click **OK**. Abaqus/CAE simultaneously creates contact interactions and tie constraints for every contact pair in the table according to the specified parameters. The created interactions and constraints are added to the Model Tree and the **Interaction Manager**; you can review, modify, suppress, and delete the created interactions using either of these interfaces.

For detailed instructions on using the automatic contact detection tool, see *Using contact and constraint detection*.

Use of the contact detection algorithm

This section discusses the use of the contact detection algorithm.

In this section:

- *The contact detection algorithm*
- *Additional criteria for defining contact pairs*
- *Contact detection for geometry*
- *Contact detection for meshed models*
- *Detection of overclosed surfaces*
- *Defining contact within the same instance and self-contact*
- *Considerations for shells*

The contact detection algorithm

Surfaces must meet two requirements to be identified by the automatic contact detection tool:

- The surfaces must be separated by a distance less than or equal to the specified separation tolerance.
- The surfaces must be intuitively opposed, as defined below.

Abaqus/CAE defines the separation between two surfaces as the distance between the points of closest approach on the surfaces. This distance is reported in the **Separation** column of the contact pair candidates table. The separation tolerance is the primary input used during the contact detection search. You should specify a separation tolerance that encompasses the separation distances between all of the potentially contacting surfaces in your model. For more information, see *Choosing a separation tolerance and extension angle* below.

Note:

The value reported in the **Separation** column may not correspond exactly to the separation used by Abaqus/Standard during an analysis. Certain automatic surface enhancements applied during the analysis to improve contact robustness (such as main surface smoothing and surface extensions) can lead to slight discrepancies between the separations calculated in the Abaqus/CAE preprocessor and the Abaqus/Standard analysis. For more details on automatic surface enhancements and contact formulations, refer to *Defining Contact Pairs in Abaqus/Standard*.

Two surfaces are considered intuitively opposed if the two surface normals constructed at the points of closest approach lie between 135° and 225° of each other (see *Figure 1*). In other words, the surfaces must be offset from each other by less than 45° at the points of closest approach. It is not possible to adjust or ignore the surface orientation requirement.

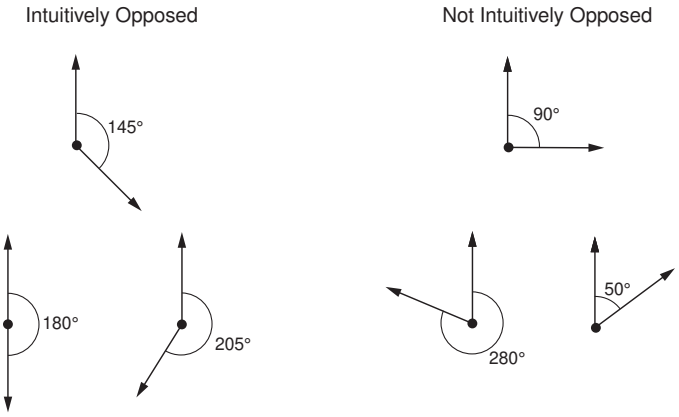

Figure 1: The relative orientation of the normals determines whether or not the surfaces are intuitively opposed.

Figure 2 illustrates a simple example of the contact pair requirements.

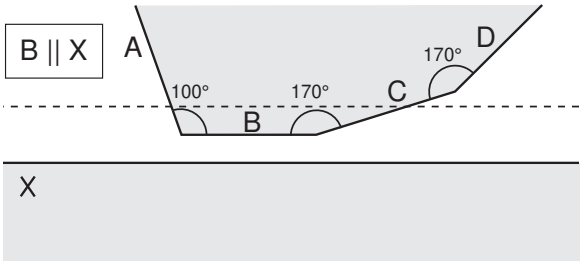

Figure 2: Two bodies involved in potential contact. The bodies are rendered in two dimensions for simplicity.

The dashed line represents the separation tolerance as calculated from surface *X*. Surface *B*, which is parallel to surface *X*, is identified as part of a contact pair because it is both within the separation tolerance and intuitively opposed to surface *X*. Similarly, surface *C* meets both of these criteria. Surface *D*, although it is intuitively opposed to surface *X*, does not lie within the separation tolerance at any point; surface *D* is not considered for inclusion in a contact pair. Surface *A*, although it is within the separation tolerance, is not intuitively opposed to surface *X*; therefore, surface *A* is also excluded from any contact pair definition. The connected surfaces (*A*, *B*, *C*, and *D*) do not form contact pairs with each other. By default, Abaqus/CAE only searches for surfaces on separate part instances. However, even if you were to enable searching within the same instance (see *Defining contact within the same instance and self-contact* below), these surfaces would not meet the orientation requirements.

Additional criteria for defining contact pairs

After using the separation and orientation checks to compile a list of potential contact pairs, the contact detection tool can perform a series of additional checks that adjust the surface definitions to make them more useful and realistic. All three of these additional checks are optional, but they are enabled by default.

Extending surfaces

By default, any surface identified by the contact detection tool is extended to include adjacent model faces within 20°, even if the adjacent faces do not meet the separation and orientation requirements. The 20° angle is measured as the offset between the normals of the detected surface and the adjacent face at the common edge. You can modify the extension angle using the **Extend each surface found by angle** option. As faces are added to the surface definition, Abaqus/CAE also checks any faces adjacent to the newly added faces. Abaqus/CAE eliminates any redundant definitions if an extended surface incorporates a face from a separately defined contact pair. For example, consider extending surfaces within 20° for the model in *Figure 2*. Abaqus/CAE creates a single contact pair: one surface consists of face *X*, and the other surface consists of faces *B*, *C*, and *D*. Face *D* is within 20° of face *C*, which is within 20° of face *B*; the redundant contact pair consisting of face *C* and face *X* is eliminated, since it is incorporated by the larger contact pair.

Merging contact pairs within a specified angle

You can use the **Merge pairs when surfaces are within angle** option to combine multiple contact pairs into a single definition. The faces involved in the contact pairs must be adjacent and they must lie within the specified angle (as described above). The merge option does not extend faces; it only combines positively identified contact pairs. By default, contact pairs with surfaces within 20° are merged by the contact detection tool. The merge option is typically used as an alternative to surface extension to merge contact pair candidates automatically without extending surface definitions beyond the separation tolerance. For example, merging pairs within 20° without extending surfaces for the model in *Figure 2* results in a single contact pair: one surface consists of face *X*, and the other surface consists of faces *B* and *C*.

Checking for surface overlap

By default, the contact detection tool eliminates any contact pairs whose surfaces do not "overlap"; two surfaces do not overlap if a normal from any point on one of the surfaces does not pass through the opposing surface. For example, the surfaces in *Figure 1* do not overlap, even though they may pass the separation and orientation checks.

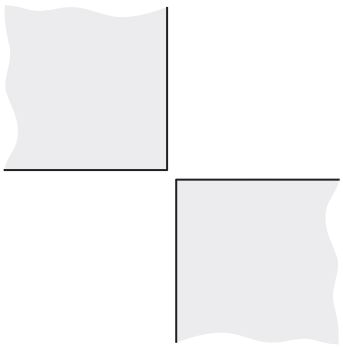

Figure 1: Non-overlapping surfaces. The bodies are rendered in two dimensions for simplicity.

You can suppress the check for surface overlap and allow the creation of contact pairs for non-overlapping surfaces by using the **Include opposing surfaces that do not overlap** option.

Contact detection for geometry

Abaqus/CAE begins searching a model comprised of geometry by dividing the model into individual faces. A face consists of the area enclosed in connected geometric edges or partitions. Once all of the faces are identified, Abaqus/CAE compares the faces to determine if they meet the separation and orientation requirements, then defines surfaces from the faces by applying extension, merging, and overlap checks (see *Additional criteria for defining contact pairs* above). Any two surfaces that meet all of the requirements are flagged as a contact pair candidate.

Abaqus/CAE automatically assigns the main and secondary designations to surfaces in a detected contact pair. Analytical rigid or discrete rigid surfaces are always assigned the main role; if the contact pair involves two rigid surfaces, the assignment of main and secondary roles is arbitrary. For contact pairs involving two deformable surfaces, Abaqus/CAE first determines if the surface geometry has been meshed and assigns the main role to the surface with the coarser mesh. If mesh information is unavailable, the surface with the larger area becomes the main surface. The algorithm that assigns main and secondary roles does not account for dissimilar underlying stiffness or element assignments; if these factors play a significant role in your contact interactions, you should review the main and secondary assignments before creating an interaction. For further discussion of main and secondary assignments, see *Selecting Surfaces Used in Contact Pairs*.

Contact detection for meshed models

Contact detection also works with mesh models. The search algorithm for meshed models works in much the same way as with geometry, but it uses element faces instead of geometric faces. By default, Abaqus/CAE only searches for contact pairs between separate part instances. Mesh models that are imported into Abaqus/CAE often consist of only a single part instance; therefore, you should enable searching within the same instance before using contact detection on these models (see *Defining contact within the same instance and self-contact* below for more details).

Warning:

Unlike geometry-based searches, the reported separation between surfaces for mesh-based surfaces is not necessarily the distance between the exact points of closest approach, but rather a close approximation. If the specified search tolerance is very large compared to the characteristic element size, the accuracy of this approximation is greatly reduced.

Before defining surfaces on element faces, Abaqus/CAE applies the same extension, merging, and overlap checks as with geometry faces (see *Additional criteria for defining contact pairs* above). Because element faces are typically much smaller than geometric faces, you should always allow some extension of the surfaces to get ample coverage from a surface definition; *Figure 1* compares the created surfaces for geometry and meshed geometry when no surface extension is allowed.

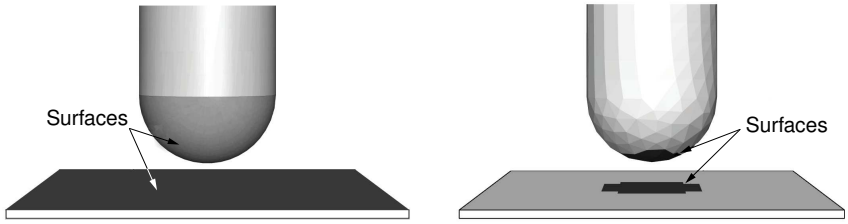

Figure 1: Discrepancies between created surfaces when no surface extension is allowed for geometry (left) and meshed geometry (right).

If you remesh your model, any surfaces defined on elements faces may become invalid. By extension, the interactions and constraints based on these faces also become invalid.

When assigning main and secondary designations to the mesh surfaces, rigid surfaces always become the main; if the contact pair involves two rigid surfaces, the assignment of main and secondary roles is arbitrary. For contact pairs involving two deformable surfaces, Abaqus/CAE considers the mesh densities on each surface; the surface with the coarser mesh becomes the main surface. If the mesh densities on the two surfaces are equivalent, the assignment of main and secondary roles is arbitrary. The algorithm that assigns main and secondary roles does not account for dissimilar underlying stiffness or element types; if these factors play a significant role in your contact interactions, you should review the main and secondary assignments before creating an interaction. For further discussion of main and secondary assignments, see *Selecting Surfaces Used in Contact Pairs*.

The contact detection tool does not detect contact between geometry and orphan elements or analytical surfaces and orphan elements. If your model includes part instances that have been meshed from geometry, you can use the options on the **Advanced** tabbed page of the contact detection dialog box to indicate whether these instances should be treated as geometry (the default) or an element mesh during the search. If your model contains instances of both geometry and orphan mesh elements, you should first mesh all of the geometries, then perform a mesh-based search to capture all possible contact pairs.

In most cases the geometry is a more faithful representation of the object being modeled than the meshed geometry. In addition, geometry-based interactions and constraints are not affected by remeshing. However, the mesh is the geometry used in the analysis. Mesh discretization can lead to slight disparities in separation distances between the

two representations, which may become important in precise analyses. After searching, you can check individual contact pairs for disparities between the native and meshed geometry by using the **Recalculate Separation** option.

Detection of overclosed surfaces

If two faces in an assembly intersect at any point, the contact detection tool reports those faces as an overclosed contact pair. Overclosed contact pairs that appear in the contact pair candidates table must still meet the surface orientation requirements. A red zero in the **Separation** column indicates that the two surfaces in the contact pair are intersecting.

Note: A black zero in the **Separation** column implies that the two surfaces are exactly touching at their closest points. There is no overclosure or intersection in this situation.

If you extend or merge an overclosed surface to include faces that are not overclosed, Abaqus/CAE reports the entire contact pair as overclosed.

You should visually inspect all overclosed surfaces before creating contact interactions. Models with severe overclosures should be adjusted to remove the overclosures (or at least lessen their severity). Minor overclosures can be addressed by using the contact adjustment options (available in the contact pair candidates table) or the interference fit options (available in the contact interaction editor).

Faces must intersect to be reported as overclosed. If a face is enclosed entirely within another part instance, the automatic contact detection tool does not report that face as being overclosed. Such a face may still meet the separation and orientation requirements with respect to an external face on the enclosing instance. By default, Abaqus/CAE eliminates enclosed faces from the contact pair candidates table because the surfaces do not "overlap" (see *Additional criteria for defining contact pairs*). If you disable the overlap checks, Abaqus/CAE reports a contact pair candidate for enclosed faces, but the contact pair candidates table does not provide any indication that the surfaces are overclosed or penetrating. Because the contact detection tool does not recognize these faces as overclosed, the adjustment options that are applied to overclosed surfaces by default (see *Default interaction and constraint parameters*) are not applied to this contact pair. If an enclosed face is embedded deeper than the separation tolerance from any external face, the automatic contact detection tool does not identify those faces as a contact pair candidate.

As an example, consider the model in *Figure 1*.

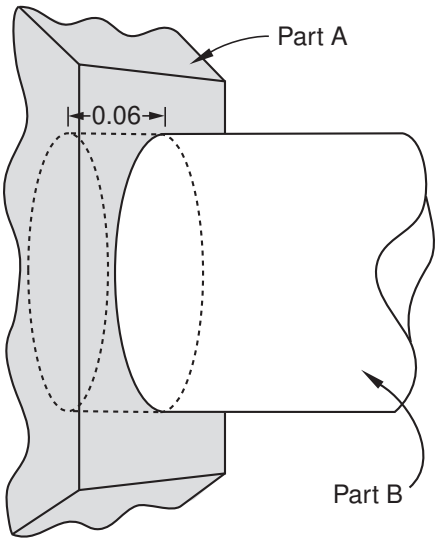

Figure 1: In this model, one end of the cylindrical part instance is entirely enclosed within another part instance.

The separation tolerance specified for this search is 0.1. The circular face at the end of part instance B is within the separation tolerance and is intuitively opposed to the rectangular face on part instance A, but there is no intersection. The contact pair candidates table lists a normal contact pair consisting of the circular face and the rectangular face separated by a distance of 0.06. The cylindrical side face of part instance B is listed as overclosed because it intersects the rectangular face of part instance A.

Although the contact detection tool does not recognize completely enclosed surfaces as being overclosed, such surfaces are still treated as overclosures during an analysis. Severe overclosures commonly lead to convergence difficulties. When reviewing overclosed contact pairs in the contact pair candidates table, check adjoining surfaces for fully enclosed faces.

Defining contact within the same instance and self-contact

You can use the contact detection tool to define contact between different areas of the same part instance or model instance. This capability is particularly useful for complicated models that are imported into Abaqus/CAE as a single part instance. If you enable the **Include pairs with surfaces on the same instance** option, Abaqus/CAE checks different geometry or element faces on the same part instance or model instance to determine whether or not they meet the separation and orientation requirements. Surfaces and contact pairs are defined on any faces that meet the requirements.

In some situations, surface extension options cause the main and secondary surfaces to overlap. If the main surface and the secondary surface consist of the same faces, Abaqus/CAE automatically adjusts the contact pair to create a self-contact interaction, in which a surface contacts itself during deformation. A single surface is created in this situation.

Considerations for shells

If a section definition has been assigned to a shell part, the contact detection tool accounts for the thickness of the shell in separation calculations. The reported separation has been adjusted according to the thickness and offset specified in the shell section assignment. You can use the **Account for shell thickness and offset** option to ignore shell section properties during a contact detection search. Varying thickness distributions are never considered in the separation calculations.

The contact detection tool automatically selects a shell side on which to create a surface (see *Specifying a particular side or end of a region*, for more information). The side is selected such that the surface normals at the points of closest approach are intuitively opposed.

When working with a model that includes orphan shell elements, make sure that the element normal orientations are consistent between elements; that is, the positive element faces (SPOS) should all be located on the same side of the shell structure (see *About Shell Elements*, for more information). If the element normal orientations are inconsistent, Abaqus/CAE misinterprets the angles between the element faces, and the surface extension and merge operations do not function appropriately.

For certain spline-based shells or faces, the same surface may interact with both sides of a shell (see *Figure 1*, for example).

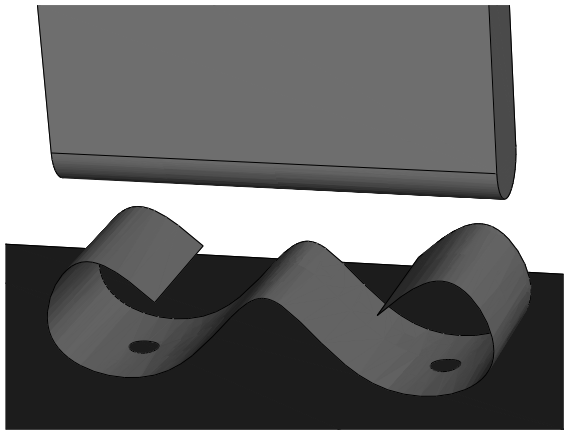

Figure 1: A spline-based shell.

Normally you would define a separate contact pair involving each side of the shell. The contact detection tool, however, cannot create multiple contact pairs that involve the same two faces; it will define a single contact pair and select the shell side according to the orientation at the point of closest approach. You must manually define another contact pair for the other side of the shell.

The contact detection tool does not create any double-sided surfaces. If appropriate, you can edit the definition of a created surface in the Model Tree to make it double-sided (see *Editing sets and surfaces*).

Default interaction and constraint parameters

After completing a search for potential contact pairs, Abaqus/CAE populates the contact pair candidates table with all of the parameters necessary to create interactions.

Names are provided for the contact pair and any created surfaces. *Table 1* outlines the naming algorithm.

Table 1: Algorithms used to create names in the contact detection tool.

Contact pairs	*Prefix*-*Contact_pair_number*-*Main_instance*-*Secondary_instance*
Main surfaces	*Prefix*-*Contact_pair_number*-*Main_instance*
Secondary surfaces	*Prefix*-*Contact_pair_number*-*Secondary_instance*
Merged main surface	*Prefix*-`All-m`
Merged secondary surface	*Prefix*-`All-s`
Merged “all” surface	*Prefix*-`All`

Use the **Names** tabbed page before searching to modify the naming prefix and control the creation of surfaces. For details, see *Specifying naming options for contact detection*.

The default parameters supplied to contact pairs by the contact detection tool are slightly different than the defaults used in the traditional interaction or constraint editor. Most notably, the contact detection tool initially assigns surface-to-surface discretization to each contact pair instead of node-to-surface discretization. See *Mesh Tie Constraints* and *Contact Formulations in Abaqus/Standard* for a discussion of surface discretization and the associated constraint enforcement methods.

The default surface adjustment options depend on the separation between the surfaces in a contact pair. You can use the **Rules** tabbed page before searching to control the default adjustment options that are assigned to detected contact pairs. You can also use this page to specify a separation tolerance within which all contact pairs default to tie constraints. For more information about the **Rules** page, see *Defining default contact pair parameters*.

Table 2 lists the default contact pair parameters supplied by Abaqus/CAE. You can edit each parameter individually before creating interactions and constraints. For detailed instructions on editing parameters and defaults, see *Reviewing and modifying detected contact pairs*.

Table 2: Default contact pair parameters for the contact detection tool.

Parameter	Default Value
Active/Suppressed	Active
Type[1]	Interaction
Sliding	Finite sliding
Discretization	Surface-to-surface
Interaction property	The first contact interaction property listed in the **Interaction Property Manager**[2]; if no interaction properties have been created, this parameter is blank
Contact controls	This parameter is blank; contact controls are unavailable in the initial step
Adjust[1]	**Off** for contact interactions between nonintersecting surfaces; **0** for contact interactions between intersecting surfaces; **On** for tie constraints
Creation step	Initial
Surface smoothing	Automatic
[1]Defaults for the Type and Adjust parameters are controlled by the **Rules** options.	
[2]The **Interaction Property Manager** lists all created interaction properties alphabetically by name.	

Note:

Some of the parameters discussed above are not visible in the contact pair candidates table by default. Click mouse button 3 anywhere in the table, and select **Edit Visible Columns** to control which parameters appear in the table.

For more information about interaction and constraint parameters, see *Mesh Tie Constraints*, *About Contact Pairs in Abaqus/Standard*, and *About Contact Pairs in Abaqus/Explicit*.

Tips for using the contact detection tool

The contact detection tool is available for use in any three-dimensional model requiring the creation of contact interactions and tie constraints. It quickly and thoroughly identifies and creates interactions and ties based on minimal specifications.

The tool greatly simplifies the contact definition process in models for which a general contact definition is not applicable. Some basic guidelines ensure the most effective and efficient use of the tool.

In this section:

- *Choosing a separation tolerance and extension angle*
- *Reviewing contact pair candidates*
- *Saving the search parameters*
- *Features that may cause difficulties for the contact detection tool*
- *Limitations of the contact detection tool*

Choosing a separation tolerance and extension angle

The specified separation tolerance is the primary driver of the contact pair search algorithm. Abaqus/CAE supplies a default separation tolerance based on the relative size of the faces in your model. You may need to modify this value depending on the expected response of your model during an analysis. To effectively capture all significant contact pairs, the specified separation tolerance should be on the same order as or greater than the expected displacements or deflections in your model.

Specifying a very large separation tolerance usually captures more contact pairs then are necessary in an analysis. While extra contact pairs do not necessarily reduce the quality of a model, the extraneous definitions are difficult to manage and can degrade performance.

When selecting an angle to control the extension of surfaces, you should consider the topology and surface characteristics of the areas that are likely to come into contact. Surfaces should extend slightly beyond the area of potential contact, so set the extension angle to capture any chamfers or soft corners along the edges of a face. Indentations, grooves, or embossments can sometimes break up the definition of a surface; the angle that these features make with the main face should dictate the extension angle.

For meshed models, you can preview the extension of surfaces before searching for contact pairs by displaying only the feature edges on a model (see *Defining mesh feature edges*). If the extension angle is equal to the feature angle, the surface definition in a particular area extends as far as the nearest visible feature edge. Adjust the feature angle until the visible edges enclose the area you want to capture, then set the extension angle accordingly.

Reviewing contact pair candidates

You should always review contact pair candidates before creating interactions and constraints. Look for any discontinuities in surface definitions.

Discontinuities are often caused by small connecting faces that are not intuitively opposed to the logical contacting surface in a contact pair (see *Figure 1*).

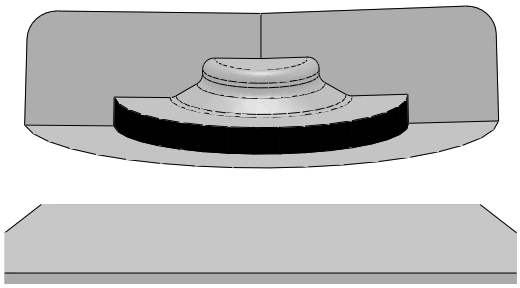

Figure 1: The automatic contact detection tool will not identify the highlighted perpendicular face.

You may want to rerun the search using revised extension and merge options to incorporate the discontinuities into larger surfaces. If necessary, add a contact pair manually using the **Add** option. You can also combine discontinuous surfaces using the **Merge** option.

You should investigate any intersecting surfaces to verify that they match your modeling intent. A contact pair with only a single overclosed node will be reported as intersecting, so slight discrepancies can cause overclosures. Overclosed contact pairs without appropriate adjustment or interference fit options can lead to convergence difficulties in an analysis. You should also check any faces or surfaces adjacent to overclosed contact pairs to ensure they are not enclosed faces. See *Detection of overclosed surfaces*, for more information.

Saving the search parameters

By default, the search parameters that you specify in the **Find Contact Pairs** dialog box persist only as long as the dialog box is open; if you close the dialog box, default search parameters are provided the next time you access the contact detection tool.

If you click  on the **Advanced** tabbed page, Abaqus/CAE sets the currently specified search parameters as the default search parameters. These parameters are supplied as defaults in all future sessions of Abaqus/CAE. The only parameter that is not saved is the search domain, which always uses a default of **Whole model**.

When you save the current search parameters, Abaqus/CAE asks if you want to save the current separation tolerance as a default. Normally Abaqus/CAE recalculates the default separation tolerance based on the current model; if you opt to save the separation tolerance, this calculation is skipped and the same value is always provided as the default separation tolerance.

The default search parameters for the contact detection tool are saved in the `abaqus_2026.gpr` file; see *Understanding Abaqus/CAE GUI settings*, for more information. To return the default search parameters to their original settings, click  on the **Advanced** tabbed page.

Features that may cause difficulties for the contact detection tool

You may encounter difficulties using the contact detection tool with certain model features and designs. These situations do not cause performance or stability problems, but the search results most often will not match your modeling intent.

Stacked shells and thin layers

Models with layers of shells or thin plates stacked closely in parallel can lead to the definition of extraneous contact pairs. The automatic contact detection tool can find contact pairs involving surfaces separated by an intermediate layer, as long as these surfaces are intuitively opposed and within the separation tolerance. In addition, if searching within the same instance is enabled and the overlapping surface check is disabled, the contact detection tool may detect potential contact between the top side and bottom side of a thin continuum plate. Abaqus/CAE creates contact pair candidates for all of these surfaces, even though they will never be in contact. This problem is most common when the layers or plates are a local feature of the model, since a larger separation tolerance is required to capture surfaces in other areas of the model. To overcome this problem, limit the search domain to a particular area of the model and use a separation tolerance that is appropriate for that area. You may also be able to use the **Entities** tabbed page of the contact detection dialog box to eliminate certain geometry or element types (shells, for example) from your search domain. Otherwise, you should delete the extraneous contact pair candidates before creating interactions.

Concave surfaces

While the contact search algorithm effectively accounts for most appropriate surfaces, it can misinterpret the relationship between a concave surface and a flat surface. Concave surfaces create difficulties because their surface normal orientation can vary widely across the span of a single surface, and the points of closest approach between surfaces is sometimes a poor reference. Consider, for example, the situations in *Figure 1*.

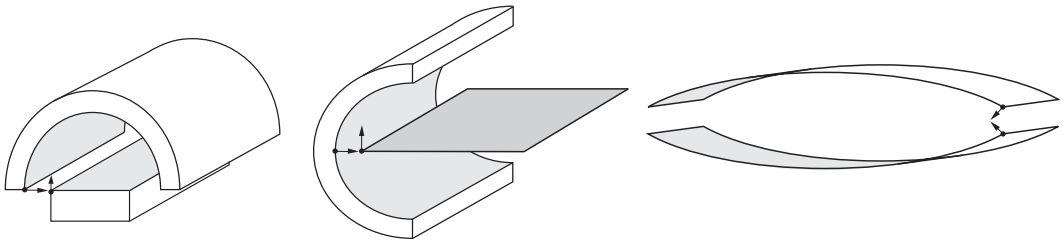

Figure 1: The normals of the shaded surfaces are not intuitively opposed at the points of closest approach.

Even if the points of closest approach in these models are within the separation tolerance, the surface normals at these points do not pass the orientation test. The contact detection tool will not report these surfaces as contact pair candidates, and adjusting the separation tolerance has no effect on this behavior. You can sometimes modify the extension angle to capture the concave surface within another surface definition. Otherwise, you must manually define the contact pair using the **Add** option.

Mechanisms involving large rotations

When modeling mechanisms that undergo large rotations, the contact detection tool often will not effectively capture your modeling intent. In such mechanisms the intended contact surfaces initially may be positioned far away from each other, while nearby surfaces never actually come into contact. The Geneva mechanism depicted in *Figure 2* is a typical example.

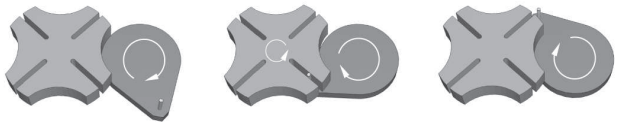

Figure 2: Motion of a Geneva mechanism.

The important contact surfaces in this model are the pin on the right-hand body and the slots on the left-hand body. In the initial configuration, the pin is relatively distant from any of the slots. The neighboring surfaces, on the other hand, are insignificant to the contact conditions of the model. Contact for such models is best defined manually using the interaction editor (see *Defining surface-to-surface contact*).

Limitations of the contact detection tool

Although helpful for simplifying the contact definition process, several limitations exist for the contact detection tool.

Contact detection cannot create contact pairs involving the following features:

- Two-dimensional models
- Axisymmetric models
- Beams and trusses
- Face-to-edge contact
- Edge-to-edge contact
- Contact between orphan mesh elements and analytical rigid surfaces
- Hybrid models containing both orphan mesh and unmeshed geometry

The minimum allowable separation tolerance is 1×10^{-5}. The maximum allowable separation tolerance is 1×10^{5}. Abaqus/CAE cannot accurately calculate separations outside of this range. If your model requires the use of a separation tolerance that does not meet these requirements, you should scale the dimensions of the entire model so that they fall within the functional range.

Understanding connectors

Connectors allow you to model a connection between two points in an assembly or between a point in an assembly and ground. To model a connector in Abaqus/CAE, you must create an assembly-level wire feature, a connector section, and a connector section assignment that associates the connector section with selected wires.

The wire feature contains one or more wires that define the underlying connector geometry. The connector section specifies the type of connection, connector behaviors, and section data. Similar to the manner in which you assign a section to a region of the model in the Property module, you create a connector section assignment to assign a connector section to a region of the model; specifically, you assign a connector section to wires. You also specify local orientations for the endpoints of the wires in the connector section assignment definition.

For more information on connectors in Abaqus/CAE, including an overview and an example of connector modeling, see *Connectors*.

Additional information

- *About Connectors*
- *Creating or modifying wire features for multiple connectors*
- *Creating connector sections*
- *Creating and modifying connector section assignments*

Understanding connector sections and functions

The connector section defines the connection type and may include connector behavior and section data. For some complex coupled connector behaviors, additional functions describing the nature of the coupling effects (connector derived components and connector potential) must be defined. A connector section can be referred to by one or more different connector section assignments.

In this section:

- *Connection types*
- *Connector behaviors*
- *What types of friction models are available?*
- *Connector derived components and connector potentials*

Connection types

Table 1 summarizes the connection types available when creating connector sections. You can define basic, assembled, complex, and MPC connection types.

Table 1: Connection types.

Basic Types		Assembled/Complex Types	MPC Types
Translational	**Rotational**		
ACCELEROMETER	*ALIGN*	*BEAM*	*Beam*
AXIAL	*CARDAN*	*BUSHING*	*Elbow*
CARTESIAN	*CONSTANT VELOCITY*	*CVJOINT*	*Link*
JOIN	*EULER*	*CYLINDRICAL*	*Pin*
LINK	*FLEXION-TORSION*	*HINGE*	*Tie*
PROJECTION CARTESIAN	*FLOW-CONVERTER*	*PLANAR*	*User-defined*
RADIAL-THRUST	*PROJECTION FLEXION-TORSION*	*RETRACTOR*	
SLIDE-PLANE	*REVOLUTE*	*SLIPRING*	
SLOT	*ROTATION*	*TRANSLATOR*	
	ROTATION-ACCELEROMETER	*UJOINT*	
	UNIVERSAL	*WELD*	

Basic types

Basic connection types include translational types and rotational types. Translational types affect translational degrees of freedom at both endpoints of the wires to which the connector section is assigned and may affect rotational degrees of freedom at the first points of the wires. Rotational types affect only rotational degrees of freedom at both endpoints of the wires. You can use a single basic connection type (translational or rotational) or one translational and one rotational type.

Assembled types

Assembled connection types are predefined combinations of basic connection types.

Complex types

Complex connection types affect a combination of degrees of freedom in the connection and cannot be combined with other connection types. They typically model highly coupled physical connections.

MPC types

MPC connection types are used to define multi-point constraints between two points.

For a description of each connection type and the equivalent basic connection types that define the kinematic constraints of assembled type connections, see *Connection Types* and *General Multi-Point Constraints*.

Connector behaviors

You can apply connector behaviors to connection types that have available components of relative motion. Available components of relative motion are displacements and rotations that are not kinematically constrained. Multiple connector behaviors can be defined in a connector section. You can specify the following connector behaviors:

- ***Elasticity***: Define spring-like elastic behavior.
- ***Damping***: Define dashpot-like damping behavior.
- ***Friction***: Define Coulomb-like and hysteretic friction using predefined or user-defined friction models.
- ***Plasticity***: Define plastic behavior.
- ***Damage***: Define damage initiation and evolution behavior.
- ***Stop***: Define limit values of the admissible range of positions.
- ***Lock***: Specify a user-defined locking criterion.
- ***Failure***: Define limit values for force, moment, or position.
- ***Reference Length***: Define the translational or angular positions at which constitutive forces and moments are zero.
- ***Integration***: Specify implicit or explicit time integration for elasticity, damping, and friction (Abaqus/Explicit analyses only).

For detailed instructions on defining connector behaviors, see *Using the connector section editors*. For more information on connector behaviors, see *Connector Behavior*.

What types of friction models are available?

You can model predefined or user-defined friction behavior. In general, for predefined friction you specify a set of geometric quantities that are characteristic of the connection type for which friction is modeled. In addition, you can define internal contact force contributions, such as prestress from the connection. Abaqus automatically defines the contact force contributions and the local tangent directions along which friction occurs.

You can model predefined friction for the following connection types:

Assembled/Complex types

- Cylindrical (Slot + Revolute)
- Hinge (Join + Revolute)
- Planar (Slide-Plane + Revolute)
- Slip Ring (complex)
- Translator (Slot + Align)
- U Joint (Join + Universal)

Basic types

- Slide-Plane
- Slot

Predefined friction is also available if you define a combined translational and rotational connection type that is equivalent to one of these assembled types. You can define only one friction behavior for a given connection type if you are modeling predefined friction.

If a predefined friction model is not available or does not adequately describe the mechanism being analyzed, you can specify a user-defined friction model (except in the case of the **Slip Ring** connection type, which does not allow a user-defined friction model). You must specify slip direction information, the friction-producing normal force or normal moment, and the friction law. You may use several connector friction behaviors to represent the frictional effects in the connector.

For detailed instructions on defining friction, see *Defining friction*. For more information, see *Connector Friction Behavior*.

Connector derived components and connector potentials

You can define complex coupled behavior for connectors using connector derived components and connector potentials. Connector derived components are user-specified component definitions based on a function of intrinsic connector components of relative motion. You can create derived components to specify the friction-generating normal force in connectors as a complex combination of connector forces and moments or to use as an intermediate result in a connector potential function.

Connector potentials are user-defined mathematical functions of intrinsic components of relative motion or derived components. These functions can be quadratic, elliptical, or maximum norms. You use connector potentials to define coupled friction, plasticity, and damage connector behaviors.

For detailed instructions on defining derived components and potentials, see *Specifying connector derived components*, and *Specifying potential terms*. For more information on connector functions, see *Connector Functions for Coupled Behavior*.

Understanding Interaction module managers and editors

You can create and manage objects in the Interaction module using managers and editors.

In this section:

- *Managing objects in the Interaction module*
- *Interaction editors*
- *Interaction property editors*
- *Contact controls editors*
- *Contact initialization editor*
- *Constraint editors*
- *Connector section editors*
- *Connector section assignment editors*

Managing objects in the Interaction module

The Interaction module provides the following managers that you can use to organize and manipulate objects associated with a given model:

- The **Interaction Manager** allows you to create and manage interactions.
- The **Interaction Property Manager** allows you to create and manage interaction properties.
- The **Contact Controls Manager** allows you to create and manage contact controls for surface-to-surface contact and self-contact interactions.
- The **Contact Initialization Manager** allows you to create and manage contact initialization rules for general contact interactions in Abaqus/Standard.
- The **Constraint Manager** allows you to create and manage constraints.
- The **Connector Section Manager** allows you to create and manage connector sections.
- The **Connector Section Assignment Manager** allows you to create and manage connector section assignments.

For example, a list of interaction properties appears in the **Interaction Property Manager** shown in *Figure 1*.

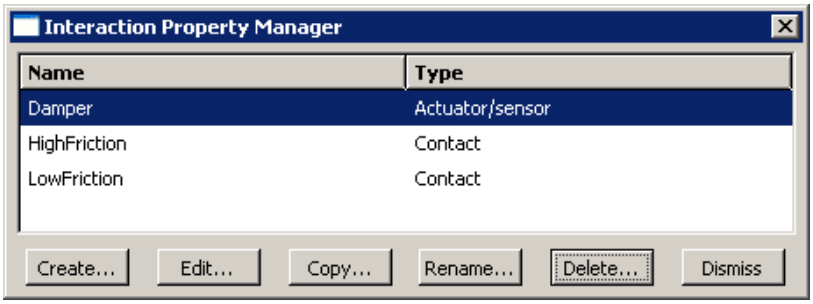

Figure 1: The Interaction Property Manager.

The **Create**, **Edit**, **Copy**, **Rename**, and **Delete** buttons in the managers allow you to create new objects or to edit, copy, rename, and delete existing ones. In the **Connector Section Assignment Manager**, you can only create, edit, or delete connector section assignments. You can also initiate these procedures using the **Interaction**, **Interaction->Property**, **Interaction->Contact Controls**, **Interaction->Contact Initialization**, **Constraint**, **Connector->Section**, and **Connector->Assignment** menus from the main menu bar. After you select a management operation from the main menu bar, the procedure is exactly the same as if you had clicked the corresponding button inside the manager dialog box.

You can use the **Copy** button in the **Interaction Manager**, the corresponding menu command, or the Model Tree to copy an interaction. You can copy an interaction from any step to any valid step, with some restrictions. For more details, see *Copying step-dependent objects using manager dialog boxes*.

The **Interaction Manager** is a step-dependent manager, which means that it contains additional information on the history of each interaction through the analysis. The **Interaction Manager** is shown in *Figure 2*.

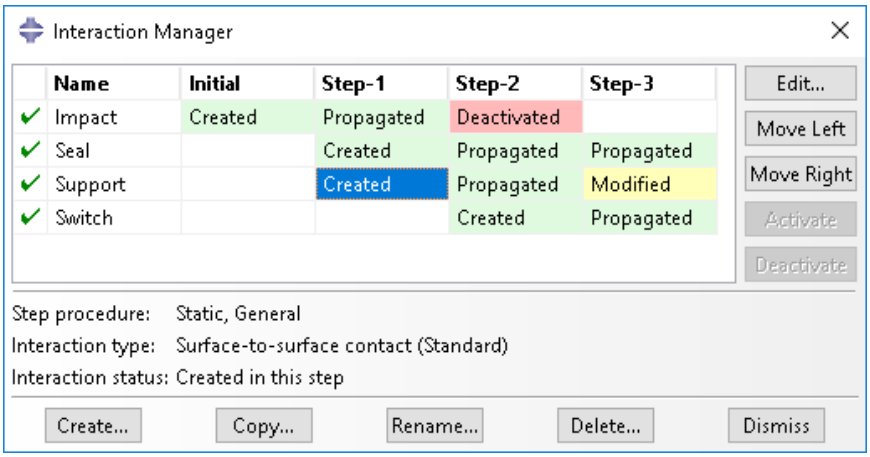

Figure 2: The Interaction Manager.

The **Move Left**, **Move Right**, **Activate**, and **Deactivate** buttons allow you to manipulate the stepwise history of interactions. For more information, see *Modifying the history of a step-dependent object*.

You can suppress and resume previously defined interactions, constraints, and connector section assignments from the managers. You can use the icons in the column along the left side of the manager to suppress these attributes or to resume previously suppressed attributes for an analysis. The suppress and resume procedures are also available from the **Interaction**, **Constraint**, and **Connector** menus in the main menu bar. For more information, see *Suppressing and resuming objects*.

For detailed instructions on creating interactions, interaction properties, constraints, connector sections, and connector section assignments, see *Using the Interaction module*.

- *What are step-dependent managers?*
- *Changing the status of an object in a step*
- *Understanding Interaction module managers and editors*

Interaction editors

To create interactions, select **Interaction->Create** from the main menu bar. A **Create Interaction** dialog box appears in which you can provide a name for the interaction, select the step in which the interaction will be created, and choose the type of the interaction.

When you click **Continue** in the **Create Interaction** dialog box after selecting any interaction type except general contact, you are prompted to select the regions to which to apply the interaction. Once you have selected the region or regions, an interaction editor appears in which you can specify additional information about the interaction, such as the interaction property that you want to associate with the interaction. For general contact interactions, the interaction editor appears when you click **Continue** in the **Create Interaction** dialog box. For example, the general contact editor for Abaqus/Explicit analyses is shown in *Figure 1*.

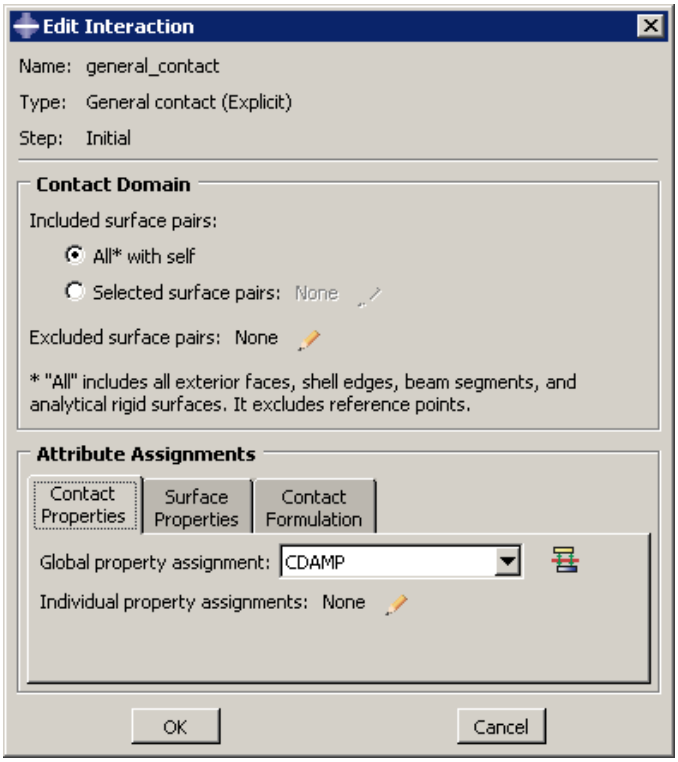

Figure 1: The general contact editor.

Each interaction editor displays the current step and the name and type of the interaction that you are defining in the top panel of the dialog box. The format of the rest of the editor varies depending on the type of interaction you are defining.

Once you have created an interaction, you can modify the interaction in the following ways:

- You can modify some or all of the data that you entered in the editor when you created the interaction.
- You can use the **Interaction Manager** to modify the stepwise history of the interaction. (For more information, see *What are step-dependent managers?*.)

You can display information on a particular editor feature by selecting **Help->On Context** from the main menu bar and then clicking the editor feature of interest.

Additional information

• *Understanding modified step-dependent objects*

- *Understanding Interaction module managers and editors*

Interaction property editors

To create interaction properties, select **Interaction->Property->Create** from the main menu bar. A **Create Interaction Property** dialog box appears in which you can specify a name for the interaction property and the type of interaction property that you want to create. Once you have specified this information, click **Continue** in the **Create Interaction Property** dialog box to display the interaction property editor.

The format of the interaction property editor depends on the type of interaction property you are defining. For example, the film condition and actuator/sensor property editors display data fields in which you can enter all of the information necessary to define the property. The film condition property editor is shown in *Figure 1*.

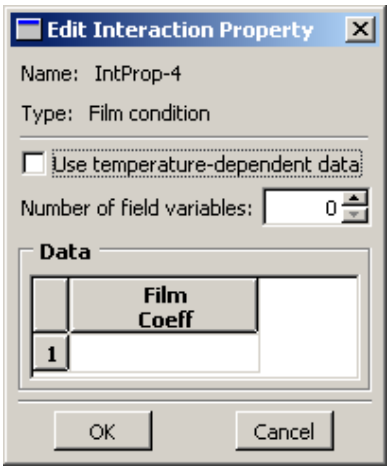

Figure 1: The film condition property editor.

The format of the contact property editor, on the other hand, is identical to the material editor in the Property module (see *Creating materials*, for more information). Like the material editor, the contact property editor contains menus from which you select options to include in the property definition, as shown in *Figure 2*.

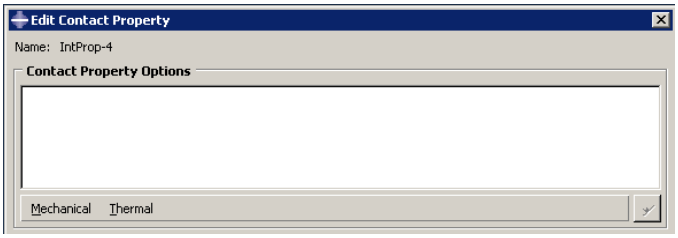

Figure 2: The contact property editor contains Mechanical and Thermal option menus.

When you select an option from a menu, the name of the option appears in the **Contact Property Options** list at the top of the editor, and the option becomes part of your interaction property definition. In addition, the option definition area in the lower half of the editor changes to provide fields in which you can specify information for the currently selected option.

For example, the **Contact Property Options** list in *Figure 3* reflects that the **Tangential Behavior** and **Normal Behavior** options (located in the **Mechanical** menu) have been included in the property definition. **Tangential Behavior** is currently selected, and the related parameters appear in the lower half of the editor. If you want to remove an option from a contact property definition, you can select that option from the **Contact Property Options** list and then click

.

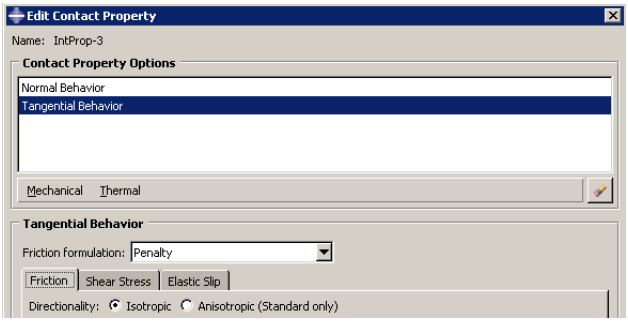

Figure 3: A mechanical contact property definition that includes the Tangential Behavior and Normal Behavior options.

You can display help on a particular feature of the editor by selecting **Help->On Context** from the main menu bar and then clicking the feature of interest. For detailed instructions on creating properties, see *Creating interaction properties*, and *Using the interaction property editors*.

Additional information

- *Managing objects*
- *Understanding modified step-dependent objects*

Contact controls editors

To create contact controls for surface-to-surface contact and self-contact interactions, select **Interaction->Contact Controls->Create** from the main menu bar. A **Create Contact Controls** dialog box appears in which you can specify a name for the contact controls and the type of contact controls that you want to create. Once you have specified this information, click **Continue** to display the contact controls editor.

Warning:

Contact controls are intended for advanced users. The default settings of these controls are appropriate for most analyses. Using nondefault values of these controls may greatly increase the computational time of the analysis or produce inaccurate results. Changing these settings in an Abaqus/Standard analysis may also cause convergence problems.

Each contact controls editor displays the name and type of the contact controls that you are defining in the top panel of the dialog box. The format of the rest of the editor varies depending on whether you are defining controls for an Abaqus/Standard or an Abaqus/Explicit analysis.

You can display help on a particular feature of the editor by selecting **Help->On Context** from the main menu bar and then clicking the feature of interest. For more information, see *Specifying contact controls in an Abaqus/Standard analysis*, and *Specifying contact controls in an Abaqus/Explicit analysis*.

Additional information

- *Customizing contact controls*

Contact initialization editor

To create contact initialization rules for a general contact interaction in Abaqus/Standard, select **Interaction->Contact Initialization->Create** from the main menu bar. The contact initialization editor appears in which you can specify a name for the initialization definition and the rules associated with that definition.

You can display help on the contact initialization editor by selecting **Help->On Context** from the main menu bar and then clicking the editor. For more information, see *Creating contact initializations*.

Additional information

• *Creating contact initializations*

Constraint editors

To create constraints, select **Constraint->Create** from the main menu bar. A **Create Constraint** dialog box appears in which you can specify the name and type of the constraint. Click **Continue** to specify the regions to which to apply the constraint (if applicable) and to display the editor in which you can enter the data necessary to define the constraint.

Each constraint editor displays the name and type of the constraint you are defining in the top panel of the dialog box. The format of the rest of the editor varies depending on the type of constraint you are defining. For example, the tie constraint editor is shown in *Figure 1*.

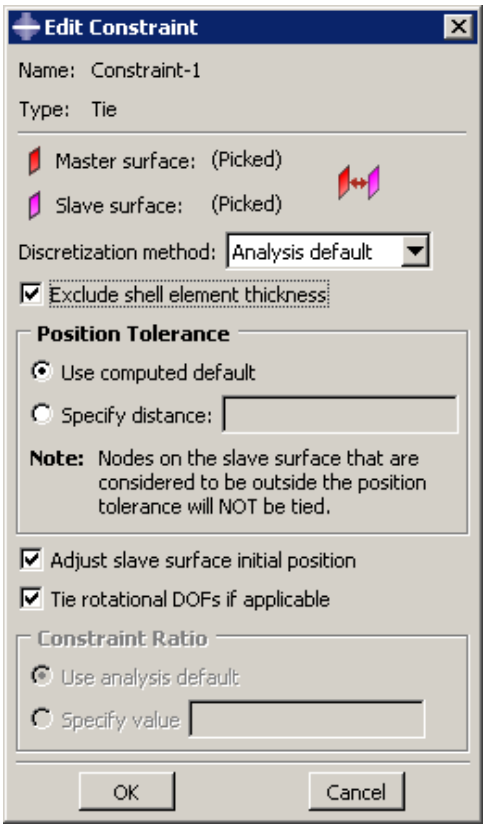

Figure 1: The tie constraint editor.

You can display information on a particular editor feature by selecting **Help->On Context** from the main menu bar and then clicking the editor feature of interest. For detailed instructions on creating constraints, see *Using the constraint editors*.

Additional information

- *Creating constraints*

Connector section editors

The connector section editor allows you to create connector sections and to add the connector behaviors available in Abaqus/Standard and Abaqus/Explicit.

To create connector sections, select **Connector->Section->Create** from the main menu bar. A **Create Connector Section** dialog box appears in which you can specify a name, category, and type for the connector section that you want to create. When you select a connection type from the **Assembled/Complex** or **Basic** category, the available and constrained components of relative motion (CORM) for that connection type are displayed in the dialog box. In addition, you can click  to see a schematic drawing of the connection type along with the Abaqus idealization of the connection. Once you have specified the name, category, and type, click **Continue** in the **Create Connector Section** dialog box to display the connector section editor. For a connection type in the **MPC** category, select the type and enter data, if required. Click **OK** to finish creating the **MPC** section and to close the **Create Connector Section** dialog box.

The connector section editor allows you to add the connector behaviors available in Abaqus/Standard and Abaqus/Explicit. When you click **Add** on the **Behavior Options** tabbed page, a list of behaviors appears. After you select a behavior, the name of the behavior appears in the **Behavior Options** list at the top of the editor, and the behavior becomes part of your connector section definition. The option definition area in the lower half of the editor changes to provide fields in which you can specify information for the currently selected behavior. If you want to remove a behavior from a connector section definition, you can select it from the **Behavior Options** list and then click **Delete**.

Note:

Abaqus/CAE does not perform any checks for dependencies on other behaviors; you should ensure that all required behaviors are defined. For example, if you define a plasticity behavior, you must also define an elasticity behavior.

You can define multiple behaviors of the same type, such as elasticity. Only forces or moments that are consistent with the available components of relative motion for the chosen connection type can be selected to define behaviors. For example, the **Behavior Options** list in *Figure 1* reflects that two **Elasticity** behaviors and a **Reference Length** behavior have been included in the connector section definition. The highlighted **Elasticity** behavior defines elastic behavior in the same direction as the selected moment.

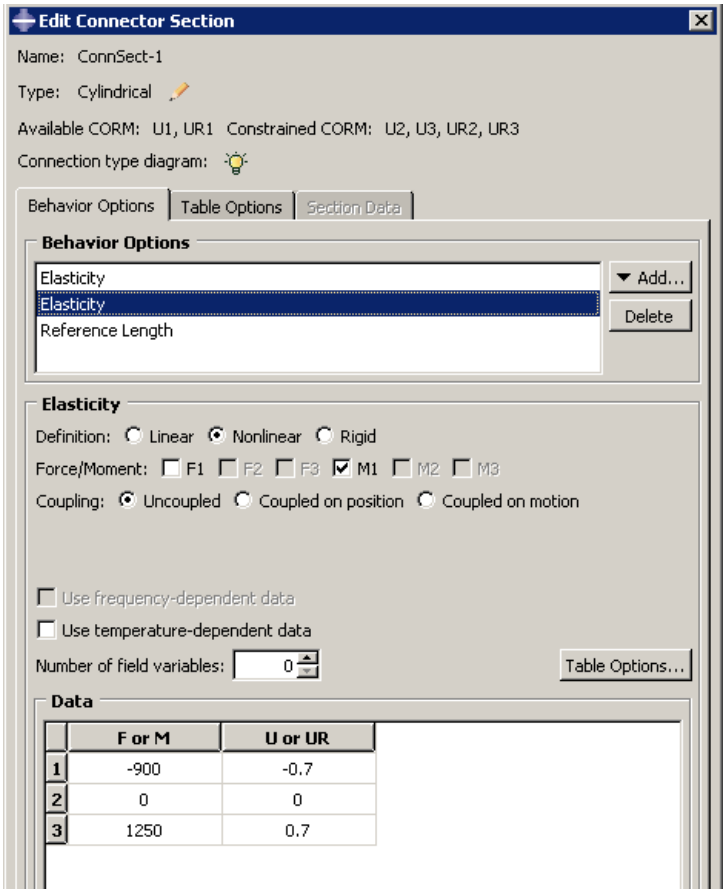

Figure 1: The connector section editor.

On the **Table Options** tabbed page, you can specify behavior settings for the regularization (Abaqus/Explicit analyses only) and the extrapolation of tabular data for all of the behavior options in a connector section. Alternatively, you can specify behavior settings for individual behavior options by clicking the **Table Options** button in the option definition area in the lower half of the editor. Behavior settings for individual behavior options take precedence over the connector section behavior settings.

When section data are applicable for the specified connection type, you can enter the data on the **Section Data** tabbed page.

You can display help on a particular feature of the editor by selecting **Help->On Context** from the main menu bar and then clicking the feature of interest. For detailed instructions on creating connector sections and defining behaviors and section data, see *Creating connector sections*, and *Using the connector section editors*.

Additional information

- *Creating connector sections*
- *Using the connector section editors*
- *Connectors*

Connector section assignment editors

To create connector section assignments, select **Connector->Assignment->Create** from the main menu bar. Select the wires to which you want to assign the connector section.

The connector section assignment editor contains three tabbed pages that allow you to specify the connector section that you want to assign to the wires and the orientations of the endpoints of the wires. For example, the connector section assignment editor that assigns the connector section `Shock_Absorber` to selected wires is shown in *Figure 1*.

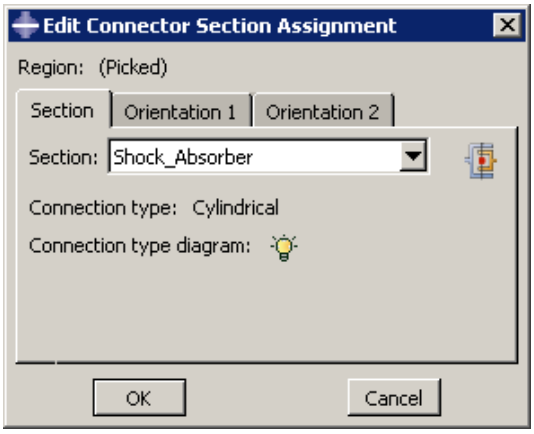

Figure 1: The connector section assignment editor.

You can display information on a particular editor feature by selecting **Help->On Context** from the main menu bar and then clicking the editor feature of interest. For detailed instructions on creating connector section assignments, see *Creating and modifying connector section assignments*.

Additional information

- *Creating or modifying wire features for multiple connectors*
- *Creating connector sections*
- *Creating and modifying connector section assignments*
- *Connectors*

Understanding symbols that represent interactions, constraints, and connectors

When you apply interactions, constraints, and connectors to regions of the model, you can choose to display symbols in the viewport that indicate where you have applied the interactions, constraints, and connectors. For information about graphical symbol types, see *Symbols used to represent interactions, constraints, and connectors*.

You can apply interactions, constraints, and connectors to geometry or to orphan nodes and elements.

Interactions and constraints

If you apply an interaction or constraint to geometry, symbols appear approximately equally spaced over the surface or surfaces to which the interaction or constraint is applied. If the interaction or constraint definition involves a node region rather than a surface, the symbols appear equally spaced on the edges of the node region and at any vertices in the node region. If the interaction or constraint is applied to a single vertex, a symbol appears at that vertex.

If you apply the interaction or constraint to orphan nodes or elements, symbols appear at the center of each element face for surface-based regions or at the nodes for node-based regions.

For interactions (and prescribed conditions) that use analytical field distributions, the symbols are scaled based on the analytical field value. In addition, a plus sign (+) or a minus sign (−) is displayed inside each symbol to indicate whether the magnitude of the interaction is positive or negative at that location. Abaqus/CAE displays scaled-down symbols for interactions when an analytical field evaluates to zero for a portion of its region. These scaled-down symbols are noticeably smaller than the default symbol size. For examples of these symbols, see *Understanding prescribed condition symbol type, color, and size*. For more information, see *Using analytical expression fields*.

Connectors

When you apply a connector to wires, squares appear at the first points of the wires and triangles appear at the second points of the wires. If you specify an orientation other than the global coordinate system for orientation 1, an orientation triad appears at the first points of the wires. For orientation 2, an orientation triad appears at the second points of the wires only if you specify a coordinate system by name; if you toggle on the option to **Use orientation 1**, the orientation triad does not appear at the second points. The connection type label appears midway along a line between the endpoints of the selected wires. You can also display the tag associated with the connector section assignment, though this display is turned off by default.

For information about controlling the visibility of these symbols, see *Controlling the display of attributes*.

Using the Interaction module toolbox

You can access all the Interaction module tools through either the main menu bar or the Interaction module toolbox. *Figure 1* shows the icons for all the tools in the Interaction module toolbox.

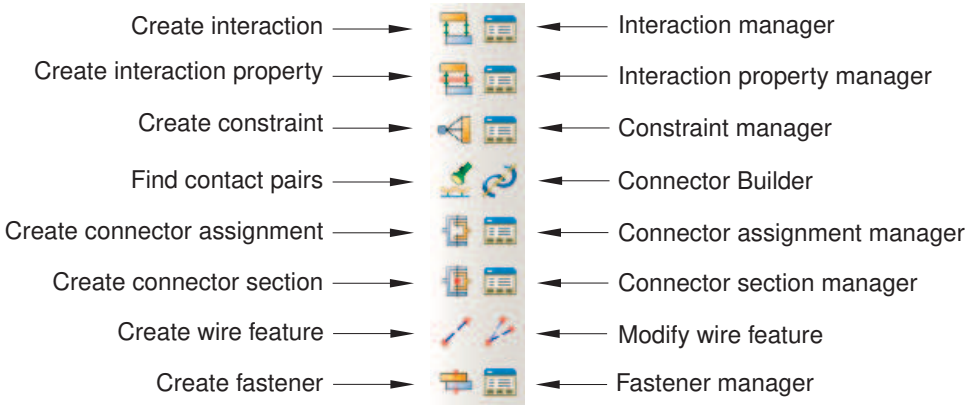

Figure 1: The Interaction module toolbox.

Using the Interaction module

This section describes in detail how to use different features of the Interaction module.

See also *What are step-dependent managers?* for information on managing interactions.

In this section:

- *Creating and modifying connector section assignments*
- *Editing the region to which an interaction or constraint is applied*
- *Using the Special menu in the Interaction module*

Creating interactions

When you create an interaction, you must specify the name of the interaction, the step in which to activate the interaction, the type of interaction, and, if required, the region of the assembly to which you want to apply the interaction.

The available types of interactions depend on the procedure selected for the step. For example, you can define heat flux on a surface only during a heat transfer, coupled temperature-displacement, or coupled thermal-electrical step. Similarly, you can define interactions with a user-defined actuator/sensor only during the initial step.

If you are creating surface-to-surface contact interactions, you can automate many of the steps in the below procedure by using the contact detection tool. For more information, see *Using contact and constraint detection*.

1. From the main menu bar, select **Interaction->Create**.

   A **Create Interaction** dialog box appears with a default name displayed in the **Name** text field.

    **Tip:** You can also create an interaction using the  tool in the Interaction module toolbox.

2. Type a name for the interaction. For more information about naming objects, see *Using basic dialog box components*.
3. Select the step in which to activate the interaction. Click the arrow next to the **Step** text field, and select from the list that appears.

   The **Types for Selected Steps** list changes to a list of all of the available interaction types.
4. From the **Types for Selected Steps** list, select the interaction type, and click **Continue**.
5. If required, select the region to which you want to apply the interaction using one of the following methods:

   - Select a region in the viewport. You can use the angle method to select a group of faces or edges from geometry or a group of element faces. For more information, see *Using the angle and feature edge method to select multiple objects*. When you have finished selecting, click mouse button 2.

      **Tip:** You can limit the types of objects that you can select in the viewport by specifying filtering options in the Selection toolbar. See *Using the selection options*, for more information.

     If the model contains a combination of mesh and geometry, click one of the following from the prompt area:

     - Click **Geometry** to apply the interaction to a geometry region or to a reference point.
     - Click **Mesh** to apply the interaction to a native or orphan mesh selection.

     By default, for most interactions a set or surface is created that contains the selected objects. You can change this behavior by toggling off the option to create a set or surface in the prompt area. A default name is provided in the prompt area, but you can enter a new name.

   - To select from a list of existing sets or surfaces, do the following:

     1. Click **Sets** or **Surfaces** on the right side of the prompt area. (The name of the button depends on the type of object you are creating. For example, if you are creating a surface-to-surface contact interaction, a **Surfaces** button appears.)

        Abaqus/CAE displays the **Region Selection** dialog box containing a list of available sets or surfaces.
     2. Select the set or surface of interest, and click **Continue**.

Note:

The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** or **Surfaces** on the right side of the prompt area.

The interaction editor appears. The region to which you are applying the interaction is highlighted in the viewport.

6. Enter all of the data necessary to define the interaction, and click **OK**. For detailed information on a particular feature of the editor, select **Help->On Context** from the main menu bar and then click the feature of interest or see *Using the interaction editors*.

   Symbols appear in the viewport that represent the interaction that you just created. For more information, see *Understanding symbols that represent interactions, constraints, and connectors*.

Additional information

- *Understanding and using toolboxes and toolbars*
- *What are step-dependent managers?*
- *Selecting objects within the viewport*
- *Using the interaction editors*

Creating interaction properties

You can create an interaction property by entering data in an interaction property editor. The format of the editor varies according to the type of property you are defining; when you create a property, you must first specify the property type so that the appropriate editor appears.

1. From the main menu bar, select **Interaction->Property->Create**.

   Tip: You can also create an interaction property using the  tool in the Interaction module toolbox.

   A **Create Interaction Property** dialog box appears.

2. Enter a property name. For more information about naming objects, see *Using basic dialog box components*.
3. Select the property type, and click **Continue**.

   The editor for the property type you have specified appears.
4. In the editor, enter all of the data necessary to define the interaction property.

   Note:

   You can display help on a particular editor feature by selecting **Help->On Context** from the main menu bar and then clicking the editor feature of interest.
5. Click **OK** to save the data and to exit the editor.

Additional information

- *Understanding interaction properties*
- *Interaction property editors*
- *Using the interaction property editors*

Customizing contact controls

The contact controls editors allow you to modify the algorithms used to enforce contact conditions. The default contact controls are usually sufficient, but customizing these controls may result in a more cost-effective solution.

Warning:

Contact controls are intended for advanced users. The default settings of these controls are appropriate for most analyses. Using nondefault values of these controls may greatly increase the computational time of the analysis or produce inaccurate results. Changing these settings in an Abaqus/Standard analysis may also cause convergence problems.

1. From the main menu bar, select **Interaction->Contact Controls->Create**.
2. In the **Create Contact Controls** dialog box that appears, do the following:
   - Name the contact controls.
   - Select **Abaqus/Standard contact controls** or **Abaqus/Explicit contact controls**.
3. Click **Continue**.

   The editor for the type of contact controls that you specified appears.
4. In the editor, enter the data necessary to customize the contact controls. For detailed instructions, see the following sections:
   - *Specifying contact controls in an Abaqus/Standard analysis*
   - *Specifying contact controls in an Abaqus/Explicit analysis*
5. If you want to reset the values in the editor to the default values, click **Defaults** at the bottom of the editor.
6. Click **OK** to save your customized settings and to exit the editor.

Creating contact initializations

By default, Abaqus adjusts the position of slightly overclosed surfaces in a general contact domain as discussed in *Contact Initialization for General Contact in Abaqus/Standard* and *Contact Initialization for General Contact in Abaqus/Explicit*. Contact initializations are used to modify the default behavior for contact surface adjustments. Each contact initialization definition contains a set of adjustment rules; the general contact definition specifies the surfaces to which each initialization definition is applied (see *Specifying and modifying contact initialization assignments for general contact*).

Contact initializations are intended to correct small gaps or overclosures between surfaces. Specifying large initialization adjustments can lead to mesh distortion and increased computational cost for an analysis.

1. From the main menu bar, select **Interaction->Contact Initialization->Create**.

   The **Create Contact Initialization** dialog box appears.

2. Enter a **Name** for the contact initialization definition, and select a **Type** for the contact initialization.

   The **Edit Contact Initializations** dialog box appears.

3. You can specify the following techniques for treating **Initial Overclosures** between two surfaces:

   - Select **Resolve with strain-free adjustments** to adjust certain surfaces to be exactly touching at the beginning of the analysis without creating strain in the model. Only portions of surfaces that lie within the specified distance range are adjusted.
   - Select **Treat as interference fits** to resolve surface overclosures gradually over the course of the first step in the analysis; this technique creates strain in the model as the surfaces are displaced. Only portions of surfaces that lie within the specified overclosure distance range are adjusted using the interference fit.

     - To establish a uniform overclosure prior to resolving the interference fit, toggle on **Specify interference distance**, and enter a value for the overclosure distance. Portions of surfaces that lie within the specified distance range (both overclosures and openings) are adjusted to be overclosed by the specified amount. The adjustments occur at the beginning of the analysis without creating strain in the model; the subsequent interference fit resolution during the first step in the analysis will create strain in the model.

   - Select **Specify clearance distance** to adjust certain surfaces to be separated by a specified value at the beginning of the analysis without creating strain in the model. Only portions of surfaces that lie within the specified distance range are adjusted.

4. Specify an overclosure distance range; nodes that are overclosed by a value less than the specified distance are adjusted using either strain-free adjustments or a gradual interference fit.

   - Select **Analysis default** to let Abaqus calculate a maximum overclosure adjustment distance based on the size of the underlying element facets on each surface.
   - Select **Specify value** to enter a maximum overclosure adjustment distance directly. If you enter a value that is smaller than the calculated analysis default for a surface, Abaqus uses the analysis default value for that surface.

   Warning:

   If two surfaces (or portions of two surfaces) are initially overclosed by a distance greater than the specified adjustment value, contact between these severely overclosed surface regions is not enforced for the duration of the analysis; see *Contact Initialization for General Contact in Abaqus/Standard*, for more information.

5. Specify an opening distance range; nodes separated from the opposing surface by a value less than the specified distance are adjusted using strain-free adjustments.
   - Select **Analysis default** to ignore all open nodes during the initialization adjustments.
   - Select **Specify value** to enter a maximum opening adjustment distance directly.
6. Specify other options.
   - Select **Adjust nodal coordinates** to resolve clearances/overclosures by adjusting the nodal coordinates without creating strain in the model. This option applies only to Abaqus/Explicit analyses and can be used only for clearances/overclosures defined in the first step of an analysis.
   - Select a **Secondary node set for clearance** to include in the initial clearance specification. The specified clearance is enforced at all secondary nodes in this node set irrespective of whether they are above or below their respective main surfaces. This option applies only to Abaqus/Explicit analyses when the clearance distance is specified. It cannot be used if either overclosure or opening distance is specified.
   - Select the **Step fraction for interference** value to define the fraction of the step time (between 0.0 and 1.0) in which the interference fit has to be solved. The default value is 1.0. This option applies only to Abaqus/Explicit analyses when the interference distance is specified.
7. If you want to reset the values in the dialog box to the default values, click **Defaults** at the bottom of the dialog box.
8. Click **OK** to save your contact initialization definition and to close the **Edit Contact Initialization** dialog box.

Additional information

• *Contact Initialization for General Contact in Abaqus/Standard*
• *Contact Initialization for General Contact in Abaqus/Explicit*
• *Defining general contact*
• *Specifying and modifying contact initialization assignments for general contact*

Creating contact stabilization definitions

Contact stabilization introduces viscous damping to oppose incremental relative motion between two surfaces. This damping can be used to stabilize unconstrained rigid body motion prior to contact closure without degrading the accuracy of results. Contact stabilization is based on a set of factors described in *Stabilization for General Contact in Abaqus/Standard*.

Each contact stabilization definition contains a set of stabilization factors; the general contact definition specifies the surfaces to which each stabilization definition is applied (see *Specifying and modifying contact stabilization assignments for general contact*).

1. From the main menu bar, select **Interaction->Contact Stabilization->Create**.

   The **Edit Contact Stabilization** dialog box appears.
2. Enter a **Name** for the contact stabilization definition.
3. Specify the stabilization type:
   - Select **Define new stabilization behavior** to define a standard stabilization.
   - Select **Reset values from previous steps** to define a special type of stabilization that cancels the effects of stabilization that was applied in previous analysis steps; the canceling stabilization must still be assigned to surfaces in the general contact definition. This type of stabilization does not require any additional data.
4. Specify a **Zero stabilization distance**; no stabilization is applied to surfaces separated by a distance greater than this value. A gap-dependent scale factor varies during the analysis between one (when the surfaces are touching) and zero (when the gap between surfaces exceeds the specified zero stabilization distance).
   - Select **Analysis default** to set the gap distance equal to a characteristic surface dimension.
   - Select **Specify** to enter the gap distance directly.
5. Specify a **Reduction factor** to determine how the damping value changes in successive increments. A value less than one causes the damping to decrease with each increment; a value greater than one (not recommended) causes the damping to increase with each increment.
6. Specify a **Scale factor** that is applied to stabilization damping effects in the normal direction.
7. Specify a **Tangential factor** that is applied to stabilization damping effects in the tangential direction.
8. If desired, select an **Amplitude** envelope to vary the stabilization over the course of the step.

   Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)

   Selecting an amplitude other than the default ramp amplitude may cause the stabilization effects to span multiple analysis steps; see *Stabilization for General Contact in Abaqus/Standard* for details.
9. If you want to reset the values in the dialog box to the default values, click **Defaults** at the bottom of the dialog box.
10. Click **OK** to save your contact stabilization definition and to close the **Edit Contact Stabilization** dialog box.

Additional information

- *Stabilization for General Contact in Abaqus/Standard*
- *Defining general contact*
- *Specifying and modifying contact stabilization assignments for general contact*

Creating constraints

You can create the following constraints:

- Tie constraints that tie two separate surfaces together so that there is no relative motion between them.
- Rigid body constraints that allow you to designate a collection of regions as a rigid body.
- Display body constraints that allow you to designate a part instance that will be used for display only.
- Coupling constraints that allow you to constrain the motion of a surface to the motion of a reference node.
- Adjust points constraints that allow you to move a point or points onto a specified surface.
- Multi-point constraints that allow you to constrain the motion of the secondary nodes of a region to the motion of a single point.
- Shell-to-solid coupling constraints that allow you to couple the motion of a shell edge to the motion of an adjacent solid face.
- Embedded region constraints that allow you to embed a region of the model within a "host" region of the model or within the whole model.
- Equation constraints that describe linear constraints between individual degrees of freedom.

1. From the main menu bar, select **Constraint->Create**.

    **Tip:** You can also create a constraint using the  tool in the Interaction module toolbox.

2. In the **Create Constraint** dialog box that appears, do the following:
   a. Name the constraint. For more information about naming objects, see *Using basic dialog box components*.
   b. Select the desired constraint type.
3. Click **Continue** to create the constraint and to close the **Create Constraint** dialog box.
4. If applicable, select the region to which to apply the constraint. For more information, see *Selecting objects within the viewport*."
5. In the editor that appears, enter any data necessary to define the constraint.

For detailed instructions on creating different types of constraints, see the following sections:

- *Defining tie constraints*
- *Defining rigid body constraints*
- *Defining display body constraints*
- *Defining coupling constraints*
- *Defining adjust points constraints*
- *Defining MPC constraints*
- *Defining shell-to-solid coupling constraints*
- *Defining embedded region constraints*
- *Defining equation constraints*

Additional information

• *Understanding and using toolboxes and toolbars*

- *Suppressing and resuming objects*
- *Selecting objects within the viewport*
- *The Set and Surface toolsets*

Selecting a process for defining connector geometry

You must create assembly-level wire features to define the underlying geometry for modeling connectors. The wire feature contains wires connecting points from the assembly in the current viewport or connecting points from the assembly to ground.

Abaqus/CAE provides two methods that you can use to create connector geometry for an assembly:

- The **Connector Builder** enables you to perform all the steps involved in modeling a connector: create a single assembly-level wire feature, optionally create reference points at its endpoints, assign it a connector section, and specify the orientations for either of its endpoints. You should use this dialog box to add a small number of wire features. See *Creating a single connector*, for instructions on using the **Connector Builder**.
- The **Create Wire Feature** dialog box enables you to create multiple wires within a single wire feature. You should use this dialog box to define a large number of similar connectors. This dialog box creates the wire feature only; you must use other dialog boxes in the Interaction module to perform the subsequent modeling steps like creating reference points and datum coordinate systems, assigning connector sections to the wires, and specifying the orientations of the wires' endpoints. See *Creating or modifying wire features for multiple connectors*, for instructions on using the **Create Wire Feature** dialog box.

Creating a single connector

The **Connector Builder** enables you to perform all of the steps involved in modeling a single connector. These steps include:

- Creating a wire feature between two points or between a point and ground.
- Creating reference points at either endpoint, and creating a datum coordinate system along the length of the wire.
- Creating a connector section assignment for the new wire feature.
- Specifying orientations for either endpoint that the wire feature connects.

Because the **Connector Builder** creates one connector at a time, you should use it to add a small number of connectors to your assembly. If you plan to define a large number of connectors, begin by adding wire features to the assembly in the **Create Wire Feature** dialog box. See *Creating or modifying wire features for multiple connectors*, for more information.

1. From the main menu bar, select **Connector->Connector Builder**.

   Tip: You can also start the **Connector Builder** using the  tool in the Interaction module toolbox.

2. Select the points that you want to connect.
   a. Select the first point and second point for the connector in the viewport.

      Note:

      You can also click **Connect to Ground** in the prompt area to ground one side of the connector. You cannot connect both points to ground.

      The **Connector Builder** opens with the points you selected in the **Endpoints** portion of the dialog box. The first point is highlighted in red and the second point is highlighted in magenta in the viewport.

   b. If desired, click  to switch the two endpoints you selected.
   c. If desired, toggle on **Create a reference point** under either point description to create a reference point at that endpoint when you save the wire feature. If the selected point is a datum point or an interesting point, Abaqus/CAE automatically creates a reference point at that location.

3. Select a connector section. If desired, click  to create a new connector section.

   The connection type is displayed in the editor. For basic, assembled, and complex connection types, you can click  to see a schematic drawing of the connection type along with the Abaqus idealization of the connection. For MPC connection types, the motion of the second point is constrained to the motion of the first point. The connection type you select also dictates the initial values selected for the connector orientations. If you change the connector section assignment, Abaqus/CAE resets these orientation settings to the default values for that connection type.

4. If desired, modify any of the following orientation settings:
   a. Project a datum coordinate system along the axis between the endpoints.

      In the **CSYS 1** portion of the dialog box, select the **Create CSYS on axis between points** option, then select **1**, **2**, or **3** as the **Axis** for the new datum coordinate system. Abaqus/CAE may select this option by default for some connection types.

b. Specify an orientation other than the global coordinate system for the first point for the connector in the **CSYS 1** portion of the dialog box. If the connector is not connected to ground and the selected connector section assignment allows you to adjust the second point in the connector, you can specify an orientation for the second point in the **CSYS 2** portion of the dialog box as well.

In either portion of the dialog box, select **Specify CSYS**, click , then use one of the following methods to select the datum coordinate system:

- Select a predefined datum coordinate system by name. Click **Datum CSYS List** from the prompt area, select a name from the list, and click **OK**.
- Select a predefined coordinate system in the viewport.
- For the second point in the connector, select **Use CSYS 1** to use the coordinate system defined for the first point at the second point in the connector as well.

The selected orientation is highlighted red in the viewport. The **Connector Builder** reappears and displays a description of the coordinate system used for the orientation for the selected point of the connector.

Tip: You can also create a new datum coordinate system to use by clicking  from the **CSYS 1** or **CSYS 2** portion of the dialog box.

c. If desired, you can specify for either endpoint an additional rotation about an axis of the datum coordinate system. Select the **Specify additional rotation** option for one of the points, enter a value for the rotation angle in degrees, and select **1**, **2**, or **3** for the **About axis** option. The **Specify additional rotation** option is available only if you specify a datum coordinate system other than the global coordinate system.

5. Click **OK** to save your connector and to close the **Connector Builder**, or click **OK/Repeat** to save the assembly-level wire, leaving the dialog box open to create a new wire.

Additional information

• *Connectors*

Creating or modifying wire features for multiple connectors

In the Interaction module, select **Connector->Geometry->Create Wire Feature** from the main menu bar to add one or more wire features. You can add disjoint wires, chained wires, or wires that are connected to ground. When you create the wire feature, you can create a geometry set that includes all of the wires in the wire feature to use during subsequent selection procedures; for example, when you select wires for the connector section assignment definition or to apply connector loads. For detailed instructions on creating assembly-level wires features, see *Adding a point-to-point wire feature*.

You can modify assembly-level wire features by selecting **Connector->Geometry->Modify Wire Feature** from the main menu bar. You select any wire from the feature that you want to modify and make changes in the **Modify Wire Feature** dialog box, as described in the procedure below. When you click **OK** in the dialog box, Abaqus/CAE does the following:

- renames and suppresses the original wire feature;
- creates a new wire feature using the same name as the original wire feature;
- renames the geometry set that had contained the original wire feature, if it existed; and
- if applicable, creates a new geometry set containing the modified wire feature.

For example, *Figure 1* shows that `Wire-1` is renamed `OldWire-1-1` and suppressed. Similarly, `Wire-1-Set-1` is renamed `OldWire-1-Set-1`.

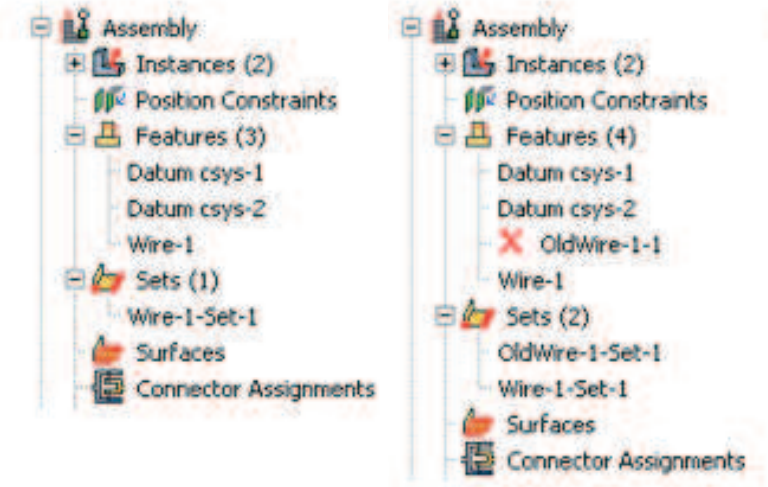

Figure 1: Model Tree showing the Features and Sets containers for the original wire feature (left) and the modified wire feature (right).

By using the default geometry set name created for a wire feature when you select wires to define connector section assignments, connector loads, and connector boundary conditions, you ensure that these objects remain valid if you modify the wire feature. Otherwise, objects that reference any part of the original wire feature are invalidated if you modify the wire feature; for example, if you define a connector force and select wires from the viewport or use a geometry set with a different name.

You can remove wires from the wire feature by selecting **Connector->Geometry->Remove Wires From Feature** from the main menu bar. The operation to remove wire edges from the feature is stored as a feature of the part; therefore, you can use the Model Tree to delete or suppress the operation.

1. From the main menu bar in the Interaction module, select **Connector->Geometry->Modify Wire Feature**.

Tip: You can also modify an assembly-level wire feature using the  tool in the Interaction module toolbox.

2. In the viewport, select any wire of the feature that you want to modify.

   The **Modify Wire Feature** dialog box appears and displays the point pairs that define the assembly-level wires in the original wire feature.

3. In the **Point Pairs** portion of the dialog box, you can do the following:

   - To add more point pairs, specify the method, click , and select the points from the viewport. The representation of the added wire is highlighted in magenta.
   - To edit a point, select the point in the table, click , and reselect a point. The selection highlighting in the viewport is updated to show the newly edited point.
   - To identify a specific point pair in the viewport, select the desired row. The line connecting the selected point pair is highlighted in red.
   - To remove a point pair, select the desired row and click .
   - To exchange the entries for **Point 1** and **Point 2** in a point pair, select the desired row and click .

4. In the **Set Creation** portion of the dialog box, toggle on **Create set of wires** if you want Abaqus/CAE to create a new geometry set of wires for the modified wire feature.
5. Click **OK** to modify the wire feature.

   The original wire feature is renamed and suppressed. The modified assembly-level wire feature appears in the Model Tree in the **Features** container under the assembly using the same name as the original wire feature.

Additional information

- *Adding a point-to-point wire feature*
- *Connectors*

Creating coincident point connectors

In the Interaction module, select **Connector->Coincident Builder** from the main menu bar to create a connector wire feature and section assignment for a group of coincident points. For detailed instructions on creating assembly-level wires features, see *Adding a point-to-point wire feature*.

1. From the main menu bar in the Interaction module, select **Connector->Coincident Builder**.
2. In the viewport, select the coincident points that you want to include in the connector wire feature, then click **Done** in the prompt area. For an overview of the methods you can use to select multiple points from the viewpoint, see *Drag-selecting multiple objects*.

   The **Coincident Point Builder** dialog box opens with the selected coincident points displayed in the **Endpoints** portion of the dialog box.
3. If desired, customize the content and order of the endpoints you want to use by doing the following:

   - Highlight the row for any coincident point, and click  to delete that coincident point pair.
   - Highlight the row for any coincident point, and click  to swap the first and second points in the coincident point pair.
4. Select a connector section. If desired, click  to create a new connector section.

   The connection type is displayed in the editor. For basic, assembled, and complex connection types, you can click  to see a schematic drawing of the connection type along with the Abaqus idealization of the connection. For MPC connection types the motion of the second point is constrained to the motion of the first point.
5. If desired, modify any of the following orientation settings:

   a. Specify an orientation other than the global coordinate system for the coincident point connector wire feature in the **CSYS 1** portion of the dialog box. If the selected connector section assignment allows you to adjust the second point in the connector, you can specify an orientation for the second point in the **CSYS 2** portion of the dialog box as well.

   In either portion of the dialog box, click , then use one of the following methods to select the datum coordinate system:

   - Select a predefined datum coordinate system by name. Click **Datum CSYS List** from the prompt area, select a name from the list, and click **OK**.
   - Select a predefined coordinate system in the viewport.
   - For the second point in the connector, select **Use CSYS 1** to use the coordinate system defined for the first point at the second point in the connector as well.

   The selected orientation is highlighted red in the viewport. The **Coincident Point Builder** reappears and displays a description of the coordinate system used for the orientation for the selected point of the connector.

    **Tip:** You can also create a new datum coordinate system by clicking  from the **CSYS 1** or **CSYS 2** portion of the dialog box.

b. If desired, you can specify an additional rotation about an axis of the datum coordinate system for either endpoint. Select the **Additional rotation angle** option for one of the points, enter a value for the rotation angle in degrees, and select **1**, **2**, or **3** for the **About axis** option. The **Additional rotation angle** option is available only if you specify a datum coordinate system other than the global coordinate system.

6. Click **OK** to create the wire feature and the connector section assignment. Abaqus/CAE also creates a set containing the assembly-level wires.

The original wire feature is renamed and suppressed. The modified assembly-level wire feature appears in the Model Tree in the **Features** container under the assembly using the same name as the original wire feature.

Additional information

• *Constraining two instances with coincident points*

Creating connector sections

You can create a connector section by selecting connection types to define the connector function.

In this section:

- *Creating connector sections for assembled, complex, and basic connection types*
- *Creating connector sections for MPC types*

Creating connector sections for assembled, complex, and basic connection types

The connector section editor allows you to specify assembled, complex, or basic connection types; connector behaviors; and section data to include in the section definition. For more information, see *Connector Elements*.

1. From the main menu bar, select **Connector->Section->Create**.

   Tip: You can also create a connector section using the  tool in the Interaction module toolbox.

   A **Create Connector Section** dialog box appears.

2. Enter a section name. For more information about naming objects, see *Using basic dialog box components*.
3. Choose one of the following connection categories:

   - Choose **Assembled/Complex** to use either predefined combinations of basic connection types or complex connection types.

     Click the arrow next to the **Assembled/Complex type** text field, and select the desired connection type from the list that appears.
   - Choose **Basic** to use translational and rotational connection types.

     1. If desired, click the arrow next to the **Translational type** text field, and select the connection type from the list that appears.
     2. If desired, click the arrow next to the **Rotational type** text field, and select the connection type from the list that appears.

     You can select one translational type, one rotational type, or one translational and one rotational type to define the connector section.

   Abaqus/CAE displays the available and constrained components of relative motion (CORM) for the connection type that you have selected. In addition, you can click  to see a schematic drawing of the connection type along with the Abaqus idealization of the connection.

   For a description of assembled, complex, and basic connection types, see *Connection Types*.
4. Click **Continue**.

   The connector section editor appears.

   Note:

   You can display help on a particular editor feature by selecting **Help->On Context** from the main menu bar and then clicking the editor feature of interest. For more information on editor features, see *Using the connector section editors*.

5. To edit the connection type, click  to the right of the connection type to display the connector section type editor. Select the connection type as described above. You must delete all behaviors from the editor before you can edit the connection type.
6. On the **Behavior Options** tabbed page, you can add, delete, and change behaviors as follows:

Adding behaviors

Click **Add** on the right side of the editor to display a list of available behaviors. Select the behaviors needed to define your connector section. You can define multiple behaviors of the same type for some behaviors. When you select a behavior, its name appears in the **Behavior Options** list, and data fields associated with the behavior appear in the data area in the bottom half of the editor. Use the data fields to enter information for the currently selected behavior. For more information, see *Using the connector section editors*.

Deleting behaviors

In the **Behavior Options** list, select the behavior that you want to delete, and click **Delete** on the right side of the editor. This procedure removes the behavior from both the behavior options list and the connector section definition.

Changing behavior data

In the **Behavior Options** list, select the behavior whose data you want to change. When the data fields associated with the behavior appear in the bottom half of the window, change the information that you have entered for the behavior as desired.

7. On the **Table Options** tabbed page, you can specify behavior settings for the regularization (Abaqus/Explicit analyses only) and the extrapolation of tabular data for all of the behavior options in a connector section. Alternatively, you can specify behavior settings for individual behavior options. The **Table Options** button is available on the **Behavior Options** tabbed page for selected behavior options. Behavior settings for individual behavior options take precedence over the connector section behavior settings. For more information, see *Specifying behavior settings for tabular data*, and *Defining Connector Behavior Using Tabular Data*.

   Specify behavior settings on the **Table Options** tabbed page as follows:

   a. In the **Regularization** portion of the page, specify the settings for the regularization of tabular data in an Abaqus/Explicit analysis. By default, Abaqus/Explicit regularizes the data into tables that are defined in terms of even intervals of the independent variables.

      - Toggle on **Regularize data** to regularize tabular data.
      - Toggle off **Regularize data** to turn off regularization of the tabular data and use the data that you define directly.

   b. If you want to regularize tabular data, specify the error tolerance.

      - Choose **Use default** to use the default value of 0.03.
      - Choose **Specify**, and enter a value for the error tolerance.

   c. In the **Extrapolation** portion of the page, specify the method for the extrapolation of tabular data. The data points that you enter make up a nonlinear curve in the constitutive space. By default, Abaqus extrapolates the dependent variables as constant values that correspond to the end points of the curve outside the specified range of the independent variables.

      - Choose **Constant** to use constant extrapolation of the dependent variables outside the specified range of the independent variables.
      - Choose **Linear** to use linear extrapolation of the dependent variables outside the specified range of the independent variables.

8. The **Section Data** tabbed page becomes available for the following connection types:

   - For the **Flow-Converter** or **Retractor** connection type, enter the following section data:

     ### Node b material flow scaling factor

     Enter the scaling factor, β_s, associated with the material flow at node *b*. Node *b* refers to the second point of a wire used to model a connector in Abaqus/CAE. The default value is 1.

     For more information, see *FLOW-CONVERTER* and *RETRACTOR*.

   - For the **Slip Ring** connection type, enter the following section data:

     ### Mass per unit reference length

     Enter the mass per unit reference length of belt material.

     ### Contact angle around node b

     The contact angle refers to the angle made by the belt wrapping around node *b*. Node *b* refers to the second point of a wire used to model a connector in Abaqus/CAE.

     For an Abaqus/Standard analysis you must specify the contact angle directly. For an Abaqus/Explicit analysis you can specify the contact angle directly, or you can let Abaqus calculate the contact angle based on the configuration of your model:

     - To let Abaqus calculate the contact angle, select **Compute**.
     - To specify the contact angle directly, select **Specify** and enter the contact angle in degrees.

     For more information, see *SLIPRING*.

9. Click **OK** to save the data and to exit the editor.

Additional information

- *Understanding connector sections and functions*
- *Connector section editors*
- *Using the connector section editors*
- *Connectors*

Creating connector sections for MPC types

The connector section editor allows you to specify MPC connection types. For more information, see *General Multi-Point Constraints*.

1. From the main menu bar, select **Connector->Section->Create**.

   Tip: You can also create a connector section using the tool in the Interaction module toolbox.

   A **Create Connector Section** dialog box appears.
2. Enter a section name. For more information about naming objects, see *Using basic dialog box components*.
3. Choose the **MPC** connection category.
4. Click the arrow next to the **MPC type** text field, and select the desired connection type from the list that appears.

   For more information, see the following sections:

   - *General Multi-Point Constraints*
   - *MPC*
5. Click **OK** to save the section definition and to close the dialog box.

Additional information

- *Understanding connector sections and functions*
- *Connector section editors*

Creating and modifying connector section assignments

You create connector section assignments by assigning connector sections to wire features (to define connectors) or attachment lines (to define discrete fasteners) and specifying local orientations associated with the endpoints of the wires or attachment lines. Depending upon the connection type, a local orientation for the first points of the selected wires or attachment lines is required, optional, or not applicable. Depending upon the connection type, a local orientation for the second points of the selected wires or attachment lines is optional or not applicable. For the local orientation requirements for each connection type, see *Connection-Type Library*. *Table 1* relates the numerical coordinate axes referred to in the connection-type library to the coordinate system axis labels used in Abaqus/CAE. You can use the Query toolset to obtain connector assignment information for selected wires or attachment lines.

Table 1: Coordinate system axis labels used for displaying local orientations associated with the endpoints of the wires or attachment lines.

Local coordinate direction	Cartesian	Cylindrical	Spherical
1	x	r	r
2	y	t	t
3	z	z	p

When you create connector section assignments, Abaqus/CAE generates identification strings to associate the assignments with connector orientations. These strings, referred to as “tags,” cannot be modified, and they are displayed in the connector section assignment manager, the Model Tree tooltips, and—optionally—the viewport (see *Controlling the display of attributes*).

1. Display the connector section assignment editor using one of the following methods:
   - To create a new connector section assignment, do the following:
     1. Select **Connector->Assignment->Create** from the main menu bar.

        Tip: You can also create a connector section assignment using the  tool in the Interaction module toolbox.

     2. Select the region (wires or attachment lines) to which you want to apply the connector section.

        Only wire features or attachment lines that have been created at the assembly level are available for selection. The best approach for selecting the region is to use the default geometry set name for the wire feature (see *Creating or modifying wire features for multiple connectors*, for more information) or attachment lines (see *Creating attachment lines by projecting points*, for more information). A single wire or attachment line feature may contain multiple wires or attachment lines. You can select individual wires or attachment lines of the feature; however, only one connector section can be associated with each individual wire or attachment line.

        Use one of the following methods to select the region:

        - Select from a list of existing sets. Click **Sets** on the right side of the prompt area, select the set of interest from the **Region Selection** dialog box that appears, and click **Continue**.
        - Select the wires or attachment lines in the viewport.

     3. Click **Done** in the prompt area.

        The connector section assignment editor appears.

- To edit an existing connector section assignment, select **Connector->Assignment->Manager** from the main menu bar to display the **Connector Section Assignment Manager**. Select the row of data that you want to change, and click **Edit**.

  The connector section assignment editor appears, and the connector symbols become highlighted in the current viewport.

  If you want to select different wires or attachment lines for the connector section assignment, click  in the **Region** portion of the editor and reselect the region.

2. On the **Section** tabbed page, select a connector section. If desired, click  to create a new connector section.

   The connection type is displayed in the editor; if applicable, you can click  to see a schematic drawing of the connection type along with the Abaqus idealization of the connection.

3. On the **Orientation 1** tabbed page, you specify the orientation for the first points of the selected wires or attachment lines if the orientation is required or optional. If the orientation is not applicable, the **Orientation 1** tabbed page is unavailable in the editor.

   a. If you want to specify an orientation other than the global coordinate system, click  and use one of the following methods to select the datum coordinate system:

   - Select a predefined datum coordinate system by name. Click **Datum CSYS List** from the prompt area, select a name from the list, and click **OK**.
   - Select a predefined coordinate system in the viewport.

   The selected orientation is highlighted red in the viewport. The connector section assignment editor reappears and displays a description of the coordinate system used for the orientation of the first points of the selected wires or attachment lines.

   b. If applicable, you can specify an additional rotation about an axis of the datum coordinate system. Select the **Additional rotation angle** option, enter a value for the rotation angle in degrees, and select **1**, **2**, or **3** for the **About axis** option. The **Additional rotation angle** option is available only if you specify a datum coordinate system other than the global coordinate system.

4. If the orientation for the second points of the selected wires or attachment lines is optional, Abaqus/CAE uses the orientation for the first points (including the additional rotation angle, if specified) as the default selection. You can specify a different coordinate system for the second points of the selected wires or attachment lines on the **Orientation 2** tabbed page. If the orientation is not applicable, the **Orientation 2** tabbed page is unavailable in the editor.

   a. On the **Orientation 2** tabbed page, toggle on **No modifications to CSYS** and click . Use one of the following methods to select the datum coordinate system:

   - Select a predefined datum coordinate system by name. Click **Datum CSYS List** from the prompt area, select a name from the list, and click **OK**.
   - Select a predefined coordinate system in the viewport.

   The selected orientation is highlighted red in the viewport. The connector section assignment editor reappears and displays a description of the coordinate system used for the orientation of the second points of the selected wires or attachment lines.

   b. If applicable, you can specify an additional rotation about an axis of the datum coordinate system. Select the **Additional rotation angle** option, enter a value for the rotation angle in degrees, and

select **1**, **2**, or **3** for the **About axis** option. The **Additional rotation angle** option is available only if you specify a datum coordinate system other than the global coordinate system.

5. Click **OK** to save your connector section assignment and to close the editor.

   Symbols appear in the viewport that represent the connector section assignment that you just created. For more information, see *Understanding symbols that represent interactions, constraints, and connectors*.

Additional information

- *Understanding connectors*
- *Connector section assignment editors*
- *Using the Query toolset to obtain connector assignment information*
- *Fasteners*
- *Connectors*

Editing the region to which an interaction or constraint is applied

You can edit the region to which an interaction is applied only in the step in which the interaction was created.

1. From the **Interaction** or **Constraint** menu in the main menu bar, select **Manager** to display the **Interaction Manager** or **Constraint Manager**.
2. Choose one of the following methods:

   - To edit an interaction, click the cell located in the row of the interaction that you want to modify and in the column of the step in which it was created and click **Edit**. Alternatively, you can just double-click the cell.

     Tip: You can also initiate this procedure by clicking the step in which the interaction was created from the **Step** list located in the context bar. From the **Interaction** menu in the main menu bar, select **Edit->*interaction name***.

   - To edit a constraint, select the name of the constraint and click **Edit**.

     Tip: You can also initiate this procedure by selecting **Edit->*constraint name*** from the main menu bar.

   If you are editing a foundation interaction, either you are prompted to edit the region by selecting or unselecting objects in the viewport or the **Region Selection** dialog box appears in which you can select a surface that you have already created using the Surface toolset.

   If you are editing any other type of interaction or a constraint, the appropriate editor appears. The editor for all interactions except general contact contains an **Edit Region** option for each region involved in the interaction or constraint definition.

   If your interaction or constraint definition includes both a main surface and a secondary surface or region, the main surface appears highlighted in red and the secondary surface or region appears highlighted in magenta during the editing procedure.

   If you are editing a surface-to-surface contact interaction, yellow arrows are displayed on the shell surfaces to show the shell normal that was selected when the interaction was created. On geometry, a single arrow is displayed at the centroid of each face on the shell surface. On native or orphan meshes, an arrow is displayed on each of the element faces on the shell surface. If you edit the main surface or the secondary surface, the arrows are displayed for the selected surface.

3. If you are editing a general contact interaction, modify the contact domain using the methods described in *Defining general contact*.

4. If you are editing a constraint or an interaction other than general contact or foundation, click  for the region that you want to modify. For example, if you are editing a surface-to-surface contact interaction and you want to modify the main surface, click  next to the **Main surface** label in the editor.
5. If you are editing a constraint or an interaction other than general contact, edit the region by selecting and unselecting objects in the viewport. If you are editing the host region to which an embedded region constraint is applied, first select the selection method. When you have finished editing the region, click mouse button 2. (For more information, see *Selecting objects within the viewport*.)

   Tip: You can limit the types of objects that you can select in the viewport by specifying filtering options in the Selection toolbar. See *Using the selection options*, for more information.

If you would rather select from a list of existing sets or surfaces, do the following:

a. Click **Sets** or **Surfaces** on the right side of the prompt area. (The name of the button depends on the type of object you are editing. For example, if you are editing an interaction, a **Surfaces** button appears.)

Abaqus/CAE displays the **Region Selection** dialog box containing a list of available sets or surfaces.

b. Select the set or surface of interest, and click **Continue**.

Note:

The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** or **Surfaces** on the right side of the prompt area.

6. Finish editing the interaction or constraint definition as desired, and then press mouse button 2 (if you are editing a foundation interaction) or click **OK** in the editor (if you are editing any other type of interaction or if you are editing a constraint).

Additional information

- *Using the Interaction module*
- *What are step-dependent managers?*

Using the Special menu in the Interaction module

Use of the Special menu in the Interaction module is discussed.

In this section:

- *The Special menu in the Interaction module*
- *Modeling cracks and seams*

The Special menu in the Interaction module

You can use the **Special** menu in the Interaction module to define inertia and crack engineering features.

- **Inertia**. You can define lumped mass, rotary inertia, and heat capacitance at a point on an assembly. In an Abaqus/Standard analysis you can also define mass and inertia proportional damping and composite damping. For more information, see *Inertia*.
- **Crack**. You can study the initiation and propagation of cracks using the following techniques:
  - An embedded seam crack with duplicate overlapping nodes
  - A contour integral analysis
  - The extended finite element method (XFEM)
  - The virtual crack closing technique (VCCT)
- **Springs/Dashpots**. You can define springs and dashpots that exhibit the same linear behavior independent of field variables. You can also define both spring and dashpot behavior on the same set of points. In an Abaqus/Explicit or an Abaqus/Standard analysis, you can model springs and dashpots that connect two points, following the line of action between the two points. In an Abaqus/Standard analysis, you can also model springs and dashpots that connect two points, acting in a fixed direction, or that connect points to ground. For more information, see *Springs and dashpots*.
- **Fasteners**. You can model point-to-point connections between two or more faces using point-based or discrete fasteners. Point-based fasteners can be defined using attachment points, reference points, or orphan nodes. Discrete fasteners can be defined using attachment lines. For more information, see *Fasteners*.

Modeling cracks and seams

When you model cracks, you assign seams to regions of your model. Abaqus/CAE places overlapping duplicate nodes along a seam when the mesh is generated. A seam cannot extend along the boundaries of a part and must be embedded within a face of a two-dimensional part or within a cell of a solid part.
Because a seam modifies the mesh, if you create a seam on a dependent part instance, it will actually be created on the underlying part, thereby affecting all instances of that part.

For fracture mechanics, a seam defines an edge or a face with overlapping nodes that can separate during an analysis. You can include a seam crack in your model. Alternatively, you can refer to the seam when creating a contour integral; however, you cannot use a seam crack with the extended finite element method (XFEM). For more information, see *Fracture mechanics*.

1. From the main menu bar in the Interaction module, select **Special->Crack->Assign seam**.
2. From the model in the viewport, select the entities representing the seam. The entities must be embedded edges within a face of a two-dimensional part or embedded faces within a cell of a solid part; you cannot select any entities that lie on the boundary of the part.
3. Click mouse button 2 to indicate that you have finished selecting the seam.

   Abaqus/CAE creates the seam.

Defining general contact

In Abaqus/Standard you can define general contact only in the initial step; in all subsequent steps this general contact interaction is active and you can modify it. In Abaqus/Explicit you can define general contact in any analysis step or the initial step; only one general contact interaction can be active in a step.
For a brief overview of general contact, see *Understanding interactions*. For a more detailed discussion, see *About General Contact in Abaqus/Standard*, and *About General Contact in Abaqus/Explicit*.

A general contact definition can create interactions involving exterior faces, analytical rigid surfaces, feature edges, edges based on beams and trusses, and, for Abaqus/Explicit, Eulerian material boundaries. Analytical rigid surfaces can interact only with entities of element-based and node-based surfaces (that is, contact between two analytical surfaces cannot be modeled).

In Abaqus/Explicit you can obtain contact data for a specific surface in the general contact domain by using the history output request editor in the Step module. In the **Domain** section of the editor, select **General contact surface** and choose the surface from the menu that appears. For more information, see *Creating an output request*.

1. From the main menu bar, select **Interaction->Create**.

   Tip: You can also create a general contact interaction using the

   tool in the Interaction module toolbox.

2. In the **Create Interaction** dialog box that appears, do the following:
   - Name the interaction. For more information about naming objects, see *Using basic dialog box components*.
   - Select the step in which the interaction will be created. In Abaqus/Standard general contact can be created only in the initial step.
   - Select the **General contact (Standard)** or **General contact (Explicit)** type of interaction, depending on the analysis steps being defined in your model.

3. Click **Continue** to close the **Create Interaction** dialog box.
   The **Edit Interaction** dialog box appears.

4. Specify the contact domain using either of the following methods:
   - Choose **All* with self** to specify contact (including self-contact) for all allowable element faces and model entities. This is the simplest way to define the contact domain.
   - To specify individual contact surface pairings:

     1. Choose **Selected surface pairs**, and click .
        The **Edit Included Pairs** dialog box appears. By default, when you select a surface from the list or the table, Abaqus/CAE highlights the surface in the viewport; however, highlighting does not apply for **(All*)**, **(Self)**, and Eulerian material surfaces. You can toggle off **Highlight selected regions** at the bottom of the dialog box to turn off selection highlighting.
     2. Select one or more surfaces from the list of existing surfaces in the first column on the left side. Select **(All*)** to specify a surface that includes all allowable element faces and model entities.

Tip: You can click

to define a new surface and add it to the list. See *Creating surfaces*, for instructions on defining surfaces.

3. Select the second surface or surfaces from the list of existing surfaces in the second column to define the surface pairings.
   - When multiple surfaces are selected in either column, all possible combinations will be generated in the table.
   - To specify self-contact, select either the same surface name or **(Self)** in the second column.
   - The order in which the surfaces are specified does not matter for the analysis.
4. Click the arrows

   in the middle of the dialog box to transfer the surface pair to the list of pairings that will be included in the contact domain.

   The table on the right side of the dialog box is updated to reflect your selections (the order of the surface pairings is irrelevant).
5. Repeat the above steps as needed to completely define the contact domain inclusions. If you want to delete included pairs, select the rows and click

   .
6. Click **OK** to save your selections and to close the **Edit Included Pairs** dialog box.

   The interaction editor reappears with updated information on the number of selected surface pairs for inclusion in the contact domain.

5. If necessary, select the surface pairs to exclude from the contact domain.
   a. Click **Edit** next to **Excluded surface pairs**.

      The **Edit Excluded Pairs** dialog box appears. By default, when you select a surface from the list or the table, Abaqus/CAE highlights the surface in the viewport; however, highlighting does not apply for **(All*)**, **(Self)**, and Eulerian material surfaces. You can toggle off **Highlight selected regions** at the bottom of the dialog box to turn off selection highlighting.
   b. Select one or more surfaces from the list of existing surfaces in the first column on the left side. Select **(All*)** to specify a surface that includes all allowable element faces and model entities.

      Tip: You can click

to define a new surface and add it to the list. See *Creating surfaces*, for instructions on defining surfaces.

c. Select the second surface or surfaces from the list of existing surfaces in the second column to define the surface pairings.

- When multiple surfaces are selected in either column, all possible combinations will be generated in the table.
- To specify that self-contact should be excluded, select either the same surface name or **(Self)** in the second column.
- The order in which the surfaces are specified does not matter for the analysis.
- If the excluded regions overlap with the included regions, the contact exclusions will take precedence over the contact inclusions.

d. Click the arrows

in the middle of the dialog box to transfer the surface pair to the list of pairings that will be excluded from the contact domain.

The table on the right side of the dialog box is updated to reflect your selections (the order of the surface pairings is irrelevant).

e. Repeat the above steps as needed to completely define the contact domain exclusions. If you want to delete excluded pairs, select the rows and click

.

f. Click **OK** to save your selections and to close the **Edit Excluded Pairs** dialog box.

The interaction editor reappears with updated information on the number of selected surface pairs for exclusion from the contact domain.

6. Specify the **Attribute Assignments** at the bottom of the interaction editor. In Abaqus/Standard you can modify the contact properties or stabilizations in any step in which the general contact interaction is active, but all other attributes are assigned for the entire analysis. In Abaqus/Explicit you can specify or modify the attributes in any step in which the general contact interaction is active. You can specify the following assignments:

- **Contact Properties**. For detailed instructions, see *Specifying and modifying contact property assignments for general contact*.
- **Contact Initializations** (Abaqus/Standard only). For detailed instructions, see *Specifying and modifying contact initialization assignments for general contact*.
- **Contact Stabilizations** (Abaqus/Standard only). For detailed instructions, see *Specifying and modifying contact stabilization assignments for general contact*.
- **Surface Properties**. For detailed instructions, see *Specifying surface property assignments for general contact*.
- **Contact Formulation**. For detailed instructions, see *Specifying contact formulation assignments for general contact*.

7. Click **OK** to create the interaction and to close the editor.

Additional information

Specifying and modifying contact property assignments for general contact

Contact properties can be assigned globally to a general contact interaction or individually to particular regions within a general contact domain.
Attributes for a general contact interaction, such as contact properties, are specified independently of the contact domain in the **Attribute Assignments** portion of the interaction editor. For a brief overview of general contact, see *Understanding interactions*.

You can change the contact property that is assigned to a general contact interaction in any step to which the original interaction definition is propagated. In Abaqus/Standard only the frictional behavior is allowed to change between the original contact property definition and the new contact property definition (see *Specifying frictional behavior for mechanical contact property options*)—Abaqus uses the original friction definition from the creation of the general contact interaction until the step in which the new property is assigned; the new friction definition is used for subsequent steps.

Additional information

- *Interaction editors*
- *Defining general contact*

Specify contact property assignments

1. Display the general contact interaction editor using one of the following methods:
   - To create a new general contact interaction, follow the instructions in *Defining general contact*.
   - To edit an existing general contact interaction, select **Interaction->Edit->*interaction name*** from the main menu bar.
2. Click the **Contact Properties** tab in the **Attribute Assignments** portion of the interaction editor (if it is not already selected).
3. If necessary, click  in the **Contact Properties** portion of the interaction editor to create a contact interaction property; see *Defining a contact interaction property*, for more information.
4. Specify the contact property assignments for the interaction using either of the following methods:
   - To assign a contact property globally to the entire contact domain, select a property from the list next to **Global property assignment**.
   - To assign different contact properties to individual surface pairs:
     1. Click  next to **Individual property assignments**.

        The **Edit Individual Contact Property Assignments** dialog box appears. By default, when you select a surface from the list or the table, Abaqus/CAE highlights the surface in the viewport; however, highlighting does not apply for **(Global)**, **(Self)**, materials, and Eulerian material surfaces. You can toggle off **Highlight selected regions** at the bottom of the dialog box to turn off selection highlighting.
     2. Select one or more combinations of surfaces and materials from the list of existing surfaces and materials in the first column on the left side. Select **(Global)** to assign a contact property between the entire contact domain and an individual surface or material.

         **Tip:** You can click  to define a new surface and add it to the list. See *Creating surfaces*, for instructions on defining surfaces.

Tip: You can click  to define a new material and add it to the list. See *Creating or editing a material*, for instructions on defining materials.

3. Select the second surface or material or combinations of surfaces and materials from the list of existing surfaces and materials in the second column to define the surface pairings.
   - When multiple surfaces and materials are selected in either column, all possible combinations will be generated.
   - To assign a property for self-contact, select either the same surface name or **(Self)** in the second column.
   - Any contact property assignments for regions that fall outside of the contact domain will be ignored.
4. From the list of existing interaction properties in the third column, select the property to assign.

   Tip: You can click  to define a new interaction property and add it to the list. See *Defining a contact interaction property*, for instructions on defining interaction properties.
5. Click the arrows  in the middle of the dialog box to transfer your selections to the list of property assignments.

   The table on the right side of the dialog box is updated to reflect your selections.
6. Repeat the above steps as needed to complete the contact property assignments. If you want to delete contact property assignments, select the rows and click .

   Note:

   The order of assignments may be relevant; when property assignments overlap, the last assignment will take precedence.
7. Click **OK** to save your selections and to close the **Edit Individual Contact Property Assignments** dialog box.

   The interaction editor reappears with updated information on the number of individual contact property assignments.

Note:

Individual contact property assignments take precedence over the global assignment.

5. Click **OK** to create the interaction and to close the editor.

Modify a contact property assignment

1. From the main menu bar, select **Interaction->Edit->*interaction name***.

   The **Edit Interaction** dialog box appears.
2. Click the **Contact Properties** tab in the **Attribute Assignments** portion of the interaction editor (if it is not already selected).

3. Click  next to **Individual property assignments**.
   The **Edit Individual Contact Property Assignments** dialog box appears.
4. Select the row or rows containing the property assignment to be modified from the table on the right side of the dialog box.
5. Select a new interaction property from the list in the third column on the left side of the dialog box.
6. Click the arrow  in the middle of the dialog box to replace the interaction property with your new selection.
7. Click **OK** to save your selections and to close the dialog box.
   The interaction editor reappears.
8. Click **OK** to save your changes and to close the interaction editor.

Specifying and modifying contact initialization assignments for general contact

Contact initializations determine how Abaqus adjusts surfaces in the general contact domain prior to the analysis. Contact initializations for surfaces are specified independently of the contact domain in the **Attribute Assignments** portion of the interaction editor. Contact initialization can be assigned only in the initial step of an analysis. For more information about contact initializations, see *Creating contact initializations*, *Contact Initialization for General Contact in Abaqus/Standard*, and *Contact Initialization for General Contact in Abaqus/Explicit*.

Additional information

- *Creating contact initializations*
- *Contact Initialization for General Contact in Abaqus/Standard*
- *Contact Initialization for General Contact in Abaqus/Explicit*

Specify contact initialization assignments

1. Display the general contact interaction editor using one of the following methods:
   - To create a new general contact interaction, follow the instructions in *Defining general contact*.
   - To edit an existing general contact interaction, select **Interaction->Edit->*interaction name*** from the main menu bar.
2. Click the **Contact Properties** tab in the **Attribute Assignments** portion of the interaction editor (if it is not already selected).
3. If necessary, click  in the **Contact Properties** portion of the interaction editor to create a contact initialization definition; see *Creating contact initializations*, for more information.
4. Click  next to **Initialization assignments**.

   The **Edit Initialization Assignments** dialog box appears. By default, when you select a surface from the list or the table, Abaqus/CAE highlights the surface in the viewport; however, highlighting does not apply for **(Global)** and **(Self)**. You can toggle off **Highlight selected regions** at the bottom of the dialog box to turn off selection highlighting.
5. Select one or more surfaces from the list of existing surfaces in the first column on the left side. Select **(Global)** to assign an initialization between the entire contact domain and an individual surface for an Abaqus/Standard analysis.

    **Tip:** You can click  to define a new surface and add it to the list. See *Creating surfaces*, for instructions on defining surfaces.
6. Select the second surface or surfaces from the list of existing surfaces in the second column to define the surface pairings.
   - When multiple surfaces are selected in either column, all possible combinations will be generated.
   - To assign an initialization for self-contact, select either the same surface name or **(Self)** in the second column for an Abaqus/Standard analysis.
   - In an Abaqus/Explicit analysis the default surfaces **(Self)** and **(Global)** are not supported.
   - Any initialization assignments for regions that fall outside of the contact domain will be ignored.

7. From the list of existing initializations in the third column, select the initialization to assign. You can create new contact initializations while you are working in the **Edit Initialization Assignments** dialog box (see *Creating contact initializations*).
8. From the list of existing secondary surface option type in the fourth column, select the secondary surface option type to assign. This list is available only if the contact initialization is defined with the clearance distance and **Adjust nodal coordinates** options.
9. Click the arrows in the middle of the dialog box to transfer your selections to the list of property assignments.

   The table on the right side of the dialog box is updated to reflect your selections.
10. Repeat the above steps as needed to complete the initialization assignments. If you want to delete initialization assignments, select the rows and click .

    Note:

    The order of assignments may be relevant; when initialization assignments overlap, the last assignment will take precedence.
11. Click **OK** to save your selections and to close the **Edit Initialization Assignments** dialog box.

    The interaction editor reappears with updated information on the number of individual initialization assignments.
12. Click **OK** to create the interaction and to close the editor.

Modify a contact initialization assignment

1. From the main menu bar, select **Interaction->Edit->*interaction name***.

   The **Edit Interaction** dialog box appears.
2. Click the **Contact Properties** tab in the **Attribute Assignments** portion of the interaction editor (if it is not already selected).
3. Click  next to **Initialization assignments**.

   The **Edit Initialization Assignments** dialog box appears.
4. Select the row or rows containing the initialization assignment to be modified from the table on the right side of the dialog box.
5. Select a new initialization from the list in the third column on the left side of the dialog box.
6. Click the arrow  in the middle of the dialog box to replace the initialization with your new selection.
7. Click **OK** to save your selections and to close the dialog box.

   The interaction editor reappears.
8. Click **OK** to save your changes and to close the interaction editor.

Specifying and modifying contact stabilization assignments for general contact

Contact stabilization introduces viscous damping between two surfaces to stabilize rigid body motion prior to the establishment of contact.
Contact stabilization definitions are assigned to surfaces independently of the contact domain in the **Attribute Assignments** portion of the interaction editor.

A contact stabilization definition can be assigned in any step of an Abaqus/Standard analysis other than the initial step. Since general contact interactions must be created in the initial step, stabilization assignments require you to edit a previously created general contact interaction.

Stabilization effects are typically enforced only in the step in which they are applied. However, if a nondefault amplitude is selected as part of the contact stabilization definition, the stabilization effects may carry over into subsequent steps as described in *Stabilization for General Contact in Abaqus/Standard*. To remove stabilization effects in this situation, you must create a separate contact stabilization definition using the **Reset values from previous steps** option and apply that stabilization definition in a subsequent step.

For more information about contact stabilization definitions, see *Creating contact stabilization definitions*.

Additional information

- *Creating contact stabilization definitions*
- *Stabilization for General Contact in Abaqus/Standard*

Specify contact stabilization assignments

1. From the main menu bar, select **Interaction->Edit->*interaction name***.
2. Click the **Contact Properties** tab in the **Attribute Assignments** portion of the interaction editor (if it is not already selected).
3. If necessary, click  in the **Contact Properties** portion of the interaction editor to create a contact stabilization definition; see *Creating contact stabilization definitions*, for more information.
4. Click  next to **Stabilization assignments**.

   The **Edit Stabilization Assignments** dialog box appears. By default, when you select a surface from the list or the table, Abaqus/CAE highlights the surface in the viewport; however, highlighting does not apply for the default surfaces labeled **(Global)** and **(Self)**. You can toggle off **Highlight selected regions** at the bottom of the dialog box to turn off selection highlighting.
5. Select one or more surfaces from the list of existing surfaces in the first column on the left side. Select **(Global)** to introduce stabilization effects between the entire contact domain and an individual surface.

    **Tip:** You can click  to define a new surface and add it to the list. See *Creating surfaces*, for instructions on defining surfaces.
6. Select the second surface or surfaces from the list of existing surfaces in the second column to define the surface pairings.
   - When multiple surfaces are selected in either column, all possible combinations are generated.
   - To assign a stabilization definition for self-contact, select either the same surface name or **(Self)** in the second column.
   - Any stabilization assignments for regions that fall outside of the contact domain are ignored.

7. From the list of existing stabilization definitions in the third column, select the stabilization to assign. You can create new contact stabilization definitions while you are working in the **Edit Stabilization Assignments** dialog box (see *Creating contact stabilization definitions*).
8. Click the arrows  in the middle of the dialog box to transfer your selections to the list of stabilization assignments.

   The table on the right side of the dialog box is updated to reflect your selections.
9. Repeat the above steps as needed to complete the stabilization assignments. If you want to delete stabilization assignments, select the rows and click .

    **Note:**

   The order of assignments may be relevant; when stabilization assignments overlap, the last assignment takes precedence.
10. Click **OK** to save your selections and to close the **Edit Stabilization Assignments** dialog box.

    The interaction editor reappears with updated information on the number of individual stabilization assignments.
11. Click **OK** to save your changes and to close the editor.

Modify a contact stabilization assignment

1. From the main menu bar, select **Interaction**->**Edit**->***interaction name***.

   The **Edit Interaction** dialog box appears.
2. Click the **Contact Properties** tab in the **Attribute Assignments** portion of the interaction editor (if it is not already selected).
3. Click  next to **Stabilization assignments**.

   The **Edit Stabilization Assignments** dialog box appears.
4. Select the row or rows containing the stabilization assignment to be modified from the table on the right side of the dialog box.
5. Select a new stabilization definition from the list in the third column on the left side of the dialog box.
6. Click the arrow  in the middle of the dialog box to replace the stabilization definition with your new selection.
7. Click **OK** to save your selections and to close the dialog box.

   The interaction editor reappears.
8. Click **OK** to save your changes and to close the interaction editor.

Specifying surface property assignments for general contact

Attributes for a general contact interaction, such as surface properties, are specified independently of the contact domain in the **Attribute Assignments** portion of the interaction editor.

For a brief overview of general contact, see *Understanding interactions*. For a more detailed discussion, see *Surface Properties for General Contact in Abaqus/Standard*, and *Assigning Surface Properties for General Contact in Abaqus/Explicit*.

You can specify the following surface properties in a general contact interaction:

Surface thickness assignments

Assign nondefault surface thicknesses to shell or membrane surfaces.

Shell/Membrane offset assignments

Assign the surface offset to define the distance (as a fraction of the surface thickness) from the midsurface to the reference surface.

Surface smoothing assignments

Assign nondefault contact smoothing to model surfaces. Contact smoothing improves the contact stress and pressure accuracy for curved surfaces (see *Smoothing Contact Surfaces in Abaqus/Standard*).

Feature edge criteria assignments

Control the feature edges to be included in the general contact domain. Feature edges of a model include shell perimeter edges and geometric feature edges. Modeling of edge-to-edge contact is not allowed for Abaqus/Standard analyses.

Crush Trigger assignments

Control the crushing behaviors relating to CZone methodology in the general contact domain. CZone is an Abaqus/Explicit capability that integrates material, element, and contact modeling aspects to simulate crushing of laminated composites due to contact with other bodies (see *CZone Analysis*). Modeling of crush trigger contact is not allowed for Abaqus/Standard analyses.

Surface friction assignments

Establish friction coefficients as mathematical combinations of coefficients specified as surface properties. Modeling of friction contact is not allowed for Abaqus/Standard analyses.

Surface beam smoothing assignments

Assign nondefault beam smoothing to model surfaces.

Surface vertex criteria assignments

Control the vertex-to-surface contact formulation in the general contact domain. Vertex criteria of a model specify the vertex nodes that should be considered by the vertex-to-surface formulation (see *Vertex Nodes*).

Surface wear surface property assignments

Assign wear surface properties to model surfaces (see *Contact Wear*).

Additional information

- *Surface Properties for General Contact in Abaqus/Standard*
- *Assigning Surface Properties for General Contact in Abaqus/Explicit*
- *Interaction editors*

• *Defining general contact*

Specify surface thickness assignments

1. Display the general contact interaction editor using one of the following methods:
   - To create a new general contact interaction, follow the instructions in *Defining general contact*.
   - To edit an existing general contact interaction, select **Interaction->Edit->*interaction name*** from the main menu.
2. Click the **Surface Properties** tab in the **Attribute Assignments** portion of the interaction editor.
   The surface thickness can be modified only for surfaces defined on shells and membranes.
3. Click  next to **Surface thickness assignments**.
   The **Edit Surface Thickness Assignments** dialog box appears. By default, when you select a surface from the list or the table, Abaqus/CAE highlights the surface in the viewport; however, highlighting does not apply for **(Global)**, and materials. You can toggle off **Highlight selected regions** at the bottom of the dialog box to turn off selection highlighting.
4. Select one or more surfaces and materials from the list of existing surfaces and materials in the column on the left. Select **(Global)** to assign the shell/membrane thickness to the entire contact domain.

    **Tips:**

   - You can click  to define a new surface and add it to the list. See *Creating surfaces*, for instructions on defining surfaces.
   - You can click  to define a new material and add it to the list. See *Creating or editing a material*, for instructions on defining materials.
5. Click the arrows  in the middle of the dialog box to transfer your selections to the list of shell/membrane thickness assignments.
   The table on the right side of the dialog box is updated to reflect your selections.
6. Specify the thickness for each surface and material in the middle column of the **Surface Thickness Assignments** table.
   - Enter the word `ORIGINAL` to set the shell/membrane thickness equal to the original shell or membrane thickness (the default);
   - enter the word `THINNING` to set the shell/membrane thickness equal to the current shell or membrane thickness (this option is available only in Abaqus/Explicit); or
   - specify a value for the shell/membrane thickness.
7. Optionally, specify a scale factor for any of the shell/membrane thickness assignments in the last column of the **Surface Thickness Assignments** table.
8. Repeat the above steps as needed to complete the shell/membrane thickness assignments. If you want to delete thickness assignments, select the rows and click .

    **Note:** The order of assignments might be relevant; when shell/membrane thickness assignments overlap, the last assignment takes precedence.

9. Click **OK** to save your selections and to close the **Edit Surface Thickness Assignments** dialog box.

   The interaction editor reappears with updated information on the number of shell/membrane thickness assignments.

10. Click **OK** to create the interaction and to close the editor.

Specify shell/membrane offset assignments

1. Display the general contact interaction editor using one of the following methods:
   - To create a new general contact interaction, follow the instructions in *Defining general contact*.
   - To edit an existing general contact interaction, select **Interaction->Edit->*interaction name*** from the main menu.

2. Click the **Surface Properties** tab in the **Attribute Assignments** portion of the interaction editor.

   The surface offset can be modified only for surfaces defined on shells and membranes.

3. Click  next to **Shell/Membrane offset assignments**.

   The **Edit Shell/Membrane Offset Assignments** dialog box appears. By default, when you select a surface from the list or the table, Abaqus/CAE highlights the surface in the viewport; however, highlighting does not apply for **(Global)**, and materials. You can toggle off **Highlight selected regions** at the bottom of the dialog box to turn off selection highlighting.

4. Select one or more surfaces and materials from the list of existing surfaces and materials in the column on the left. Select **(Global)** to assign the shell/membrane offset to the entire contact domain.

    **Tips:**

   - You can click  to define a new surface and add it to the list. See *Creating surfaces*, for instructions on defining surfaces.
   - You can click  to define a new material and add it to the list. See *Creating or editing a material*, for instructions on defining materials.

5. Click the arrows  in the middle of the dialog box to transfer your selections to the list of shell/membrane offset assignments.

   The table on the right side of the dialog box is updated to reflect your selections.

6. Specify the offset fraction for each surface and material in the second column of the **Shell/Membrane Offset Assignments** table. The offset fraction defines the distance (as a fraction of the thickness) from the midsurface to the reference surface.
   - Enter the word `ORIGINAL` to set the shell/membrane offset equal to the original shell or membrane offset (the default).
   - Enter `SPOS` to specify the top surface of the shell/membrane as the reference surface.
   - Enter `SNEG` to specify the bottom surface of the shell/membrane as the reference surface.
   - Specify a value between –0.5 (indicates the bottom surface of the shell/membrane) and 0.5 (indicates the top surface of the shell/membrane) for the offset fraction.

7. Repeat the above steps as needed to complete the shell/membrane offset assignments. If you want to delete offset assignments, select the rows and click .

Note: The order of assignments might be relevant; when shell/membrane offset assignments overlap, the last assignment takes precedence.

8. Click **OK** to save your selections and to close the **Edit Shell/Membrane Offset Assignments** dialog box.

   The interaction editor reappears with updated information on the number of shell/membrane offset assignments.

9. Click **OK** to create the interaction and to close the editor.

Specify surface smoothing assignments

1. Display the general contact interaction editor using one of the following methods:

   - To create a new general contact interaction, follow the instructions in *Defining general contact*.
   - To edit an existing general contact interaction, select **Interaction->Edit->*interaction name*** from the main menu.

   In an Abaqus/Standard general contact interaction, surface smoothing assignments can be specified only in the initial step. In an Abaqus/Explicit general contact interaction, surface smoothing assignments can be specified or modified in any analysis step.

2. Click the **Surface Properties** tab in the **Attribute Assignments** portion of the interaction editor.

3. Click  next to **Surface smoothing assignments**.

   The **Edit Surface Smoothing Assignments** dialog box appears. By default, when you select a surface from the list or the table, Abaqus/CAE highlights the surface in the viewport and displays the detected axis or center of curvature that will be used in the smoothing calculation. You can toggle off **Highlight selected regions** at the bottom of the dialog box to turn off selection highlighting.

4. Toggle **Automatically assign smoothing for geometric faces** to determine whether Abaqus/CAE applies surface smoothing automatically to all appropriate surfaces in the general contact domain. This option is on by default for Abaqus/Standard general contact interactions and off by default for Abaqus/Explicit general contact interactions.

5. Select one or more surfaces from the list of existing surfaces in the column on the left.

   Tip: You can click  to define a new surface and add it to the list. See *Creating surfaces*, for instructions on defining surfaces.

6. Click the arrows  in the middle of the dialog box to transfer your selections to the list of surface smoothing assignments.

   The table on the right side of the dialog box is updated to reflect your selections.

7. Specify the smoothing to apply to each surface in the second column of the **Surface Smoothing Assignments** table. The smoothing specified for these surfaces overrides the default global smoothing if it is applied.

   - Select **REVOLUTION** to apply circumferential smoothing to a curved surface that is symmetric about an axis of revolution (or a two-dimensional arc that is symmetric about a central point).
   - Select **SPHERICAL** to apply spherical smoothing to a curved surface that is symmetric about a central point.

- Select **TOROIDAL** to apply toroidal smoothing to a curved surface that is a circular arc symmetric about an axis of revolution.
- Select **NONE** to prevent smoothing from being applied to the specified surface.

8. Repeat the above steps as needed to complete the surface smoothing assignments. If you want to delete smoothing assignments, select the rows and click .

   Note: The order of assignments might be relevant; when smoothing assignments overlap, the last assignment takes precedence.

9. Click **OK** to save your selections and to close the **Edit Surface Smoothing Assignments** dialog box.

   The interaction editor reappears with updated information on the number of surface smoothing assignments.

10. Click **OK** to create the interaction and to close the editor.

Specify feature edge criteria assignments

1. Display the general contact interaction editor using one of the following methods:
   - To create a new general contact interaction, follow the instructions in *Defining general contact*.
   - To edit an existing general contact interaction, select **Interaction->Edit->*interaction name*** from the main menu.

2. Click the **Surface Properties** tab in the **Attribute Assignments** portion of the interaction editor.

3. Click  next to **Feature edge criteria assignments**.

   The **Edit Feature Edge Criteria Assignments** dialog box appears. By default, when you select a surface from the list or the table, Abaqus/CAE highlights the surface in the viewport; however, highlighting does not apply for **(Global)**, and materials. You can toggle off **Highlight selected regions** at the bottom of the dialog box to turn off selection highlighting.

4. Select one or more surfaces and materials from the list of existing surfaces in the first column on the left side of the dialog box. Select **(Global)** to assign the surface feature to the entire contact domain.

   Tips:

   - You can click  to define a new surface and add it to the list. See *Creating surfaces*, for instructions on defining surfaces.
   - You can click  to define a new material and add it to the list. See *Creating or editing a material*, for instructions on defining materials.

5. Select the configuration from the second column on the left (this option is available only for Abaqus/Explicit).

6. Click the arrows  in the middle of the dialog box to transfer your selections to the list of surface feature assignments.

   The table on the right side of the dialog box is updated to reflect your selections.

7. Specify the feature edge criteria for each surface and material in the second and third columns of the **Surface Feature Assignments** table by doing one of the following:

- Enter the word `PERIMETER` to include only perimeter edges in the general contact domain.
- Enter the word `ALL` to include all edges in the general contact domain (this option is available only for Abaqus/Explicit).
- Enter the word `PICKED` to include in the general contact domain only edges that were explicitly selected as part of the surface definition (this option is available only for shell geometries and elements in Abaqus/Explicit).
- Enter the word `NONE` to include no feature edges in the general contact domain.
- Specify an angle in degrees to include perimeter edges and geometric edges with feature angles greater than or equal to the specified angle in the general contact domain. The specified value must be between 0° and 180°. For examples of how the feature angle is calculated for different edges, see *Feature Edges*.

8. Repeat the above steps as needed to complete the surface feature assignments. If you want to delete surface feature assignments, select the rows and click .

   Note: The order of assignments might be relevant; when surface feature assignments overlap, the last assignment takes precedence.

9. For an Abaqus/Explicit general contact interaction, toggle **Use dynamic feature edges** to activate or deactivate the dynamic feature edge criterion for the contact surface.
10. Click **OK** to save your selections and to close the **Edit Feature Edge Criteria Assignments** dialog box.

    The interaction editor reappears with updated information on the number of feature edge criteria assignments.
11. Click **OK** to create the interaction and to close the editor.

Specify crush trigger assignments

1. Display the general contact interaction editor using one of the following methods:
   - To create a new general contact interaction, follow the instructions in *Defining general contact*.
   - To edit an existing general contact interaction, select **Interaction->Edit->*interaction name*** from the main menu.
2. Click the **Surface Properties** tab in the **Attribute Assignments** portion of the interaction editor.
3. Click  next to **Crush trigger assignments**.

   The **Edit Crush Trigger Assignments** dialog box appears. By default, when you select a surface from the list or the table, Abaqus/CAE highlights the surface in the viewport; however, highlighting does not apply for **(Global)** and materials. You can toggle off **Highlight selected regions** at the bottom of the dialog box to turn off selection highlighting.
4. Select one or more surfaces and materials from the list of existing surfaces in the first column on the left side of the dialog box. Select **(Global)** to assign the surface feature to the entire contact domain.

   Tips:

   - You can click  to define a new surface and add it to the list. See *Creating surfaces*, for instructions on defining surfaces.

- You can click  to define a new material and add it to the list. See *Creating or editing a material*, for instructions on defining materials.

5. Click the arrows  in the middle of the dialog box to transfer your selections to the list of crush trigger assignments.

   The table on the right side of the dialog box is updated to reflect your selections.

6. Specify the trigger option for each surface and material in the second column of the **Crush Trigger Assignments** table by doing one of the following:

   - Enter the word `TRIGGER` to specify that node develops contact pressures consistent with the assigned contact pressure-overclosure relationship.
   - Enter the word `NO_TRIGGER` to specify that nodes will be reassigned trigger status during the simulation if adjacent nodes begin crushing or adjacent elements experience material failure.
   - Enter the word `NO_CRUSH` to specify that the nodes have no crush associated with adjacent elements and will never crush.

7. Specify the crush stress, crush initiation angle, and crush continuation angle for each surface and material in the third, fourth, and fifth columns of the **Crush Trigger Assignments** table by doing the following:

   - Specify a scalar value representing the stress required to initiate crushable behavior as a factor of the crush stress in the column **Crush Stress**.
   - Specify an angle in degrees representing the crush initiation angle.
   - Specify an angle in degrees representing the crush continuation angle.

8. Repeat the above steps as needed to complete the crush trigger assignments. If you want to delete crush trigger assignments, select the rows and click .

    **Note:** The order of assignments might be relevant; when crush trigger assignments overlap, the last assignment takes precedence.

9. Click **OK** to save your selections and to close the **Edit Crush Trigger Assignments** dialog box.

   The interaction editor reappears with updated information on the number of crush trigger assignments.

10. Click **OK** to create the interaction and to close the editor.

Specify surface friction assignments

1. Display the general contact interaction editor using one of the following methods:

   - To create a new general contact interaction, follow the instructions in *Defining general contact*.
   - To edit an existing general contact interaction, select **Interaction->Edit->*interaction name*** from the main menu.

2. Click the **Surface Properties** tab in the **Attribute Assignments** portion of the interaction editor.

3. Click  next to **Surface friction assignments**.

   The **Edit Surface Friction Assignments** dialog box appears. By default, when you select a surface from the list or the table, Abaqus/CAE highlights the surface in the viewport; however, highlighting

does not apply for **(Global)** and materials. You can toggle off **Highlight selected regions** at the bottom of the dialog box to turn off selection highlighting.

4. Select one or more surfaces and materials from the list of existing surfaces and materials in the column on the left. Select **(Global)** to assign the surface-based friction coefficient to the entire contact domain.

   Tips:

   - You can click  to define a new surface and add it to the list. See *Creating surfaces*, for instructions on defining surfaces.
   - You can click  to define a new material and add it to the list. See *Creating or editing a material*, for instructions on defining materials.

5. Click the arrows  in the middle of the dialog box to transfer your selections to the list of surface friction assignments.

   The table on the right side of the dialog box is updated to reflect your selections.

6. Specify the surface-based friction coefficients for each surface and material in the second column of the **Surface Friction Assignments** table.
7. Repeat the above steps as needed to complete the surface friction assignments. If you want to delete surface friction assignments, select the rows and click .

   Note: The order of assignments might be relevant; when surface friction assignments overlap, the last assignment takes precedence.

8. Click **OK** to save your selections and to close the **Edit Surface Friction Assignments** dialog box.

   The interaction editor reappears with updated information on the number of surface friction assignments.

9. Click **OK** to create the interaction and to close the editor.

Specify surface beam smoothing assignments

1. Display the general contact interaction editor using one of the following methods:
   - To create a new general contact interaction, follow the instructions in *Defining general contact*.
   - To edit an existing general contact interaction, select **Interaction->Edit->*interaction name*** from the main menu.

2. Click the **Surface Properties** tab in the **Attribute Assignments** portion of the interaction editor.
3. Click  next to **Surface beam smoothing assignments**.

   The **Edit Beam Smoothing Assignments** dialog box appears. By default, when you select a surface from the list or the table, Abaqus/CAE highlights the surface in the viewport and displays the detected axis or center of curvature that is used in the smoothing calculation. You can toggle off **Highlight selected regions** at the bottom of the dialog box to turn off selection highlighting.

4. Select one or more surfaces from the list of existing surfaces in the column on the left.

   Tip: You can click  to define a new surface and add it to the list. See *Creating surfaces*, for instructions on defining surfaces.

5. Click the arrows  in the middle of the dialog box to transfer your selections to the list of beam smoothing assignments.

   The table on the right side of the dialog box is updated to reflect your selections.

6. Specify the smoothing to apply to each surface in the second column of the **Beam Smoothing Assignments** table. The smoothing specified for these surfaces overrides the default global smoothing if it is applied.

   Specify a value between 0.0 and 0.5 for the beam smoothing.

7. Repeat the above steps as needed to complete the beam smoothing assignments. If you want to delete beam smoothing assignments, select the rows and click .

    **Note:** The order of assignments might be relevant; when beam smoothing assignments overlap, the last assignment takes precedence.

8. Click **OK** to save your selections and to close the **Edit Beam Smoothing Assignments** dialog box.

   The interaction editor reappears with updated information on the number of beam smoothing assignments.

9. Click **OK** to create the interaction and to close the editor.

Specify surface vertex criteria assignments

1. Display the general contact interaction editor using one of the following methods:

   - To create a new general contact interaction, follow the instructions in *Defining general contact*.
   - To edit an existing general contact interaction, select **Interaction->Edit->*interaction name*** from the main menu.

2. Click the **Surface Properties** tab in the **Attribute Assignments** portion of the interaction editor.

3. Click  next to **Surface vertex criteria assignments**.

   The **Edit Vertex Criteria Assignments** dialog box appears. By default, when you select a surface from the list or the table, Abaqus/CAE highlights the surface in the viewport; however, highlighting does not apply for **(Global)** and materials. You can toggle off **Highlight selected regions** at the bottom of the dialog box to turn off selection highlighting.

4. Select one or more surfaces and materials from the list of existing surfaces in the first column on the left side of the dialog box. Select **(Global)** to assign the surface feature to the entire contact domain.

    **Tips:**

   - You can click  to define a new surface and add it to the list. See *Creating surfaces*, for instructions on defining surfaces.
   - You can click  to define a new material and add it to the list. See *Creating or editing a material*, for instructions on defining materials.

5. Click the arrows  in the middle of the dialog box to transfer your selections to the list of vertex criteria assignments.

   The table on the right side of the dialog box is updated to reflect your selections.

6. Specify the vertex criteria for each surface and material in the second column of the **Vertex Criteria Assignments** table by doing one of the following:
   - Enter the word `ALL_VERTICES` to specify that all vertex nodes should be considered by the vertex-to-surface formulation.
   - Enter the word `NO_VERTICES` to specify that no vertex nodes should be considered by the vertex-to-surface formulation.
   - Specify an angle in degrees representing the vertex angle threshold. The specified value must be between 10° and 90°.
7. Repeat the above steps as needed to complete the vertex criteria assignments. If you want to delete vertex criteria assignments, select the rows and click .

    **Note:** The order of assignments might be relevant; when vertex criteria assignments overlap, the last assignment takes precedence.
8. Click **OK** to save your selections and to close the **Edit Vertex Criteria Assignments** dialog box.
   The interaction editor reappears with updated information on the number of vertex criteria assignments.
9. Click **OK** to create the interaction and to close the editor.

Specify wear surface property assignments

1. Display the general contact interaction editor using one of the following methods:
   - To create a new general contact interaction, follow the instructions in *Defining general contact*.
   - To edit an existing general contact interaction, select **Interaction->Edit->*interaction name*** from the main menu bar.
2. Click the **Surface Properties** tab in the **Attribute Assignments** portion of the interaction editor if it is not already selected.
3. If necessary, click  in the **Surface Properties** portion of the interaction editor to create a wear surface interaction property (see *Defining a wear interaction property*).
4. Specify the wear surface property assignments for the interaction using either of the following methods:
   - To assign a wear surface property globally to the entire contact domain, select a property from the list next to **Global Wear Surface Property Assignment**.
   - To assign different contact properties to individual surface pairs:

     a) Click  next to **Wear Surface Property Assignments**.

     The **Edit wear surface property assignments** dialog box appears. By default, when you select a surface from the list or the table, Abaqus/CAE highlights the surface in the viewport; however, highlighting does not apply for **(Global)**, **(Self)**, materials, and Eulerian material surfaces. You can toggle off **Highlight selected regions** at the bottom of the dialog box to turn off selection highlighting.

     b) Select one or more combinations of surfaces and materials from the list of existing surfaces and materials in the first column on the left side. Select **(Global)** to assign a contact property between the entire contact domain and an individual surface or material.

Tips:

- You can click  to define a new surface and add it to the list. See *Creating surfaces* for instructions on defining surfaces.
- You can click  to define a new material and add it to the list. See *Creating or editing a material* for instructions on defining materials.

c) From the list of existing wear interaction properties in the third column, select the property to assign.

Tip: You can click  to define a new interaction property and add it to the list. See *Defining a wear interaction property* for instructions on defining interaction properties.

d) Click the arrows  in the middle of the dialog box to transfer your selections to the list of wear surface property assignments.

The table on the right side of the dialog box updates to reflect your selections.

e) Repeat the above steps as needed to complete the contact property assignments.

If you want to delete wear surface property assignments, select the rows and click .

Note: The order of assignments might be relevant; when wear surface property assignments overlap, the last assignment takes precedence.

f) Click **OK** to save your selections and to close the **Edit Wear Surface Property Assignments** dialog box.

The interaction editor reappears with updated information on the number of wear surface property assignments.

5. Click **OK** to create the interaction and to close the editor.

Specifying contact formulation assignments for general contact

Attributes for a general contact interaction, such as contact formulation, are specified independently of the contact domain in the **Attribute Assignments** portion of the interaction editor.

For a brief overview of general contact, see *Understanding interactions*. For a more detailed discussion of main-secondary formulations, see *Contact Controls Specific to General Contact in Abaqus/Standard* and *Contact Formulation for General Contact in Abaqus/Explicit*.

Additional information

- *Contact Controls Specific to General Contact in Abaqus/Standard*
- *Contact Formulation for General Contact in Abaqus/Explicit*
- *Interaction editors*
- *Defining general contact*

Specify main-secondary assignments for general contact

By default, Abaqus/Standard automatically assigns a main and a secondary role to each surface in an interacting pair; Abaqus/Explicit uses a balanced main-secondary formulation for all surfaces (except node-based surfaces and analytical rigid surfaces). You can override the default assignments and directly specify the main-secondary assignments for surface pairings in a general contact interaction.

1. Display the general contact interaction editor using one of the following methods:
   - To create a new general contact interaction, follow the instructions in *Defining general contact*.
   - To edit an existing general contact interaction, select **Interaction->Edit->*interaction name*** from the main menu bar.
2. Click the **Contact Formulation** tab in the **Attribute Assignments** portion of the interaction editor.
3. Click  next to the following field:
   - **Main-secondary assignments** for Abaqus/Standard general contact definitions.
   - **Pure main-secondary assignments** for Abaqus/Explicit general contact definitions.

   The **Edit Main-Secondary Assignments** dialog box appears. By default, when you select a surface from the list or the table, Abaqus/CAE highlights the surface in the viewport; however, highlighting does not apply for **(Global)** and **(Self)**. You can turn off **Highlight selected regions** at the bottom of the dialog box to turn off selection highlighting.
4. Select one or more surfaces from the list of existing surfaces in the first column on the left side. Select **(Global)** to assign a pure main-secondary weighting for contact between the entire contact domain and an individual surface.

    **Tip:** You can click  to define a new surface and add it to the list. See *Creating surfaces* for instructions on defining surfaces.
5. Select the second surface or surfaces from the list of existing surfaces in the second column to define the surface pairings.
   - When multiple surfaces are selected in either column, all possible combinations will be generated.

- For Abaqus/Standard general contact definitions, select either the same surface name or **(Self)** in the second column to specify a balanced main-secondary formulation for self-contact interactions on a particular surface.
- If the main and secondary surfaces overlap, self-contact is excluded for the overlapping regions.

6. Click the arrows  in the middle of the dialog box to transfer your selections to the list of main-secondary assignments.

   The table on the right side of the dialog box is updated to reflect your selections.

7. Specify the type for the first surface in the last column of the **Main-Secondary Assignments** table.
   - Select **SECONDARY** to indicate the first surface is the secondary surface.
   - Select **MAIN** to indicate that the first surface is the main surface.
   - Select **BALANCED** to specify balanced main-secondary contact between the two surfaces (available only in Abaqus/Standard).

   For self-contact surface pairings, you must select **BALANCED**.

8. Repeat the above steps as needed to complete the main-secondary assignments. If you want to delete main-secondary assignments, select the rows and click .
9. Click **OK** to save your selections.

   The interaction editor reappears with updated information on the number of directly specified main-secondary assignments.

10. Click **OK** to create the interaction and to close the editor.

Specify polarity assignments for general contact

1. Display the general contact interaction editor using one of the following methods:
   - To create a new general contact interaction, follow the instructions in *Defining general contact*.
   - To edit an existing general contact interaction, select **Interaction->Edit->*interaction name*** from the main menu bar.

2. Click the **Contact Formulation** tab in the **Attribute Assignments** portion of the interaction editor.
3. Click  next to the **Polarity assignments** for Abaqus/Explicit general contact definitions.

   The **Edit Polarity Assignments** dialog box appears. By default, when you select a surface from the list or the table, Abaqus/CAE highlights the surface in the viewport; however, highlighting does not apply for **(Global)**. You can toggle off **Highlight selected regions** at the bottom of the dialog box to turn off selection highlighting.

4. Select one or more surfaces from the list of existing surfaces in the first column on the left side. Select **(Global)** to assign a polarity weighting for contact between the entire contact domain and an individual surface.

   Tip: You can click  to define a new surface and add it to the list. See *Creating surfaces* for instructions on defining surfaces.

5. Select the second surface or surfaces from the list of existing surfaces in the second column to define the surface pairings.

- When multiple surfaces are selected in either column, all possible combinations will be generated.
- If the surfaces overlap, self-contact is excluded for the overlapping regions.

6. Click the arrows  in the middle of the dialog box to transfer your selections to the list of polarity assignments.

   The table on the right side of the dialog box is updated to reflect your selections.

7. Specify the option in the third column of the **Polarity Assignments** table, to indicate the side of the (double-sided) elements in the second surface.

   - Select **SPOS** to indicate that the SPOS side of the (double-sided) elements in the second surface should be considered for contact with the first surface.
   - Select **SNEG** to indicate that the SNEG side of the (double-sided) elements in the second surface should be considered for contact with the first surface.
   - Select **TWO_SIDED** to indicate that both sides of the (double-sided) elements in the second surface should be considered for contact with the first surface.

8. Repeat the above steps as needed to complete the polarity assignments. If you want to delete polarity assignments, select the rows and click .
9. Click **OK** to save your selections.

   The interaction editor reappears with updated information on the number of directly specified polarity assignments.

10. Click **OK** to create the interaction and to close the editor.

Specify sliding transition assignments for general contact

1. Display the general contact interaction editor using one of the following methods:

   - To create a new general contact interaction, follow the instructions in *Defining general contact*.
   - To edit an existing general contact interaction, select **Interaction->Edit->*interaction name*** from the main menu bar.

2. Click the **Contact Formulation** tab in the **Attribute Assignments** portion of the interaction editor.
3. Click  next to the **Sliding Transition assignments** for Abaqus/Standard general contact definitions.

   The **Edit Sliding Transition Assignments** dialog box appears. By default, when you select a surface from the list or the table, Abaqus/CAE highlights the surface in the viewport; however, highlighting does not apply for **(Global)** and **(Self)**. You can turn off **Highlight selected regions** at the bottom of the dialog box to turn off selection highlighting.

4. Select one or more surfaces from the list of existing surfaces in the first column on the left side. Select **(Global)** to assign a sliding transition weighting for contact between the entire contact domain and an individual surface.

    **Tip:** You can click  to define a new surface and add it to the list. See *Creating surfaces* for instructions on defining surfaces.

5. Select the second surface or surfaces from the list of existing surfaces in the second column to define the surface pairings.

- When multiple surfaces are selected in either column, all possible combinations will be generated.
- For Abaqus/Standard general contact definitions, select either the same surface name or **(Self)** in the second column to specify a formulation for self-contact interactions on a particular surface.
- If the surfaces overlap, self-contact is excluded for the overlapping regions.

6. Click the arrows  in the middle of the dialog box to transfer your selections to the list of sliding transition assignments.

   The table on the right side of the dialog box is updated to reflect your selections.

7. Specify the smoothness of the contact force redistribution on sliding in the third column of the **Sliding Transition Assignments** table.

   - Select **ELEMENT_ORDER_SMOOTHING** to indicate the smoothness of the contact force redistribution on sliding should be of the same order as the elements underlying the secondary surface.
   - Select **LINEAR_SMOOTHING** to indicate linear smoothness of the contact force redistribution on sliding.
   - Select **QUADRATIC_SMOOTHING** to indicate quadratic smoothness of the contact force redistribution on sliding.

8. Repeat the above steps as needed to complete the sliding transition assignments. If you want to delete sliding transition assignments, select the rows and click .
9. Click **OK** to save your selections.

   The interaction editor reappears with updated information on the number of directly specified sliding transition assignments.

10. Click **OK** to create the interaction and to close the editor.

Specify edge-to-edge formulation assignments for general contact

1. Display the general contact interaction editor using one of the following methods:

   - To create a new general contact interaction, follow the instructions in *Defining general contact*.
   - To edit an existing general contact interaction, select **Interaction->Edit->*interaction name*** from the main menu bar.

2. Click the **Contact Formulation** tab in the **Attribute Assignments** portion of the interaction editor.
3. Toggle on **Edge-to-Edge formulation assignment** for Abaqus/Standard general contact definitions.
4. Specify the **Formulation**.

   - Select **BOTH** to activate both formulations for edge-to-edge contact.
   - Select **NO** to deactivate edge-to-edge contact.
   - Select **RADIAL** to activate the radial edge-to-edge contact formulation.
   - Select **CROSS** to activate the formulation based on the cross product of the edge directions for edge-to-edge contact.

5. Click **OK** to create the interaction and to close the editor.

Specify sliding formulation assignments for general contact

1. Display the general contact interaction editor using one of the following methods:

- To create a new general contact interaction, follow the instructions in *Defining general contact*.
- To edit an existing general contact interaction, select **Interaction->Edit->*interaction name*** from the main menu bar.

2. Click the **Contact Formulation** tab in the **Attribute Assignments** portion of the interaction editor.
3. Click  next to the **Sliding formulation assignments** for Abaqus/Standard general contact definitions.
   The **Edit Sliding Formulation Assignments** dialog box appears. By default, when you select a surface from the list or the table, Abaqus/CAE highlights the surface in the viewport; however, highlighting does not apply for **(Global)** and **(Self)**. You can turn off **Highlight selected regions** at the bottom of the dialog box to turn off selection highlighting.
4. Select one or more surfaces from the list of existing surfaces in the first column on the left side. Select **(Global)** to assign a sliding formulation for contact between the entire contact domain and an individual surface.

    **Tip:** You can click  to define a new surface and add it to the list. See *Creating surfaces* for instructions on defining surfaces.

5. Select the second surface or surfaces from the list of existing surfaces in the second column to define the surface pairings.
   - When multiple surfaces are selected in either column, all possible combinations will be generated.
   - For Abaqus/Standard general contact definitions, select either the same surface name or **(Self)** in the second column to specify a formulation for self-contact interactions on a particular surface.
   - If the surfaces overlap, self-contact is excluded for the overlapping regions.
6. Click the arrows  in the middle of the dialog box to transfer your selections to the list of sliding formulation assignments.
   The table on the right side of the dialog box is updated to reflect your selections.
7. Select the sliding value in the third column of the **Sliding Formulation Assignments** table.
   - Select **Small Sliding** to specify the surface pairings to consider for the small-sliding approach.
   - Select **None** to exclude the surface pairings in the small-sliding approach.
8. Repeat the above steps as needed to complete the sliding formulation assignments. If you want to delete sliding formulation assignments, select the rows and click .
9. Click **OK** to save your selections.
   The interaction editor reappears with updated information on the number of directly specified sliding formulation assignments.
10. Click **OK** to create the interaction and to close the editor.

Specify beam cross-section for general contact

1. Display the general contact interaction editor using one of the following methods:
   - To create a new general contact interaction, follow the instructions in *Defining general contact*.
   - To edit an existing general contact interaction, select **Interaction->Edit->*interaction name*** from the main menu bar.

2. Click the **Contact Controls Assignment** tab in the **Attribute Assignments** portion of the interaction editor.
3. Toggle **Beam Cross Section assignment** for Abaqus/Explicit general contact definitions.
4. Specify the **Beam Cross Section assignment**:
   - Select **CIRCUMSCRIBED CIRCLE** to activate contact calculations based on a circumferential approximation of the beam element.
   - Select **EXACT** to activate contact calculations based on the actual cross section of the beam element.
5. Click **OK** to create the interaction and to close the editor.

Defining surface-to-surface contact

A surface-to-surface contact definition can be used as an alternative to general contact to model contact interactions between specific surfaces in a model.
Certain interaction behaviors can be defined only by using surface-to-surface contact. For a brief overview of surface-to-surface contact and other types of interactions available in Abaqus, see *Understanding interactions*, and *About Contact Interactions*.

You can define surface-to-surface contact in any step, including the initial step. Select **Interaction->Create** from the main menu bar, and select the main and secondary surfaces. You can define contact between edges of a wire or between faces of a solid or shell. Certain connectivity restrictions apply to contact surfaces depending on the type of contact formulation. You can deactivate a surface-to-surface contact interaction in a step and, if desired, reactivate this interaction in a subsequent step. You can deactivate the interaction in a step if it will no longer be needed in the analysis.

If you are creating multiple surface-to-surface contact interactions, you may want to use the contact detection tool. This tool automates the process of selecting surfaces and allows you to create multiple interactions simultaneously. For more information, see *Using contact and constraint detection*.

You can obtain contact data for a specific surface-to-surface contact interaction by using the field and history output request editors in the Step module. In the **Domain** section of the editors, select **Interaction** and choose the name of the surface-to-surface contact interaction from the menu that appears. For more information, see *Creating an output request*.

The procedure for defining surface-to-surface contact depends on whether you are performing an analysis using Abaqus/Standard or Abaqus/Explicit. This section provides instructions for using the interaction editor to define the different surface-to-surface contact options.

In this section:

- *Defining surface-to-surface contact in an Abaqus/Standard analysis*
- *Defining surface-to-surface contact in an Abaqus/Explicit analysis*
- *Specifying interference fit options*

Defining surface-to-surface contact in an Abaqus/Standard analysis

Certain interaction behaviors can be defined in Abaqus/Standard only by using surface-to-surface contact; see *Contact Simulation Capabilities in Abaqus/Standard* for more information.

1. From the main menu bar, select **Interaction->Create**.

   Tip: You can also create a surface-to-surface contact interaction using the  tool in the Interaction module toolbox.

2. In the **Create Interaction** dialog box that appears, do the following:
   - Name the interaction. For more information about naming objects, see *Using basic dialog box components*.
   - Select the step in which the interaction will be created.
   - Select the **Surface-to-surface contact (Standard)** type of interaction.
3. Click **Continue** to close the **Create Interaction** dialog box.
4. Use one of the following methods to select the main surface:
   - Use an existing surface to define the region. On the right side of the prompt area, click **Surfaces**. Select an existing surface from the **Region Selection** dialog box that appears, and click **Continue**.

     Note:

     The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Surfaces** on the right side of the prompt area.

   - Use the mouse to select a region in the viewport. (For more information, see *Selecting objects within the current viewport*.) Click mouse button 2 to indicate you have finished selecting. Certain connectivity restrictions apply to contact surfaces depending on the type of contact formulation. For detailed information, see *About Contact Pairs in Abaqus/Standard*.

     If the model contains a combination of mesh and geometry, click one of the following from the prompt area:

     - Click **Geometry** if you want to select the surface from a geometry region.
     - Click **Mesh** if you want to select the surface from a native or orphan mesh selection.

     You can use the angle method to select a group of faces or edges from geometry or a group of element faces from a mesh. For more information, see *Using the angle and feature edge method to select multiple objects*.

   The main surface that you select becomes highlighted in red in the viewport.
5. Select the secondary surface.
   a. In the prompt area, select one of the following:
      - Select **Surface** if you want to select a surface.
      - Select **Node Region** if you want to select a region from which to create a contact node set.

   b. Use one of the same methods described earlier to select the secondary surface or region.

The secondary surface or region that you select becomes highlighted in magenta in the viewport. The **Edit Interaction** dialog box appears.

6. The **Switch Surfaces** option allows you to interchange your main and secondary surface selections without having to start over. The **Switch Surfaces**  icon is available only if you selected **Surface** in the previous step.
7. Choose the sliding formulation.
   - Choose **Finite sliding** to use the finite-sliding formulation, which is the most general and allows any arbitrary motion of the surfaces.
   - Choose **Small sliding** to use the small-sliding formulation, which assumes that although two bodies may undergo large motions, there will be relatively little sliding of one surface along the other.

   For more information, see *Contact Formulations in Abaqus/Standard*.
8. Select the discretization method.
   - Select **Node to surface** to use the node-to-surface discretization method.
   - Select **Surface to surface** to use the surface-to-surface discretization method.

   For more information, see *Discretization of Contact Pair Surfaces*.
9. Different fields become available depending upon the combination of your sliding formulation and discretization method selections.
   - By default, shell and membrane thicknesses are included in contact calculations for the following combinations: **Small sliding** and **Node to surface**, **Small sliding** and **Surface to surface**, and **Finite sliding** and **Surface to surface**. You can toggle on **Exclude shell/membrane element thickness** to ignore shell and membrane thickness for any of these combinations.

     Contact interactions using **Finite sliding** and **Node to surface** do not account for surface thickness. For more information, see *Accounting for Shell and Membrane Thickness*.
   - For contact interactions using the **Node to surface** discretization method, you can specify a smoothing factor in the **Degree of smoothing for main surface** field. For more information, see *Smoothing Main Surfaces for the Finite-Sliding, Node-to-Surface Formulation*.
   - By default, a selective scheme of supplementary contact constraints is used for the following combinations: **Finite sliding** and **Node to surface**, **Small sliding** and **Node to surface**, and **Small sliding** and **Surface to surface**. For these combinations, you can specify when to **Use supplementary contact points** as follows:
     - Choose **Selectively** to use a selective scheme of supplementary contact constraints.
     - Choose **Never** to forgo the use of supplementary contact constraints.
     - Choose **Always** to add supplementary contact constraints when applicable.

     For more information, see *Supplementary Contact Constraints*.
   - For contact interactions using **Finite sliding** and **Surface to surface**, you can choose the **Contact tracking** method.
     - Choose **Single configuration (state)** to use the state-based tracking algorithm.
     - Choose **Two configurations (path)** to use the path-based tracking algorithm.

     For more information, see *Path-Based Versus State-Based Tracking Algorithms*.

Note:

If your contact interaction uses the surface-to-surface discretization method and one or more of the surfaces in the contact interaction is an analytical rigid surface, you should choose the state-based tracking algorithm.

10. Specify the secondary node adjustment option. For more information, see *Contact Initialization for Contact Pairs in Abaqus/Standard* and *Defining Tied Contact in Abaqus/Standard*.
11. For contact interactions using the **Surface to surface** discretization method, you can apply a smoothing to contacting surfaces that reduces inaccuracies in contact pressures caused by mesh discretization on curved geometries. Click the **Surface Smoothing** tab, and select one of the following options:

    - Choose **Do not smooth** to prevent smoothing from being applied.
    - Choose **Automatically smooth 3D geometry surfaces when applicable** to apply smoothing to axisymmetric or spherical surfaces (or portions of surfaces) that are identified automatically by Abaqus/CAE. Automatic smoothing has no effect on mesh parts or two-dimensional models.

    For more information about contact smoothing techniques, see *Smoothing Contact Surfaces in Abaqus/Standard*.
12. For contact interactions using the **Small sliding** formulation, you can specify an initial clearance between the nodes on the secondary surface and the main surface. Click the **Clearance** tab, select a clearance type from the **Initial clearance** field, and enter all of the data necessary to define the clearance and contact direction. For more information, see *Additional Contact Initialization Options for Small-Sliding Contact in Abaqus/Standard*.
13. If you specify node-to-surface discretization for your contact interaction, you can also limit bonding to secondary nodes in a particular subset. Click the **Bonding** tab, toggle on **Limit bonding to secondary nodes in subset**, and select a node set from the list.

    You can limit bonding for either of the following:

    - When you want to specify a subset of initially secondary nodes that should experience cohesive forces. Strain-free adjustments will be made for those nodes initially not in contact but specified in the node set. All secondary nodes outside of this set (including those that are initially contacting the main surface) will experience only compressive contact forces over the course of the analysis. For more information, see *Specifying cohesive behavior properties for mechanical contact property options*.
    - When you want to identify the initially bonded region of the secondary surface in a VCCT crack. The unbonded portion of the secondary surface behaves as a regular contact surface. The predetermined crack surfaces are assumed to be initially partially bonded so that the crack tips can be identified explicitly during the analysis. For more information, see *Defining Initially Bonded Crack Surfaces in Abaqus/Standard*.
14. Select a contact interaction property. If desired, click  to create the interaction property.

    For more information, see *Defining a contact interaction property* and *Contact Constraint Enforcement Methods in Abaqus/Standard*.
15. To specify interference fit options, click **Interference Fit**. Interference fit options cannot be specified in the initial step. See *Specifying interference fit options* below for more detailed instructions on entering interference fit options.

16. If desired, click the arrow next to the **Contact controls** field and select the customized contact controls to use for this interaction. Only previously created Abaqus/Standard contact controls appear in the list. For more information, see *Specifying contact controls in an Abaqus/Standard analysis*.
17. To deactivate and reactivate a contact interaction in a step, toggle **Active in this step**. The contact interaction is active in the step in which it was created. For more information, see *Removing and Reactivating Contact Pairs*.
18. Click **OK** to create the interaction and to close the editor.

Additional information

- *About Contact Pairs in Abaqus/Standard*
- *Interaction editors*
- *Customizing contact controls*

Defining surface-to-surface contact in an Abaqus/Explicit analysis

Certain interaction behaviors can be defined in Abaqus/Explicit only by using surface-to-surface contact; see *Contact Simulation Capabilities in Abaqus/Explicit* for more information.

1. From the main menu bar, select **Interaction->Create**.

   Tip: You can also create a surface-to-surface contact interaction using the  tool in the Interaction module toolbox.

2. In the **Create Interaction** dialog box that appears, do the following:
   - Name the interaction. For more information about naming objects, see *Using basic dialog box components*.
   - Select the step in which the interaction will be created.
   - Select the **Surface-to-surface contact (Explicit)** type of interaction.
3. Click **Continue** to close the **Create Interaction** dialog box.
4. Use one of the following methods to select the main surface:
   - Use an existing surface to define the region. On the right side of the prompt area, click **Surfaces**. Select an existing surface from the **Region Selection** dialog box that appears, and click **Continue**.

     Note:

     The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Surfaces** on the right side of the prompt area.

   - Use the mouse to select a region in the viewport. (For more information, see *Selecting objects within the current viewport*.) Click mouse button 2 to indicate you have finished selecting. Certain connectivity restrictions apply to contact surfaces depending on the type of contact formulation. For detailed information, see *About Contact Pairs in Abaqus/Explicit*.

     If the model contains a combination of mesh and geometry, click one of the following from the prompt area:

     - Click **Geometry** if you want to select the surface from a geometry region.
     - Click **Mesh** if you want to select the surface from a native or orphan mesh selection.

     You can use the angle method to select a group of faces or edges from geometry or a group of element faces from a mesh. For more information, see *Using the angle and feature edge method to select multiple objects*.

   The main surface that you select becomes highlighted in red in the viewport.
5. Select the secondary surface.
   a. In the prompt area, select one of the following:
      - Select **Surface** if you want to select a surface.
      - Select **Node Region** if you want to select a region from which to create a contact node set.

   b. Use one of the same methods described earlier to select the secondary surface or region.

The secondary surface or region that you select becomes highlighted in magenta in the viewport.

The **Edit Interaction** dialog box appears.

6. The **Switch Surfaces** option allows you to interchange your main and secondary surface selections without having to start over. The **Switch Surfaces**  icon is available only if you selected **Surface** in the previous step.
7. Choose the mechanical constraint formulation.
   - Choose **Kinematic contact method** to use a kinematic predictor/corrector contact algorithm.
   - Choose **Penalty contact method** to use the penalty contact algorithm.

   For more information, see *Contact Constraint Enforcement Methods in Abaqus/Explicit*.
8. Choose the sliding formulation.
   - Choose **Finite sliding** to use the finite-sliding formulation, which is the most general and allows any arbitrary motion of the surfaces.
   - Choose **Small sliding** to use the small-sliding formulation, which assumes that although two bodies may undergo large motions, there will be relatively little sliding of one surface along the other.

   The small-sliding formulation can be specified for interactions created in only the initial step or the first general analysis step. Interactions created in subsequent steps always use the finite-sliding formulation by default. For more information, see *Contact Formulations for Contact Pairs in Abaqus/Explicit*.
9. For contact interactions using the **Small sliding** formulation, you can specify an initial clearance between the nodes on the secondary surface and the main surface. Clearance options are available only in the first general analysis step. Select a clearance type from the **Initial clearance** field, and enter all of the data necessary to define the clearance and contact direction. For more information, see *Specifying Initial Clearance Values Precisely*.
10. Select a contact interaction property. If desired, click  to create the interaction property; see *Defining a contact interaction property*, for more information.
11. Choose the weighting factor. For more information, see *Contact Formulations for Contact Pairs in Abaqus/Explicit*.
12. If desired, click the arrow next to the **Contact controls** field and select the customized contact controls to use for this interaction. Only previously created Abaqus/Explicit contact controls appear in the list. For more information, see *Specifying contact controls in an Abaqus/Explicit analysis*.
13. To deactivate and reactivate a contact interaction in a step, toggle **Active in this step**. The contact interaction is active in the step in which it was created.
14. Click **OK** to create the interaction and to close the editor.

Additional information

- *About Contact Pairs in Abaqus/Explicit*
- *Interaction editors*
- *Customizing contact controls*

Specifying interference fit options

When you are defining surface-to-surface contact for Abaqus/Standard, you can specify interference fit options that help Abaqus/Standard resolve excessive overclosure between surfaces in the initial configuration of a model. For more information, see *Modeling Contact Interference Fits in Abaqus/Standard*.

To open the **Interference Fit Options** dialog box, click **Interference Fit** in the Abaqus/Standard interaction editor (see *Defining surface-to-surface contact in an Abaqus/Standard analysis*" above for details).

1. In the **Interference Fit Options** dialog box, select **Gradually remove secondary node overclosure during the step** to prescribe allowable intereferences.
2. Select one of the following options:
   - Select **Automatic shrink fit (first general analysis step only)** if you want Abaqus/Standard to assign a different allowable interference to each secondary node that is equal to that node's initial penetration. If you select this option, skip to Step 6.
   - Select **Uniform allowable interference** to specify a single allowable interference that will be applied to every secondary node.
3. Click the arrow to the right of the **Amplitude** field to select the name of an amplitude curve that defines the magnitude of the prescribed interference during the step. Alternatively, you can select **(Ramp)** to apply the prescribed interference immediately at the beginning of the step and ramp it down to zero linearly over the step.

   If necessary, you can click  to define a new amplitude curve. For more information, see *Selecting an amplitude type to define*.
4. In the **Magnitude at start of step** field, enter the magnitude of the allowable interference at the start of the step.
5. If desired, select the **Interference Direction** option **Along direction** to specify a shift direction vector. The relative shift is applied to the secondary nodes before Abaqus/Standard determines the contact conditions. If you select this option, enter the following:
   - In the **X** field, enter the *X*-direction cosine of the shift direction vector.
   - In the **Y** field, enter the *Y*-direction cosine of the shift direction vector.
   - In the **Z** field, enter the *Z*-direction cosine of the shift direction vector.
6. Click **OK** to save the interference fit options that you have specified and to return to the **Edit Interaction** dialog box.

Defining self-contact

A self-contact definition can be used as an alternative to general contact to model contact interactions between different areas of a single surface.
Certain interaction behaviors can be defined only by using self-contact. For a brief overview of self-contact and other types of interactions available in Abaqus, see *Understanding interactions*, and *About Contact Interactions*.

You can define self-contact in any step, including the initial step. Select **Interaction->Create** from the main menu bar and select the surface. You can define self-contact between an edge of a wire, a face of a solid, or a face of a shell. Certain connectivity restrictions apply to contact surfaces depending on the type of contact formulation. You can deactivate a self-contact interaction in a step and, if desired, reactivate this interaction in a subsequent step. You can also deactivate the interaction in a step if it will no longer be needed in the analysis.

You can obtain contact data for a specific self-contact interaction by using the field and history output request editors in the Step module. In the **Domain** section of the editors, select **Interaction** and choose the name of the self-contact interaction from the menu that appears. For more information, see *Creating an output request*.

The procedure for defining self-contact depends on whether you are performing an analysis using Abaqus/Standard or Abaqus/Explicit. This section provides instructions for using the interaction editor to define the different surface-to-surface contact options.

In this section:

- *Defining self-contact in an Abaqus/Standard analysis*
- *Defining self-contact in an Abaqus/Explicit analysis*

Defining self-contact in an Abaqus/Standard analysis

Certain interaction behaviors can be defined in Abaqus/Standard only by using self-contact; see *Contact Simulation Capabilities in Abaqus/Standard* for more information.

1. From the main menu bar, select **Interaction->Create**.

   Tip: You can also create a self-contact interaction using the  tool in the Interaction module toolbox.

2. In the **Create Interaction** dialog box that appears, do the following:
   - Name the interaction. For more information about naming objects, see *Using basic dialog box components*.
   - Select the step in which the interaction will be created.
   - Select the **Self-contact (Standard)** type of interaction.
3. Click **Continue** to close the **Create Interaction** dialog box.
4. Use one of the following methods to select the surface:
   - Use an existing surface to define the region. On the right side of the prompt area, click **Surfaces**. Select an existing surface from the **Region Selection** dialog box that appears, and click **Continue**.

     Note:

     The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Surfaces** on the right side of the prompt area.

   - Use the mouse to select a region in the viewport. (For more information, see *Selecting objects within the current viewport*.) Certain connectivity restrictions apply to contact surfaces depending on the type of contact formulation. For detailed information, see *About Contact Pairs in Abaqus/Standard*.

     If the model contains a combination of mesh and geometry, click one of the following from the prompt area:

     - Click **Geometry** if you want to select the surface from a geometry region.
     - Click **Mesh** if you want to select the surface from a native or orphan mesh selection.

     You can use the angle method to select a group of faces or edges from geometry or a group of element faces from a mesh. For more information, see *Using the angle and feature edge method to select multiple objects*.

   The **Edit Interaction** dialog box appears.
5. Select the discretization method.
   - Select **Node to surface** to use the node-to-surface discretization method.
   - Select **Surface to surface** to use the surface-to-surface discretization method.

   For more information, see *Discretization of Contact Pair Surfaces*.
6. Different fields become available depending upon your discretization method selection.

- For contact interactions using the **Node to surface** discretization method, you can specify the following:

  1. Enter a smoothing factor in the **Degree of smoothing** field. For more information, see *Smoothing Main Surfaces for the Finite-Sliding, Node-to-Surface Formulation*.
  2. By default, a selective scheme of supplementary contact constraints is used. You can specify when to **Use supplementary contact points** as follows:

     - Choose **Selectively** to use a selective scheme of supplementary contact constraints.
     - Choose **Never** to forgo the use of supplementary contact constraints.
     - Choose **Always** to add supplementary contact constraints when applicable.

     For more information, see *Supplementary Contact Constraints*.

- For contact interactions using the **Surface to surface** discretization method, you can specify the following:

  1. By default, shell and membrane thicknesses are included in the contact calculations. You can toggle on **Exclude shell/membrane element thickness** to ignore shell and membrane thickness. Contact interactions using the **Node to surface** discretization method do not account for surface thickness.
  2. Choose the **Constraint position**.

     - Choose **Node centered** to center contact constraints at secondary nodes.
     - Choose **Face centered** to center contact constraints within secondary faces.

     For more information, see *Defining Self-Contact*.
  3. Choose the **Contact tracking** algorithm.

     - Choose **Single configuration (state)** to use the state-based tracking algorithm.
     - Choose **Two configurations (path)** to use the path-based tracking algorithm.

     For more information, see *Path-Based Versus State-Based Tracking Algorithms*.

     Note:

     If you use the surface-to-surface discretization method and the surface for which you are defining self-contact is an analytical rigid surface, you should choose the state-based tracking algorithm.

7. Select a contact interaction property. If desired, click  to create the interaction property; see *Defining a contact interaction property* for more information.

   If you choose the **Surface to surface** discretization method, the contact interaction property that you select cannot specify a “hard” contact pressure-overclosure relationship. For more information, see *Contact Constraint Enforcement Methods in Abaqus/Standard* and *Defining mechanical contact property options*.

8. If desired, click the arrow next to the **Contact controls** field and select the customized contact controls to use for this interaction. Only previously created Abaqus/Standard contact controls appear in the list. For more information, see *Specifying contact controls in an Abaqus/Standard analysis*.

9. To deactivate and reactivate a contact interaction in a step, toggle **Active in this step**. The contact pair is active in the step in which it was created. For more information, see *Removing and Reactivating Contact Pairs*.
10. Click **OK** to create the interaction and to close the editor.

Additional information

- *About Contact Pairs in Abaqus/Standard*
- *Interaction editors*
- *Customizing contact controls*

Defining self-contact in an Abaqus/Explicit analysis

Certain interaction behaviors can be defined in Abaqus/Explicit only by using self-contact; see *Contact Simulation Capabilities in Abaqus/Explicit* for more information.

1. From the main menu bar, select **Interaction->Create**.

   Tip: You can also create a self-contact interaction using the  tool in the Interaction module toolbox.

2. In the **Create Interaction** dialog box that appears, do the following:
   - Name the interaction. For more information about naming objects, see *Using basic dialog box components*.
   - Select the step in which the interaction will be created.
   - Select the **Self-contact (Explicit)** type of interaction.
3. Click **Continue** to close the **Create Interaction** dialog box.
4. Use one of the following methods to select the surface:
   - Use an existing surface to define the region. On the right side of the prompt area, click **Surfaces**. Select an existing surface from the **Region Selection** dialog box that appears, and click **Continue**.

     Note:

     The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Surfaces** on the right side of the prompt area.

   - Use the mouse to select a region in the viewport. (For more information, see *Selecting objects within the current viewport*.) Certain connectivity restrictions apply to contact surfaces depending on the type of contact formulation. For detailed information, see *About Contact Pairs in Abaqus/Explicit*.

     If the model contains a combination of mesh and geometry, click one of the following from the prompt area:

     - Click **Geometry** if you want to select the surface from a geometry region.
     - Click **Mesh** if you want to select the surface from a native or orphan mesh selection.

     You can use the angle method to select a group of faces or edges from geometry or a group of element faces from a mesh. For more information, see *Using the angle and feature edge method to select multiple objects*.

   The **Edit Interaction** dialog box appears.
5. Choose the mechanical constraint formulation.
   - Choose **Kinematic contact method** to use a kinematic predictor/corrector contact algorithm.
   - Choose **Penalty contact method** to use the penalty contact algorithm.

   For more information, see *Contact Constraint Enforcement Methods in Abaqus/Explicit*.

6. Select a contact interaction property. If desired, click  to create the interaction property; see *Defining a contact interaction property*, for more information.
7. If desired, click the arrow next to the **Contact controls** field and select the customized contact controls to use for this interaction. Only previously created Abaqus/Explicit contact controls appear in the list. For more information, see *Specifying contact controls in an Abaqus/Explicit analysis*.
8. To deactivate and reactivate the contact interaction, toggle **Active in this step**. The contact pair is active in the step in which it was created.
9. Click **OK** to create the interaction and to close the editor.

Additional information

- *About Contact Pairs in Abaqus/Explicit*
- *Interaction editors*

Specifying contact controls in an Abaqus/Standard analysis

You can specify contact controls for surface-to-surface contact and self-contact interactions in an Abaqus/Standard analysis. For a detailed discussion, see *Generally Applicable Contact Controls in Abaqus/Standard*.

Warning:

Contact controls are intended for advanced users. The default settings of these controls are appropriate for most analyses. Using nondefault values of these controls may greatly increase the computational time of the analysis, produce inaccurate results, or cause convergence problems.

1. From the main menu bar, select **Interaction->Contact Controls->Create**.
2. In the **Create Contact Controls** dialog box that appears, do the following:
   - Name the contact controls.
   - Select **Abaqus/Standard contact controls** as the type of contact controls.
3. Click **Continue** to close the **Create Contact Controls** dialog box.
   The **Edit Contact Controls** dialog box appears.
4. In the **Stabilization** portion of the editor, you can specify controls relating to automatic stabilization of rigid body motions in contact problems using viscous damping.
   - Select one of the following:
     - Select **Automatic stabilization** to use the default damping coefficient calculated automatically by Abaqus/Standard. If desired, you can enter a value for the **Factor** by which the default damping coefficient will be multiplied.
     - Select **Stabilization coefficient** to specify the damping coefficient directly, and enter a value.
   - In the **Tangent fraction** field, enter a value for the fraction of the normal stabilization by which to modify the tangential stabilization. By default, the tangential and normal stabilization are the same.
   - Enter a value for the **Fraction of damping at end of step**.
   - Specify the **Clearance at which damping becomes zero**.
     - Select **Computed** to use the default clearance value calculated by Abaqus/Standard.
     - Select **Specify** to enter a value for the clearance at which the damping becomes zero.
5. In the **Augmented Lagrange** portion of the editor, you can specify controls for interactions defined with a contact interaction property that uses augmented Lagrangian surface behavior.
   - In the **Stiffness scale factor** field, enter a value for the factor by which Abaqus/Standard will scale the default penalty stiffnesses to obtain the stiffnesses used for the contact pairs. The default value is 1.
   - In the **Penetration tolerance** field, select one of the following to specify the allowable penetration that is permitted to violate the impenetrability condition:
     - Select **Absolute**, and enter a value for the allowable penetration.
     - Select **Relative**, and enter the ratio of the allowable penetration to the characteristic contact surface face dimension. The default value is 0.001.

6. Click **OK** to create the contact controls and to close the editor.

Additional information

- *About Contact Pairs in Abaqus/Standard*
- *Contact controls editors*
- *Customizing contact controls*

Specifying contact controls in an Abaqus/Explicit analysis

You can specify contact controls for surface-to-surface contact and self-contact interactions in an Abaqus/Explicit analysis. For more information, see *Contact Controls for Contact Pairs in Abaqus/Explicit*.

Warning:

Contact controls are intended for advanced users. The default settings of these controls are appropriate for most analyses. Using nondefault values of these controls may greatly increase the computational time of the analysis or produce inaccurate results.

1. From the main menu bar, select **Interaction->Contact Controls->Create**.
2. In the **Create Contact Controls** dialog box that appears, do the following:
   - Name the contact controls.
   - Select **Abaqus/Explicit contact controls** as the type of contact controls.
3. Click **Continue** to close the **Create Contact Controls** dialog box.

   The **Edit Contact Controls** dialog box appears.
4. By default, the maximum number of increments between global contact searches is 4 for self-contact interactions and 100 for surface-to-surface contact interactions. If you want to specify the maximum number of increments between global searches, toggle on **Specify max number of increments** in the **Global Search Frequency** portion of the editor and enter a value.
5. By default, Abaqus/Explicit uses techniques for local contact searches (local tracking) that use a minimum amount of computational time. If you have difficulty enforcing the appropriate contact conditions, you can toggle off **Fast local tracking** to use a more conservative local contact search. This setting applies only for surface-to-surface contact interactions.
6. In the **Penalty stiffness scaling factor** field, enter a value for the factor by which Abaqus/Explicit will scale the default penalty stiffness to obtain the stiffnesses used for the penalty contact pairs. The default value is 1.
7. In the **Warp check increment** field, enter the number of increments between checks for highly warped facets on main surfaces. The default value is 20. More frequent checks will cause a slight increase in computational time.
8. In the **Angle criteria for highly warped facet (degrees)** field, enter a value for the out-of-plane warping angle (in degrees) at which Abaqus/Explicit will consider a facet to be highly warped. The out-of-plane warping angle is defined as the amount of variation of the surface normal over a facet. The default value is 20°.
9. Click **OK** to create the contact controls and to close the editor.

Additional information

Defining a fluid cavity interaction

A fluid cavity interaction allows you to define a liquid- or gas-filled volume within a model. You can define a fluid cavity interaction in the initial step of an Abaqus/Standard or Abaqus/Explicit analysis. The fluid cavity interaction cannot be modified or deactivated in subsequent analysis steps. For a detailed discussion, see *Fluid Cavity Definition*.

1. From the main menu bar, select **Interaction->Create**.

   Tip: You can also create a fluid cavity interaction using the tool in the Interaction module toolbox.

2. In the **Create Interaction** dialog box that appears, do the following:
   - Name the interaction. For more information about naming objects, see *Using basic dialog box components*.
   - Select **Initial** for the step in which the interaction will be created.
   - Select the **Fluid cavity** type of interaction.
3. Click **Continue** to close the **Create Interaction** dialog box.
4. Select the cavity point.

   The cavity point is a reference node used to identify the cavity. It should not be connected to any elements in the model. For symmetrical models the cavity point must lie on the axis or axes of symmetry. You can choose a cavity point from the viewport or from a saved set. The default selection method is based on the selection method you most recently employed. To change methods, click **Select in Viewport** or **Sets** on the right side of the prompt area.
5. If your model contains both mesh and geometry regions, select **Geometry** or **Mesh** in the prompt area to specify the region that contains the cavity.
6. Select the cavity surface.

   The cavity surface is made up of all the model faces that enclose the cavity. You can choose the faces of a cavity surface from the viewport or select a saved surface. The default selection method is based on the selection method you most recently employed. To change methods, click **Select in Viewport** or **Surfaces** on the right side of the prompt area.

   The **Edit Interaction** dialog box appears.
7. Select a fluid cavity property. If desired, click to create the interaction property; see *Defining a fluid cavity interaction property*, for more information.
8. If desired, toggle on **Specify ambient pressure**, and enter a pressure to account for the effects of external ambient pressure on the fluid cavity.
9. For two-dimensional models, you must specify an out-of-plane thickness.

   The out-of-plane thickness is used to define the cavity volume.
10. For Abaqus/Explicit analyses using a pneumatic fluid cavity interaction property, toggle on **Use adiabatic behavior** if desired.
11. If desired, toggle off **Check surface normals** to prevent Abaqus/CAE from checking that all surface normals bounding the fluid cavity point in toward the cavity.

    This check can be computationally expensive for complex cavity geometry.
12. Click **OK** to create the interaction and to close the editor.

Symbols that represent the fluid cavity interaction that you just created appear in the viewport. For more information, see *Understanding symbols that represent interactions, constraints, and connectors*.

Additional information

- *Fluid Cavity Definition*
- *Interaction editors*

Defining a fluid exchange interaction

A fluid exchange interaction allows you to define the movement of fluid between a cavity and the surrounding environment or between two cavities. The fluid exchange interaction cannot be modified or deactivated in subsequent analysis steps. For a detailed discussion, see *Fluid Exchange Definition*.

1. From the main menu bar, select **Interaction->Create**.

   Tip: You can also create a fluid cavity interaction using the  tool in the Interaction module toolbox.

2. In the **Create Interaction** dialog box that appears, do the following:
   - Name the interaction. For more information about naming objects, see *Using basic dialog box components*.
   - Select **Initial** for the step in which the interaction will be created.
   - Select the **Fluid exchange** type of interaction.
3. Click **Continue** to close the **Create Interaction** dialog box.

   Abaqus/CAE opens the **Edit Interaction** dialog box.
4. Toggle on the desired exchange definition, **To environment** or **Between cavities**.
5. Select the primary fluid cavity interaction, **Fluid cavity interaction 1**.
6. If you are defining an exchange between cavities, select **Fluid cavity interaction 2**.
7. Select a **Fluid exchange property**. If desired, click  to create the interaction property; see *Defining a fluid exchange interaction property*, for more information.
8. Enter a value for the **Effective exchange area**.

   The effective exchange area represents the cross-sectional area of a pipe that the fluid is exchanged through.
9. Click **OK** to create the interaction and to close the editor.

   Symbols that represent the fluid exchange interaction that you just created appear in the viewport. For more information, see *Understanding symbols that represent interactions, constraints, and connectors*.

Additional information

- *Fluid Cavity Definition*
- *Interaction editors*

Defining a fluid exchange activation interaction

A fluid exchange activation interaction allows you to activate a fluid exchange between two fluid cavities or between a fluid cavity and the environment.

Before you begin: You must create a fluid cavity and fluid exchange interactions.

1. From the main menu bar, select **Interaction->Create**.

   Tip: You can also create a fluid exchange activation interaction using the  tool in the Interaction module toolbox.

2. In the **Create Interaction** dialog box that appears, do the following:
   a. Name the interaction.

      For more information about naming objects, see *Using basic dialog box components*.

   b. Select the step.

      Fluid exchange activation is active only in dynamic steps.

   c. Select the **Fluid exchange activation** type of interaction.
3. Click **Continue** to close the **Create Interaction** dialog box.

   Abaqus/CAE opens the **Edit Interaction** dialog box.
4. Select an **Amplitude** to define a multiplier for the fluid exchange magnitude.

   Tip: Alternatively, you can click  to create a new amplitude. For more information, see *The Amplitude toolset*.

5. Enter the **Delta leakage area** to define the rate of the fluid leakage.
6. Enter a list of **Fluid exchanges** that need to be activated in this step.
7. Select **Consider blockages by contacted surface** to consider vent or leakage area obstruction by contacted surfaces.
8. Select **Allow outflow only** if the flow is allowed only from the first fluid cavity to the second fluid cavity in the fluid exchange.
9. Click **OK** to create the interaction and to close the editor.

   Symbols that represent the fluid exchange activation interaction that you just created appear in the viewport. For more information, see *Understanding symbols that represent interactions, constraints, and connectors*.

- *Fluid Exchange Definition*
- *Interaction editors*

Defining a fluid inflator interaction

A fluid inflator interaction allows you to inflate a fluid cavity to model the flow characteristics of inflators used for airbag systems.

Before you begin: You must create a fluid cavity interaction.

Create the fluid cavity carefully, making sure that both the reference point and the cavity surfaces are contained within a single part. This helps avoid multiple definitions of the fluid inflator in the input file.

1. From the main menu bar, select **Interaction->Create**.

   Tip: You can also create a fluid inflator interaction using the tool in the Interaction module toolbox.

2. In the **Create Interaction** dialog box that appears, do the following:
   a. Name the interaction. For more information about naming objects, see *Using basic dialog box components*.
   b. Select **Initial** for the step in which the interaction will be created.
   c. Select the **Fluid inflator** type of interaction.
3. Click **Continue** to close the **Create Interaction** dialog box.

   Abaqus/CAE opens the **Edit Interaction** dialog box.
4. Select a **Fluid cavity interaction** that defines the fluid cavity reference node to identify the cavity.
5. Select a **Fluid inflator property**. Click to create the interaction property (see *Defining a fluid inflator interaction property* for more information).
6. Click **OK** to create the interaction and to close the editor.

   Symbols that represent the fluid inflator interaction that you just created appear in the viewport. For more information, see *Understanding symbols that represent interactions, constraints, and connectors*.

Additional information

- *Inflator Definition*
- *Interaction editors*

Defining a fluid inflator activation interaction

A fluid inflator activation interaction allows you to activate the inflation of fluid into a fluid cavity to model the flow characteristics of inflators used for airbag systems.

Before you begin: You must create a fluid cavity and fluid inflator interactions.

1. From the main menu bar, select **Interaction->Create**.

   Tip: You can also create a fluid inflator activation interaction using the  tool in the Interaction module toolbox.

2. In the **Create Interaction** dialog box that appears, do the following:
   a. Name the interaction.

      For more information about naming objects, see *Using basic dialog box components*.

   b. Select the step.

      Fluid inflator activation is active only in dynamic steps.

   c. Select the **Fluid inflator activation** type of interaction.
3. Click **Continue** to close the **Create Interaction** dialog box.

   Abaqus/CAE opens the **Edit Interaction** dialog box.
4. Select an **Inflation time amplitude** to define a mapping between the inflation time and the actual time.

   Tip: Alternatively, you can click  to create a new amplitude. For more information, see *The Amplitude toolset*.

5. Select a **Mass flow amplitude** to modify the mass flow rate.

   Tip: Alternatively, you can click  to create a new amplitude. For more information, see *The Amplitude toolset*.

6. Specify a list of **Fluid inflators** that need to be activated in this step.
7. Click **OK** to create the interaction and to close the editor.

   Symbols that represent the fluid inflator activation interaction that you just created appear in the viewport. For more information, see *Understanding symbols that represent interactions, constraints, and connectors*.

- *Inflator Definition*
- *Interaction editors*

Defining a model change interaction

A model change interaction allows you to deactivate and reactivate elements to simulate removal of part of the model, either temporarily or for the remainder of the analysis. You can create a model change interaction in all Abaqus/Standard steps except for static, Riks steps and linear perturbation steps. For a detailed discussion, see *Element and Contact Pair Removal and Reactivation*.

1. From the main menu bar, select **Interaction->Create**.

   Tip: You can also create a model change interaction using the  tool in the Interaction module toolbox.

2. In the **Create Interaction** dialog box that appears, do the following:
   - Name the interaction. For more information about naming objects, see *Using basic dialog box components*.
   - Select the step in which the interaction will be created.
   - Select the **Model change** type of interaction.

3. Click **Continue** to close the **Create Interaction** dialog box.

   The **Edit Interaction** dialog box appears.

4. Specify the model change definition.
   - Choose **Region** to define the region for the model change interaction for the current simulation.
   - Choose **Restart** to allow element or contact model changes in a subsequent restart analysis. Use this model change definition when there are no other model change interactions present. Do not use this definition if you deactivated contact pairs in the first analysis step, or if you created contact pairs after the first analysis step.

5. If you selected the **Region** model change definition, perform the following steps:

   a. Select the region type and region.

   - Select **Geometry** to use model geometry for the model change region, click  to select the region, and make your selection in the viewport.
   - Select **Skins** to use skins for the model change region, and click  to select the region. From the prompt area, select **(pick entire skin)** or **(pick partial skin)**, then make your selection in the viewport. If the selected part has multiple skins, Abaqus/CAE displays the ambiguous picking options in the prompt area while you make your selection.
   - Select **Stringers** to use stringers for the model change region, and click  to select the region. From the prompt area, select **(pick entire stringer)** or **(pick partial stringer)**, then make your selection in the viewport. If the selected part has multiple stringers, Abaqus/CAE displays the ambiguous picking options in the prompt area while you make your selection.
   - Select **Elements** to use elements for the model change region, and click  to select the region. From the prompt area, select **individually** or **by angle**, then make your selection in the viewport. The mesh must be visible to select elements. For more information on this selection method, see *Using the angle and feature edge method to select multiple objects*.

For all region types, you can use an existing set to define the region. On the right side of the prompt area, click **Sets**. Select a valid set from the **Region Selection** dialog box that appears, and click **Continue**.

The default selection method is based on the selection method you most recently employed. To revert to the old method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

b. Select the activation state of the region elements.

- Select **Deactivated in this step** to deactivate the selected region in the current step.
- Select **Reactivated in this step** to activate the selected region in the current step. In subsequent steps you can select this option to reactivate the selected region if it was previously deactivated.

c. If you selected **Reactivated in this step**, you can toggle on **Reactivate elements with strain (if applicable)** to include strain for reactivated stress/displacement elements. Toggle this option off to reset the elements to the initial strain configuration.

6. Click **OK** to create the interaction and to close the editor.

Symbols that represent the model change interaction that you just created appear in the viewport. For more information, see *Understanding symbols that represent interactions, constraints, and connectors*.

Additional information

• *Element and Contact Pair Removal and Reactivation*

• *Interaction editors*

Defining a Standard-Explicit co-simulation interaction

You use a Standard-Explicit co-simulation interaction to define the interface region and coupling schemes for an Abaqus/Standard to Abaqus/Explicit co-simulation. Select **Interaction->Create** from the main menu bar, and select the region for exchanging data. For more information, see *Co-simulation*."

A Standard-Explicit co-simulation interaction can be created only in a general static, implicit dynamic, or explicit dynamic step. The interaction is valid only in the step in which it is created and is not propagated to subsequent steps. Only one Standard-Explicit co-simulation interaction can be active in a model.

1. From the main menu bar, select **Interaction->Create**.

   Tip: You can also create a Standard-Explicit co-simulation interaction using the  tool in the Interaction module toolbox.

2. In the **Create Interaction** dialog box that appears, do the following:
   - Name the interaction. For more information about naming objects, see *Using basic dialog box components*.
   - Select the step in which the interaction will be created.
   - Select the **Standard-Explicit co-simulation** type of interaction.
3. Click **Continue** to close the **Create Interaction** dialog box.
4. In the prompt area, select one of the following for the co-simulation region type:
   - Select **Surface** if you want to select a surface.
   - Select **Node Region** if you want to select nodes.
5. Use one of the following methods to select the region:
   - Use an existing set or surface to define the region. On the right side of the prompt area, click **Sets** or **Surfaces**. Select an existing set or surface from the **Region Selection** dialog box that appears, and click **Continue**.

     Note:

     The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** or **Surfaces** on the right side of the prompt area.

   - Use the mouse to select a region in the viewport. (For more information, see *Selecting objects within the current viewport*.)

     If the model contains a combination of mesh and geometry, click one of the following from the prompt area:

     - Click **Geometry** if you want to select the surface from a geometry region.
     - Click **Mesh** if you want to select the surface from a native or orphan mesh selection.

     You can use the angle method to select a group of faces or edges from geometry or a group of element faces from a mesh. For more information, see *Using the angle and feature edge method to select multiple objects*.

6. Choose the **Incrementation control** method. The same incrementation method must be used in the Abaqus/Standard and Abaqus/Explicit analyses. This option is not available in a static general step.
   - Choose **Allow subcycling** to allow the Abaqus/Standard increment size to differ from those in Abaqus/Explicit; fields will be exchanged as needed.
   - Choose **Lock time steps** to force Abaqus/Standard to match the increment size of Abaqus/Explicit; fields will be exchanged at each of the shared increments.

7. Choose the **Coupling step period**. In Abaqus/Standard analyses, Abaqus always uses the next increment size as the suggested coupling step size.
   - Choose **Determined by analysis** to have Abaqus use the next increment size as the suggested coupling step size.
   - Choose **Specified**, and enter a value for the coupling step size (available only in an Abaqus/Explicit analysis).

8. Click **OK** to create the interaction and to close the editor.

Defining pressure penetration

A pressure penetration interaction allows you to simulate the pressure of a fluid penetrating between two surfaces involved in surface-to-surface contact. The fluid pressure is applied normal to the surfaces. The bodies forming the joint can both be deformable, as is the case with threaded connectors; or one can be rigid, as occurs when a soft gasket is used as a seal between stiffer structures.

Pressure penetration interactions can be applied in three-dimensional, planar (two-dimensional), or axisymmetric models. A pressure penetration interaction can be used only in an Abaqus/Standard analysis.

Before defining the pressure penetration interaction, you must create a surface-to-surface contact interaction to specify the main and secondary surfaces for the pressure penetration; see *Defining surface-to-surface contact in an Abaqus/Standard analysis*. When you create the surface-to-surface contact interaction, any combination of **Sliding formulation** and **Discretization method** can be used (for compatibility with pressure penetration).

In the pressure penetration definition you identify the contact surfaces, the regions on the surfaces exposed to the fluid pressure, the magnitude of the fluid pressure, and the critical contact pressure acting on the regions. In a three-dimensional model points, edges, and faces can be selected as the regions exposed to the fluid pressure. In a two-dimensional model only points can be selected. In a two-dimensional model you must identify the penetration points on both the main and secondary surfaces (unless the main surface is an analytical rigid surface).

The fluid can penetrate from either one or multiple regions on the surface. These regions are always subjected to the pressure penetration, regardless of their contact status. Fluid will penetrate into the region between the contacting bodies until a point is reached where the contact pressure is greater than the specified critical value, cutting off further penetration of the fluid.

1. From the main menu bar, select **Interaction->Create**.

   Tip: You can also create a pressure penetration interaction using the tool in the Interaction module toolbox.

2. In the **Create Interaction** dialog box that appears, do the following:
   - Name the interaction. For more information about naming objects, see *Using basic dialog box components*.
   - Select the step in which the interaction will be created.
   - Select the **Pressure penetration** type of interaction.

3. Click **Continue** to close the **Create Interaction** dialog box.
4. From the **Contact interaction** list, select the surface-to-surface contact interaction to which the pressure penetration will be applied.

   The main and secondary surfaces of the contact interaction are shown in the dialog box, and the surfaces are highlighted in the viewport.
5. For a three-dimensional model, do the following in the **Penetration Regions** table:
   a. Identify the first region on the secondary surface that is exposed to the fluid pressure.

      Double-click the empty cell in the **Region on Secondary** column, or select the cell and click the button; then use one of the following methods to select the region:
      - Use the mouse to select a face, edge, or point on the model in the viewport. If you are working in a mesh, you can use the mouse to select nodes.

- Choose an existing set to specify the face, edge, or point. On the right side of the prompt area, click **Sets**. Select an existing face, edge, or vertex from the **Region Selection** dialog box that appears, and click **Continue**.

  Note:

  The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

It is not necessary to identify the **Region on Main** for a three-dimensional model. However, doing so may help you resolve any problems that you encounter with the analysis. You can select the **Region on Main** in exactly the same way as the **Region on Secondary**.

Note:

If the selected contact interaction has an analytical rigid main surface, the **Region on Main** column appears dimmed, indicating that adding or editing main surface points is unavailable. Any main surface regions that have already been specified will be ignored.

b. Enter the **Critical Contact Pressure** below which fluid will start to penetrate. The higher this value, the easier the fluid penetrates. The default is zero, in which case the fluid penetrates only if contact is lost.

c. Enter the magnitude of the reference **Fluid Pressure**.

If the analysis step is a steady-state dynamic (linear perturbation) step, you can specify both the real (in-phase) and imaginary (out-of-phase) parts of the pressure in the **Fluid Pressure (Real)** and **Fluid Pressure (Imaginary)** columns of the table.

d. To add a row to the table and to continue selecting additional penetration regions, click the  button. This action takes you directly to the region picking step in the viewport. Repeat as needed to specify all the regions.

e. To edit a penetration region, select the region in the table, click the  button, and reselect the region.

f. To delete a region, select the row in the table and click the  button.

6. For a planar (two-dimensional) or axisymmetric model, do the following in the **Penetration Regions** table:

a. Identify the first pair of points exposed to the fluid pressure.

Double-click the empty cell in the **Region on Main** column, or select the cell and click the  button; then use one of the following methods to select the point:

- Use the mouse to select the point on the model in the viewport.
- Choose an existing set to specify the point. On the right side of the prompt area, click **Sets**. Select an existing node or vertex from the **Region Selection** dialog box that appears, and click **Continue**.

Note:

The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

Repeat the process to select the corresponding penetration point on the secondary surface, using the **Region on Secondary** column of the table.

Note:

If the selected contact interaction has an analytical rigid main surface, the **Region on Main** column appears dimmed, indicating that adding or editing main surface points is unavailable. Any main surface points that have already been specified will be ignored.

b. Enter the **Critical Contact Pressure** below which fluid will start to penetrate. The higher this value, the easier the fluid penetrates. The default is zero, in which case the fluid penetrates only if contact is lost.

c. Enter the magnitude of the reference **Fluid Pressure**.

If the analysis step is a steady-state dynamic (linear perturbation) step, you can specify both the real (in-phase) and imaginary (out-of-phase) parts of the pressure in the **Fluid Pressure (Real)** and **Fluid Pressure (Imaginary)** columns of the table.

d. To add a row to the table and to continue selecting penetration points, click the  button. This action takes you directly to the point picking step in the viewport. Repeat as needed to specify all the points.

e. To edit a penetration point, select the point in the table, click the  button, and reselect the point.

f. To delete a pair of penetration points, select the row in the table and click the  button.

7. In the **Penetration time** field, enter the time period for the fluid pressure penetration to reach the full current magnitude on newly penetrated surface segments. The default penetration time is 0.001 of the current step time. The penetration time is not available in a linear perturbation analysis.
8. Optionally, you can define the variation of the fluid pressure during the step by selecting an amplitude curve in the **Amplitude** list. By default, the reference magnitude is applied immediately at the beginning of the step or ramped up linearly over the step, depending on the amplitude variation assigned to the step. Fluid pressure amplitude curves are not available for some steps.
9. Click **OK** to create the interaction and to close the editor.

Defining acoustic impedance

You can model acoustic impedance by providing boundary impedances or nonreflecting boundaries for acoustic and coupled acoustic-structural analyses. Select **Interaction->Create** from the main menu bar, and select the surface to form an acoustic boundary. Acoustic impedance interactions are active only in dynamic steps that utilize the acoustic degree of freedom. You can create an acoustic impedance interaction in a static step; Abaqus ignores the acoustic effects in the static step but propagates the interaction through any applicable linear perturbation steps that follow. If you create an acoustic impedance interaction in a linear perturbation step, the interaction is not propagated to any of the subsequent steps.

For a brief overview of acoustic impedance, see *Understanding interactions*. For a more detailed discussion, see *Acoustic and Shock Loads*.

1. From the main menu bar, select **Interaction->Create**.

   Tip: You can also create an acoustic impedance interaction using the  tool in the Interaction module toolbox.

2. In the **Create Interaction** dialog box that appears, do the following:
   - Name the interaction. For more information about naming objects, see *Using basic dialog box components*.
   - Select the step. Acoustic impedance is active only in dynamic steps that utilize the acoustic degree of freedom.
   - Select the **Acoustic impedance** type of interaction.
3. Click **Continue** to close the **Create Interaction** dialog box.
4. Use one of the following methods to select the surface:
   - Use an existing surface to define the region. On the right side of the prompt area, click **Surfaces**. Select an existing surface from the **Region Selection** dialog box that appears, and click **Continue**.

     Note:

     The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Surfaces** on the right side of the prompt area.

   - Use the mouse to select a region in the viewport. (For more information, see *Selecting objects within the current viewport*.)

     If the model contains a combination of mesh and geometry, click one of the following from the prompt area:

     - Click **Geometry** if you want to select the surface from a geometry region.
     - Click **Mesh** if you want to select the surface from a native or orphan mesh selection.

     You can use the angle method to select a group of faces or edges from geometry or a group of element faces from a mesh. For more information, see *Using the angle and feature edge method to select multiple objects*.
5. In **Definition** field in the **Edit Interaction** dialog box that appears, choose one of the following:

- Choose **Tabular** to define impedance using a table of admittance or impedance values in an acoustic impedance property.
- Choose **Nonreflecting** to define nonreflecting boundaries for impedance.

6. If you selected the **Tabular** definition option, select an acoustic impedance property. If desired, click  to create the interaction property; see *Defining an acoustic impedance interaction property*.
7. If you selected the **Nonreflecting** definition option, click the arrow to the right of the **Nonreflecting type** field; and select one of the options from the list that appears to define the nonreflecting geometry.
   - Select **Planar** to specify a radiation condition appropriate for plane waves normally incident to a planar boundary.
   - Select **Improved planar** to specify a radiation condition appropriate for plane waves with arbitrary angles of incidence. In linear perturbation steps, improved planar acoustic impedance interactions default to planar acoustic impedance interactions.
   - Select **Circular** to specify a radiation condition appropriate for a circular boundary in two dimensions or a right circular cylinder in three dimensions.
   - Select **Spherical** to specify a radiation condition appropriate for a spherical boundary.
   - Select **Elliptical** to specify a radiation condition appropriate for an elliptical boundary in two dimensions or a right elliptical cylinder in three dimensions.
   - Select **Prolate spheroidal** to specify a radiation condition appropriate for a prolate spheroidal boundary.
8. If you selected the **Circular** or **Spherical** nonreflecting definition option, enter the radius of the circle or sphere defining the boundary surface in the **Radius** field.
9. If you selected the **Elliptical** or **Prolate spheroidal** nonreflecting definition option, perform the following steps:
   a. In the **Axis length** field, enter the semimajor axis length, *a*, of the ellipse or prolate spheroid defining the surface. *a* is 1/2 of the maximum distance between two points on the ellipse or spheroid, analogous to the radius of a circle or sphere.
   b. In the **Eccentricity** field, enter the eccentricity, ϵ, of the ellipse or prolate spheroid. The eccentricity is the square root of one minus the square of the ratio of the semiminor axis, *b*, to the semimajor axis, *a*: $\epsilon = \sqrt{1-(b/a)^2}$.
   c. In the **Center coordinates** field, enter the *X*-coordinate, *Y*-coordinate, and *Z*-coordinate of the center of the ellipse or prolate spheroid defining the radiating surface.
   d. In the **Direction cosine** field, enter the *X*-component, *Y*-component, and *Z*-component of the direction cosine of the major axis of the ellipse or prolate spheroid defining the radiating surface.

Defining incident waves

You can model incident wave loading due to external acoustic wave sources.
Select **Interaction->Create** from the main menu bar, and select the source point, the standoff point (for all incident wave loading definitions except for those using the CONWEP model), and the surface. When specifying source points and standoff points, you can select only reference points that are not associated with any other model component. You can create incident wave interactions in the following types of analyses: implicit dynamic, explicit dynamic, direct steady-state dynamic, and subspace-based steady-state dynamic. Incident wave interactions are active only in the steps in which they are created and do not propagate to any of the following steps. If your model includes incident wave interactions, you must edit the model attributes (see below) to specify an acoustic wave formulation for the model.

For a brief overview of incident wave interactions, see *Understanding interactions*. For a more detailed discussion, see *Coupled Acoustic-Structural Analysis*, and *Incident Wave Loading due to External Sources*.

Additional information

- *Coupled Acoustic-Structural Analysis*
- *Acoustic and Shock Loads*
- *Specifying model attributes*
- *Interaction editors*

Specify the acoustic wave formulation for the model

If your model contains incident wave interactions, you must edit the model attributes to specify an acoustic wave formulation. You select a scattered wave formulation or a total wave formulation using the procedure described in *Specifying model attributes*. The formulation that you select applies for all of the incident wave interactions in your model. For more information, see *Scattered and Total Wave Formulations*.

Define an incident wave interaction

1. From the main menu bar, select **Interaction->Create**.

   Tip: You can also create an incident wave interaction using the tool in the Interaction module toolbox.

2. In the **Create Interaction** dialog box that appears, do the following:
   - Name the interaction. For more information about naming objects, see *Using basic dialog box components*.
   - Select the step. You can define an incident wave interaction only during an implicit, explicit, direct steady-state, or subspace-based steady-state dynamic analysis. An incident wave interaction is active only in the step in which it is created.
   - Select the **Incident wave** type of interaction.
3. Click **Continue** to close the **Create Interaction** dialog box.
4. Select the incident wave source point by selecting a reference point that is not associated with any other model component. For more information, see *Creating a reference point*.

   The source point that you select becomes highlighted in red in the viewport.
5. For all incident wave definitions except for those using the CONWEP model, select the incident wave standoff point by selecting a reference point that is not associated with any other model component. For more information, see *Creating a reference point*.

The standoff point that you select becomes highlighted in green in the viewport.

6. For an incident wave definition of air or surface blast data using the definitions of CONWEP data, click **CONWEP (Air/Surface blast)** in the prompt area.

   Abaqus/CAE specifies a **Definition** of **CONWEP** for this incident wave definition.

7. Use one of the following methods to select the surface:

   - Use an existing surface to define the region. On the right side of the prompt area, click **Surfaces**. Select an existing surface from the **Region Selection** dialog box that appears, and click **Continue**.

     Note:

     The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Surfaces** on the right side of the prompt area.

   - Use the mouse to select a region in the viewport.

   The surface or region that you select becomes highlighted in magenta in the viewport, and the **Edit Interaction** dialog box appears.

8. For all incident wave definitions except for those using the CONWEP model, click the arrow to the **Definition** field and select an option from the list that appears. For direct and subspace-based steady-state dynamic analyses, you can only specify the fluid pressure time history at the standoff point.

   - Select **Pressure** to specify the fluid pressure time history at the standoff point.
   - Select **Acceleration** to specify the fluid particle acceleration time history at the standoff point.
   - Select **UNDEX** to specify UNDEX bubble data.

9. In the **Wave Data** portion of the editor, perform the following steps:

   a. Select an incident wave interaction property. If desired, click  to create the interaction property; see *Defining an incident wave interaction property*, for more information. The following requirements exist:

      - If you selected the **Pressure** definition, you must select an interaction property with a planar definition or a spherical definition with either an acoustic or generalized decay propagation model.
      - If you selected the **Acceleration** definition, you must select an interaction property with a planar definition.
      - If you selected the **UNDEX** definition, you must select an interaction property with a spherical definition and an UNDEX charge propagation model.
      - If you selected the **CONWEP** definition, you must select an interaction property with an air blast or surface blast definition.

   b. In the **Reference magnitude** field, enter the reference magnitude used to scale the values given in the amplitude definition.

10. If you selected the **Pressure** or **Acceleration** definition, perform the following steps from the **Standoff Point** portion of the editor:

    - For an implicit or explicit dynamic analysis, select a **Pressure amplitude** or an **Acceleration amplitude**, depending on the time history definition.

- For a direct or subspace-based steady-state dynamic analysis, toggle on **Real amplitude** and/or **Imaginary amplitude** and select an amplitude.

If desired, click  to create a new amplitude; see *Selecting an amplitude type to define*.

11. If you selected the **UNDEX** definition, perform the following steps in the **UNDEX Data** portion of the editor:
    a. In the **Direction cosine of fluid surface normal** field, enter the *X*-component, *Y*-component, and *Z*-component of the direction cosine of the fluid surface normal.
    b. In the **Initial depth** field, enter the initial depth of the UNDEX charge.
12. If you selected the **CONWEP** definition, perform the following steps in the **CONWEP Data** portion of the editor:
    a. In the **Time of detonation** field, specify the time when the blast occurs in terms of the total time for the entire analysis.
    b. In the **Magnitude scale factor** field, specify the factor by which you want to scale CONWEP data units to analysis data units.
13. Click **OK** to create the interaction and to close the editor.

Defining cyclic symmetry

You can define a cyclic symmetry interaction to model an entire 360° structure using only a single repetitive sector. Select **Interaction->Create**, choose **Cyclic symmetry**, and specify the geometric region by selecting a main surface or node region, a secondary surface or node region, and an axis of symmetry for the structure. You can also control the number of sectors that create the full 360° structure, select the cyclic symmetry nodal diameters for which an eigenfrequency analysis will be performed, and select the cyclic symmetry nodal diameter that will be excited for a steady-state dynamics step.

You can create a cyclic symmetry interaction in the initial step, and only one cyclic symmetry interaction can be active in a model.

For more information about cyclic symmetry in Abaqus, see *Analysis of Models that Exhibit Cyclic Symmetry*.

1. From the main menu bar, select **Interaction->Create**.

   Tip: You can also create a cyclic symmetry interaction using the  tool in the Interaction module toolbox.

2. In the **Create Interaction** dialog box that appears, do the following:
   - Name the interaction. For more information about naming objects, see *Using basic dialog box components*.
   - Select the initial step.
   - Select the **Cyclic symmetry** type of interaction.
3. Click **Continue** to close the **Create Interaction** dialog box.
4. Select the main surface.
   a. In the prompt area, select one of the following:
      - Select **Surface** if you want to select a surface.
      - Select **Node Region** if you want to select a region from which to create a node-based surface.

   b. Use one of the following methods to select the main surface:
      - Use an existing surface to define the region. On the right side of the prompt area, click **Surfaces**. Select an existing surface from the **Region Selection** dialog box that appears, and click **Continue**.

        Note:

        The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Surfaces** on the right side of the prompt area.

      - Use the mouse to select a region in the viewport. (For more information, see *Selecting objects within the current viewport*.) Click mouse button 2 to indicate that you have finished selecting.

        If the model contains a combination of mesh and geometry, click one of the following from the prompt area:
        - Click **Geometry** if you want to select the surface from a geometry region.
        - Click **Mesh** if you want to select the surface from a native or orphan mesh selection.

You can use the angle method to select a group of faces or edges from geometry or a group of element faces from a mesh. For more information, see *Using the angle and feature edge method to select multiple objects*.

The main surface that you select becomes highlighted in red in the viewport.

5. Select the secondary surface.
   a. In the prompt area, select one of the following:
      - Select **Surface** if you want to select a surface.
      - Select **Node Region** if you want to select a region from which to create a node-based surface.
   b. Use one of the same methods described in the previous step to select the secondary surface or region.

      The secondary surface or region that you select becomes highlighted in magenta in the viewport.

      Abaqus/CAE prompts you to define the axis of symmetry.
6. Use one of the following methods to select the first point on the axis of symmetry:
   - Use an existing set to define the region. The set must contain a single point or vertex. On the right side of the prompt area, click **Sets**. Select an existing set from the **Region Selection** dialog box that appears, and click **Continue**.

     Note:

     The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.
   - Use the mouse to select a node or vertex in the viewport. (For more information, see *Selecting objects within the current viewport*.)

     If the model contains a combination of mesh and geometry, click one of the following from the prompt area:
     - Click **Geometry** if you want to select the surface from a geometry region.
     - Click **Mesh** if you want to select the surface from a native or orphan mesh selection.

   The point that you select becomes highlighted in red in the viewport.
7. Using one of the methods described in the previous step, select the second point on the axis of symmetry.

   The point that you select becomes highlighted in magenta in the viewport, and the **Edit Cyclic Symmetry** dialog box opens.
8. From the **Position Tolerance** options, specify the distance within which Abaqus will tie nodes on the secondary surface to the main surface. Choose one of the following options:
   - Select **Use computed distance** to use a distance calculated automatically based on the element formulations and types of surfaces used in the constraints.
   - Select **Specify distance**, and enter a value to set the distance within which secondary nodes will be tied to the main surface.
9. Toggle off **Adjust secondary surface initial position** to prevent Abaqus from moving all tied nodes on the secondary surface onto the main surface.

By default, this option is toggled on and all tied nodes are moved in the initial configuration without applying strains to the model.

10. Specify the **Total number of sectors** that comprise the full 360° structure.
11. From the **Extracted Nodal Diameters** options, specify the range of cyclic symmetry nodal diameters for which the eigenfrequency analysis will be performed. You can define this range in the initial step or in a frequency extraction step only. Specify this range using either of the following options:
    - Select **All possible nodal diameters** to extract every possible cyclic symmetry nodal diameter.
    - Select **Specified range** to extract every cyclic symmetry nodal diameter between a **Lowest nodal diameter** and **Highest nodal diameter** that you specify. The highest nodal diameter must be less than or equal to half the number of sectors.
12. Specify the **Excited nodal diameter** associated with the loading in the load definition. You can select the excited nodal diameter in the initial step or in a mode-based steady-state dynamics step. Only one cyclic symmetry nodal diameter can be excited.
13. Click **OK**.

    Abaqus/CAE creates the cyclic symmetry interaction.

Defining foundations

You can model an elastic foundation by defining the foundation stiffness per area of a selected surface. Select **Interaction->Create** from the main menu bar, and select the surface to be modeled as an elastic foundation. For a brief overview of elastic foundations, see *Understanding interactions*. For a more detailed discussion, see *Element Foundations*.

Elastic foundations allow you to model the stiffness effects of a distributed support without actually modeling the details of the support. You can create elastic foundation interactions only in the initial step. Once an elastic foundation is activated, you cannot deactivate it in later analysis steps.

1. From the main menu bar, select **Interaction->Create**.

   Tip: You can also create an elastic foundation interaction using the tool in the Interaction module toolbox.

2. In the **Create Interaction** dialog box that appears, do the following:
   - Use an existing surface to define the region. On the right side of the prompt area, click **Surfaces**. Select an existing surface from the **Region Selection** dialog box that appears, and click **Continue**.The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Surfaces** on the right side of the prompt area.
   - Name the interaction. For more information about naming objects, see *Using basic dialog box components*.
   - Select the initial step.
   - Select the **Elastic foundation** type of interaction.
3. Click **Continue** to close the **Create Interaction** dialog box.
4. Use one of the following methods to select the surface:
   - Use the mouse to select a region in the viewport. (For more information, see *Selecting objects within the current viewport*.)
   - If the model contains a combination of mesh and geometry, click one of the following from the prompt area:
     - Click **Geometry** if you want to select the surface from a geometry region.
     - Click **Mesh** if you want to select the surface from a native or orphan mesh selection.

     You can use the angle method to select a group of faces or edges from geometry or a group of element faces from a mesh. For more information, see *Using the angle and feature edge method to select multiple objects*.
5. In the text field that appears in the prompt area, enter the foundation stiffness per area.

   Abaqus/CAE creates the elastic foundation interaction.

Additional information

Defining a cavity radiation interaction

This section describes how you can create a cavity radiation interaction in Abaqus/CAE and use cavity symmetry to reduce the expense of the calculations.

In this section:

- *Defining cavity radiation properties and view factors*
- *Defining cavity radiation symmetry*

Defining cavity radiation properties and view factors

You can model heat transfer due to radiation in enclosures by creating a cavity radiation interaction. Select **Interaction->Create** from the main menu bar, and select the surface. For a brief overview of cavity radiation, see *Understanding interactions*. For a more detailed discussion, see *Cavity Radiation in Abaqus/Standard*.

1. From the main menu bar, select **Interaction->Create**.

   Tip: You can also create a cavity radiation interaction using the  tool in the Interaction module toolbox.

2. In the **Create Interaction** dialog box that appears, do the following:
   - Name the interaction. For more information about naming objects, see *Using basic dialog box components*.
   - Select the step. You can define cavity radiation only during a heat transfer or coupled thermal-electrical step.
   - Select the **Cavity radiation** type of interaction.
3. Click **Continue** to close the **Create Interaction** dialog box.
4. Use one of the methods below to select the cavity surface. Select only the portion of the surface to which one *cavity radiation interaction property* applies.
   - Use an existing surface to define the region. On the right side of the prompt area, click **Surfaces**. Select an existing surface from the **Region Selection** dialog box that appears, and click **Continue**.

     Note:

     The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Surfaces** on the right side of the prompt area.

   - Use the mouse to select a region in the viewport. (For more information, see *Selecting objects within the current viewport*.)

     If the model contains a combination of mesh and geometry, click one of the following from the prompt area:

     - Click **Geometry** if you want to select the surface or vertex from a geometry region.
     - Click **Mesh** if you want to select the surface or node from a native or orphan mesh selection.

     You can use the angle method to select a group of faces or edges from geometry or a group of element faces from a mesh. For more information, see *Using the angle and feature edge method to select multiple objects*.

   Abaqus/CAE displays the **Edit Interaction** dialog box, and the surface name or `(Picked)` appears in the **Surface** column on the **Properties** tabbed page.
5. To define additional cavity surfaces, click mouse button 3 in the table, select **Add Row**, and do one of the following:
   - Double-click an empty cell in the **Surfaces** column.
   - Click mouse button 3 in an empty table row, and select **Edit Surface**.

Note:

You can also use these techniques to replace an existing cavity surface; Abaqus/CAE does not indicate or retain your original selection when you edit an existing surface.

6. Choose the cavity type in the **Definition** field.
   - Select **Closed** to specify a set of closed surfaces for radiation.
   - Select **Open** to include some radiation to the surroundings, and specify an **Ambient temperature** for the open cavity definition.

7. Specify the **Properties** options.
   a. Select the **Blocking surface checks**. By default, Abaqus checks for blocking surfaces within the cavity when performing radiation view factor calculations.
      - Choose **All** to indicate that all blocking checks are active.
      - Choose **None** to skip blocking checks.
      - Choose **Partial** to specify potential blocking surfaces that Abaqus should check.

      For more information, see *Controlling Checks for Surface Blocking*.

   b. If you chose the **Partial** option, double-click an empty cell in the **Blocking Surface** table to select surfaces that you want Abaqus to check.

      Tip: You can also click mouse button 3 in the **Blocking Surface** table and choose **Edit Surface**, **Add Row**, or **Delete Row** to edit the table.

      The surface selection methods are the same as those described in Step 4.

   c. Select the heat reflection behavior.
      - Choose **Yes** for gray body radiation. Gray bodies have an emissivity between zero and one, as defined by a cavity radiation interaction property.
      - Choose **No** for black body radiation. Black bodies have a fixed emissivity of one—no heat is reflected.

   d. If you chose gray body radiation in the previous step, you must specify a cavity radiation interaction property for each row in the table. You can use any of the following methods:
      - Click a cell in the **Property** column to choose a predefined cavity radiation interaction property.
      - Click mouse button 3 in the table, and select **Create Property** to create a new interaction property or **Edit Property** to edit the existing cavity radiation interaction property in the selected row. (For more information, see *Defining a cavity radiation interaction property*.)
      - Enter a value in the **Emissivity** column. Abaqus/CAE automatically creates a cavity radiation interaction property with a default name and the specified emissivity.

   When you are finished, each row in the table contains a surface and an emissivity value or `(table)`, indicating that there is a tabular emissivity defined in the interaction property. **Property** cells may be empty if you entered an emissivity value—Abaqus/CAE will add a default interaction property name when you close the **Edit Interaction** dialog box.

8. Specify the **View factors** options.
   a. If desired, toggle on **Specify blocking range** and enter a value for the distance beyond which Abaqus should not calculate view factors due to blocking effects.

b. Specify the **Accuracy tolerance**. The default value is 0.05.

The view factor tolerance indicates the allowable deviation from the ideal sum of view factors. Abaqus ends the analysis if the tolerance is exceeded for a closed cavity. If the tolerance is exceeded for an open cavity, radiation to the ambient environment occurs.

c. Specify the **Infinitesimal facet area ratio**. The default value is 64.

This value represents the ratio of the largest facet area to the smallest facet area. Abaqus calculates this ratio for each facet pair.

d. Specify the **Gauss integration points per edge**. The default value is 3.

This value is used for the numerical integration method. Possible values range from 1 to 5.

e. Specify the **Lumped area distance-square value**. The default value is 5.

This value represents the ratio of the distance between the centroids of each facet pair, squared, to the area of the larger facet. If the calculated value is greater than this setting, Abaqus uses a lumped area approximation for the integration.

f. If desired, click the **Defaults** button to reset all view factor entries to the Abaqus default values.

If the calculated value for a pair of facets is less than or equal to the **Lumped area distance-square value** setting and the **Infinitesimal facet area ratio** is exceeded, Abaqus uses an infinitesimal-to-finite area approximation. If the **Lumped area distance-square value** is exceeded but the facet area ratio is not exceeded, Abaqus completes a numerical integration of the contour integral to get an accurate value.

For more information, see *Controlling the Accuracy of View Factor Calculations*.

9. Specify the **Symmetry** options. For detailed information on the available cavity radiation symmetry types, see *Defining cavity radiation symmetry*."

10. Specify the absolute zero temperature, θ^Z, on the temperature scale being used and the Stefan-Boltzmann constant, σ, in the **Edit Model Attributes** dialog box, as described in *Specifying model attributes*.

11. Click **OK** to create the interaction and to close the editor.

- *Cavity Radiation in Abaqus/Standard*

Defining cavity radiation symmetry

Using symmetry reduces the computational size of your cavity model. The available symmetries and combinations vary according to the model type. The table in *Combining Symmetries*, indicates the available symmetry combinations. You can use the following symmetry types to complete the cavity definition:

Reflection

Select a **Number of reflection symmetries**, and select a reference z-symmetry value (axisymmetric models), a symmetry axis (two-dimensional models), or a symmetry plane (three-dimensional models) for each reflection.

Abaqus/CAE adds the reflected surfaces to the cavity definition and reduces the remaining number of symmetries allowed in the model. Toggle on **Highlight** to view the current parameter selections in the viewport.

Periodic

Select a **Number of periodic symmetries** and number of repetitions for each periodic symmetry. For axisymmetric models, select a reference z-symmetry value and a periodic z-distance value. For two-dimensional and three-dimensional models, select a symmetry axis and a distance vector or a symmetry plane and a distance vector, respectively, for each periodic symmetry.

Abaqus/CAE adds the periodic surfaces to the cavity surfaces you selected for the **Properties** options and reduces the remaining number of symmetries allowed in the model. Toggle on **Highlight** to view the current parameter selections in the viewport.

Cyclic

Toggle on **Use cyclic symmetric** and select the total number of sectors. Select the symmetry point and a point on the axis of symmetry (two-dimensional models) or the first and second points on the axis of symmetry and a point on the symmetry plane (three-dimensional models).

Cyclic symmetry creates new sectors by rotating the original geometry clockwise about the axis of symmetry. Cyclic symmetry is not available for axisymmetric models.

The following conditions must be met:

- For two-dimensional models the selected point on the axis of symmetry must be on the clockwise side of the geometry defining the original sector.
- For three-dimensional models the selected point on the symmetry plane must be on the counterclockwise side of the geometry defining the original sector.
- The total number of sectors must define a complete circle (360°). If you change the number of sectors, you must redefine the geometry to represent the correct portion of the model.

For more information on cyclic symmetry, including figures showing the sector definitions, see *Cyclic Symmetry*.

Warning:

Abaqus/CAE does not check that the defined symmetries produce a physically realistic cavity model.

Defining a surface film condition interaction

You can model heat transfer from surfaces due to convection by creating a surface film condition interaction. Select **Interaction->Create** from the main menu bar and select the surface.
For a brief overview of film conditions, see *Understanding interactions*. For a more detailed discussion, see *Thermal Loads*.

1. From the main menu bar, select **Interaction->Create**.

   Tip: You can also create a surface film condition interaction using the  tool in the Interaction module toolbox.

2. In the **Create Interaction** dialog box that appears, do the following:
   a. Name the interaction.

      For more information about naming objects, see *Using basic dialog box components*.

   b. Select the step. You can define convection from a surface only during a heat transfer, coupled temperature-displacement, coupled thermal-electrical, coupled thermal-electrochemical, coupled thermal-electrochemical structure, or coupled thermal-electrochemical structure pore pressure step.
   c. Select the **Surface film condition** type of interaction.
3. Click **Continue** to close the **Create Interaction** dialog box.
4. Use one of the following methods to select the surface:

   - Use an existing surface to define the region. On the right side of the prompt area, click **Surfaces**. Select an existing surface from the **Region Selection** dialog box that appears, and click **Continue**.

     Note: The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Surfaces** on the right side of the prompt area.

   - Use the mouse to select a region in the viewport. (For more information, see *Selecting objects within the current viewport*.)
   - If the model contains a combination of mesh and geometry, click one of the following from the prompt area:
     - Click **Geometry** if you want to select the surface or vertex from a geometry region.
     - Click **Mesh** if you want to select the surface or node from a native or orphan mesh selection.

   You can use the angle method to select a group of faces or edges from geometry or a group of element faces from a mesh. For more information, see *Using the angle and feature edge method to select multiple objects*.
5. In the **Edit Interaction** dialog box that appears, click the arrow to the right of the **Definition** field, and select an option from the list that appears:

   - Select **Embedded Coefficient** to specify the film coefficient in this dialog box.
   - Select **Property Reference** to define the film coefficient as a function of temperature and field variables using a film condition interaction property.
   - Select **User-defined** to define nonuniform film coefficients in user subroutine *FILM*. (This option is valid only in Abaqus/Standard analyses). See the following sections for more information:
     - *Specifying general job settings*

- *FILM*

- Select an analytical field to define a spatially varying film coefficient. The analytical field does not affect the sink temperature. Only analytical fields that are valid for this interaction type are displayed in the selection list. Alternatively, you can click $f(x)$ to create a new analytical field. (See *The Analytical Field toolset* for more information.)

6. If you selected the **Embedded Coefficient** or analytical field definition option, perform the following steps:
   a. In the **Film coefficient** field, enter the film coefficient, *h*.
   b. If you want to vary the film coefficient with time, click the arrow to the right of the **Film coefficient amplitude** field and select an amplitude from the list that appears. If desired, click to create a new amplitude; see *Selecting an amplitude type to define* for more information.
   c. In the **Sink temperature** field, enter the sink temperature, θ^0.
   d. If you want to define a spatially varying sink temperature, click the arrow to the right of the **Sink definition** field and select an analytical field, labeled with an (A), or a discrete field, labeled with a (D). Only analytical fields and discrete fields that are valid for temperature are available in the selection list. See *The Analytical Field toolset* and *The Discrete Field toolset* for more information. Alternatively, you can click to create a new discrete field.
   e. If you want to vary the sink temperature with time, click the arrow to the right of the **Sink amplitude** field and select an amplitude from the list that appears. If desired, click to create a new amplitude; see *Selecting an amplitude type to define* for more information.
7. If you selected the **Property Reference** definition option, perform the following steps:
   a. Select a film interaction property. If desired, click to create the interaction property; see *Defining a film condition interaction property* for more information.
   b. In the **Sink temperature** field, enter the sink temperature, θ^0.
   c. If you want to define a spatially varying sink temperature, click the arrow to the right of the **Sink definition** field and select an analytical field, labeled with an (A), or a discrete field, labeled with a (D). Only analytical fields and discrete fields that are valid for temperature are available in the selection list. See *The Analytical Field toolset* and *The Discrete Field toolset* for more information. Alternatively, you can click to create a new discrete field.
   d. If you want to vary the sink temperature with time, click the arrow to the right of the **Sink amplitude** field and select an amplitude from the list that appears. If desired, click to create a new amplitude; see *Selecting an amplitude type to define* for more information.
8. If you selected the **User-defined** definition option, perform the following steps:
   a. In the **Film coefficient** field, enter the film coefficient, *h*.
   b. In the **Sink temperature** field, enter the sink temperature, θ^0.
   c. Enter the Job module, and display the job editor for the analysis job of interest. (For more information, see *Creating, editing, and manipulating jobs*.)
   d. In the job editor, click the **General** tab, and specify the file containing the user subroutine *FILM*. For more information, see *Specifying general job settings*.

Note: You can specify only one user subroutine file in the job editor; if your analysis involves more than one user subroutine, you must combine the user subroutines into one file and then specify that file.

9. Check the **Toggle on dynamic surface activation** check box to specify the film condition on the evolving faces of an element.
10. Click **OK** to create the interaction and to close the editor.

Additional information

- *Interaction editors*
- *Using analytical expression fields*
- *Creating expression fields*
- *Thermal Loads*

Defining a concentrated film condition interaction

You can model heat transfer from one or more points in an assembly due to convection by creating a concentrated film condition interaction. Select **Interaction->Create** from the main menu bar and select one or more nodes or vertices or a saved set of nodes or vertices.
For a brief overview of film conditions, see *Understanding interactions*. For a more detailed discussion, see *Thermal Loads*.

1. From the main menu bar, select **Interaction->Create**.

   Tip: You can also create a concentrated film condition interaction using the tool in the Interaction module toolbox.

2. In the **Create Interaction** dialog box that appears, do the following:
   a. Name the interaction. For more information about naming objects, see *Using basic dialog box components*.
   b. Select the step.

      You can define convection from a nodal area only during a heat transfer, coupled temperature-displacement, coupled thermal-electrical, coupled thermal-electrochemical, coupled thermal-electrochemical structure, or coupled thermal-electrochemical structure pore pressure step.
   c. Select the **Concentrated film condition** type of interaction.
3. Click **Continue** to close the **Create Interaction** dialog box.
4. Use one of the following methods to select the points:

   - Use an existing set of nodes or vertices to define the region. On the right side of the prompt area, click **Sets**. Select an existing set from the **Region Selection** dialog box that appears, and click **Continue**.

     Note: The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

   - Use the mouse to select nodes or vertices in the viewport. (For more information, see *Selecting objects within the current viewport*.)
   - If the model contains a combination of mesh and geometry, click one of the following from the prompt area:
     - Click **Geometry** if you want to select vertices from a geometry region.
     - Click **Mesh** if you want to select nodes from a native or orphan mesh selection.

   You can use the angle method to select a group of nodes from a mesh. For more information, see *Using the angle and feature edge method to select multiple objects*.
5. In the **Edit Interaction** dialog box that appears, click the arrow to the right of the **Definition** field and select an option from the list that appears:

   - Select **Embedded Coefficient** to specify the film coefficient in this dialog box.
   - Select **Property Reference** to define the film coefficient as a function of temperature and field variables using a film condition interaction property.
   - Select **User-defined** to define nonuniform film coefficients in user subroutine *FILM*. (This option is valid only in Abaqus/Standard analyses). See the following sections for more information:

- *Specifying general job settings*
- *FILM*

- Select an analytical field to define a spatially varying film coefficient. The analytical field does not affect the sink temperature. Only analytical fields that are valid for this interaction type are displayed in the selection list. Alternatively, you can click $f(x)$ to create a new analytical field. (See *The Analytical Field toolset* for more information.)

6. If desired, specify how the concentrated film condition is applied to the boundary of an adaptive mesh domain. This option is valid only for Abaqus/Explicit analyses. Click the arrow to the right of the **Adaptive mesh boundary type** field, and select an option from the list that appears. For more information, see *Defining ALE Adaptive Mesh Domains in Abaqus/Explicit*.
   - Select **Lagrangian** to apply a concentrated film to a node that follows the material (nonadaptive).
   - Select **Sliding** to apply a concentrated film to a node that can slide over the material. Mesh constraints are typically applied to the node to fix it spatially.
   - Select **Eulerian** to apply a concentrated film to a node that can move independently of the material. This option is used only for boundary regions where the material can flow into or out of the adaptive mesh domain. Mesh constraints must be used normal to an Eulerian boundary region to allow material to flow through the region. If no mesh constraints are applied, an Eulerian boundary region will behave in the same way as a sliding boundary region.
7. In the **Associated nodal area** field, enter the area associated with the node where the concentrated film condition is applied.
8. If you selected the **Embedded Coefficient** or analytical field definition option, perform the following steps:
   a. In the **Film coefficient** field, enter the film coefficient, h.
   b. If you want to vary the film coefficient with time, click the arrow to the right of the **Film coefficient amplitude** field and select an amplitude from the list that appears. If desired, click  to create a new amplitude; see *Selecting an amplitude type to define*, for more information.
   c. In the **Sink temperature** field, enter the sink temperature, θ^0.
   d. If you want to define a spatially varying sink temperature, click the arrow to the right of the **Sink definition** field and select an analytical field, labeled with an (A), or a discrete field, labeled with a (D). Only analytical fields and discrete fields that are valid for temperature are available in the selection list. See *The Analytical Field toolset* and *The Discrete Field toolset* for more information. Alternatively, you can click  to create a new discrete field.
   e. If you want to vary the sink temperature with time, click the arrow to the right of the **Sink amplitude** field and select an amplitude from the list that appears. If desired, click  to create a new amplitude; see *Selecting an amplitude type to define*, for more information.
9. If you selected the **Property Reference** definition option, perform the following steps:
   a. Select a film interaction property. If desired, click  to create the interaction property; see *Defining a film condition interaction property*, for more information.
   b. In the **Sink temperature** field, enter the sink temperature, θ^0.
   c. If you want to define a spatially varying sink temperature, click the arrow to the right of the **Sink definition** field and select an analytical field, labeled with an (A), or a discrete field, labeled with

a (D). Only analytical fields and discrete fields that are valid for temperature are available in the selection list. See *The Analytical Field toolset* and *The Discrete Field toolset* for more information.

Alternatively, you can click  to create a new discrete field.

d. If you want to vary the sink temperature with time, click the arrow to the right of the **Sink amplitude** field and select an amplitude from the list that appears. If desired, click  to create a new amplitude; see *Selecting an amplitude type to define* for more information.

10. If you selected the **User-defined** definition option, perform the following steps:

a. In the **Film coefficient** field, enter the film coefficient, h.

b. In the **Sink temperature** field, enter the sink temperature, θ^0.

c. Enter the Job module, and display the job editor for the analysis job of interest. (For more information, see *Creating, editing, and manipulating jobs*.)

d. In the job editor, click the **General** tab, and specify the file containing the user subroutine *FILM*. For more information, see *Specifying general job settings*.

Note: You can specify only one user subroutine file in the job editor; if your analysis involves more than one user subroutine, you must combine the user subroutines into one file and then specify that file.

11. Click **OK** to create the interaction and to close the editor.

Additional information

- *Interaction editors*

- *Thermal Loads*

Defining a surface radiative interaction

You can model heat transfer between a nonconcave surface and a nonreflecting environment due to radiation by creating a surface radiation interaction. Surface radiation can also be used to approximate cavity radiation for a closed cavity in three-dimensional models. Select **Interaction->Create** from the main menu bar, and select the surface. For a brief overview of radiative interactions, see *Understanding interactions*. For a more detailed discussion, see *Thermal Loads*. For more information about cavity radiation, see *Defining a cavity radiation interaction* and *Cavity Radiation in Abaqus/Standard*.

1. From the main menu bar, select **Interaction->Create**.

   Tip: You can also create a surface radiative interaction using the  tool in the Interaction module toolbox.

2. In the **Create Interaction** dialog box that appears, do the following:
   a. Name the interaction.

      For more information about naming objects, see *Using basic dialog box components*.

   b. Select the step. You can define radiation from a surface only during a heat transfer, coupled temperature-displacement, coupled thermal-electrical, coupled thermal-electrochemical, coupled thermal-electrochemical structure, or coupled thermal-electrochemical structure pore pressure step.
   c. Select the **Surface radiation** type of interaction.
3. Click **Continue** to close the **Create Interaction** dialog box.
4. Use one of the following methods to select the surface:

   - Use an existing surface to define the region. On the right side of the prompt area, click **Surfaces**. Select an existing surface from the **Region Selection** dialog box that appears, and click **Continue**.

     Note: The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Surfaces** on the right side of the prompt area.

   - Use the mouse to select a region in the viewport. (For more information, see *Selecting objects within the current viewport*.)
   - If the model contains a combination of mesh and geometry, click one of the following from the prompt area:
     - Click **Geometry** if you want to select the surface or vertex from a geometry region.
     - Click **Mesh** if you want to select the surface or node from a native or orphan mesh selection.

   You can use the angle method to select a group of faces or edges from geometry or a group of element faces from a mesh. For more information, see *Using the angle and feature edge method to select multiple objects*.
5. In the **Edit Interaction** dialog box that appears, select the **Radiation type**.
   a. Select **To ambient** to specify heat transfer to the surrounding environment.
   b. Select **Cavity approximation (3D only)** to approximate cavity radiation in three-dimensional models using uniform emissivity, a closed cavity, and an average cavity temperature.
6. If you selected **To ambient** in the previous step, complete the radiation definition as follows:

a. Click the arrow to the right of the **Emissivity distribution** field, and select the option of your choice from the list that appears:

- Select **Uniform** to define an emissivity that is uniform over the surface.
- Select an analytical field to define a spatially varying emissivity. Only analytical fields that are valid for this interaction type are displayed in the selection list. Alternatively, you can click $f(x)$ to create a new analytical field. (See *The Analytical Field toolset* for more information.)

b. In the **Emissivity** field, enter the emissivity of the surface, ϵ.

c. In the **Ambient temperature** field, enter the ambient temperature, θ^0.

d. If you want to vary the ambient temperature with time, click the arrow to the right of the **Ambient temperature amplitude** field and select an amplitude from the list that appears. If desired, click  to create a new amplitude; see *Selecting an amplitude type to define* for more information.

7. If you selected **Cavity approximation (3D only)** in Step 5, enter the emissivity of the surface, ϵ, in the **Emissivity** field.

8. Specify the absolute zero temperature, θ^Z, on the temperature scale being used and the Stefan-Boltzmann constant, σ, in the **Edit Model Attributes** dialog box, as described in *Specifying model attributes*.

9. Check the **Toggle on dynamic surface activation** check box to specify the radiation condition on the evolving faces of an element.

10. Click **OK** to create the interaction and to close the editor.

Defining a concentrated radiative interaction

You can model heat transfer between one or more points in an assembly and a nonreflecting environment due to radiation by creating a concentrated radiation to ambient interaction. Select **Interaction->Create** from the main menu bar, and select one or more nodes or vertices or a saved set of nodes or vertices. For a brief overview of radiative interactions, see *Understanding interactions*. For a more detailed discussion, see *Thermal Loads*.

1. From the main menu bar, select **Interaction->Create**.

   Tip: You can also create a concentrated radiative interaction using the  tool in the Interaction module toolbox.

2. In the **Create Interaction** dialog box that appears, do the following:
   a. Name the interaction.

      For more information about naming objects, see *Using basic dialog box components*.

   b. Select the step.

      You can define radiation from a nodal area only during a heat transfer, coupled temperature-displacement, coupled thermal-electrical, coupled thermal-electrochemical, coupled thermal-electrochemical structure, or coupled thermal-electrochemical structure pore pressure step.

   c. Select the **Concentrated radiation to ambient** type of interaction.
3. Click **Continue** to close the **Create Interaction** dialog box.
4. Use one of the following methods to select the points:

   - Use an existing set of nodes or vertices to define the region. On the right side of the prompt area, click **Sets**. Select an existing set from the **Region Selection** dialog box that appears, and click **Continue**.

     Note: The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

   - Use the mouse to select nodes or vertices in the viewport. (For more information, see *Selecting objects within the current viewport*.)

     If the model contains a combination of mesh and geometry, click one of the following from the prompt area:

     - Click **Geometry** if you want to select vertices from a geometry region.
     - Click **Mesh** if you want to select nodes from a native or orphan mesh selection.

     You can use the angle method to select a group of nodes from a mesh. For more information, see *Using the angle and feature edge method to select multiple objects*.

5. In the **Edit Interaction** dialog box that appears, perform the following steps:
   a. If desired, specify how the concentrated radiation condition is applied to the boundary of an adaptive mesh domain. This option is valid only for Abaqus/Explicit analyses. Click the arrow to the right of the **Adaptive mesh boundary type** field, and select an option from the list that appears. For more information, see *Defining ALE Adaptive Mesh Domains in Abaqus/Explicit*.

      - Select **Lagrangian** to apply a concentrated radiation condition to a node that follows the material (nonadaptive).

- Select **Sliding** to apply a concentrated radiation condition to a node that can slide over the material. Mesh constraints are typically applied to the node to fix it spatially.
- Select **Eulerian** to apply a concentrated radiation condition to a node that can move independently of the material. This option is used only for boundary regions where the material can flow into or out of the adaptive mesh domain. Mesh constraints must be used normal to an Eulerian boundary region to allow material to flow through the region. If no mesh constraints are applied, an Eulerian boundary region will behave in the same way as a sliding boundary region.

b. In the **Associated nodal area** field, enter the area associated with the node where the concentrated radiation condition is applied.

c. Click the arrow to the right of the **Emissivity distribution** field, and select the option of your choice from the list that appears:

- Select **Uniform** to define an emissivity that is uniform over the region.
- Select an analytical field to define a spatially varying emissivity. Only analytical fields that are valid for this interaction type are displayed in the selection list. Alternatively, you can click $f(x)$ to create a new analytical field. (See *The Analytical Field toolset* for more information.)

d. In the **Emissivity** field, enter the emissivity of the surface, ϵ.

e. In the **Ambient temperature** field, enter the ambient temperature, θ^0.

f. If you want to vary the ambient temperature with time, click the arrow to the right of the **Ambient temperature amplitude** field and select an amplitude from the list that appears. If desired, click  to create a new amplitude; see *Selecting an amplitude type to define*, for more information.

6. Specify the absolute zero temperature, θ^Z, on the temperature scale being used and the Stefan-Boltzmann constant, σ, in the **Edit Model Attributes** dialog box, as described in *Specifying model attributes*.
7. Click **OK** to create the interaction and to close the editor.

Additional information

- *Interaction editors*

- *Creating expression fields*
- *Thermal Loads*

Defining an actuator/sensor interaction

You can create an actuator/sensor interaction at a single vertex of your model. An actuator/sensor interaction provides an interface to user subroutine *UEL*. The subroutine, in turn, represents a linear or nonlinear user-defined element. Actuator/sensor interactions must be defined during the initial step and are valid only for Abaqus/Standard analyses.

Warning:

This feature is intended for advanced users only. Its use in all but the simplest test examples will require considerable coding by the user/developer. *User-Defined Elements*, should be read before proceeding.

1. From the main menu bar, select **Interaction->Create**.

   Tip: You can also create an actuator/sensor interaction using the  tool in the Interaction module toolbox.

2. In the **Create Interaction** dialog box that appears, do the following:
   - Name the interaction. For more information about naming objects, see *Using basic dialog box components*.
   - Select the initial step.
   - Select the **Actuator/sensor** type of interaction.
3. Click **Continue** to close the **Create Interaction** dialog box.
4. From the assembly, select the point where the interaction will be applied. Click mouse button 2 to indicate you have finished selecting the point.

   Tip: You can limit the types of objects that you can select in the viewport by specifying filtering options in the Selection toolbar. See *Using the selection options*, for more information.

   Abaqus/CAE displays the **Edit Interaction** dialog box.
5. Enter the necessary data in the **Edit Interaction** dialog box. The required data are a function of your user-defined element subroutine. You may need to create real and integer actuator/sensor interaction properties. For more information, see *Defining an actuator/sensor interaction property*.

   The following table indicates the correspondence between the fields in the **Edit Interaction** dialog box and the variables in user subroutine *UEL*.

Field	UEL variable
User element type id	`JTYPE`
Degrees of freedom	`NDOFEL`
Number of coordinate components	`MCRD`
Solution-dependent state variables	`SVARS` and `NSVARS`

The real and integer values entered into an actuator/sensor interaction property are used by the `PROPS`, `JPROPS`, `NPROPS`, and `NJPROPS` variables. For a description of all the variables that can be passed into user subroutine *UEL*, see *User-Defined Elements*.

Additional information

- *User-Defined Elements*
- *UEL*
- *Interaction editors*

Defining contact mass scaling

In Abaqus/Explicit contact mass scaling can be defined for all steps, and this contact mass scaling definition is active for all subsequent steps.

A contact mass scaling definition can apply mass scaling to the contact surfaces/elements involved in the contact definition in Abaqus/Explicit only.

1. From the main menu bar, select **Interaction->Create**.

   Tip: You can also create a general contact interaction using the  tool in the Interaction module toolbox.

2. In the **Create Interaction** dialog box that appears, do the following:
   - Name the interaction. For more information about naming objects, see *Using basic dialog box components*.
   - Select the step in which the interaction will be created. Contact mass scaling can be created in any explicit step in which contact is already defined.
   - Select the **Contact Mass Scaling (Explicit)** type of interaction.

3. Click **Continue** to close the **Create Interaction** dialog box.

   The **Edit Interaction** dialog box appears.

4. Specify the Location (The Default is Element Mass Scaling)
5. If the location selected is Specified Surfaces, then select the surfaces to include in contact mass scaling from the list of available surfaces.

   a. Click the arrows 

   in the middle of the dialog box to transfer the surfaces to the list of surfaces that will be included in the contact mass scaling.

6. Click **OK** to create the interaction and to close the editor.

Additional information

- **CONTACT MASS SCALING*

Using the interaction property editors

This section explains how to enter data in the interaction property editors to define specific types of interaction properties.

In this section:

- *Defining a contact interaction property*
- *Defining a film condition interaction property*
- *Defining a cavity radiation interaction property*
- *Defining a fluid cavity interaction property*
- *Defining a fluid exchange interaction property*
- *Defining an acoustic impedance interaction property*
- *Defining an incident wave interaction property*
- *Defining an actuator/sensor interaction property*
- *Defining a fluid inflator interaction property*
- *Defining a wear interaction property*

Defining a contact interaction property

The contact property editor contains the following menus from which you can choose options to include in the property definition: **Mechanical**, **Thermal**, and **Electrical**.

A contact interaction property can be referred to by a general contact, surface-to-surface contact, or self-contact interaction. For more information, see *About Mechanical Contact Properties*, *Thermal Contact Properties*, and *Electrical Contact Properties*.

The **Contact Property Options** list at the top of the editor displays the options currently included in the property definition; the list is updated as you add and delete options. You can add, delete, or change property options as follows:

Adding property options

Select the options needed to define your property from the **Mechanical**, **Thermal**, and **Electrical** menus. When you select an option, its name appears in the **Contact Property Options** list, and data fields associated with the option appear in the data area in the bottom half of the editor. Use the data fields to enter information for the currently selected option.

Deleting property options

In the **Contact Property Options** list, select the option that you want to delete, and click **Delete** on the right side of the editor. This procedure removes the option from both the options list and the property definition.

Changing option data

In the **Contact Property Options** list, select the option whose data you want to change. When the data fields associated with the option appear in the bottom half of the window, change the information that you have entered for the option as desired.

In this section:

- *Defining mechanical contact property options*
- *Defining thermal contact property options*
- *Defining electrical contact property options*

Defining mechanical contact property options

You can define mechanical contact property options to specify tangential behavior (friction and elastic slip), normal behavior (hard, soft, or damped contact and separation), and damping due to friction.

In this section:

- *Specifying frictional behavior for mechanical contact property options*
- *Specifying pressure-overclosure relationships for mechanical contact property options*
- *Specifying damping for mechanical contact property options*
- *Specifying cohesive behavior properties for mechanical contact property options*
- *Specifying cohesive damage properties for mechanical contact property options*
- *Specifying fracture criterion properties for crack propagation*
- *Specifying geometric properties for mechanical contact property options*

Specifying frictional behavior for mechanical contact property options

You can specify a friction model that defines the force resisting the relative tangential motion of the surfaces in a mechanical contact analysis. For more information, see *Frictional Behavior*.

1. From the main menu bar, select **Interaction->Property->Create**.
2. In the **Create Interaction Property** dialog box that appears, do the following:
   - Name the interaction property. For more information about naming objects, see *Using basic dialog box components*.
   - Select the **Contact** type of interaction property.
3. Click **Continue** to close the **Create Interaction Property** dialog box.
4. From the menu bar in the contact property editor, select **Mechanical->Tangential Behavior**.
5. In the editor that appears, click the arrow to the right of the **Friction formulation** field, and select how you want to define friction between the contact surfaces:
   - Select **Frictionless** if you want Abaqus to assume that surfaces in contact slide freely without friction.
   - Select **Penalty** to use a stiffness (penalty) method that permits some relative motion of the surfaces (an "elastic slip") when they should be sticking. While the surfaces are sticking (i.e., $\tau_{eq} < \tau_{crit}$), the magnitude of sliding is limited to this elastic slip. Abaqus will continually adjust the magnitude of the penalty constraint to enforce this condition. For more information, see *Stiffness Method for Imposing Frictional Constraints in Abaqus/Standard* and *Stiffness Method for Imposing Frictional Constraints in Abaqus/Explicit*.
   - Select **Static-Kinetic Exponential Decay** to specify static and kinetic friction coefficients directly. In this model it is assumed that the friction coefficient decays exponentially from the static value to the kinetic value. Alternatively, you can enter test data to fit the exponential model. (This **Friction formulation** option also allows you to specify elastic slip.) For more information, see *Specifying Static and Kinetic Friction Coefficients*.
   - Select **Rough** to specify an infinite coefficient of friction. For more information, see *Preventing Slipping regardless of Contact Pressure*.
   - Select **Lagrange Multiplier (Standard only)** to enforce the sticking constraints at an interface between two surfaces using the Lagrange multiplier implementation. With this method there is no relative motion between two closed surfaces until $\tau_{eq} = \tau_{crit}$. For more information, see *Lagrange Multiplier Method for Imposing Frictional Constraints in Abaqus/Standard*.
   - Select **User-defined** to define the shear interaction between the contact surfaces with user subroutine *FRIC* or *VFRIC*. For more information, see *User-Defined Friction Model*.
6. If you selected the **Penalty** or **Lagrange Multiplier (Standard only)** friction formulation, perform the following steps:
   a. Display the **Friction** tabbed page.
   b. Choose the **Directionality**:
      - Choose **Isotropic** to enter a uniform friction coefficient.
      - Choose **Anisotropic (Standard only)** to allow for different friction coefficients in the two orthogonal directions on the contact surface. For more information, see *Anisotropic Friction with Directional Preference Associated with Contact Orientation*.
   c. Toggle on **Use slip-rate-dependent data** if the friction coefficient is dependent on slip rate.

d. Toggle on **Use contact-pressure-dependent data** if the friction coefficient is dependent on the contact pressure.

e. Toggle on **Use temperature-dependent data** if the friction coefficient is dependent on temperature.

f. Click the arrows to the right of the **Number of field variables** field to specify the number of field variables on which the friction coefficient depends.

g. Enter the required data in the data table provided.

h. Display the **Shear Stress** tabbed page, and choose a **Shear stress limit** option:

- Choose **No limit** if you do not want to limit the shear stress that can be carried by the interface before the surfaces begin to slide.
- Choose **Specify** to enter an equivalent shear stress limit, τ_{max}. If you choose this option, sliding will occur if the magnitude of the equivalent shear stress reaches this value, regardless of the magnitude of the contact pressure stress. For more information, see *Using the Optional Shear Stress Limit*.

i. If you selected the **Penalty** friction formulation, display the **Elastic Slip** tabbed page, and specify how you want to define elastic slip:

- If you are performing an Abaqus/Standard analysis, choose an option to **Specify maximum elastic slip**:
  - Choose **Fraction of characteristic surface dimension** to calculate the allowable elastic slip as a small fraction of the characteristic contact surface length.
  - Choose **Absolute distance** to enter the absolute magnitude of the allowable elastic slip, γ_t. (For a steady-state transport analysis set this parameter equal to the absolute magnitude of the allowable elastic slip velocity ($\dot{\gamma}_t$) to be used in the stiffness method for sticking friction.)
- If you are performing an Abaqus/Explicit analysis, choose an **Elastic slip stiffness** option:
  - Choose **Infinite (no slip)** to deactivate shear softening.
  - Choose **Specify** to activate softened tangential behavior. Enter the slope of the curve that defines the shear traction as a function of the elastic slip between the two surfaces.

For more information, see *Shear Stress Versus Elastic Slip While Sticking*.

7. If you selected the **Static-Kinetic Exponential Decay** friction formulation, perform the following steps:

a. Display the **Friction** tabbed page.

b. Choose an option for defining the exponential decay friction model:

- Choose **Coefficients** to provide the static friction coefficient, the kinetic friction coefficient, and the decay coefficient directly.
- Choose **Test data** to provide test data points to fit the exponential model.

For more information, see *Specifying Static and Kinetic Friction Coefficients*.

c. If you selected the **Coefficients** definition option, enter the following in the data table provided:

- Static friction coefficient, μ_s.
- Kinetic friction coefficient, μ_k.
- Decay coefficient, d_c.

If you selected the **Test data** definition option, enter the following in the data table provided:

- In the first row, enter the static friction coefficient, μ_1.
- In the second row, enter the dynamic friction coefficient, μ_2 and the reference slip rate, $\dot{\gamma}_2$, at which μ_2 is measured.
- In the third row, enter the kinetic friction coefficient, μ_∞. This value corresponds to the asymptotic value of the friction coefficient at infinite slip rate, $\dot{\gamma}_\infty$. If this data line is omitted, Abaqus/Standard automatically calculates μ_∞ such that $(\mu_2 - \mu_\infty) / (\mu_1 - \mu_\infty) = 0.05$.

d. Display the **Elastic Slip** tabbed page, and specify how you want to define elastic slip:

- If you are performing an Abaqus/Standard analysis, choose an option to **Specify maximum elastic slip**:
  - Choose **Fraction of characteristic surface dimension** to calculate the allowable elastic slip as a small fraction of the characteristic contact surface length.
  - Choose **Absolute distance** to enter the absolute magnitude of the allowable elastic slip, γ_i. (For a steady-state transport analysis set this parameter equal to the absolute magnitude of the allowable elastic slip velocity ($\dot{\gamma}_i$) to be used in the stiffness method for sticking friction.)
- If you are performing an Abaqus/Explicit analysis, choose an **Elastic slip stiffness** option:
  - Choose **Infinite (no slip)** to deactivate shear softening.
  - Choose **Specify** to activate shear softening. Enter the slope of the curve that defines the shear traction as a function of the elastic slip between the two surfaces.

For more information, see *Shear Stress Versus Elastic Slip While Sticking*.

8. If you selected the **User-defined** friction formulation, perform the following steps:

a. Click the arrows to the right of the **Number of state-dependent variables** field to indicate the number state variables that will be defined in user subroutine *FRIC* or *VFRIC*.

b. In the **Friction Properties** table, enter the values of properties needed by user subroutine *FRIC* or *VFRIC*. (For detailed information on how to enter data, see *Entering tabular data*.)

For more information, see *User-Defined Friction Model*.

9. Click **OK** to create the contact property and to exit the **Edit Contact Property** dialog box. Alternatively, you can select another contact property option to define from the menus in the **Edit Contact Property** dialog box.

Specifying pressure-overclosure relationships for mechanical contact property options

You can define a constitutive model for the contact pressure-overclosure relationship that governs the motion of the surfaces in a mechanical contact analysis. For more information, see *Contact Pressure-Overclosure Relationships*.

1. From the main menu bar, select **Interaction->Property->Create**.
2. In the **Create Interaction Property** dialog box that appears, do the following:
   - Name the interaction property. For more information about naming objects, see *Using basic dialog box components*.
   - Select the **Contact** type of interaction property.
3. Click **Continue** to close the **Create Interaction Property** dialog box.
4. From the menu bar in the contact property editor, select **Mechanical->Normal Behavior**.
5. From the **Pressure-Overclosure** field, select **"Hard" Contact** to use the classical Lagrange multiplier method of constraint enforcement in an Abaqus/Standard analysis and to use penalty contact enforcement in an Abaqus/Explicit analysis.

   You can also toggle off **Allow separation after contact** if you want to prevent surfaces from separating once they have come into contact. This method is applicable only to Abaqus/Standard analyses.

   If you select **"Hard" Contact**, you can also customize settings for the constraint enforcement method. For more information about constraint enforcement methods, see *Contact Constraint Enforcement Methods in Abaqus/Explicit*. To specify these settings, select an option from the **Constraint enforcement method** list and do the following:

   a. Select **Default** to enforce constraints using a contact pressure-overclosure relationship.
   b. Select **Augmented Lagrange (Standard)** to enforce contact constraints using the augmented Lagrange method. This method is applicable only to Abaqus/Standard analyses.

      If you select this option, specify the following additional settings from the **Contact Stiffness** options:

      - From the **Stiffness value** field, either select **Use default** to have Abaqus calculate the penalty contact stiffness automatically or select **Specify** and enter a positive value for the penalty contact stiffness.
      - Specify a factor by which to multiply the chosen penalty stiffness in the **Stiffness scale factor** field.
      - Specify the **Clearance at which contact pressure is zero**. The default value is 0.

   c. Select the **Penalty (Standard)** constraint enforcement method to enforce contact constraints using the penalty method. This method is applicable only to Abaqus/Standard analyses.

      If you select this option, specify the following additional settings from the **Contact Stiffness** options:

      - From the **Behavior** field, either select **Linear** to use the linear penalty method for the enforcement of the contact constraint or select **Nonlinear** to use the nonlinear penalty method for the enforcement of the contact constraint. For more information, see *Penalty Method*.
      - Specify the contact stiffness.
        - For the linear penalty method, specify the contact stiffness in the **Stiffness value** field. You can select **Use default** to have Abaqus calculate the penalty contact stiffness automatically or you can select **Specify** and enter a positive value for the linear penalty stiffness.
        - For the nonlinear penalty method, specify the contact stiffness in the **Maximum stiffness value** field. You can select **Use default** to have Abaqus calculate the penalty contact stiffness

automatically or you can select **Specify** and enter a positive value for the final nonlinear penalty stiffness.

- Specify a factor by which to multiply the chosen penalty stiffness in the **Stiffness scale factor** field.
- For the nonlinear penalty method, you can specify values for the following options:
  - Enter the ratio of the initial penalty stiffness over the final penalty stiffness in the **Initial/Final stiffness ratio** field.
  - Enter the scale factor for the upper quadratic limit d, which is equal to the scale factor times the characteristic contact facet length, in the **Upper quadratic limit scale factor** field.
  - Enter the ratio $(e-c_0)/(d-c_0)$ that defines the lower quadratic limit e in the **Lower quadratic limit ratio** field.
- Specify the **Clearance at which contact pressure is zero**. The default value is 0.

d. Select **Direct (Standard)** to enforce contact constraints directly without approximation or use of augmentation iterations.

6. From the **Pressure-Overclosure** field, select **Exponential** to define an exponential pressure-overclosure relationship. If you select this option, specify the following:

a. Enter the contact pressure at zero clearance, p_0, and the clearance at which the contact pressure is zero, c_0, in the data table.

b. Specify the limit on the contact stiffness that the model can attain, k_{max} (applies only for Abaqus/Explicit analyses).

- Choose **Infinite (no slip)** to set k_{max} equal to infinity for kinematic contact and equal to the default penalty stiffness for penalty contact.
- Choose **Specify**, and enter a value for the maximum stiffness.

7. From the **Pressure-Overclosure** field, select **Linear** to define a linear pressure-overclosure relationship. If you select this option, specify the following:

- Enter a positive value for the slope of the pressure-overclosure curve, *k*, in the **Contact stiffness** field.

8. From the **Pressure-Overclosure** field, select **Tabular** to define a piecewise-linear pressure-overclosure relationship in tabular form. If you select this option, specify the following:

- Enter data in ascending order of overclosure to define the overclosure as a function of pressure. The data table must begin with a zero pressure. The pressure-overclosure relationship is extrapolated beyond the last overclosure point by continuing the same slope.

9. From the **Pressure-Overclosure** field, select **Scale Factor (General Contact, Explicit)** to define a piecewise-linear pressure-overclosure relationship based on scaling the default contact stiffness. This option is available only for the general contact algorithm in Abaqus/Explicit. If you select this option, specify the following:

a. To define the overclosure measure as a percentage of the minimum element size, select **factor** in the **Overclosure** field and enter a positive value r.

b. To define the overclosure measure directly, select **measure** in the **Overclosure** field and enter a positive value d.

c. Enter a value, s, greater than one to define the geometric scaling of the "base" stiffness in the **Contact stiffness scale factor** field.

d. Enter a positive value s_0 to define an additional scale factor for the "base" default contact stiffness in the **Initial stiffness scale factor** field. The default value is 1.

10. Click **OK** to create the contact property and to exit the **Edit Contact Property** dialog box. Alternatively, you can select another contact property option to define from the menus in the **Edit Contact Property** dialog box.

Specifying damping for mechanical contact property options

You can define a damping model that defines forces resisting the relative motions of the contacting surfaces in a mechanical contact analysis. For more information, see *Contact Damping*.

1. From the main menu bar, select **Interaction->Property->Create**.
2. In the **Create Interaction Property** dialog box that appears, do the following:
   - Name the interaction property. For more information about naming objects, see *Using basic dialog box components*.
   - Select the **Contact** type of interaction property.
3. Click **Continue** to close the **Create Interaction Property** dialog box.
4. From the menu bar in the contact property editor, select **Mechanical->Damping**.
5. In the editor that appears, click the arrow to the right of the **Definition** field, and select an option for determining the dimensionality of the damping coefficient:
   - Select **Damping coefficient** to specify the damping coefficient with units of pressure per relative velocity. For more information, see *Specifying the Damping Coefficient Such That the Damping Force Is Directly Proportional to the Rate of Relative Motion between the Surfaces*.
   - Select **Critical damping fraction (Explicit only)** to specify a unitless damping coefficient in terms of the fraction of critical damping associated with the contact stiffness; this method is available only for Abaqus/Explicit. For more information, see *Specifying the Damping Coefficient as a Fraction of Critical Damping in Abaqus/Explicit*.
6. Choose an option for specifying the **Tangent fraction** (the ratio of the tangential damping coefficient to the normal damping coefficient):
   - Choose **Use default** to accept the default tangent fraction value. For Abaqus/Standard the default is 0.0, so the damping coefficient for the tangential direction is zero. For Abaqus/Explicit the default value for the tangent fraction is 1.0, so the damping coefficient for the tangential direction is equal to the damping coefficient for the normal direction.
   - Choose **Specify value** to enter a value for the tangent fraction.

   For more information, see *Specifying the Tangential Damping Coefficient*.
7. Choose a shape for the curve that describes the relationship between clearance and the damping coefficient:
   - Choose **Step (Explicit only)** if you are performing an Abaqus/Explicit analysis. The damping coefficient will remain at the specified constant value while the surfaces are in contact and at zero otherwise.
   - Choose **Linear (Standard only)** to define a damping coefficient that increases linearly from zero at a particular clearance value (c_0) to its full value when the surfaces are in contact.
   - Choose **Bilinear (Standard only)** to define a damping coefficient that increases linearly from zero at a particular clearance value (c_0) to its full value when clearance has been reduced to another value (c). As clearance continues to decrease from c to zero, the damping coefficient remains constant at its full value.
8. Enter the appropriate data in the table provided:
   - If you are performing an Abaqus/Explicit analysis, enter a value for the damping coefficient or for the critical damping fraction (depending on your selection in Step 5.)

- If you are performing an Abaqus/Standard analysis and selected **Linear (Standard only)** in the previous step, enter the following:
  - In the first row, enter a value for the damping coefficient.
  - In the second row, enter a value for c_0, the clearance at which the damping coefficient is zero.
- If you are performing an Abaqus/Standard analysis and selected **Bilinear (Standard only)** in the previous step, enter the following:
  - In the first row, enter a value for the damping coefficient.
  - In the second row, enter a value for c, the clearance at which the damping coefficient reaches its full value.
  - In the third row, enter a value for c_0, the clearance at which the damping coefficient is zero.

9. Click **OK** to create the contact property and to exit the **Edit Contact Property** dialog box. Alternatively, you can select another contact property option to define from the menus in the **Edit Contact Property** dialog box.

Specifying cohesive behavior properties for mechanical contact property options

You can define cohesive behavior properties that are accounted for in surface contact interactions. For more information, see *Contact Cohesive Behavior*.

In addition, you complete the definition of a crack propagation capability by defining a fracture-based cohesive behavior surface interaction. You activate the crack propagation by assigning it to the pair of surfaces that are initially partially bonded. If the fracture criterion is met, crack propagation occurs between these two surfaces. Cohesive behavior is also used to specify the elastic behavior of the bonds.

1. From the main menu bar, select **Interaction->Property->Create**.
2. In the **Create Interaction Property** dialog box that appears, do the following:
   - Name the interaction property. For more information about naming objects, see *Using basic dialog box components*.
   - Select the **Contact** type of interaction property.
3. Click **Continue** to close the **Create Interaction Property** dialog box.
4. From the menu bar in the contact property editor, select **Mechanical->Cohesive Behavior**.
5. Toggle on **Allow cohesive behavior during repeated post-failure contacts** to modify the default post-failure behavior when progressive damage has been defined. By default, cohesive behavior is not enforced for nodes on the secondary surface once ultimate failure has occurred at those nodes. When this option is toggled on, Abaqus/CAE enforces cohesive behavior for recurrent contacts at nodes on the secondary surface subsequent to ultimate failure.
6. From the **Eligible Secondary Nodes** options, select one of the following:
   - Select **Any secondary nodes experiencing contact** to define cohesive behavior not only for all nodes of the secondary surface that are in contact with the main surface at the start of a step, but also for secondary nodes that are not initially in contact but may come in contact during the course of a step.
   - Select **Only secondary nodes initially in contact** to restrict cohesive behavior to only those nodes of the secondary surface that are in contact with the main surface at the start of a step.
   - Select **Specify the bonding node set in the surface-to-surface Std interaction** to restrict cohesive behavior to a subset of secondary nodes defined when you specify initial bonded contact conditions. This option is available only for Abaqus/Standard analyses.
7. From the **Traction-separation Behavior** options, accept the default contact penalty enforcement method or toggle on **Specify stiffness coefficients** and perform the following additional steps:
   a. Specify whether you want to specify stiffness coefficients for **Uncoupled** or **Coupled** traction behavior.
   b. Toggle on **Use temperature-dependent data** if the traction-separation behavior is dependent on temperature.
   c. Click the arrows to the right of the **Number of field variables** field to specify the number of field variables on which the traction-separation behavior depends.
   d. Enter the required data in the data table provided.
8. Click **OK** to create the contact property and to exit the **Edit Contact Property** dialog box. Alternatively, you can select another contact property option to define from the menus in the **Edit Contact Property** dialog box.

Specifying cohesive damage properties for mechanical contact property options

You can define damage initiation, evolution, and stabilization properties that will be accounted for in surface contact interactions. For more information, see *Contact Cohesive Behavior*.

1. From the main menu bar, select **Interaction->Property->Create**.
2. In the **Create Interaction Property** dialog box that appears, do the following:
   - Name the interaction property. For more information about naming objects, see *Using basic dialog box components*.
   - Select the **Contact** type of interaction property.
3. Click **Continue** to close the **Create Interaction Property** dialog box.
4. From the menu bar in the contact property editor, select **Mechanical->Damage**.
5. From the **Initiation** tabbed page, perform the following steps:
   a. From the **Criterion** list, choose one of the following:
      - Select **Maximum nominal stress** to specify a damage initiation criterion based on the maximum nominal stress criterion for cohesive elements.
      - Select **Maximum separation** to specify a damage initiation criterion based on the maximum separation value.
      - Select **Quadratic traction** to specify a damage initiation criterion based on the quadratic traction–interaction criterion for cohesive elements.
      - Select **Quadratic separation** to specify a damage initiation criterion based on the quadratic separation–interaction criterion for cohesive elements.
   b. Toggle on **Use temperature-dependent data** if the damage initiation behavior is dependent on temperature.
   c. Click the arrows to the right of the **Number of field variables** field to specify the number of field variables on which the damage initiation behavior depends.
   d. Enter the required data in the data table provided.
6. If you want to specify damage evolution criteria; toggle on **Specify damage evolution**, click the **Evolution** tab, and perform the following steps:
   a. From the **Type** options, select one of the following:
      - Select **Displacement** to define the evolution of damage as a function of the total displacement (for elastic materials in cohesive elements) or the plastic displacement (for bulk elastic-plastic materials) after the initiation of damage.
      - Select **Energy** to define the evolution of damage in terms of the energy required for failure (fracture energy) after the initiation of damage.
   b. From the **Softening** options, select one of the following:
      - Select **Linear** to specify a linear softening stress-strain response (after the initiation of damage) for linear elastic materials or a linear evolution of the damage variable with deformation (after the initiation of damage) for elastic-plastic materials.
      - Select **Exponential** to specify an exponential softening stress-strain response (after the initiation of damage) for linear elastic materials or an exponential evolution of the damage variable with deformation (after the initiation of damage) for elastic-plastic materials.

- Select **Tabular** to specify the evolution of the damage variable with deformation (after the initiation of damage) in tabular form. This option is available only for damage evolution defined in terms of displacement.

c. If you want to specify mode-dependent behavior, toggle on **Specify mixed mode behavior** and select one of the following options:

- Select **Tabular** to specify the fracture energy or displacement (total or plastic) directly as a function of the shear-normal mode mix for cohesive elements. This method must be used to specify the mixed-mode behavior for cohesive elements when damage evolution is defined in terms of displacement.
- Select **Power law** to specify the fracture energy as a function of the mode mix by means of a power law mixed-mode fracture criterion.
- Select **Benzeggagh-Kenane** to specify the fracture energy as a function of the mode mix by means of the Benzeggagh-Kenane mixed-mode fracture criterion.

d. If you specified **Tabular** for the mixed mode behavior, select one of the following:

- Select **Energy** to define the mode mix in terms of a ratio of fracture energy in the different modes.
- Select **Traction** to define the mode mix in terms of a ratio of traction components.

e. If you toggled on **Specify mixed mode behavior** and selected either **Power law** or **Benzeggagh-Kenane** as the fracture criterion, you can specify the exponent in the power law or the Benzeggagh-Kenane criterion that defines the variation of fracture energy with mode mix for cohesive elements. Toggle on **Specify power-law/criterion** and enter a value for the exponent in the field.

f. Toggle on **Use temperature-dependent data** if the damage evolution behavior is dependent on temperature.

g. Click the arrows to the right of the **Number of field variables** field to specify the number of field variables on which the damage evolution behavior depends.

h. Enter the required data in the data table provided.

7. If you want to specify viscous regularization of the constitutive equations defining surface-based cohesive behavior; toggle on **Specify damage stabilization**, click the **Stabilization** tab, and specify a viscosity coefficient.

8. Click **OK** to create the contact property and to exit the **Edit Contact Property** dialog box. Alternatively, you can select another contact property option to define from the menus in the **Edit Contact Property** dialog box.

Specifying fracture criterion properties for crack propagation

You can specify the fracture criterion that is used to model crack propagation using the virtual crack closure technique (VCCT) in an Abaqus/Standard model. The fracture criterion specifies the critical energy release rates. For more information, see *Crack Propagation Analysis*.

1. From the main menu bar, select **Interaction->Property->Create**.
2. In the **Create Interaction Property** dialog box that appears, do the following:
   - Name the interaction property. For more information about naming objects, see *Using basic dialog box components*.
   - Select the **Contact** type of interaction property.
3. Click **Continue** to close the **Create Interaction Property** dialog box.
4. From the menu bar in the contact property editor, select **Mechanical->Fracture Criterion**.
5. Select the **Type** of criterion for crack propagation along initially partially bonded surfaces—the virtual crack closure technique (**VCCT**) criterion or the enhanced virtual crack closure technique (**Enhanced VCCT**) criterion. The virtual crack closure techniques are available only in an Abaqus/Standard analysis.
6. If you are using the crack propagation criterion in an enriched region, choose the direction of crack growth relative to the local 1-direction when the fracture criterion is satisfied. The crack can extend at a direction normal to the direction of the maximum tangential stress (default), normal to the element local 1-direction, or parallel to the element local 1-direction.
7. Select the mixed mode behavior:
   - Select **BK** to specify the fracture energy as a function of the mode mix by means of the Benzeggagh-Kenane mixed mode fracture criterion.
   - Select **Power** to specify the fracture energy as a function of the mode mix by means of a power law mixed mode fracture criterion.
   - Select **Reeder** to specify the fracture energy as a function of the mode mix by means of the Reeder mixed mode fracture criterion.
8. If desired, specify the tolerance within which the crack propagation criterion must be satisfied. The default is 0.2.
9. If desired, specify the tolerance within which the unstable crack propagation criterion must be satisfied to allow multiple nodes at and ahead of the crack tip to debond without cutting back the increment size in one increment when the VCCT criterion is satisfied for an unstable crack problem. The default value is infinity.
10. If desired, specify the viscosity coefficient used in the viscous regularization. The default value is 0.0.
11. If you selected **VCCT** for the type of fracture criterion, define the energy release rates (for both crack onset and crack propagation) at each mode: G_{IC}, G_{IIC}, and G_{IIIC}.
12. If you selected **Enhanced VCCT** for the type of fracture criterion, do the following:
    - Define the energy release rates for crack onset at each mode: G_{IC}, G_{IIC}, and G_{IIIC}.
    - Define the energy release rates for crack propagation at each mode: G^P_{IC}, G^P_{IIC}, and G^P_{IIIC}.
13. If you selected either **Reeder** or **BK** as the fracture criterion, define the exponent in the Reeder law or the Benzeggagh-Kenane model, η.

14. If you selected **Power** as the fracture criterion, define the three exponents in the power law model, a_m, a_n, and a_o.
15. Toggle on **Use temperature-dependent data** if the fracture criterion is dependent on temperature.
16. Click the arrows to the right of the **Number of field variables** field to specify the number of field variables on which the fracture criterion depends.
17. Enter the required data in the data table provided.
18. Click **OK** to create the contact property and to exit the **Edit Contact Property** dialog box. Alternatively, you can select another contact property option to define from the menus in the **Edit Contact Property** dialog box.

Specifying geometric properties for mechanical contact property options

You can define additional geometric properties that will be accounted for in surface contact interactions.

1. From the main menu bar, select **Interaction->Property->Create**.
2. In the **Create Interaction Property** dialog box that appears, do the following:
   - Name the interaction property. For more information about naming objects, see *Using basic dialog box components*.
   - Select the **Contact** type of interaction property.
3. Click **Continue** to close the **Create Interaction Property** dialog box.
4. From the menu bar in the contact property editor, select **Mechanical->Geometric Properties**.
5. If you are performing an Abaqus/Standard analysis, you can specify an out-of-plane surface thickness for two-dimensional models or a cross-sectional area for every node on a node-based surface. Enter this value in the **Out-of-plane surface thickness or cross-sectional area (Standard)** field.
6. If you are performing an Abaqus/Explicit analysis, you can specify the thickness of an interfacial layer between the two interacting surfaces. Toggle on **Thickness of interfacial layer (Explicit)**, and enter the thickness.
7. If desired, toggle on **Thickness to determine the contacting surfaces to be tracked**, and enter the thickness.
8. If desired, select the **Surface interaction model type**.
   - Select **Default** if the surface interaction model is not defined in a user subroutine.
   - Select **User** to define the surface interaction model in user subroutine *UINTER* in an Abaqus/Standard analysis or in user subroutine *VUINTER* in an Abaqus/Explicit analysis.
   - Select **User Interaction** to define the surface interaction model in user subroutine *VUINTERACTION* in an Abaqus/Explicit analysis.
9. If you selected **User** or **User Interaction** as the model type:
   - Specify the number of **State-dependent variables** required in the user subroutine. The default is 0.
   - Specify the **Number of property values** needed as data to define the surface interaction model in the user subroutine. The default is 0.
10. If you are performing an Abaqus/Standard analysis and if you selected **User** or **User Interaction** as the model type, toggle on **Use unsymmetric equation solution procedures (Standard)** to use unsymmetric equation solution procedures.
11. Click **OK** to create the contact property and to exit the **Edit Contact Property** dialog box. Alternatively, you can select another contact property option to define from the menus in the **Edit Contact Property** dialog box.

Defining thermal contact property options

You can define thermal contact property options to specify thermal conductance, heat generation, and thermal radiation due to friction.

In this section:

- *Specifying thermal conductance for thermal contact property options*
- *Specifying heat generation for thermal contact property options*
- *Specifying radiation for thermal contact property options*

Specifying thermal conductance for thermal contact property options

You can specify thermal conductance to define conductive heat transfer between closely adjacent (or contacting) surfaces. For more information, see *Contact Conductance between Surfaces*.

1. From the main menu bar, select **Interaction->Property->Create**.
2. In the **Create Interaction Property** dialog box that appears, do the following:
   - Name the interaction property. For more information about naming objects, see *Using basic dialog box components*.
   - Select the **Contact** type of interaction property.
3. Click **Continue** to close the **Create Interaction Property** dialog box.
4. From the menu bar in the contact property editor, select **Thermal->Thermal Conductance**.

   The **Edit Contact Property** dialog box appears.
5. In the editor that appears, click the arrow to the right of the **Definition** field, and select an option for defining thermal conductance:
   - Select **Tabular** to enter data relating thermal conductance to the clearance or pressure between the contact surfaces.
   - Select **User-defined** to define thermal conductance in user subroutine *GAPCON*. If you select this option, skip to Step 9.
6. Indicate whether you want to define thermal conductance as a function of the clearance between the surfaces, the contact pressure between the surfaces, or both.
7. If you want to define thermal conductance as a function of clearance, display the **Clearance Dependency** tabbed page, and do the following:
   a. Toggle on **Use temperature-dependent data** if the data are dependent on temperature.
   b. Toggle on **Use mass flow rate-dependent data (Standard only)** if the data are dependent on the average mass flow rate per unit area, $\overline{|\dot{m}|}$.
   c. Click the arrows to the right of the **Number of field variables** field to specify the number of field variables on which the data depend.
   d. In the data table, define thermal conductance as a function of gap clearance.

      The tabular data must start at zero clearance (closed gap) and define thermal conductance as clearance increases. You must provide at least two pairs of points. The value of thermal conductance drops to zero immediately after the last data point, so there is no conductance when the clearance is greater than the value corresponding to the last data point. If conductance is not also defined as a function of contact pressure, it will remain constant at the zero clearance value for all pressures.
8. If you want to define thermal conductance as a function of contact pressure, display the **Pressure Dependency** tabbed page, and do the following:
   a. Toggle on **Use temperature-dependent data** if the data are dependent on temperature.
   b. Toggle on **Use mass flow rate-dependent data (Standard only)** if the data are dependent on the average mass flow rate per unit area, $\overline{|\dot{m}|}$.
   c. Click the arrows to the right of the **Number of field variables** field to specify the number of field variables on which the data depend.
   d. In the data table, define thermal conductance as a function of contact pressure at the interface.

      The tabular data must start at zero contact pressure (or, in the case of contact that can support a tensile force, the data point with the most negative pressure) and define thermal conductance as pressure increases. The value of thermal conductance remains constant for contact pressures outside

of the interval defined by the data points. If conductance is not also defined as a function of clearance, it is zero for all positive values of clearance and discontinuous at zero clearance

9. Click **OK** to create the contact property and to exit the **Edit Contact Property** dialog box. Alternatively, you can select another contact property option to define from the menus in the **Edit Contact Property** dialog box.

Specifying heat generation for thermal contact property options

You can specify heat generation due to the dissipation of energy created by the mechanical or electrical interaction of contacting surfaces.
For more information, see *Modeling Heat Generated by Nonthermal Surface Interactions*.

1. From the main menu bar, select **Interaction->Property->Create**.
2. In the **Create Interaction Property** dialog box that appears, do the following:
   a. Name the interaction property. For more information about naming objects, see *Using basic dialog box components*.
   b. Select the **Contact** type of interaction property.
3. Click **Continue** to close the **Create Interaction Property** dialog box.
4. From the menu bar in the contact property editor, select **Thermal->Heat Generation**.
5. In the editor that appears, specify the **Fraction of dissipated energy caused by friction or electric currents that is converted to heat**:
   - Choose **Use default (1.0)** to convert all the dissipated energy to heat.
   - Choose **Specify** to enter the fraction of your choice.
6. Specify the **Fraction of converted heat distributed to secondary surface**:
   - Choose **Use default (0.5)** to distribute the heat equally between the main and secondary surfaces.
   - Choose **Specify** to enter the fraction of the heat to be distributed to the secondary surface. The remaining fraction will be distributed to the main surface.
7. Specify the **Mechanical Interaction Fraction**: Enter a value for the fraction of dissipated energy converted into heat generated by mechanical interaction.
8. Specify the **Mechanical Interaction Weighting Factor**: Enter a value for the weighting factor for the distribution of heat between the interacting surfaces generated by mechanical interaction.
9. Specify the **Electrical Conduction Solids Fraction**: Enter a value for the fraction of dissipated energy converted into heat generated by electrical conduction in the solids.
10. Specify the **Electrical Conduction Solids Weighting Factor**: Enter a value for the weighting factor for the distribution of heat between the interacting surfaces generated by electrical conduction in the solids.
11. Specify the **Electrical Conduction Liquids Fraction**: Enter a value for the fraction of dissipated energy converted into heat generated by electrical conduction in the liquids.
12. Specify the **Electrical Conduction Liquids Weighting Factor**: Enter a value for the weighting factor for the distribution of heat between the interacting surfaces generated by electrical conduction in the liquids.
13. Click **OK** to create the contact property and to exit the **Edit Contact Property** dialog box. Alternatively, you can select another contact property option to define from the menus in the **Edit Contact Property** dialog box.

Specifying radiation for thermal contact property options

You can specify radiative heat transfer between closely adjacent surfaces. For more information, see *Modeling Radiation between Surfaces When the Gap Is Small*.

1. From the main menu bar, select **Interaction->Property->Create**.
2. In the **Create Interaction Property** dialog box that appears, do the following:
   - Name the interaction property. For more information about naming objects, see *Using basic dialog box components*.
   - Select the **Contact** type of interaction property.
3. Click **Continue** to close the **Create Interaction Property** dialog box.
4. From the menu bar in the contact property editor, select **Thermal->Radiation**.
5. In the editor that appears, enter values for the emissivity, ϵ, of the main and secondary surfaces.
6. In the table provided, define the view factor as a function of clearance.

   The view factor should have a value between 0.0 and 1.0. At least two pairs of points are required. The tabular data must start at zero clearance (closed gap) and define the view factor as the clearance increases. The value of the view factor drops to zero immediately after the last data point, so there is no radiative heat transfer when the clearance is greater than the value corresponding to the last data point.
7. Click **OK** to create the contact property and to exit the **Edit Contact Property** dialog box. Alternatively, you can select another contact property option to define from the menus in the **Edit Contact Property** dialog box.

Defining electrical contact property options

You can define electrical contact property options to specify electrical conductance and diffusivity.

In this section:

- *Specifying gap conductance for electrical contact property options*
- *Specifying gap diffusivity for electrical contact property options*

Specifying gap conductance for electrical contact property options

You can specify gap conductance between closely adjacent or contacting surfaces. The conductance is proportional to the difference in electric potentials across the interface.
The conduction is a function of the clearance (separation) between the surfaces and can be a function of the contact pressure. For more information, see *Electrical Contact Properties*.

1. From the main menu bar, select **Interaction->Property->Create**.
2. In the **Create Interaction Property** dialog box that appears, do the following:
   - Name the interaction property. For more information about naming objects, see *Using basic dialog box components*.
   - Select the **Contact** type of interaction property.
3. Click **Continue** to close the **Create Interaction Property** dialog box.
4. From the menu bar in the contact property editor, select **Electrical->Electrical Conductance**.
   The **Edit Contact Property** dialog box appears.
5. In the editor that appears, click the arrow to the right of the **Definition** field, and select an option for defining electrical conductance:
   - Select **Tabular** to enter data relating electrical conductance to the separation between the contact surfaces.
   - Select **User-defined** to define the conductance in user subroutine *GAPELECTR*. If you select this option, skip to Step 12.
6. Indicate whether you want to define the electrical conductivity in the **Solid** material or **Liquid** electrolyte.
7. Indicate whether you want to define electrical conductance as a function of the clearance between the surfaces, the contact pressure between the surfaces, or both.
8. If you want to define electrical conductance as a function of clearance for the electrical conductivity in the solid material, display the **Clearance Dependency** tabbed page, and do the following:
   a. Toggle on **Use temperature-dependent data** if the data are dependent on temperature.
   b. Click the arrows to the right of the **Number of field variables** field to specify the number of field variables on which the data depend.
   c. In the data table, define electrical conductance as a function of gap clearance.
      The tabular data must start at zero clearance (closed gap) and define electrical conductance as clearance increases. You must provide at least two pairs of points. The value of electrical conductance drops to zero immediately after the last data point, so there is no conductance when the clearance is greater than the value corresponding to the last data point. If conductance is not also defined as a function of contact pressure, it will remain constant at the zero clearance value for all pressures.
9. If you want to define electrical conductance as a function of contact pressure for the electrical conductivity in solid material, display the **Pressure Dependency** tabbed page, and do the following:
   a. Toggle on **Use temperature-dependent data** if the data are dependent on temperature.
   b. Click the arrows to the right of the **Number of field variables** field to specify the number of field variables on which the data depend.
   c. In the data table, define electrical conductance as a function of contact pressure at the interface.
      The tabular data must start at zero contact pressure (or, in the case of contact that can support a tensile force, the data point with the most negative pressure) and define electrical conductance as pressure increases. The value of electrical conductance remains constant for contact pressures outside of the interval defined by the data points. If conductance is not also defined as a function of clearance, it is zero for all positive values of clearance and discontinuous at zero clearance

10. If you want to define electrical conductance as a function of clearance for the electrical conductivity in liquid electrolyte, display the **Clearance Dependency** tabbed page, and do the following:

a. Toggle on **Use temperature-dependent data** if the data are dependent on temperature.

b. Toggle on **Use ion-concentration-dependent data** if the data are dependent on ion-concentration.

c. Click the arrows to the right of the **Number of field variables** field to specify the number of field variables on which the data depend.

d. In the data table, define electrical conductance as a function of gap clearance.

The tabular data must start at zero clearance (closed gap) and define electrical conductance as clearance increases. You must provide at least two pairs of points. The value of electrical conductance drops to zero immediately after the last data point, so there is no conductance when the clearance is greater than the value corresponding to the last data point. If conductance is not also defined as a function of contact pressure, it will remain constant at the zero clearance value for all pressures.

11. If you want to define electrical conductance as a function of contact pressure for the electrical conductivity in liquid electrolyte, display the **Pressure Dependency** tabbed page, and do the following:

a. Toggle on **Use temperature-dependent data** if the data are dependent on temperature.

b. Toggle on **Use ion-concentration-dependent data** if the data are dependent on ion concentration.

c. Click the arrows to the right of the **Number of field variables** field to specify the number of field variables on which the data depend.

d. In the data table, define electrical conductance as a function of contact pressure at the interface.

The tabular data must start at zero contact pressure (or, in the case of contact that can support a tensile force, the data point with the most negative pressure) and define electrical conductance as pressure increases. The value of electrical conductance remains constant for contact pressures outside of the interval defined by the data points. If conductance is not also defined as a function of clearance, it is zero for all positive values of clearance and discontinuous at zero clearance

12. Click **OK** to create the contact property and to exit the **Edit Contact Property** dialog box.

Alternatively, you can select another contact property option to define from the menus in the **Edit Contact Property** dialog box.

Specifying gap diffusivity for electrical contact property options

You can specify gap diffusivity between closely adjacent or contacting surfaces.
The diffusivity is proportional to the distance across the interface up to a cutoff gap distance directly beyond which no ionic or species flux occurs. The diffusivity is a function of the clearance (separation) between the surfaces and a function of the contact pressure, ion concentration, or species concentration. For more information, see *Electrical Contact Properties*.

1. From the main menu bar, select **Interaction->Property->Create**.
2. In the **Create Interaction Property** dialog box that appears, do the following:
   a. Name the interaction property.

      For more information about naming objects, see *Using basic dialog box components*.

   b. Select the **Contact** type of interaction property.
3. Click **Continue** to close the **Create Interaction Property** dialog box.
4. From the menu bar in the contact property editor, select **Electrical->Diffusivity**.
5. In the **Edit Contact Property** dialog box that appears, indicate if you want to define diffusivity as a function of Ion Concentration or Species Concentration.
6. Specify the **Cut Off Flow Across**: Enter a value for the cutoff clearance distance above which no ion or species diffusion occurs across a contact interface.
7. If you want to define diffusivity as a function of Ion Concentration, display the **Concentration Dependency** tabbed page, and do the following:
   a. Toggle on **Use temperature-dependent data** if the data are dependent on temperature.
   b. Click the arrows to the right of the **Number of field variables** field to specify the number of field variables on which the data depend.
   c. In the data table, define diffusivity as a function of contact diffusivity and contact pressure and ion concentration.

      The tabular data must contain at least two pairs of points.
8. If you want to define diffusivity as a function of Species Concentration, display the **Concentration Dependency** tabbed page, and do the following:
   a. Toggle on **Use temperature-dependent data** if the data are dependent on temperature.
   b. Click the arrows to the right of the **Number of field variables** field to specify the number of field variables on which the data depend.
   c. In the data table, define diffusivity as a function of contact diffusivity and contact pressure and species concentration.

      The tabular data must contain at least two pairs of points.
9. Click **OK** to create the contact property and to exit the **Edit Contact Property** dialog box. Alternatively, you can select another contact property option to define from the menus in the **Edit Contact Property** dialog box.

Defining a film condition interaction property

You can define a film coefficient as a function of temperature and field variables. A film condition interaction property can be referred to only by a surface film condition interaction or a concentrated film condition interaction. For more information, see *Defining a surface film condition interaction*, and *Defining a concentrated film condition interaction*.

1. From the main menu bar, select **Interaction->Property->Create**.
2. In the **Create Interaction Property** dialog box that appears, do the following:
   - Name the interaction property. For more information about naming objects, see *Using basic dialog box components*.
   - Select the **Film condition** type of interaction property.
3. Click **Continue** to close the **Create Interaction Property** dialog box.
4. Toggle on **Use temperature-dependent data** to define a film coefficient that varies with temperature. A column labeled **Temp** appears in the data table.
5. To define a film coefficient that depends on field variables, click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables. Field variable columns appear in the data table.
6. In the data table, enter the film coefficient, h (units of $JT^{-1}L^{-2}\theta^{-1}$), as a function of temperature and field variables. You can enter data into the table using the keyboard. Alternatively, you can click mouse button 3 anywhere in the table to view a list of options for specifying tabular data. For detailed information on each option, see *Entering tabular data*.
7. Click **OK** to create the film condition interaction property and to exit the editor.

Additional information

• *Thermal Loads*

Defining a cavity radiation interaction property

You can define the emissivity of cavity surfaces as a function of temperature and field variables. A cavity radiation interaction property can be referred to only by a cavity radiation interaction. For more information, see *Defining a cavity radiation interaction*.

1. From the main menu bar, select **Interaction->Property->Create**.
2. In the **Create Interaction Property** dialog box that appears, do the following:
   - Name the interaction property. For more information about naming objects, see *Using basic dialog box components*.
   - Select the **Cavity radiation** type of interaction property.
3. Click **Continue** to close the **Create Interaction Property** dialog box.
4. Toggle on **Use temperature-dependent data** to define a cavity radiation property that varies with temperature. A column labeled **Temp** appears in the data table.
5. To define a cavity radiation property that depends on field variables, click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables. Field variable columns appear in the data table.
6. In the data table, enter the emissivity, ϵ, as a function of temperature and field variables. You can enter data into the table using the keyboard. Alternatively, you can click mouse button 3 anywhere in the table to view a list of options for specifying tabular data. For detailed information on each option, see *Entering tabular data*.
7. Click **OK** to create the cavity radiation interaction property and to exit the editor.

Additional information

• *Cavity Radiation in Abaqus/Standard*

Defining a fluid cavity interaction property

The fluid cavity interaction editor contains hydraulic and pneumatic fluid type definitions.

Fluid cavity interaction properties can be referred to only by fluid cavity interactions. For more information, see *Defining a fluid cavity interaction*.

In this section:

- *Defining hydraulic fluid cavity property options*
- *Defining pneumatic fluid cavity property options*

Defining hydraulic fluid cavity property options

You should use a hydraulic fluid definition to model nearly incompressible or fully incompressible fluid behavior within a cavity. Hydraulic fluids must include a density, and they may include a bulk modulus and expansion data. For more information, see *Hydraulic Fluids*.

1. From the main menu bar, select **Interaction->Property->Create**.
2. In the **Create Interaction Property** dialog box that appears, do the following:
   - Name the interaction property. For more information about naming objects, see *Using basic dialog box components*.
   - Select the **Fluid cavity** type of interaction property.
3. Click **Continue** to close the **Create Interaction Property** dialog box.

   Abaqus/CAE opens the **Edit interaction property** dialog box.
4. Choose the **Hydraulic** fluid definition.
5. Enter the **Fluid density**.
6. In the **Fluid Bulk Modulus** tab, toggle on **Specify fluid bulk modulus** to enter a bulk modulus and to allow the entry of temperature and field variable data.

   The fluid bulk modulus is required for Abaqus/Explicit and optional for Abaqus/Standard.
7. Toggle on **Use temperature-dependent data** to define a fluid bulk modulus that varies with temperature. A column labeled **Temp** appears in the data table.
8. To define a fluid bulk modulus that depends on field variables, click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables. Field variable columns appear in the data table.
9. In the data table, enter the bulk modulus as a function of temperature and field variables. You can enter data into the table using the keyboard. Alternatively, you can click mouse button 3 anywhere in the table to view a list of options for specifying tabular data. For detailed information on each option, see *Entering tabular data*.
10. In the **Fluid Expansion** tab, toggle on **Specify fluid thermal expansion coefficients** to specify expansion data.
11. Toggle on **Use temperature-dependent data** to define fluid expansion that varies with temperature. A column labeled **Temp** appears in the data table.
12. To define fluid expansion that depends on field variables, click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables. Field variable columns appear in the data table.
13. If the fluid expansion is dependent on temperature or field variables, enter the **Reference temperature** for use in calculation of the expansion coefficient.
14. In the data table, enter the fluid expansion coefficient as a function of temperature and field variables. You can enter data into the table using the keyboard. Alternatively, you can click mouse button 3 anywhere in the table to view a list of options for specifying tabular data. For detailed information on each option, see *Entering tabular data*.
15. Click **OK** to create the hydraulic fluid cavity interaction property and to exit the editor.

Defining pneumatic fluid cavity property options

Pneumatic fluids must include an ideal gas molecular weight; and, for an Abaqus/Explicit analysis, they may include molar heat capacity data. For more information, see *Pneumatic Fluids*.

1. From the main menu bar, select **Interaction->Property->Create**.
2. In the **Create Interaction Property** dialog box that appears, do the following:
   - Name the interaction property. For more information about naming objects, see *Using basic dialog box components*.
   - Select the **Fluid cavity** type of interaction property.
3. Click **Continue** to close the **Create Interaction Property** dialog box.

   Abaqus/CAE opens the **Edit interaction property** dialog box.
4. Choose the **Pneumatic** fluid definition.
5. Enter the **Ideal gas molecular weight**.
6. For an Abaqus/Explicit analysis, toggle on **Specify molar heat capacity**, if desired, to include heat transfer data.
7. If you are specifying molar heat capacity, select either **Polynomial** or **Tabular** for the data type.
8. If you chose **Polynomial** in the previous step, enter coefficients for the five terms in the polynomial equation—enter zero for any terms that are not needed. If you chose **Tabular** in the previous step, do the following to complete the data table:
   a. Toggle on **Use temperature-dependent data** to define fluid expansion that varies with temperature. A column labeled **Temp** appears in the data table.
   b. To define fluid expansion that depends on field variables, click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables. Field variable columns appear in the data table.
   c. In the data table, enter the molar heat capacity as a function of temperature and field variables. You can enter data into the table using the keyboard. Alternatively, you can click mouse button 3 anywhere in the table to view a list of options for specifying tabular data. For detailed information on each option, see *Entering tabular data*.
9. Click **OK** to create the pneumatic fluid cavity interaction property and to exit the editor.

Defining a fluid exchange interaction property

You use a fluid exchange interaction property to define the method of fluid transfer between a cavity and the environment or between two cavities. A fluid exchange interaction property can be referred to only by a fluid exchange interaction. For more information, see *Defining a fluid exchange interaction*.

1. From the main menu bar, select **Interaction->Property->Create**.
2. In the **Create Interaction Property** dialog box that appears, do the following:
   - Name the interaction property. For more information about naming objects, see *Using basic dialog box components*.
   - Select the **Fluid exchange** type of interaction property.
3. Click **Continue** to close the **Create Interaction Property** dialog box.
   Abaqus/CAE opens the **Edit interaction property** dialog box.
4. Choose one of the following fluid exchange definitions:

Bulk viscosity

The fluid exchange rate is based on the viscous resistance coefficient and the hydrodynamic resistance coefficient. Both coefficients may include dependence on the average absolute pressure, average temperature, and the average value of any user-defined field variables.

Mass flux

The fluid exchange rate is based on the mass flow rate per unit area for the effective area defined in the fluid exchange interaction.

Mass rate leakage

The fluid exchange rate is based on a mass flow rate driven by the absolute value of the pressure differential between the primary cavity and the environment or the second cavity. The mass flow rate and the absolute value of the pressure difference both start at zero and must be positive. Mass rate leakage may include dependence on the average absolute pressure, average temperature, and the average value of any user-defined field variables.

Volume flux

The fluid exchange rate is based on the volumetric flow rate per unit area for the effective area defined in the fluid exchange interaction.

Volume rate leakage

The fluid exchange rate is based on a volume flow rate driven by the absolute value of the pressure differential between the primary cavity and the environment or the second cavity. The volume flow rate and the absolute value of the pressure difference both start at zero and must be positive. Volume rate leakage may include dependence on the average absolute pressure, average temperature, and the average value of any user-defined field variables.

5. If you selected the **Bulk viscosity**, **Mass rate leakage**, or **Volume rate leakage** fluid exchange definition, do the following to complete the fluid exchange property definition:
   a. Toggle on the desired options to add data columns to the table.

You can add pressure- or temperature-dependent data, and you can add field variables.

b. In the data table, enter the appropriate data as a function of temperature, pressure, and field variables. You can enter data into the table using the keyboard. Alternatively, you can click mouse button 3 anywhere in the table to view a list of options for specifying tabular data. For detailed information on each option, see *Entering tabular data*.

6. If you selected the **Mass flux** or **Volume flux** fluid exchange definition, enter the mass flow rate per unit area or volumetric flow rate per unit area, respectively.

7. Click **OK** to create the fluid exchange interaction property and to exit the editor.

Additional information

• *Fluid Exchange Definition*

Defining an acoustic impedance interaction property

You use an acoustic impedance interaction property to define the proportionality factors between the pressure and the normal components of surface displacement and velocity in an acoustic analysis. An acoustic impedance interaction property can be referred to only by an acoustic impedance interaction. For more information, see *Defining acoustic impedance*.

1. From the main menu bar, select **Interaction->Property->Create**.
2. In the **Create Interaction Property** dialog box that appears, do the following:
   - Name the interaction property. For more information about naming objects, see *Using basic dialog box components*.
   - Select the **Acoustic impedance** type of interaction property.
3. Click **Continue** to close the **Create Interaction Property** dialog box.
4. From the **Data type** field, choose the type of tabular data that you will use to define the acoustic impedance.
   - Select **Impedance** to specify an impedance using real and imaginary parts of the impedance.
   - Select **Admittance** to specify an impedance using admittance values.
5. Toggle on **Use frequency-dependent data** to define an acoustic impedance that varies with frequency. A column labeled **Frequency** appears in the data table.
6. If you are using impedance data, enter the following data in the table:
   - **Re (Z)**, the real part of the surface impedance. (Units of F L^{-3}T.)
   - **Im (Z)**, the imaginary part of the surface impedance. (Units of F L^{-3}T.)
7. If you are using admittance data, enter the following data in the table:
   - $1/c_1$, the proportionality factor between pressure and velocity of the surface in the normal direction. This quantity is the real part of the complex admittance. (Units of $F^{-1}L^3T^{-1}$.)
   - $1/k_1$, the proportionality factor between pressure and displacement of the surface in the normal direction. This quantity is the imaginary part of the complex admittance, divided by the angular frequency. (Units of $F^{-1}L^3$.)
8. Click **OK** to create the acoustic impedance interaction property and to exit the editor.

Additional information

• *Acoustic and Shock Loads*

Defining an incident wave interaction property

You can define the speed of the incident wave and other characteristics of the wave loading. For spherical incident wave loading, you can optionally specify the loading effects due to an UNDEX bubble or spatial decay of the incident wave field. An incident wave interaction property can be referred to only by an incident wave interaction. Incident wave interaction properties that specify UNDEX data can be referred to only by incident wave interactions with an UNDEX definition. For more information, see *Defining incident waves*.

1. From the main menu bar, select **Interaction->Property->Create**.
2. In the **Create Interaction Property** dialog box that appears, do the following:
   - Name the interaction property. For more information about naming objects, see *Using basic dialog box components*.
   - Select the **Incident wave** type of interaction property.
3. Click **Continue** to close the **Create Interaction Property** dialog box.
4. In the **Speed of sound in fluid** field, enter the sound speed in fluid, c_f.
5. In the **Fluid density** field, enter fluid mass density, ρ_f.
6. From the **Definition** field, choose the type of wave to define the incident wave property.
   - Select **Planar** to specify a planar incident wave.
   - Select **Spherical** to specify a spherical incident wave.
   - Select **Diffuse** to specify a field of planar waves incident from multiple angles.
   - Select **Air blast** to specify air blast loading on structures using the CONWEP model.
   - Select **Surface blast** to specify surface blast loading on structures using the CONWEP model.
7. If you are specifying a spherical incident wave, select the propagation model. For more information, see *Describing Incident Wave Loading*.
   - Select **Acoustic** to specify an incident wave in which the amplitude is inversely proportional to the distance from the source.
   - Select **UNDEX charge** to specify UNDEX bubble data.
   - Select **Generalized decay** to specify spatial decay of the incident wave field.
8. If you selected the **UNDEX charge** propagation model, click the **Physical**, **Material**, and **Bubble Model** tabs and specify the following values:

Physical Data

- Ratio of specific heats for gas, γ.
- Acceleration due to gravity, g.
- Atmospheric pressure, p_{atm}.
- Flow drag coefficient, C_D.
- Flow drag exponent, E_D.
- Toggle on **Neglect wave effects in fluid and gas** to neglect the wave effects.

Material Data

- Charge material constant, *K*.
- Charge material constant, *k*.
- Charge material constant, *A*.
- Charge material constant, *B*.
- Adiabatic charge constant, K_c.
- Density of charge material, ρ_c.
- Mass of charge material, m_c.

Bubble Model Step Data

- Time duration, T_{final}.
- Maximum number of time steps for the bubble simulation, N_{steps}. The bubble amplitude simulation ceases when the number of steps reaches N_{steps} or the time duration, T_{final}, is reached.
- Relative step size control parameter, Ω_{rel}.
- Absolute step size control parameter, X_{abs}.
- Step size control exponent, β. The step size, Δt, is decreased or increased according to the error estimate: $(\Omega_{\text{rel}}\,|x| + X_{\text{abs}})^{\beta} \le \Delta t \left|\frac{dx}{dt}\right|^{\beta}$.

9. If you selected the **Generalized decay** propagation model, enter values for the dimensionless constants **A**, **B**, and **C**, where $A > -1$, $B > -1$, and $C \ge 0$.
10. If you are defining a diffuse incident wave, specify the seed number in the **Seed number** field for the diffuse source calculation.
11. If you selected the **Air blast** or **Surface blast** definition, specify the following settings in the **CONWEP Charge** portion of the dialog box:
    - In the **Equivalent mass of TNT** field, specify the equivalent mass of TNT in any preferred mass unit.
    - In the **Conversion for mass to kilograms** field, specify a multiplication factor to convert the preferred mass unit to kilograms.
    - In the **Conversion for length to meters** field, specify a multiplication factor to convert the analysis length unit to meters.
    - In the **Conversion for time to seconds** field, specify a multiplication factor to convert the analysis time unit to seconds.
    - In the **Conversion for pressure to pascals** field, specify a multiplication factor to convert the analysis pressure unit to pascals.

12. Click **OK** to create the incident wave interaction property and to exit the editor.

Additional information

• *Acoustic and Shock Loads*

Defining an actuator/sensor interaction property

An actuator/sensor interaction property provides the PROPS, JPROPS, NPROPS, and NJPROPS variables that are passed into a *UEL* user subroutine used with an actuator/sensor interaction. For more information, see *Defining an actuator/sensor interaction*.

1. From the main menu bar, select **Interaction->Property->Create**.
2. In the **Create Interaction Property** dialog box that appears, do the following:
   - Name the interaction property. For more information about naming objects, see *Using basic dialog box components*.
   - Select the **Actuator/sensor** type of interaction property.
3. Click **Continue** to close the **Create Interaction Property** dialog box.
4. Click the **Real Properties** tab, and enter the real property values to provide the PROPS and NPROPS variables that are passed into a *UEL* user subroutine.
5. Click the **Integer Properties** tab, and enter the integer property values to provide the JPROPS and NJPROPS variables that are passed into a *UEL* user subroutine.
6. Click **OK** to create the actuator/sensor interaction property and to exit the editor.

Additional information

- *User-Defined Elements*
- *UEL*

Defining a fluid inflator interaction property

You use a fluid inflator interaction property to model the deployment of an airbag. A fluid inflator interaction property can be referred to only by a fluid inflator interaction. The fluid inflator property defines the mass flow rate and temperature as a function of inflation time either directly or by entering tank test data. It also defines the mixture of gases entering the fluid cavity. For more information, see *Defining a fluid inflator interaction*.

1. From the main menu bar, select **Interaction->Property->Create**.
2. In the **Create Interaction Property** dialog box that appears, do the following:
   - Name the interaction property. For more information about naming objects, see *Using basic dialog box components*.
   - Select the **Fluid inflator** type of interaction property.
3. Click **Continue** to close the **Create Interaction Property** dialog box.
   Abaqus/CAE opens the **Edit interaction property** dialog box.
4. In the **Fluid Inflator Property** tab, select one of the following fluid inflator definitions:

Dual pressure

The inflator mass flow rate and temperature of the gas entering the fluid cavity are calculated using the dual pressure method. You enter a table of tank pressure and inflator pressure versus inflation time; and specify the volume of the tank, the effective area, and the discharge coefficient.

Temperature and mass

The inflator mass flow rate and temperature are given directly as functions of inflation time.

Tank test

The inflator mass flow rate and the temperature of the gas entering the fluid cavity are determined by the results of a tank test. To calculate the mass flow rate using the results of a tank test, you enter a table of tank pressure and inflator temperature versus inflation time, and specify the volume of the tank.

Inflator pressure and mass flow rate

The inflator mass flow rate and inflator pressure are used to obtain the gas temperature. You can enter a table of the mass flow rate and inflator pressure versus inflation time and specify the effective area and discharge coefficient.

5. If you selected the **Dual pressure** or **Inflator pressure and mass flow rate** fluid inflator definition, enter the **Effective area**. The effective area is the total inflator orifice area.
6. If you selected the **Dual pressure** or **Tank test** fluid inflator definition, enter the **Tank volume**.
7. If you selected the **Dual pressure** or **Inflator pressure and mass flow rate** fluid inflator definition, enter the **Discharge coefficient**.
8. In the data table, enter the appropriate data. You can enter data into the table using the keyboard. Alternatively, you can click mouse button 3 anywhere in the table to view a list of options for specifying tabular data. For detailed information on each option, see *Entering tabular data*.
9. In the **Fluid Inflator Mixture** tab, enter the number of fluids to define for this inflator.

10. In the **Type** field, select whether you want to specify the mixture in terms of the mass fraction or molar fraction.
11. In the data table, for each fluid, select the fluid cavity interaction property that defines the fluid behavior. Then enter the inflation time values and enter the corresponding mass fraction or molar fraction for that fluid.
12. Click **OK** to create the fluid inflator interaction property and to exit the editor.

Additional information

• *Inflator Definition*

Defining a wear interaction property

You can specify the surface wear (erosion) due to various microscale mechanisms, such as abrasion and fretting.

For more information, see *Contact Wear*.

1. From the main menu bar, select **Interaction->Property->Create**.
2. In the **Create Interaction Property** dialog box that appears, do the following:
   a. Name the interaction property.

      For more information about naming objects, see *Using basic dialog box components*.

   b. Select the **Wear** type of interaction property.
3. Click **Continue** to close the **Create Interaction Property** dialog box.

   Abaqus/CAE opens the **Edit interaction property** dialog box.
4. Toggle on **Friction coefficient** to specify that the Archard's wear equation depends explicitly on the friction coefficient.
5. Toggle on **Unitless wear coefficient** to specify that the wear coefficient is dimensionless. Otherwise, the wear coefficient has dimensions of inverse of stress.
6. If **Unitless wear coefficient** is on, specify the **Reference stress** value equal to the magnitude of hardness of the material forming the wear surface.
7. To define a wear property that depends on surface temperature, toggle on **Use surface temperature dependent data**.

   Surface Temperature variable columns appear in the data table.
8. To define a wear property that depends on wear distance, toggle on **Use surface wear distance dependent data**.

   Surface Wear Distance variable columns appear in the data table.
9. To define a wear property that depends on contact pressure, toggle on **Use contact pressure dependent data**.

   Contact Pressure variable columns appear in the data table.
10. To define a wear property that depends on field variables, click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables.

    Field variable columns appear in the data table.
11. In the data table, enter the appropriate data.

    You can enter data into the table using the keyboard. Alternatively, you can click mouse button 3 anywhere in the table to view a list of options for specifying tabular data.

    For detailed information on each option, see *Entering tabular data*.
12. Click **OK** to create the wear interaction property and to exit the editor.

Additional information

• *Contact Wear*

Using the constraint editors

This section explains how to enter data in the constraint editor to define specific types of constraints.

In this section:

- *Defining tie constraints*
- *Defining rigid body constraints*
- *Defining display body constraints*
- *Defining coupling constraints*
- *Defining adjust points constraints*
- *Defining MPC constraints*
- *Defining shell-to-solid coupling constraints*
- *Defining embedded region constraints*
- *Defining equation constraints*

Defining tie constraints

A tie constraint ties two separate surfaces together so that there is no relative motion between them. This type of constraint allows you to fuse together two regions even though the meshes created on the surfaces of the regions might be dissimilar. You can define a tie constraint between edges of a wire or between faces of a solid or shell.
For more information, see *Understanding constraints*, and *Mesh Tie Constraints*.

If you are creating multiple tie constraints, you might want to use the automatic contact detection tool. This tool automates the process of selecting surfaces and allows you to create multiple constraints simultaneously. For more information, see *Using contact and constraint detection*.

1. From the main menu bar, select **Constraint->Create**.

   Tip: You can also create a tie constraint using the  tool in the Interaction module toolbox.

2. In the **Create Constraint** dialog box that appears, do the following:
   a. Name the constraint. For more information about naming objects, see *Using basic dialog box components*.
   b. From the **Type** list, select **Tie**, then click **Continue**.
3. Select the main surface.
   a. In the prompt area, select one of the following:
      - Select **Surface** if you want to select a named surface.
      - Select **Node Region** if you want to select a region from which to create a node-based surface.

   b. Use one of the following methods to select the main surface:
      - Use an existing surface to define the region. On the right side of the prompt area, click **Surfaces**. Select an existing surface name from the **Region Selection** dialog box that appears, and click **Continue**.

        Note:

        The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Surfaces** on the right side of the prompt area.

      - Use the mouse to select a region in the viewport. (For more information, see *Selecting objects within the current viewport*.) Click mouse button 2 to indicate that you have finished selecting.

        If the model contains a combination of mesh and geometry, click one of the following from the prompt area:

        - Click **Geometry** if you want to select the surface or vertex from a geometry region.
        - Click **Mesh** if you want to select the surface or node from a native or orphan mesh selection.

        You can use the angle method to select a group of faces or edges from geometry or a group of element faces from a mesh. For more information, see *Using the angle and feature edge method to select multiple objects*.

      The main surface that you select becomes highlighted in red in the viewport.
4. Select the secondary surface.
   a. In the prompt area, select one of the following:

- Select **Surface** if you want to select a surface.
- Select **Node Region** if you want to select a region from which to create a node-based surface.

b. Use one of the same methods described in the previous step to select the secondary surface or region.

The secondary surface or region that you select becomes highlighted in magenta in the viewport.

The constraint editor appears.

5. The **Switch Surfaces** option allows you to interchange your main and secondary surface selections without having to start over. The **Switch Surfaces**  icon is available only when the main and secondary regions are the same type—both surfaces or both node-based regions.
6. From the editor, select the **Discretization method**.
   - Select **Analysis default** to use the default discretization method: surface-to-surface for Abaqus/Standard and node-to-surface for Abaqus/Explicit.
   - Select **Node to surface** to generate the tie coefficients according to the interpolation functions at the point where the secondary node projects onto the main surface.
   - Select **Surface to surface** to generate the tie coefficients such that stress accuracy is optimized for the specified surface pairing.
7. Toggle on **Exclude shell element thickness** if you want to ignore shell thickness effects in calculations involving position tolerances and adjustments for initial gaps.
8. Choose one of the following **Position Tolerance** methods:
   - **Use computed default**. Abaqus determines the nodes to be tied using the default position tolerance. For more information, see *Mesh Tie Constraints*.
   - **Specify distance**. You can specify an absolute distance from the main surface within which all nodes on the secondary surface to be tied must lie.
9. Toggle on **Adjust secondary surface initial position** if you want Abaqus to move all the nodes of the secondary surface onto the main surface in the initial configuration.
10. Toggle on **Tie rotational DOFs if applicable** if you want Abaqus to constrain the rotational degrees of freedom that exist on both main and secondary surfaces.
11. Toggle on **Tie temperature DOFs if applicable** if you want Abaqus to constrain the temperature degrees of freedom that exist on both main and secondary surfaces.
12. Toggle on **Tie pore pressure DOFs if applicable** if you want Abaqus to constrain the pore pressure degrees of freedom that exist on both main and secondary surfaces.
13. Toggle on **Tie electric potential in solid DOFs if applicable** if you want Abaqus to constrain the electric potential in solid degrees of freedom that exist on both main and secondary surfaces.
14. Toggle on **Tie electric potential in fluid DOFs if applicable** if you want Abaqus to constrain the electric potential in fluid degrees of freedom that exist on both main and secondary surfaces.
15. Toggle on **Tie ion concentration in fluid DOFs if applicable** if you want Abaqus to constrain the ion concentration in fluid degrees of freedom that exist on both main and secondary surfaces.
16. If desired, you can specify a value for the constraint ratio. You must toggle off **Tie rotational DOFs if applicable** to make the constraint ratio option available.

17. Click **OK** to save your constraint definition and to close the editor.

Additional information

• *Understanding constraints*

Defining rigid body constraints

You can create a rigid body constraint by specifying the regions that you want to include in the rigid body and by specifying a rigid body reference point. For detailed information about rigid bodies, see *Rigid Body Definition*.

1. From the main menu bar, select **Constraint->Create**.

   Tip: You can also create a rigid body constraint using the tool in the Interaction module toolbox.

2. In the **Create Constraint** dialog box that appears, do the following:
   a. Name the constraint. For more information about naming objects, see *Using basic dialog box components*.
   b. From the **Type** list, select **Rigid Body**, and then click **Continue**.

   The constraint editor appears.

3. From the editor, select all of the regions that you want to include in the rigid body.
   a. Select one of the following from the **Region type** list:

   - Select **Body** if you want to include the elements of a geometric region or orphan elements in the rigid body.
   - Select **Pin** to include nodes that will have only translational degrees of freedom associated with the rigid body.
   - Select **Tie** to include nodes that will have both translational and rotational degrees of freedom associated with the rigid body.
   - Select **Analytical Surface** to include an analytical surface in the rigid body.

   b. After you select a region type, click on the right side of the editor.
   c. Select a region of the assembly to associate with the **Region type** category selected in the previous step. Use one of the following methods to select the region:

   - Use an existing set or surface to define the region. On the right side of the prompt area, click **Sets** or **Surfaces**. Select an existing set or surface from the **Region Selection** dialog box that appears, and click **Continue**.

     Note:

     The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** or **Surfaces** on the right side of the prompt area.

   - Use the mouse to select the region in the viewport. (For more information, see *Selecting objects within the current viewport*.)

     If the model contains a combination of mesh and geometry, click one of the following from the prompt area:

     - Click **Geometry** if you want to select a geometry region.
     - Click **Mesh** if you want to select nodes from a native or orphan mesh selection.

You can use the angle method to select a group of faces or edges from geometry or a group of element faces from a mesh. For more information, see *Using the angle and feature edge method to select multiple objects*.

d. To remove a region type from the rigid body, select that region type, and then click  on the right side of the editor.

4. Repeat Step 3 as often as necessary to select all of the regions that you want to include in the rigid body.
5. Select the rigid body reference point:

   a. In the bottom half of the editor, click .

   b. Use one of the techniques described above to select a vertex or node to serve as the rigid body reference point. For more information, see *The Reference Point toolset*."
6. Toggle on **Adjust point to center of mass at start of analysis** if you want Abaqus to reposition the rigid body reference point at the calculated center of mass of the rigid body.
7. Toggle on **Constrain selected regions to be isothermal** to specify an isothermal rigid body for a fully coupled thermal-stress analysis.
8. Click **OK** to save your constraint definition and to close the editor.

Additional information

- *Understanding constraints*
- *Rigid Body Definition*

Defining display body constraints

You can create a display body constraint by selecting a part instance that will be displayed but will not be included in the analysis. You can constrain the display body to be fixed in space, or you can constrain it to follow selected nodes in the assembly. You can apply a display body constraint to any part instance in the model. For more information, see *Display Body Definition*. In addition, you can control the appearance of display bodies in the Visualization module; for more information, see *Customizing the appearance of display bodies*. For an example of a model that includes a display body constraint combined with connectors, see *Display bodies*."

1. From the main menu bar, select **Constraint->Create**.

   Tip: You can also create a display body constraint using the tool in the Interaction module toolbox.

2. In the **Create Constraint** dialog box that appears, do the following:
   a. Name the constraint. For more information about naming objects, see *Using basic dialog box components*.
   b. From the **Type** list, select **Display body**; then click **Continue**.
3. Select the part instance that will be a display body.

   The constraint editor appears.
4. By default, the part instance is fixed; alternatively, you can constrain it to follow selected points in the assembly. From the **Motion control** field of the constraint editor, choose one of the following:

No motion

Choose **No motion** to fix the selected part instance in space during the analysis. This is the default option.

Follow single point

Choose **Follow single point**, click , and select the point to which the part instance will be constrained. You must select the point from a different part instance, and that part instance must not be a display body. During the analysis the display body will follow the translations and rotations of the selected point.

Follow three points

Choose **Follow three points**, click , and select the three points to which the part instance will be constrained. You must select the points from a different part instance, and that part instance must not be a display body. During the analysis the display body will follow the translations and rotations of the coordinate system defined by the selected points. The first point indicates the origin of the coordinate system, the second point indicates the *X*-direction, and the third point indicates the *X*–*Y* plane. The points should be non-colinear and should remain non-colinear during the analysis.

5. Click **OK** to save your constraint definition and to close the editor.

Additional information

- *Display bodies*
- *Understanding constraints*
- *The Reference Point toolset*

Defining coupling constraints

You use a coupling constraint to constrain the motion of a surface to the motion of one or more points. You can create a coupling constraint by specifying one or more control points, a constraint region, and an influence radius that defines the points in the constraint region to include in the constraint. You can specify a kinematic or distributing coupling constraint type. For detailed information about coupling constraints, see *Coupling Constraints*.

1. From the main menu bar, select **Constraint->Create**.

   Tip: You can also create a coupling constraint using the tool in the Interaction module toolbox.

2. In the **Create Constraint** dialog box that appears, do the following:
   a. Name the constraint. For more information about naming objects, see *Using basic dialog box components*.
   b. From the **Type** list, select **Coupling**, and then click **Continue**.
3. Select one or more points to define the constraint control points using one of the following methods:

   - Select one or more points in the viewport.

     Tip: The **Select the Entity Closest to the Screen** tool in the **Selection** toolbar is toggled off by default. If you make an ambiguous selection, Abaqus/CAE highlights the point and displays a description of the point in the lower-left corner of the viewport. Use the **Next** and **Previous** buttons to cycle through the possible selections, and click **OK** to confirm your selection.

     (For more information, see *Selecting objects within the current viewport*.) Click mouse button 2 to indicate that you have finished selecting.

     If the model contains a combination of mesh and geometry, click one of the following from the prompt area:

     - Click **Geometry** if you want to select the constraint control point from geometry or select a reference point.
     - Click **Mesh** if you want to select the constraint control point from a native or orphan mesh selection.

   - Use an existing set to define the region. On the right side of the prompt area, click **Sets**. Select an existing set from the **Region Selection** dialog box that appears, and click **Continue**.

     Note: The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

   The points that you select become highlighted in red in the viewport.
4. In the prompt area, select one of the following to define the constraint region type:

   - Select **Surface** if you want to select a surface.
   - Select **Node Region** if you want to select a region from which to create a node-based surface.

5. Select the constraint region using one of the following methods:

   - Select a region in the viewport. (For more information, see *Selecting objects within the current viewport*.) Click mouse button 2 to indicate that you have finished selecting.

     If the model contains a combination of mesh and geometry, click one of the following from the prompt area:

     - Click **Geometry** if you want to select the surface from a geometry region.
     - Click **Mesh** if you want to select the surface from a native or orphan mesh selection.

   - Use an existing surface to define the region. On the right side of the prompt area, click **Surfaces**. Select an existing surface from the **Region Selection** dialog box that appears, and click **Continue**.

     Note: The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Surfaces** on the right side of the prompt area.

   The region that you select becomes highlighted magenta in the viewport, and the constraint editor appears.

6. From the editor, choose one of the following **Coupling type** categories:

   - Choose **Kinematic** to define a kinematic coupling constraint between the control points and the points in the constraint region, and toggle on the degrees of freedom that you want to constrain.
   - Choose **Distributing** to define a distributing coupling constraint between the control points and the points in the constraint region. Abaqus/CAE automatically constrains the translational degrees of freedom.

     1. Toggle on the rotational degrees of freedom that you want to constrain.
     2. Choose the **Translational Coupling type** option: **Translational Continuum distributing** or **Translational Structural distributing**.
     3. Choose the **Rotational Coupling type** option: **Rotational Continuum distributing** or **Rotational Structural distributing**.
     4. Click the arrow next to the **Weighting method** field, and select a weighting method from the list that appears. For more information, see *Coupling Constraints*.

   - Choose **Uniform** to define a uniform coupling constraint between the control points and the points in the constraint region.

     1. Choose from the combo box any one nonmechanical degree of freedom that you want to constrain or **NONE**.
     2. If you selected temperature, also select the **Temperature DOF Type** you want to constrain.

7. From the editor, choose one of the following methods to define the **Influence radius**:

   - **To outermost point on the region**. Abaqus includes all points (nodes) on the specified region in the coupling definition.
   - **Specify**. You can specify the radius of a sphere, centered about the constraint control points, to limit the points in the coupling definition. For more information on selecting the coupling points, see *Coupling Constraints*.

8. If desired, toggle on **Adjust control points to lie on surface**. Abaqus/CAE will move the control points to lie on the constraint surface.

9. If you want to change the coordinate system (**CSYS**) for the coupling constraint, click  and use one of the following methods:

   - Select a predefined datum coordinate system by name.

     1. From the prompt area, click **Datum CSYS List** to display a list of datum coordinate systems.
     2. Select a name from the list, and click **OK**.

   - Select a predefined coordinate system in the viewport.

     Tip: The  tool in the **Selection** toolbar is toggled off by default. For coordinate systems with coincident origins, when you cycle through all the possible selections, Abaqus/CAE highlights the coordinate system and displays the description of the coordinate system in the viewport.

   - Click **Use Global CSYS** from the prompt area to use the global coordinate system.

10. Click **OK** to save your constraint definition and to close the editor.

Additional information

- *Understanding constraints*

Defining adjust points constraints

You use an adjust points constraint to move a point or points onto a specified surface. For more information about adjusting points, see *Adjusting Nodal Coordinates*. This adjustment may be useful in assembled fastener template models and other applications; see *About assembled fasteners*, and *Creating assembled fasteners*.

An adjust points constraint should not be used in assembled fastener template models when the main model attachment points are located on bolt hole center points. Any point along the bolt hole centerline will be moved incorrectly to a random location along the perimeter of the hole instead of being projected along the surface normal to the center of the hole.

1. From the main menu bar, select **Constraint->Create**.

   Tip: You can also create an adjust points constraint using the tool in the Interaction module toolbox.

2. In the **Create Constraint** dialog box that appears, do the following:
   a. Name the constraint. For more information about naming objects, see *Using basic dialog box components*.
   b. From the **Type** list, select **Adjust points**, and then click **Continue**.
3. Select the point or set of points to be moved, using one of the following methods:

   - Select one or more points in the viewport.

     Tip: The **Select the Entity Closest to the Screen** tool in the **Selection** toolbar is toggled off by default. If you make an ambiguous selection, Abaqus/CAE highlights the point and displays a description of the point in the lower left corner of the viewport. Use the **Next** and **Previous** buttons to cycle through the possible selections, and click **OK** to confirm your selection.

     Click mouse button 2 to indicate that you have finished selecting. For more information, see *Selecting objects within the current viewport*.

     If the model contains a combination of mesh and geometry, click one of the following from the prompt area:

     - Click **Geometry** if you want to select the points from a geometry region or select one or more reference points.
     - Click **Mesh** if you want to select the points from a native or orphan mesh selection.

   - Use an existing set to define the point or points. On the right side of the prompt area, click **Sets**. Select an existing set of points from the **Region Selection** dialog box that appears, and click **Continue**.

     Note:

     The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

   The points that you select become highlighted in red in the viewport.

4. In the prompt area, select the type of region onto which the points will be moved.
   - Select **Surface** if you want to select a surface.
   - Select **Node Region** if you want to select a region from which to create a node-based surface.
5. Select the surface onto which the points will be moved using one of the following methods:
   - Select a surface in the viewport. Click mouse button 2 to indicate that you have finished selecting.

     If the model contains a combination of mesh and geometry, click one of the following from the prompt area:
     - Click **Geometry** if you want to select the surface from a geometry region or select one or more reference points.
     - Click **Mesh** if you want to select the surface from a native or orphan mesh selection.
   - Use an existing surface or set to define the region. On the right side of the prompt area, click **Surfaces** or **Sets**. Select an existing surface or set from the **Region Selection** dialog box that appears, and click **Continue**.

     Note:

     The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Surfaces** (or **Sets**) on the right side of the prompt area.

   The region that you select is highlighted in magenta in the viewport, and the constraint editor appears.
6. Click **OK** to save your constraint definition and to close the editor.

Additional information

• *Understanding constraints*

• *Adjusting Nodal Coordinates*

Defining MPC constraints

You use an MPC constraint to constrain the motion of secondary nodes of a region to the motion of a point. You can create an MPC constraint by specifying a control point and a region composed of nodes, edges, and surfaces. For detailed information about multi-point constraints, see *General Multi-Point Constraints*.

1. From the main menu bar, select **Constraint->Create**.

   Tip: You can also create a multi-point constraint using the tool in the Interaction module toolbox.

2. In the **Create Constraint** dialog box that appears, do the following:
   a. Name the constraint. For more information about naming objects, see *Using basic dialog box components*.
   b. From the **Type** list, select **MPC Constraint**, then click **Continue**.
3. Select a point to define the constraint control point using one of the following methods:

   - Use the mouse to select a point in the viewport.

     Tip: The **Select the Entity Closest to the Screen** tool in the **Selection** toolbar is toggled off by default. If you make an ambiguous selection, Abaqus/CAE highlights the point and displays a description of the point in the lower left corner of the viewport. Use the **Next** and **Previous** buttons to cycle through the possible selections, and click **OK** to confirm your selection.

     (For more information, see *Selecting objects within the current viewport*.) Click mouse button 2 to indicate that you have finished selecting.

     If the model contains a combination of mesh and geometry, click one of the following from the prompt area:

     - Click **Geometry** if you want to select the control point from a geometry region.
     - Click **Mesh** if you want to select the control point from a native or orphan mesh selection.

   - Use an existing set to define the region. On the right side of the prompt area, click **Sets**. Select an existing set from the **Region Selection** dialog box that appears, and click **Continue**.

     Note:

     The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

   The point that you select becomes highlighted in red in the viewport.
4. Select the region for the secondary nodes. Use one of the following methods to select the region:

   - Use the mouse to select a region in the viewport. (For more information, see *Selecting objects within the current viewport*.) The region that you select can span multiple part instances. Click mouse button 2 to indicate that you have finished selecting.

If the model contains a combination of mesh and geometry, click one of the following from the prompt area:

- Click **Geometry** if you want to select a geometry region.
- Click **Mesh** if you want to select the region from a native or orphan mesh selection.

You can use the angle method to select a group of nodes from a mesh. For more information, see *Using the angle and feature edge method to select multiple objects*.

- Use an existing set to define the region. On the right side of the prompt area, click **Sets**. Select an existing set from the **Region Selection** dialog box that appears and click **Continue**.

Note:

The default selection method is based on the selection method that you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

The region that you select becomes highlighted in magenta in the viewport.

The constraint editor appears.

5. From the editor, select the **MPC type**.
   - Select **Beam** to define a rigid beam connection to constrain the displacement and rotation of each secondary node to the displacement and rotation of the control point.
   - Select **Tie** to make all active degrees of freedom equal at each secondary node and the control point.
   - Select **Link** to define a pinned rigid link between each secondary node and the control point.
   - Select **Pin** to define a pinned joint between each secondary node and the control point.
   - Select **Elbow** to constrain nodes of ELBOW31 or ELBOW32 elements together (see *Pipes and Pipebends with Deforming Cross-Sections: Elbow Elements*).
   - Select **User-defined** to define a multi-point constraint in user subroutine *MPC* (for Abaqus/Standard). See the following sections for more information:
     - *Specifying general job settings*
     - *MPC*

6. If you selected a user-defined MPC type, do the following:
   a. Choose the coding mode for user subroutine *MPC*.
      - Choose **DOF-by-DOF** if you want each call to the user subroutine to constrain one individual degree of freedom.
      - Choose **Node-by-Node** if you want each call to the user subroutine to impose a set of constraints all at once.

   b. In the **Constraint type** field, enter an integer value to be used in the user subroutine to distinguish between different constraint types. The default value is 0.

7. If you want to change the coordinate system (**CSYS**) for the coupling constraint, click  and use one of the following methods:
   - Select a predefined datum coordinate system by name.

1. From the prompt area, click **Datum CSYS List** to display a list of datum coordinate systems.
2. Select a name from the list, and click **OK**.

- Select a predefined coordinate system in the viewport.

  Tip: The  tool in the **Selection** toolbar is toggled off by default. For coordinate systems with coincident origins, when you cycle through all of the possible selections, Abaqus/CAE highlights the coordinate system and displays the description of the coordinate system in the viewport.

- Click **Use Global CSYS** from the prompt area to use the global coordinate system.

8. Click **OK** to save your constraint definition and to close the editor.

Defining shell-to-solid coupling constraints

You use a shell-to-solid coupling constraint to couple the motion of a shell edge to the motion of an adjacent solid face. You can create a shell-to-solid coupling constraint by specifying a shell edge surface and a solid face region. The shell edge surface and the solid face region being coupled must belong to different part instances unless the shell edge surface is part of a midsurface region within a solid model.

For detailed information about shell-to-solid coupling constraints, see *Shell-to-Solid Coupling*.

Abaqus/CAE creates shell-to-solid coupling constraints automatically only when shell sections and solid sections exist within the same part and they are nearly perpendicular to each other with a solid surface detected on both sides of the shell surface.

1. From the main menu bar, select **Constraint->Create**.

   Tip: You can also create a shell-to-solid coupling constraint using the  tool in the Interaction module toolbox.

2. In the **Create Constraint** dialog box that appears, do the following:
   a. Name the constraint. For more information about naming objects, see *Using basic dialog box components*.
   b. From the **Type** list, select **Shell-to-solid coupling**, and then click **Continue**.
3. Use one of the following methods to select the shell edge surface:

   - Use an existing surface to define the region. On the right side of the prompt area, click **Surfaces**. Select an existing surface from the **Region Selection** dialog box that appears, and click **Continue**.

     Note:

     The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Surfaces** on the right side of the prompt area.

   - Use the mouse to select a region in the viewport. (For more information, see *Selecting objects within the current viewport*.) Click mouse button 2 to indicate that you have finished selecting.

     If the model contains a combination of mesh and geometry, click one of the following from the prompt area:

     - Click **Geometry** if you want to select the surface from a geometry region.
     - Click **Mesh** if you want to select the surface from a native or orphan mesh selection.

     You can use the angle method to select a group of faces or edges from geometry or a group of element faces from a mesh. For more information, see *Using the angle and feature edge method to select multiple objects*.

   The shell edge surface that you select becomes highlighted in red in the viewport.
4. Select the solid face region.
   a. In the prompt area, click the arrow next to the text field and select one of the following:

      - Select **Surface** if you want to select a surface.
      - Select **Node Region** if you want to select a region from which to create a node-based surface.

b. Use one of the same methods described in the previous step to select the solid face region.

The solid face region that you select becomes highlighted in magenta in the viewport

The constraint editor appears.

5. From the editor, choose one of the following **Position Tolerance** methods:

- **Use computed default**. Abaqus determines the nodes on the shell edge surface to be coupled with the solid face region using the default position tolerance. For more information, see *Shell-to-Solid Coupling*.
- **Specify distance**. You can specify an absolute distance from the solid face region within which all shell nodes to be included in the coupling must lie.

6. From the editor, choose one of the following **Influence Distance** methods:

- **Use analysis default**. Abaqus determines the nodes on the solid face region to be coupled with the shell edge surface using the default influence distance. For more information, see *Shell-to-Solid Coupling*.
- **Specify value**. You can specify a distance from the shell edge surface within which all solid nodes to be included in the coupling must lie.

7. Click **OK** to save your constraint definition and to close the editor.

Additional information

• *Understanding constraints*

• *Shell-to-Solid Coupling*

Defining embedded region constraints

You use an embedded region constraint to embed a region of the model within a "host" region of the model or within the whole model. You can create an embedded region constraint by specifying the embedded region, the host region, a weight factor roundoff tolerance, and an absolute exterior tolerance or fractional exterior tolerance. For more information, see *Embedded Elements*.

1. From the main menu bar, select **Constraint->Create**.

   Tip: You can also create an embedded region constraint using the  tool in the Interaction module toolbox.

2. In the **Create Constraint** dialog box that appears, do the following:
   a. Name the constraint. For more information about naming objects, see *Using basic dialog box components*.
   b. From the **Type** list, select **Embedded region**, and then click **Continue**.
3. Select the embedded region using one of the following methods:

   - Select a region in the viewport. (For more information, see *Selecting objects within the current viewport*.) Click mouse button 2 to indicate that you have finished selecting.

     If the model contains a combination of mesh and geometry, click one of the following from the prompt area:

     - Click **Geometry** if you want to select a geometry region.
     - Click **Mesh** if you want to select the region from a native or orphan mesh selection.

   - Use an existing set to define the region. On the right side of the prompt area, click **Sets**. Select an existing set from the **Region Selection** dialog box that appears, and click **Continue**.

     Note:

     The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

   The region that you select becomes highlighted in red in the viewport.
4. Select the host region.

   In the prompt area, select one of the following:

   - **Select Region** if you want to select a region in the viewport or use an existing set to define the region. Use one of the methods described in the previous step to select the host region.

     The region that you select becomes highlighted magenta in the viewport.
   - **Whole Model** if you want to embed the embedded region within the whole model.

   The constraint editor appears.
5. In the editor, specify values for the tolerance parameters. If you specify values for both exterior tolerance parameters, Abaqus will use the smaller of the two tolerances.

   - **Weight factor roundoff tolerance**. You can specify a small value below which the weighting factors will be zeroed out. The default value is 10^{-6}.

- **Absolute exterior tolerance**. You can specify the absolute value by which a node on the embedded region may lie outside the host region. If this parameter is omitted or has a value of 0.0, the **Fractional exterior tolerance** will apply.
- **Fractional exterior tolerance**. You can specify the fractional value by which a node on the embedded region may lie outside the host region. The fractional value is based on the average element size within the host region. The default value is 0.05.

6. Click **OK** to save your constraint definition and to close the editor.

Additional information

• *Understanding constraints*

• *Embedded Elements*

Defining equation constraints

You can create an equation constraint by entering data in the **Edit Constraint** dialog box.
The terms of an equation consist of a coefficient applied to a degree of freedom of every node in a set. For detailed information about equations, see *Linear Constraint Equations*.

1. From the main menu bar, select **Constraint->Create**.

   Tip: You can also create an equation constraint using the tool in the Interaction module toolbox.

2. In the **Create Constraint** dialog box that appears, do the following:
   a. Name the constraint. For more information about naming objects, see *Using basic dialog box components*.
   b. From the **Type** list, select **Equation**, and then click **Continue**.

   The constraint editor appears.

3. In the table in the editor, enter a row of data for each term in the equation. The equation must have at least two terms. Click for a description of the relationship between the data in the table and the desired equation.

   Each row should contain the following information:

   - The coefficient.
   - The name of an existing set. (For information on creating sets, see *The Set and Surface toolsets*.) You can enter a set that contains one or more nodes in the first row of the table. Subsequent sets can contain multiple nodes as long as all the sets contain an equal number of nodes.
   - The degree of freedom.
   - The ID of the coordinate system in which you will apply the constraint. You can either accept the default coordinate system or select an existing datum coordinate system. If the desired datum coordinate system does not exist, you can create it using the Datum toolset. (For more information, see *Creating datum coordinate systems*.)

     To determine the ID of a coordinate system, select **Tools->Query** from the main menu bar. For more information, see *Obtaining general information about the model*.

4. Click **OK** to save your equation definition and to close the constraint editor.

Additional information

- *Understanding constraints*
- *Linear Constraint Equations*

Using contact and constraint detection

The contact detection tool greatly simplifies the process for defining contact interactions and tie constraints in a model. This section explains in detail how to use the contact detection dialog box to locate and create interactions or constraints automatically.

For an overview of contact detection and a discussion of the search methods used by Abaqus/CAE, see *Understanding contact and constraint detection*.

In this section:

- *Specifying search criteria for contact detection*
- *Searching for contact pairs*
- *Reviewing and modifying detected contact pairs*
- *Creating interactions for automatically detected contact pairs*

Specifying search criteria for contact detection

The contact detection tool identifies potential contact pairs in a model using an array of user-defined parameters. Select **Interaction->Find contact pairs** or **Constraint->Find contact pairs** from the main menu, then enter the contact detection parameters.

In this section:

- *Specifying general search options for contact detection*
- *Specifying naming options for contact detection*
- *Specifying entity options for contact detection*
- *Defining default contact pair parameters*
- *Specifying advanced search options for contact detection*

Specifying general search options for contact detection

General search options indicate the range in which you want Abaqus/CAE to look for contact pair candidates. You can specify which areas of the model include contact pairs, as well as the estimated distance between surfaces that will require interaction or constraint definitions.

1. From the main menu, select either **Interaction->Find contact pairs** or **Constraint->Find contact pairs**.

    **Tip:** You can also find contact pairs using the  tool in the Interaction module toolbox.

   Abaqus/CAE displays the contact detection dialog box.
2. Display the **Search Options** tabbed page if it is not visible already.
3. Specify the **Search domain**:
   - Select **Whole model** to include every instance in the current model.
   - Select **Instance** to include only specified part instances and child part instances. Use the following procedure to specify the instances:
     1. Click .
     2. Select the instances from the viewport (for information on selecting instances, see *Selecting objects within the viewport*").
     3. After you have selected all of the desired instances, click **Done** in the prompt area.
   - Select **Displayed entities** to include only those portions of the model that are currently displayed in the viewport. You can use the assembly display options and display groups to control the display of the model. For details, see *Controlling instance visibility*, and *Using display groups to display subsets of your model*."
4. Enter the maximum distance between potential contact pair surfaces in the **Include pairs within separation tolerance** field. For tips on selecting a separation tolerance, see *Choosing a separation tolerance and extension angle*.
5. By default, Abaqus/CAE extends surface definitions to any faces (for geometry) or facets (for meshed models) within 20° of the surfaces detected by the search. You can adjust this angle by changing the value in the **Extend each surface found by angle** field. To prevent the extension of surface definitions, toggle off **Extend each surface found by angle**. For further details on how Abaqus/CAE extends surfaces, see *Additional criteria for defining contact pairs*.
6. By default, Abaqus/CAE creates contact pairs from surfaces located on different part instances or model instances. To search for contact pairs involving different regions on the same part instance or model instance or to search for potential self-contact interactions, toggle on **Include pairs with surfaces on the same instance**. For details, see *Defining contact within the same instance and self-contact*.

Additional information

- *Understanding contact and constraint detection*
- *Using contact and constraint detection*

Specifying naming options for contact detection

In addition to creating contact pair interactions, the automatic contact detection tool also creates named surfaces for each surface involved in a contact pair (see *Default interaction and constraint parameters*). The **Names** tabbed page provides some options for tuning this surface creation behavior.

1. From the main menu, select either **Interaction->Find contact pairs** or **Constraint->Find contact pairs**.

   Tip: You can also find contact pairs using the tool in the Interaction module toolbox.

   Abaqus/CAE displays the contact detection dialog box.
2. Display the **Names** tabbed page.
3. In the **Name prefix** field, enter the prefix that will be used when naming each contact pair and surface (as discussed in *Default interaction and constraint parameters*).
4. To prevent the creation of named surfaces, toggle off **Name each surface found**. This option will not affect the creation of contact pairs.
5. The **Create additional named surfaces containing** field allows you to create additional composite surfaces:
   - To create a single named surface composed of all contact pair surfaces acting as a main surface, toggle on **All main**. Any main surfaces from preexisting contact pairs are also included in the created composite surface.
   - To create a single named surface composed of all contact pair surfaces acting as a secondary surface, toggle on **All secondary**. Any secondary surfaces from preexisting contact pairs are also included in the created composite surface.
   - To create a single named surface composed of all surfaces involved in contact pair definitions, toggle on **All**. Any surfaces from preexisting contact pairs are also included in the created composite surface.

Additional information

- *Understanding contact and constraint detection*
- *Using contact and constraint detection*

Specifying entity options for contact detection

The **Entities** tabbed page allows you to control the types of geometry and elements that are included in a search. You can use these options to ignore certain features of a model or part instance that are not essential to contact interactions or constraints; for example, a layer of membrane elements on the outside of a solid body. Removing features from a search may also improve performance; for example, if all the contacting faces in a complex model are planar, removing cylindrical and spline-based features from the contact pair search may lead to faster search times. In general, the default entity options provide acceptable performance and should be modified only if a search is taking an excessively long time to complete.

1. From the main menu, select either **Interaction->Find contact pairs** or **Constraint->Find contact pairs**.

    **Tip:** You can also find contact pairs using the  tool in the Interaction module toolbox.

   Abaqus/CAE displays the contact detection dialog box.
2. Display the **Entities** tabbed page.
3. By default, Abaqus/CAE factors in shell thickness and offset properties when calculating the separation between shell entities. To ignore shell section properties and calculate separations based solely on the geometric representation of shell entities in a model, toggle off **Account for shell thickness and offset during search**.
4. When searching for geometry, toggle the following features in the **Search the following geometric entities** field to include or exclude them from the search domain:
   - **Planar** refers to all flat faces in a model. These features are toggled on by default.
   - **Cylindrical/Spherical/Toroidal** refers to curved faces in a model that were generated by extruding or revolving a straight, circular, or elliptical line. These features are toggled on by default.
   - **Spline-based** refers to irregularly curved faces in a model that were generated from spline lines or paths (see *Sketching splines* for more information). These features are toggled on by default.
5. When searching for meshed geometry, toggle the following element types in the **Search the following mesh entities** field to include or exclude them from the search domain:
   - **Solid** refers to faces on solid continuum elements. These elements are toggled on by default.
   - **Shell** refers to faces on shell elements. These elements are toggled on by default.
   - **Membrane** refers to faces on membrane or surface elements. These elements are toggled off by default.

Additional information

- *Understanding contact and constraint detection*
- *Using contact and constraint detection*

Defining default contact pair parameters

Contact detection rules allow you to specify a set of conditional options that determine the default settings assigned to detected contact pairs. You can always change the contact pair settings after they are detected, but specifying rules before a search allows you to define appropriate contact pairs quickly according to your particular modeling intent. The rules are applied when Abaqus/CAE performs a search for contact pair candidates. For more information about contact pair default settings, see *Default interaction and constraint parameters*.

1. From the main menu, select either **Interaction->Find contact pairs** or **Constraint->Find contact pairs**.

   Tip: You can also find contact pairs using the tool in the Interaction module toolbox.

   Abaqus/CAE displays the contact detection dialog box.
2. Display the **Rules** tabbed page.
3. Click .

   Abaqus/CAE displays the **Edit Rules** dialog box.
4. To create tie constraints for all contact pairs whose surfaces lie within a particular tolerance, toggle on **Use tie constraints when the separation value does not exceed** and enter the tolerance in the field provided. This rule is disabled by default.
5. To set the position tolerance on tie constraints equal to the surface separation reported by the contact detection tool, toggle on **Set tie position tolerance to separation value when nonzero**. This rule is disabled by default. For more information about position tolerances for tie constraints, see *Mesh Tie Constraints*.
6. To set the surface adjustment setting on contact interactions equal to the surface separation reported by the contact detection tool, toggle on **Adjust separated interactions by the separation value**. This rule is disabled by default. For more information about surface adjustment options, see *Contact Initialization for Contact Pairs in Abaqus/Standard*.
7. To move any overclosed secondary nodes in a contact interaction directly onto the main surface, toggle on **Adjust interactions to remove overclosure**. The adjustment is performed during the analysis. This rule is enabled by default. For more information about surface adjustment options, see *Contact Initialization for Contact Pairs in Abaqus/Standard*.
8. Click **OK**.

Additional information

- *Understanding contact and constraint detection*
- *Using contact and constraint detection*

Specifying advanced search options for contact detection

The advanced search options provide an added level of control over the search range and the creation of contact pair surfaces. The general search options are sufficient in most cases; however, you may want to use the advanced options to account for unique modeling conditions. See *Tips for using the contact detection tool*, for a discussion of various modeling conditions and the recommended search techniques.

1. From the main menu, select either **Interaction->Find contact pairs** or **Constraint->Find contact pairs**.

   Tip: You can also find contact pairs using the  tool in the Interaction module toolbox.

   Abaqus/CAE displays the contact detection dialog box.

2. Display the **Advanced** tabbed page.
3. By default, Abaqus/CAE merges any contact pairs whose adjacent surfaces lie within 20° of each other (for details on this calculation, see *Additional criteria for defining contact pairs*). You can adjust this angle by changing the value in the **Merge pairs when surfaces are within angle** field. To prevent the merging of adjacent contact pairs, toggle off **Merge pairs when surfaces are within angle**.
4. By default, Abaqus/CAE includes overclosed and intersecting surfaces when searching for contact pairs. To ignore overclosed surfaces, toggle off **Include overclosed surfaces**. For details on how the automatic contact detection tool interprets overclosed surfaces, see *Detection of overclosed surfaces*.
5. By default, Abaqus/CAE does not create a contact pair candidate if two surfaces are laterally offset from each other (i.e., the surface normals from either surface never intersect the opposite surface). To include these surfaces in the contact pair candidates table, toggle on **Include opposing surfaces that do not overlap**. Such surfaces must still meet the separation and orientation requirements for the search. See *Additional criteria for defining contact pairs*, for further discussion of this option.
6. If your search includes part instances that have been meshed from geometry, indicate how Abaqus/CAE should interpret these instances during the search:

   - To treat the instances as geometry, select **Geometry**. Abaqus/CAE uses the **Geometry** option by default.
   - To treat the instances as element meshes, select **Mesh**.

   Tip: To detect contact between geometry and mesh instances, first mesh the geometry, then perform a mesh-based search.

   For a discussion of the differences between geometry and meshes, see *Contact detection for meshed models*.

7. To save the current search parameters as defaults for future sessions of Abaqus/CAE, click  (for more information, see *Saving the search parameters*). To reset saved search parameters to the original defaults, click .

Additional information

- *Understanding contact and constraint detection*
- *Using contact and constraint detection*

Searching for contact pairs

Once you have indicated the appropriate contact criteria, Abaqus/CAE searches your model to locate the surfaces that meet those criteria. For a discussion of how Abaqus/CAE interprets search criteria and detects contact pair candidates, see *Use of the contact detection algorithm*.

1. From the main menu, select either **Interaction->Find contact pairs** or **Constraint->Find contact pairs**.

   Tip: You can also find contact pairs using the  tool in the Interaction module toolbox.

   Abaqus/CAE displays the contact detection dialog box.
2. Enter the search parameters as described in *Specifying search criteria for contact detection*.
3. Click **Find Contact Pairs**.
4. Abaqus/CAE searches for potential contact pairs. When the search is complete, Abaqus/CAE populates the contact pair candidates table.

   To end a search before it is complete, click **Stop** in the prompt area.

Additional information

- *Understanding contact and constraint detection*
- *Using contact and constraint detection*

Reviewing and modifying detected contact pairs

This section discusses to review and modify the contact pair definitions.

After searching for contact pairs (described in *Specifying search criteria for contact detection* and *Searching for contact pairs*), you have the opportunity to review the search results before creating interactions and tie constraints. The search results are presented in the contact pair candidates table: each contact pair comprises a row in the table; each column represents a parameter of the contact pair definition. Default values are provided for every necessary interaction parameter.

In this section:

- *Confirming search results in the viewport*
- *Configuring the layout of the contact pair candidates table*
- *Reviewing detected contact pairs*
- *Modifying contact pair definitions*
- *Creating suppressed interactions and constraints*
- *Miscellaneous review procedures*

Confirming search results in the viewport

As a visual aid, toggle on **Highlight in viewport** to highlight specified entities on your model in the viewport.

Select the entities you want to highlight:

Selected pairs

Highlights the surfaces involved in the contact pair or pairs that are currently selected in the contact pair candidates table. The main surface is highlighted in red; the secondary surface is highlighted in magenta. For axisymmetric or spherical surfaces, Abaqus/CAE also displays the axis of symmetry or spherical center for the surface; the axis or center point is used in surface smoothing calculations if they are applied (see *Modifying contact pair definitions*).

Selected main surfaces

Highlights the assigned main surfaces in the contact pair or pairs that are currently selected in the contact pair candidates table. For axisymmetric or spherical surfaces, Abaqus/CAE also displays the axis of symmetry or spherical center for the surface; the axis or center point is used in surface smoothing calculations if they are applied (see *Modifying contact pair definitions*).

Selected secondary surfaces

Highlights the assigned secondary surfaces in the contact pair or pairs that are currently selected in the contact pair candidates table. For axisymmetric or spherical surfaces, Abaqus/CAE also displays the axis of symmetry or spherical center for the surface; the axis or center point is used in surface smoothing calculations if they are applied (see *Modifying contact pair definitions*).

Search domain

Highlights the part instances in the model specified by the current **Search domain** field (see *Specifying general search options for contact detection*).

Selected pairs + search domain

Highlights both the currently selected contact pairs and the entire search domain.

Additional information

- *Understanding contact and constraint detection*
- *Using contact and constraint detection*

Configuring the layout of the contact pair candidates table

A number of options are available to configure the display of the contact pair candidates table. You can customize the table to display only those elements that are essential to your modeling goals.

1. Toggle on **Show previously created interactions and ties** to add any previously defined contact interactions and tie constraints to the contact pair candidates table. You can edit previously defined interactions and ties in the same manner as newly detected contact pairs.
2. To limit the table display to only those contact pair candidates whose name contains a particular string, type that string in the **Name filter** field and press **[Enter]**. Click  to see examples of valid filtering syntax.

   Abaqus/CAE still creates interactions and constraints for contact pair candidates that are hidden by a filter.
3. Add or remove columns from the table display as necessary:
   a. Click mouse button 3 anywhere on the contact pair candidates table, and select **Edit Visible Columns** from the menu that appears.

      The **Edit Visible Columns** dialog box appears.
   b. In the **Edit Visible Columns** dialog box, toggle on the columns you want to display; toggle off the columns you want to hide:

Suppression

Indicates whether the contact pair will be active or suppressed upon creation (see *Creating suppressed interactions and constraints*). This column is hidden by default.

Name

Displays the name of the contact pair. This column is displayed by default.

Separation

Displays the distance between the two surfaces in the contact pair (see *Use of the contact detection algorithm*). This column is displayed by default.

Main surface name

Displays the name of the surface acting as the main in the contact pair. This column is hidden by default.

Secondary surface name

Displays the name of the surface acting as the secondary in the contact pair. This column is hidden by default.

Main instance name

Displays the name of the part instance on which the main surface is located. This column is hidden by default.

Secondary instance name

Displays the name of the part instance on which the secondary surface is located. This column is hidden by default.

Type

Indicates whether Abaqus/CAE is creating a contact interaction or a tie constraint for the contact pair. This column is displayed by default.

Sliding

Indicates the tracking approach used in the contact interaction formulation. This column is displayed by default.

Discretization

Indicates the surface discretization used in the contact interaction or tie constraint formulation. This column is displayed by default.

Property

Indicates the contact interaction property used in the contact formulation. This column is displayed by default.

Contact controls

Indicates the contact controls used in the contact formulation. This column is hidden by default and is unavailable in the initial step.

Adjust

For contact interactions, displays the range within which secondary nodes will be adjusted to lie precisely on the main surface. If nodes in a set are being adjusted, this column displays the name of the set.

For tie constraints, indicates whether or not all tied secondary nodes will be adjusted to lie precisely on the main surface.

This column is displayed by default.

Create step

Displays the name of the step in which Abaqus/CAE is activating the contact interaction or tie constraint. This column is hidden by default.

Surface smoothing

Indicates whether or not surface smoothing is applied to axisymmetric or spherical surfaces in the contact pair (see *Smoothing Contact Surfaces in Abaqus/Standard*). This column is displayed by default.

c. Do one of the following:

- Click **OK** to apply the settings and to close the **Edit Visible Columns** dialog box.

- Click **Apply** to apply the settings and to leave the **Edit Visible Columns** dialog box open.
- Click **Cancel** to ignore any changes and to close the **Edit Visible Columns** dialog box.

4. Sort the table contents according to parameter values by clicking the column heading for the parameter of interest. An up arrow in the column heading indicates the values are listed in ascending order; a down arrow indicates the parameter values are listed in descending order.

Additional information

- *Understanding contact and constraint detection*
- *Using contact and constraint detection*

Reviewing detected contact pairs

You should review the contact pair candidates in the contact pair candidates table to ensure the surfaces involved are accurate and sufficient for your modeling needs.

Click on each contact pair name with the **Highlight in viewport** option toggled on to see the locations of each potential surface interaction or tie. If necessary you can add, remove, or modify the contact pair candidates.

1. Add a row to the table for any unidentified contact pairs you would like to include in your model:
   a. Click mouse button 3 anywhere in the contact pair candidates table, and select **Add** from the menu that appears. You can also click the  button above the contact pair candidates table.
   b. Select a main surface in the viewport, and click **OK** in the prompt area.

      For details on surface selection, see *Selecting objects within the viewport*.
   c. Select a secondary surface in the viewport, and click **OK**.

      Abaqus/CAE adds a contact pair candidate row to the contact pair candidates table based on the surfaces you selected. Default values are provided for each column in the row.
2. Remove any contact pair candidates that are not necessary for your modeling purposes. Click mouse button 3 anywhere on the row representing the contact pair candidate you want to remove, and select **Delete** from the menu that appears. You can also click the row you want to remove and then click the  button above the contact pair candidates table.
3. If multiple contact pairs will use identical parameters in their contact interaction or tie constraint definition, you can combine them into a single contact pair:
   a. In the contact pair candidates table, highlight the rows representing the contact pairs you want to combine (see *Selecting multiple items from lists and tables*, for instructions on selecting multiple rows in a table).
   b. Click mouse button 3 on any highlighted cell, and select **Merge** from the menu that appears. You can also click the  button above the contact pair candidates table.

      Abaqus/CAE replaces the selected contact pairs with a single contact pair. The selected main surfaces are merged into a single surface, and the selected secondary surfaces are merged into a single surface. The merged contact pair uses the parameters from the selected contact pair that appeared highest in the contact pair candidates table.

       **Note:**

      When combining contact pairs, the resultant merged surfaces must meet the orientation and connectivity requirements discussed in *About Contact Pairs in Abaqus/Standard* and *About Contact Pairs in Abaqus/Explicit*.

Modifying contact pair definitions

The contact pair candidates table presents all of the identified contact pair candidates in a format that allows you to easily review and modify the parameters of each contact pair definition.
Abaqus/CAE supplies default values for each parameter of the contact pair definition (see *Default interaction and constraint parameters*).

You can customize some of the default parameter settings to suit your modeling needs by using the **Rules** tabbed page (see *Defining default contact pair parameters*). However, you may still need to modify some parameters manually before creating interactions and constraints. The **Rules** options cannot account for such modeling issues as the appropriateness of small-sliding contact or assignment of varying frictional contact properties. You also may need to swap the assignment of main and secondary roles in contact pairs to ensure continuity and robustness.

To modify a parameter, change the value that is displayed in the corresponding cell of the contact pair candidates table. You modify cell values in one of four ways:

- To change a name parameter, click on the cell and type a new name. The old name is overwritten as you type.
- For cells that accept specific values, first click the cell to activate it. Then click the arrow next to the cell and select the desired value from the list that appears.
- For cells that require more detailed information to define the parameter, double-click the cell and enter the appropriate information in the dialog box that appears.
- For all cells other than name parameters, click mouse button 3 on the cell and select **Edit Cells** from the menu that appears. You can also click the cell and then click the  button above the contact pair candidates table. Enter the appropriate information in the dialog box that appears.

You cannot modify values for the following parameters:

- **Separation**
- **Main Instance**
- **Secondary Instance**

Each row of the contact pair candidates table represents a single contact pair candidate. The following instructions apply to a single row. Repeat them as often as necessary for each row in the table. For instructions on editing parameters for multiple contact pair candidates simultaneously, see *Miscellaneous review procedures*.

1. In the **Name** column, change the name of the contact pair, if desired.
2. In the **Main Surface** or **Secondary Surface** column, change the name of the generated main surface or secondary surface, if desired.

   The **Main Surface** and **Secondary Surface** columns are not displayed in the contact pair candidates table by default. See *Configuring the layout of the contact pair candidates table*, for instructions on adding these columns to the table.
3. Click mouse button 3 on any cell in the row, and select **Switch Surfaces** from the menu that appears to reverse the role of the main and secondary surfaces for the selected contact pair. You can also click the row and then click the  button above the contact pair candidates table. (To determine the role assignments in a contact pair, see *Confirming search results in the viewport*.)
4. To indicate whether a contact interaction or a tie constraint is created for the contact pair candidate, select **Interaction** or **Tie** in the **Type** column.

   You cannot change the **Type** for previously created tie constraints or interactions that include node-based regions.
5. To specify the tracking approach that will be used in an Abaqus/Standard contact formulation, select a value in the **Sliding** column:

- Select **Finite** to use the finite-sliding tracking approach.
- Select **Small** to use the small-sliding tracking approach.

Abaqus/CAE ignores the **Sliding** column when creating tie constraints and for Abaqus/Explicit analyses. For more information on the tracking approach, see *Contact Formulations in Abaqus/Standard*.

6. To specify the surface discretization that will be used in a contact or tie formulation, select a value in the **Discretization** column:

   - Select **Node-Surf** to use node-to-surface discretization.
   - Select **Surf-Surf** to use surface-to-surface discretization.

   For more information on surface discretization, see *Mesh Tie Constraints*; *Contact Formulations in Abaqus/Standard*; and *Contact Formulations for Contact Pairs in Abaqus/Explicit*.

7. For contact interactions, select the interaction property in the **Property** column.

   If the appropriate contact property is not available, you can create a new one:

   a. Click mouse button 3 anywhere in the contact pair candidates table, and select **Create Property** from the menu that appears.
   b. Create a contact interaction property as described in *Defining a contact interaction property*.

      When you have finished using the interaction property editor, the property you created will be available under the **Property** column in the contact pair candidates table.

   Abaqus/CAE ignores the **Property** column when creating tie constraints.

8. For contact interactions, select the contact controls in the **Contact Controls** column.

   The **Contact Controls** column is not displayed in the contact pair candidates table by default. See *Configuring the layout of the contact pair candidates table* for instructions on adding this column to the table.

   If the appropriate contact controls are not available, you can create them:

   a. Click mouse button 3 anywhere in the contact pair candidates table, and select **Create Contact Controls** from the menu that appears.
   b. Create the contact controls as described in *Customizing contact controls*.

      When you have finished specifying the contact controls, the controls you created will be available under the **Contact Controls** column in the contact pair candidates table.

   Abaqus/CAE ignores the **Contact Controls** column when creating tie constraints.

9. Use the adjustment options to reposition a secondary surface (or portions of a secondary surface) precisely onto the main surface at the beginning of an analysis:

   a. Double-click the cell in the **Adjust** column.

      The **Secondary Node/Surface Adjustment Options** dialog box appears.

   b. The options available in the **Secondary Node/Surface Adjustment Options** dialog box depend on the value in the **Type** column for the associated contact pair candidate:

      - If you are creating a contact interaction, select one of the following options:

No adjustment

Abaqus/CAE will not reposition any nodes or surfaces.

Adjust only to remove overclosure

Abaqus/CAE will reposition any initially overclosed secondary nodes or constraint points precisely onto the main surface.

Specify tolerance for adjustment zone

Abaqus/CAE will reposition any secondary nodes or constraint points located within the specified distance from the main surface precisely onto the main surface.

Adjust secondary nodes in set

Abaqus/CAE will adjust the secondary nodes or constraint points included in the specified geometry set precisely onto the main surface.

Abaqus/CAE ignores the **Adjust** column for contact interactions in an Abaqus/Explicit analysis. For more information about adjustment options for contact interactions, see *Contact Initialization for Contact Pairs in Abaqus/Standard*.

- If you are creating a tie constraint, you can modify both the adjustment options and the tie position tolerance in the **Secondary Node/Surface Adjustment Options** dialog box:
  - By default, Abaqus adjusts all tied secondary nodes so they lie precisely on the main surface. To prevent adjustment of the secondary nodes (but still tie the secondary node degrees of freedom to the main surface), toggle off **Adjust secondary surface initial position**.
  - Abaqus ties only those secondary nodes that lie within a specific distance from the main surface. To let Abaqus calculate a reasonable distance automatically, select **Use computed default**. To specify a distance directly, select **Specify distance**, and enter the distance in the field provided.

  For more information about adjustment options and position tolerances for tie constraints, see *Mesh Tie Constraints*.

c. Click **OK**.

10. To change the analysis step in which the contact pair is activated, select a step name in the **Create Step** column.

The **Create Step** column is not displayed in the contact pair candidates table by default. See *Configuring the layout of the contact pair candidates table*, for instructions on adding this column to the table.

11. For contact interactions using surface-to-surface discretization, select whether or not contact smoothing will be applied in the **Surface Smoothing** column:

- Select **Automatic** to let Abaqus/CAE identify any surfaces (or portions of surfaces) in the contact pair that are axisymmetric or spherical. If the **Highlight in viewport** option is enabled, Abaqus/CAE displays the axis of symmetry or spherical center for any identified surfaces in the viewport. Abaqus smooths these surfaces during contact calculations to minimize inaccuracies caused by mesh discretization. The **Automatic** option is available only for geometry models.
- Select **None** to prevent contact smoothing from being applied to any surfaces in the contact pair.

Abaqus/CAE ignores the **Surface Smoothing** column for tie constraints and for contact interactions in an Abaqus/Explicit analysis. For more information about contact surface smoothing, see *Smoothing Contact Surfaces in Abaqus/Standard*.

Additional information

- *Understanding contact and constraint detection*
- *Using contact and constraint detection*

Creating suppressed interactions and constraints

In certain situations you may not be certain about the necessity of certain contact pair candidates. You can delete such candidates from the contact pair candidates table and avoid creating interactions for them, but you may later have to go back and recreate them if they prove necessary.
To address these situations, the contact detection tool offers the option to create interactions and constraints that are suppressed initially. Suppressed interactions and constraints are fully defined, but Abaqus ignores them when writing an input file or performing an analysis. A simple procedure activates these interactions and constraints and, thus, reintroduces them to the model definition (see *Suppressing and resuming objects*, for details).

There are two ways to create an initially suppressed contact pair:

- Click mouse button 3 anywhere in the row for the appropriate contact pair, and select **Suppress** from the menu that appears. The background of the row for the contact pair changes to gray, indicating that the created interaction or constraint will be suppressed initially. To return the contact pair to active status, click mouse button 3 on the appropriate row and select **Resume** from the menu that appears.
- Click the cell in the **Suppression** column for the appropriate contact pair. Click the cell again to return the contact pair to active status.

Note:

The **Suppression** column is not displayed by default. See *Configuring the layout of the contact pair candidates table*, for instructions on adding this column to the table.

A green check mark in the **Suppression** cell indicates that the created interaction or constraint is active. A red “X” in this cell indicates that the created interaction or constraint is suppressed initially.

Miscellaneous review procedures

Abaqus/CAE offers additional tools for manipulating data in the contact pair candidates table.

Recalculating the separation between surfaces

For part instances that are meshed from geometry, you can specify whether the contact detection tool treats these instances as geometry or an element mesh during the search (see *Specifying advanced search options for contact detection*). After performing the search, you can recalculate the separation between meshed surfaces in a contact pair candidate based on either the geometry or mesh representation. You can also use this technique to calculate the separation between surfaces in previously defined interactions or ties that appear in the contact pair candidates table (see *Configuring the layout of the contact pair candidates table*).

1. Click mouse button 3 on the row representing a contact pair, and select **Recalculate Separation** from the menu that appears. You can also click the row and then click the  button above the contact pair candidates table.
2. In the **Recalculate Separation** dialog box that appears, select **Mesh** to calculate surface separation based on the meshed representation of the model. Select **Geometry** to calculate surface separation based on the geometry representation of the model.
3. Click **OK**.

   Abaqus/CAE recalculates the separation between surfaces in the highlighted contact pair candidate and updates the cell in the **Separation** column.

Editing multiple cells

You can set multiple cells to the same value using a single procedure:

1. Highlight multiple cells within the same column (see *Selecting multiple items from lists and tables*).
2. Click mouse button 3 anywhere within the highlighted cells, and select **Edit Cells** from the menu that appears.

   You can also click the  button above the contact pair candidates table.
3. In the dialog box that appears, select the desired value.
4. Click **OK**.

   Abaqus/CAE sets all of the highlighted cells to the selected value.

Highlighting the entire table

To quickly highlight every cell in the table, click mouse button 3 anywhere in the table and select **Select All** from the menu that appears.

Additional information

- *Understanding contact and constraint detection*
- *Using contact and constraint detection*

Creating interactions for automatically detected contact pairs

Abaqus/CAE creates contact interactions and tie constraints for every item in the contact pair candidates table based on the parameters you have specified.

1. From the main menu, select either **Interaction->Find contact pairs** or **Constraint->Find contact pairs**.

   Tip: You can also find contact pairs using the tool in the Interaction module toolbox.

   Abaqus/CAE displays the contact detection dialog box.
2. Enter the search parameters as described in *Specifying search criteria for contact detection*.
3. Search for contact pairs as described in *Searching for contact pairs*.
4. In the contact pair candidates table, enter all of the parameters necessary to define the interactions and ties as described in *Reviewing and modifying detected contact pairs*.
5. Click **OK**.

   Abaqus/CAE creates the specified contact interactions and tie constraints.

Additional information

- *About Contact Pairs in Abaqus/Explicit*

Using the connector section editors

After you specify a connection type for a connector section, you can define connector behaviors for connection types that have one or more available components of relative motion. If you change the connection type after you have defined connector behaviors, you will have to delete the connector behaviors and redefine them for the new connection type. This section explains how to enter data related to connector behaviors in the connector section editor.

In this section:

- *Defining elasticity*
- *Defining damping*
- *Defining friction*
- *Configuring tangential behavior for connector friction*
- *Specifying predefined friction parameters or contact forces*
- *Defining plasticity*
- *Defining damage*
- *Defining damage evolution*
- *Defining a stop*
- *Defining a lock*
- *Defining failure*
- *Defining a reference length*
- *Defining time integration*
- *Specifying behavior settings for tabular data*
- *Specifying connector derived components*
- *Specifying potential terms*

Defining elasticity

You can define spring-like elasticity behavior for the available components of relative motion. For more information, see *Connector Elastic Behavior*.

1. Display the connector section editor using one of the following methods:
   - To create a new connector section, follow the procedure outlined in *Creating connector sections*.
   - To edit an existing connector section, select **Connector->Section->Manager** from the main menu bar, select the connector section from the list that appears, and click **Edit**.
2. In the **Edit Connector Section** dialog box, do one of the following:
   - To define a new elasticity behavior, click **Add** and select **Elasticity** from the menu that appears.
   - To edit an existing elasticity behavior, select the behavior from the **Behavior Options** list to display the associated data fields for that option.
3. Choose the **Definition**.
   - Choose **Linear** to define linear elastic stiffnesses.
   - Choose **Nonlinear** to define forces/moments as tabular functions of available components of relative motion.
   - Choose **Rigid** to define rigid-like elastic behavior.
4. If you are defining linear elastic behavior,
   a. In the **Force/Moment** field, toggle on the forces or moments consistent with the available components of relative motion for which you are defining elastic behavior.
   b. In the **Coupling** field, choose one of the following:
      - Choose **Uncoupled** to specify the individual elastic stiffnesses for the available components of relative motion; for example, **D11**, **D22**, and **D33**, as determined by **Force/Moment** selections. You can use a single elasticity behavior to specify all of the stiffnesses, even if the values are different for each available component of relative motion.
      - Choose **Coupled** to specify elastic stiffnesses coupled with the available components of relative motion; for example, **D11**, **D12**, and **D13**, as determined by **Force/Moment** selections.
5. If you are defining nonlinear, uncoupled behavior,
   a. In the **Force/Moment** field, toggle on the forces or moments that are consistent with the available components of relative motion for which you are defining elastic behavior. If the behavior is the same for multiple components, you can define a single elasticity behavior that will use this one function. If the behavior is different for multiple components, you must define separate elasticity behaviors.
   b. Choose **Uncoupled** in the **Coupling** field to specify forces/moments as a tabular function of their respective available components of relative motion.
6. If you are defining nonlinear, coupled behavior,
   a. In the **Force/Moment** field, toggle on the forces or moments that are consistent with the available components of relative motion for which you are defining elastic behavior.
   b. Choose **Coupled on position** or **Coupled on motion** in the **Coupling** field to specify forces/moments as functions of one or more relative position or constitutive displacement/rotation components, respectively.

c. In the **Independent components** field, toggle on the available components of relative position or constitutive motion for which you are defining coupled elastic behavior. You may need to use the unsymmetric equation solver in the step editor to improve convergence.

7. If you are defining rigid elastic behavior, toggle on the available components of relative motion for which you are defining rigid elastic behavior.
8. To define behavior data that depend on frequency, temperature, or field variables, do the following:
   a. If available, toggle on **Use frequency-dependent data** to define behavior data that vary with frequency. A column labeled **Frequency** appears in the data table.
   b. Toggle on **Use temperature-dependent data** to define behavior data that vary with temperature. A column labeled **Temp** appears in the data table.
   c. To define behavior data that depend on field variables, click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables. Field variable columns appear in the data table.
9. Enter data in the table. You can enter data into the table using the keyboard. Alternatively, you can click mouse button 3 anywhere in the table to view a list of options for specifying tabular data. For detailed information on each option, see *Entering tabular data*.
10. To modify the behavior settings for the regularization (Abaqus/Explicit analyses only) or the extrapolation of the data, use the procedure described in *Specifying behavior settings for tabular data*.
11. Select one of the following:
    - If you want to continue defining behaviors, click **Add**, select the desired behavior, and continue the connector section definition. For instructions on defining other behaviors, see *Using the connector section editors*.
    - If you want to view or edit an existing behavior, select the behavior from the **Behavior Options** list. For instructions on editing behaviors, see *Using the connector section editors*.
    - If you want to save your connector section definition and exit the editor, click **OK.**

Additional information

- *Connector Elastic Behavior*
- *Connector section editors*
- *Creating connector sections*

Defining damping

You can define dashpot-like damping behavior for the available components of relative motion. For more information, see *Connector Damping Behavior*.

1. Display the connector section editor using one of the following methods:
   - To create a new connector section, follow the procedure outlined in *Creating connector sections*.
   - To edit an existing connector section, select **Connector->Section->Manager** from the main menu bar, select the connector section from the list that appears, and click **Edit**.
2. In the **Edit Connector Section** dialog box, do one of the following:
   - To define a new damping behavior, click **Add** and select **Damping** from the menu that appears.
   - To edit an existing damping behavior, select the behavior from the **Behavior Options** list to display the associated data fields for that behavior.
3. Choose the **Damping type**.
   - Choose **Viscous** to specify velocity proportional damping.
   - Choose **Structural** to specify displacement proportional damping.
4. Choose the **Definition**.
   - Choose **Linear** to define linear damping coefficients.
   - Choose **Nonlinear** to define forces/moments as tabular functions of the relative velocities.
5. If you are defining linear damping behavior,
   a. In the **Force/Moment** field, toggle on the forces or moments consistent with the relative velocities for which you are defining damping behavior.
   b. In the **Coupling** field, choose one of the following:
      - Choose **Uncoupled** to specify the individual damping coefficients associated with the relative velocities; for example, **C11**, **C22**, and **C33**, as determined by **Force/Moment** selections. You can use a single damping option to specify all the coefficients, even if the values are different for each relative velocity.
      - Choose **Coupled** to specify damping coefficients coupled associated with the relative velocities; for example, **C11**, **C12**, and **C13**, as determined by **Force/Moment** selections.
6. If you are defining nonlinear, uncoupled behavior,
   a. In the **Force/Moment** field, toggle on the forces or moments that are consistent with the relative velocities for which you are defining damping behavior. If the behavior is the same for multiple components, you can define a single damping behavior that will use this one function. If the behavior is different for multiple components, you must define separate damping behaviors.
   b. Choose **Uncoupled** in the **Coupling** field to specify forces/moments as a tabular function of their respective available components of relative velocity.
7. If you are defining nonlinear, coupled behavior,
   a. In the **Force/Moment** field, toggle on the forces or moments that are consistent with the relative velocities for which you are defining damping behavior.
   b. Choose **Coupled on position** or **Coupled on motion** in the **Coupling** field to specify forces/moments as functions of one or more relative position or velocity components, respectively.

c. In the **Independent components** field, toggle on the available components of relative position or constitutive motion for which you are defining coupled damping behavior. You might need to use the unsymmetric equation solver in the step editor to improve convergence.

8. To define behavior data that depend on frequency, temperature, or field variables, do the following:
   a. If available, toggle on **Use frequency-dependent data** to define behavior data that vary with frequency. A column labeled **Frequency** appears in the tabular data area.
   b. Toggle on **Use temperature-dependent data** to define behavior data that vary with temperature. A column labeled **Temp** appears in the tabular data area.
   c. To define behavior data that depend on field variables, click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables. Field variable columns appear in the tabular data area.
9. Enter damping data in the table. You can enter data into the table using the keyboard. Alternatively, you can click mouse button 3 anywhere in the table to view a list of options for specifying tabular data. For detailed information on each option, see *Entering tabular data*.
10. To modify the behavior settings for the regularization (Abaqus/Explicit analyses only) or the extrapolation of the data, use the procedure described in *Specifying behavior settings for tabular data*.
11. Select one of the following:
    - If you want to continue defining behaviors, click **Add**, select the desired behavior, and continue the connector section definition. For instructions on defining other behaviors, see *Using the connector section editors*.
    - If you want to view or edit an existing behavior, select it from the **Behavior Options** list. For instructions on editing behaviors, see *Using the connector section editors*.
    - If you want to save your connector section definition and exit the editor, click **OK.**

Additional information

- *Connector Damping Behavior*
- *Connector section editors*
- *Creating connector sections*

Defining friction

You can define frictional effects for the available components of relative motion. For more information, see *Connector Friction Behavior*.

1. Display the connector section editor.
   - To create a new connector section, follow the procedure outlined in *Creating connector sections*.
   - To edit an existing connector section, select **Connector->Section->Manager** from the main menu bar, select the connector section from the list that appears, and click **Edit**.
2. In the **Edit Connector Section** dialog box, do one of the following:
   - To define a new friction behavior, click **Add** and select **Friction** from the menu that appears.
   - To edit an existing friction behavior, select the behavior from the **Behavior Options** list to display the associated data fields for that option.
3. Choose the **Friction model**. For more information, see *What types of friction models are available?*.
   - Choose **Predefined** to use a predefined friction model. Abaqus displays the slip direction along which friction occurs.
   - Choose **User-defined** to specify the slip direction in which friction forces or moments are applied and to define friction-generating contact force contributions.
4. If you are specifying a user-defined friction model, choose the **Slip direction**.
   - Choose **Specify direction** to specify the available component of relative motion along which friction forces or moments are applied. You can define multiple friction behaviors to model friction for more than one component, but Abaqus allows only one friction behavior for each component.
   - Choose **Compute using force potential** to compute the instantaneous slip direction using a force potential. Select the **Force Potential** tabbed page, and define at least one force potential term. For more information, see *Specifying potential terms*.
5. Choose the **Stick stiffness**.
   - Choose **Use default** to have Abaqus compute an appropriate stick stiffness.
   - Choose **Specify** to enter the stick stiffness associated with frictional behavior in the direction specified by the slip direction.
6. Configure the **Tangential Behavior**. For more information, see *Configuring tangential behavior for connector friction*.
7. If you are specifying a predefined friction model, specify the **Predefined Friction Parameters**. If you are specifying a user-defined friction model, specify the **Contact Force**. For more information, see *Specifying predefined friction parameters or contact forces*.
8. Select one of the following:
   - If you want to continue defining behaviors, click **Add**, select the desired behavior, and continue the connector section definition. For instructions on defining other behaviors, see *Using the connector section editors*.
   - If you want to view or edit an existing behavior, select the behavior from the **Behavior Options** list. For instructions on editing behaviors, see *Using the connector section editors*.

- If you want to save your connector section definition and exit the editor, click **OK.**

Additional information

• *Connector Friction Behavior*
• *What types of friction models are available?*

• *Specifying potential terms*

Configuring tangential behavior for connector friction

You can select a friction formulation for predefined and user-defined connector friction models.

You use the **Tangential Behavior** tabbed page in the connector section editor to make the selection. For more information, see *Using the Basic Coulomb Friction Model*. You can choose from the following:

- **Penalty**. Specify a friction coefficient.
- **Static-Kinetic Exponential Decay**. Specify separate static and kinetic friction coefficients with a smooth transition zone defined by an exponential curve.

Additional information

• *Defining friction*

Configure tangential behavior using the Penalty friction formulation

1. Display the connector section editor by following the procedure outlined in *Defining friction*, and select the **Tangential Behavior** tabbed page.
2. From the **Friction formulation** field, select **Penalty**.
3. On the **Friction Coefficient** tabbed page, enter the following data:

Friction Coeff

Friction coefficient, μ.

Slip Rate

If desired, toggle on **Use slip-rate-dependent data** and enter the slip rate, $\dot{\gamma}_{eq}$.

Contact Pressure

If desired, toggle on **Use contact-pressure-dependent data** and enter the contact pressure, p.

Temp

If desired, toggle on **Use temperature-dependent data** and enter the average temperature at the contact point, $\overline{\theta}$, between the two contact surfaces.

Field 1, Field 2, etc.

If desired, specify the **Number of field variables** and enter the average value of the first field variable, $\overline{f}^1$, the average value of the second field variable, $\overline{f}^2$, etc.

4. On the **Shear Stress** tabbed page, specify the shear stress limit.

No limit

Indicates no limit on the equivalent shear stress.

Specify

Enter the equivalent shear stress limit, τ_{max}; that is, the maximum achievable value of the equivalent shear stress.

5. On the **Elastic Slip** tabbed page, choose a method for modifying the allowable elastic slip (applies only to Abaqus/Standard analyses).

Fraction of characteristic model dimension

Enter the ratio of the allowable maximum elastic slip to a characteristic model dimension. The default value is 0.0001.

Absolute distance

Enter the absolute magnitude of the allowable elastic slip, γ_i, to be used in the stiffness method for sticking friction.

Configure tangential behavior using the Static-Kinetic Exponential Decay friction formulation

1. Display the connector section editor by following the procedure outlined in *Defining friction*, and select the **Tangential Behavior** tabbed page.
2. From the **Friction formulation** field, select **Static-Kinetic Exponential Decay**.
3. On the **Friction Coefficients** tabbed page, choose the exponential decay definition and enter the coefficients or test data.

- **Coefficients**. Provide the static friction coefficient, kinetic friction coefficient, and decay coefficient directly.

Static Coeff

Enter the static friction coefficient, μ_s.

Kinetic Coeff

Enter the kinetic friction coefficient, μ_k.

Decay Coeff

Enter the decay coefficient, d_c.

- **Test data**. Provide test data points to fit the exponential model.

Friction Coeff

- Enter the static coefficient of friction specified at $\dot{\gamma}_{eq} = 0.0$.
- Enter the dynamic friction coefficient, an experimental measurement taken at a reference slip rate, $\dot{\gamma}_2$.
- Enter the kinetic friction coefficient, μ_∞. This value corresponds to the asymptotic value of the friction coefficient at infinite slip rate, $\dot{\gamma}_\infty$.

Slip Rate

Enter the reference slip rate, $\dot{\gamma}_2$, used to measure the dynamic friction coefficient.

4. On the **Elastic Slip** tabbed page, choose a method for modifying the allowable elastic slip (applies only to Abaqus/Standard analyses).

Fraction of characteristic model dimension

Enter the ratio of the allowable maximum elastic slip to a characteristic model dimension. The default value is 0.0001.

Absolute distance

Enter the absolute magnitude of the allowable elastic slip, γ_i, to be used in the stiffness method for sticking friction.

Specifying predefined friction parameters or contact forces

You can specify geometric constants and internal contact forces for predefined connector friction models and a friction-generating contact force and internal contact forces for user-defined connector friction models.
You use the **Predefined Friction Parameters** tabbed page in the connector section editor to specify geometric constants and internal contact forces for predefined connector friction models. You use the **Contact Force** tabbed page in the connector section editor to specify a friction-generating contact force and internal contact forces for user-defined connector friction models. For more information, see *Connector Friction Behavior*.

Additional information

- *Defining friction*
- *Specifying connector derived components*

Specify predefined friction parameters

1. Display the connector section editor by following the procedure outlined in *Defining friction*, and enter the necessary data.
2. Select **Predefined** as the **Friction model**.
3. Select the **Predefined Friction Parameters** tabbed page.
4. Specify the geometric constants and internal contact forces depending on the connection type that you have selected. To display the connection type description that defines the required data entries, see *Connection types*.

Specify a friction-generating contact force and internal contact forces

1. Display the connector section editor by following the procedure outlined in *Defining friction*, and enter the necessary data.
2. Select **User-defined** as the **Friction model**.
3. Select the **Contact Force** tabbed page.
4. If desired, toggle on **Specify component** to define a friction-generating contact force/moment using an intrinsic connector component or a derived connector component.
   - Choose **Intrinsic component**, and select the force/moment that is consistent with the available component of relative motion for which you are defining the friction-generating contact force/moment.
   - Choose **Derived component**, and click  to define a connector derived component. For more information, see *Specifying connector derived components*.
5. If **Specify component** is toggled off, you must enter a value for the internal contact force in the data table in the **Internal Contact Force** portion of the **Contact Force** tabbed page. If desired, you can do the following to specify the internal contact force:

Use independent components

Toggle on **Use independent components**, choose **Position** or **Motion**, and select the available components of relative position or constitutive motion to be used as independent variables. Enter the connector relative position or constitutive motion in the direction specified by the independent component in the corresponding field of the table.

Accum Slip

Toggle on **Use accumulated slip dependence**, and enter the accumulated slip in the slip direction.

Temp

Toggle on **Use temperature-dependent data**, and enter the temperature.

Field 1, Field 2, etc.

Specify the **Number of field variables**, and enter the value of the first field variable, the value of the second field variable, etc.

Internal Contact Force

Specify the internal contact force data.

6. To modify the behavior settings for the regularization (Abaqus/Explicit analyses only) or the extrapolation of the data, use the procedure described in *Specifying behavior settings for tabular data*.

Defining plasticity

You can define plasticity behavior for the available components of relative motion. For more information, see *Connector Plastic Behavior*. If you specify a plasticity behavior option, you must also specify an elasticity behavior option.

1. Display the connector section editor using one of the following methods:
   - To create a new connector section, follow the procedure outlined in *Creating connector sections*.
   - To edit an existing connector section, select **Connector->Section->Manager** from the main menu bar, select the connector section from the list that appears, and click **Edit**.
2. In the **Edit Connector Section** dialog box, do one of the following:
   - To define a new plasticity behavior, click **Add** and select **Plasticity** from the menu that appears.
   - To edit an existing plasticity behavior, select the behavior from the **Behavior Options** list to display the associated data fields for that behavior.
3. If you are defining uncoupled plasticity behavior,
   a. Choose **Uncoupled** in the **Coupling** field to specify forces/moments as a tabular function of their respective available components of relative motion.
   b. In the **Force/Moment** field, toggle on the forces or moments that are consistent with the available components of relative motion for which you are defining plasticity behavior. If the behavior is the same for multiple components, you can define a single plasticity behavior that will use this one function. If the behavior is different for multiple components, you must define separate plasticity behaviors.
4. If you are defining coupled plasticity behavior,
   a. Choose **Coupled** in the **Coupling** field.
   b. Select the **Force Potential** tabbed page, and define at least one force potential term. For more information, see *Specifying potential terms*.
5. Select the hardening behavior.
   - Toggle on **Specify isotropic hardening** to define the initial yield value and, optionally, the evolution of the yield surface size, F^0, as a function of the equivalent plastic relative motion, $\overline{u}^{pl}$.
   - Toggle on **Specify kinematic hardening** to define the translation of the yield surface in force space through the backforce, α.

   At least one hardening behavior, isotropic or kinematic, must be defined. You can select both types of hardening to define a combined isotropic/kinematic hardening behavior.
6. If you toggled on **Specify isotropic hardening**:
   a. Select the **Isotropic Hardening** tabbed page.
   b. Choose the **Definition**.
      - Choose **Tabular** to specify the force-constitutive motion data directly in tabular form.
      - Choose **Exponential Law** to specify the material parameters of the exponential law used to calculate the equivalent force defining the size of the yield surface.
7. If you toggled on **Specify kinematic hardening**:
   a. Select the **Kinematic Hardening** tabbed page.
   b. Choose the **Definition**.

- Choose **Half-cycle** to specify the force-constitutive motion data obtained from the first half cycle of a unidirectional tension or compression experiment.
- Choose **Stabilized** to specify the force-constitutive motion data obtained from the stabilized cycle of a specimen that is subjected to symmetric cycles.
- Choose **Parameters** to specify the material parameters directly.

8. To define behavior data that depend on temperature or field variables, do the following on the **Isotropic Hardening** or **Kinematic Hardening** tabbed page:
   a. Toggle on **Use temperature-dependent data** to define behavior data that vary with temperature. A column labeled **Temp** appears in the tabular data area.
   b. To define behavior data that depend on field variables, click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables. Field variable columns appear in the tabular data area.
9. Enter plastic hardening data in the tables on the **Isotropic Hardening** and/or **Kinematic Hardening** tabbed pages. You can enter data into the tables using the keyboard. Alternatively, you can click mouse button 3 anywhere in the tables to view a list of options for specifying tabular data. For detailed information on each option, see *Entering tabular data*.
10. To modify the behavior settings for the regularization (Abaqus/Explicit analyses only) or the extrapolation of the data, use the procedure described in *Specifying behavior settings for tabular data*. For an Abaqus/Explicit analysis that includes isotropic hardening using a **Tabular** definition, you can also specify settings for the evaluation of rate-dependent data.
11. Select one of the following:
    - If you want to continue defining behaviors, click **Add**, select the desired behavior, and continue the connector section definition. For instructions on defining other behaviors, see *Using the connector section editors*.
    - If you want to view or edit an existing behavior, select it from the **Behavior Options** list. For instructions on editing behaviors, see *Using the connector section editors*.
    - If you want to save your connector section definition and exit the editor, click **OK**.

Additional information

- *Connector Plastic Behavior*
- *Connector section editors*

- *Specifying potential terms*

Defining damage

You can define damage behavior for the available components of relative motion. For more information, see *Connector Damage Behavior*. If you specify a damage behavior option, you must also specify an elasticity behavior option. In addition, if you are defining plastic motion–based damage initiation behavior, you must also specify a plasticity behavior option.

1. Display the connector section editor using one of the following methods:
   - To create a new connector section, follow the procedure outlined in *Creating connector sections*.
   - To edit an existing connector section, select **Connector->Section->Manager** from the main menu bar, select the connector section from the list that appears, and click **Edit**.
2. In the **Edit Connector Section** dialog box, do one of the following:
   - To define a new damage behavior, click **Add** and select **Damage** from the menu that appears.
   - To edit an existing damage behavior, select the behavior from the **Behavior Options** list to display the associated data fields for that behavior.
3. In the **Coupling** field, choose one of the following:
   - Choose **Uncoupled** to specify damage criteria for each available component of relative motion independently.
   - Choose **Coupled** to specify damage criteria that couple all or some of the available components of relative motion.
4. If you are defining uncoupled damage behavior, toggle on the forces or moments that are consistent with the available components of relative motion for which you are defining damage behavior in the **Force/Moment** field. If the behavior is the same for multiple components, you can define a single damage behavior that will use this one function. If the behavior is different for multiple components, you must define separate damage behaviors.
5. Choose the **Initiation criterion**.
   - Choose **Force** to specify the damage initiation criterion in terms of forces/moments in the connector. You provide the lower (compression) limit, the upper (tension) limit, or both limits for the force/moment damage initiation values.
   - Choose **Motion** to specify the damage initiation criterion in terms of relative constitutive displacements/rotations in the connector. You provide the lower (compression) limit, the upper (tension) limit, or both limits for the constitutive displacement/rotation damage initiation values.
   - Choose **Plastic motion** to specify the damage initiation criterion in terms of an equivalent relative plastic motion in the connector. You provide the relative equivalent plastic displacement/rotation at which damage will be initiated as a function of the relative equivalent plastic rate. You must also specify a plasticity behavior option; see *Defining plasticity*, for more information.
6. If you are defining coupled damage behavior, you must specify a connector potential as follows:
   - If you selected **Force** or **Motion** as the **Initiation criterion**, you must specify a connector potential to define an equivalent force magnitude or an equivalent motion magnitude. Select the **Initiation Potential** tabbed page, and define at least one force potential term. For more information, see *Specifying potential terms*.
   - If you selected **Plastic motion** as the **Initiation criterion**, you must specify a connector potential in a coupled connector plasticity behavior option to define an equivalent relative plastic motion. To define coupled connector plasticity behavior using a force potential, see *Defining plasticity*.

If the coupled plasticity definition includes at least two terms in the force potential, you can provide the **Mode-Mix Ratio** in the data table on the **Initiation** tabbed page of the damage behavior option to reflect the relative weight of the first two terms in their contribution to the potential. See *Mode Mix Ratio*, for information on how this quantity is defined.

7. To define the damage initiation criterion, do the following on the **Initiation** tabbed page:
   a. To define a damage initiation criterion that depends on temperature or field variables:
      1. Toggle on **Use temperature-dependent data** to define behavior data that vary with temperature. A column labeled **Temp** appears in the data table.
      2. To define behavior data that depend on field variables, click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables. Field variable columns appear in the data table.

   b. Enter the appropriate damage initiation criterion data in the table. You can enter data into the table using the keyboard. Alternatively, you can click mouse button 3 anywhere in the table to view a list of options for specifying tabular data. For detailed information on each option, see *Entering tabular data*.
   c. To modify the behavior settings for the regularization (Abaqus/Explicit analyses only) or the extrapolation of the data, use the procedure described in *Specifying behavior settings for tabular data*. For an Abaqus/Explicit analysis that includes plastic motion–based damage initiation criteria, you can also specify settings for the evaluation of rate-dependent data.
8. If desired, define the damage evolution law that specifies how the damage variable evolves, as described in *Defining damage evolution*.
9. Select one of the following:
   - If you want to continue defining behaviors, click **Add**, select the desired behavior, and continue the connector section definition. For instructions on defining other behaviors, see *Using the connector section editors*.
   - If you want to view or edit an existing behavior, select it from the **Behavior Options** list. For instructions on editing behaviors, see *Using the connector section editors*.
   - If you want to save your connector section definition and exit the editor, click **OK**.

Additional information

- *Connector Damage Behavior*
- *Connector section editors*
- *Creating connector sections*
- *Defining plasticity*
- *Defining damage evolution*

Defining damage evolution

Connector damage evolution specifies the evolution law for the damage variable. Upon evolution, the connector response will be degraded. If you do not specify a damage evolution law for a particular damage behavior, the associated damage variable is held fixed at 0.0 and the damage behavior does not contribute to degrading the response in the connector. For more information, see *Connector Damage Behavior*.

1. Define a damage behavior as described in *Defining damage*.
2. In the **Edit Connector Section** dialog box, toggle on **Specify damage evolution** and select the **Evolution** tabbed page.
3. If you are defining uncoupled force-based or constitutive motion-based damage initiation behavior,
   - Choose **Motion** as the **Evolution type** to define a motion-based damage evolution law, and choose the **Evolution softening** type.
     - Choose **Linear** to define a linear damage evolution law. You provide the difference between the constitutive relative motion at ultimate failure and the constitutive relative motion at damage initiation.
     - Choose **Exponential** to define an exponential damage evolution law. You provide the difference between the relative motions at ultimate failure and at damage initiation and the exponential coefficient.
     - Choose **Tabular** to define the damage variable directly as a tabular function of the differences between the relative motions at ultimate failure and the relative motions at damage initiation.
   - Choose **Energy** as the **Evolution type** to define an energy-based damage evolution law. You provide the post-damage initiation dissipated energy at ultimate failure.
4. If you are defining uncoupled plastic motion–based damage initiation behavior,
   a. Define an uncoupled plasticity behavior option. For more information, see *Defining plasticity*.
   b. Choose the **Evolution type**.
      - Choose **Motion** to define a motion-based damage evolution law, and choose the **Evolution softening** type. The equivalent plastic relative motion is calculated from the associated plasticity behavior definition.
        - Choose **Linear** to define a linear damage evolution law. You provide the difference between the associated equivalent plastic relative motion at ultimate failure and the associated equivalent plastic relative motion at damage initiation.
        - Choose **Exponential** to define an exponential damage evolution law. You provide the difference between the equivalent relative plastic motions at ultimate failure and at damage initiation and the exponential coefficient.
        - Choose **Tabular** to define the damage variable directly as a tabular function of the differences between the equivalent relative plastic motions at ultimate failure and the relative motions at damage initiation.
      - Choose **Energy** to define an energy-based damage evolution law. You provide the post-damage initiation dissipated energy at ultimate failure.
5. If you are defining coupled force-based or constitutive motion-based damage initiation behavior,
   - Choose **Motion** as the **Evolution type** to define a motion-based damage evolution law and do the following:

1. Choose the **Evolution softening** type.
   - Choose **Linear** to define a linear damage evolution law. You provide the difference between the equivalent motion at ultimate failure and the equivalent motion at damage initiation.
   - Choose **Exponential** to define an exponential damage evolution law. You provide the difference between the relative motions at ultimate failure and at damage initiation and the exponential coefficient.
   - Choose **Tabular** to define the damage variable directly as a tabular function of the differences between the relative motions at ultimate failure and the relative motions at damage initiation.
2. Select the **Evolution Potential** tabbed page, and define at least one force potential term. For more information, see *Specifying potential terms*.

- Choose **Energy** as the **Evolution type** to define an energy-based damage evolution law. You provide the post-damage initiation dissipated energy at ultimate failure.

6. If you are defining coupled plastic motion–based damage initiation behavior,
   a. Define a coupled plasticity behavior option. For more information, see *Defining plasticity*.

      If the associated coupled plasticity definition includes at least two terms in the force potential, the data that you provide for damage evolution may also be a function of the mode mix ratio. The **Mode-Mix Ratio** defines the relative weight of the first two terms in their contribution to the potential. See *Mode Mix Ratio*, for information on how this quantity is defined.
   b. Choose the **Evolution type**.
      - Choose **Motion** to define a motion-based damage evolution law, and choose the **Evolution softening** type. The equivalent plastic relative motion is calculated from the associated plasticity behavior definition.
        - Choose **Linear** to define a linear damage evolution law. You provide the difference between the associated equivalent plastic relative motion at ultimate failure and the associated equivalent plastic relative motion at damage initiation.
        - Choose **Exponential** to define an exponential damage evolution law. You provide the difference between the equivalent relative plastic motions at ultimate failure and at damage initiation and the exponential coefficient.
        - Choose **Tabular** to define the damage variable directly as a tabular function of the differences between the equivalent relative plastic motions at ultimate failure and the relative motions at damage initiation.
      - Choose **Energy** to define an energy-based damage evolution law. You provide the post-damage initiation dissipated energy at ultimate failure.

7. On the **Evolution** tabbed page, toggle on **Specify affected components** and toggle on the forces or moments that are consistent with the available components of relative motion that will be affected by the damage evolution law.
8. Choose the **Degradation** type to specify the contribution of this damage behavior to the overall damage effect if several damage behaviors are defined for the same connector section.
   - Choose **Maximum** to compare the damage value associated with this behavior to the damage values from any other damage behaviors defined for this connector section and consider only the maximum value for the overall damage.
   - Choose **Multiplicative** to combine the damage values for all the damage behaviors associated with this connector section in a multiplicative fashion to obtain the overall damage.

9. To define a damage evolution law that depends on temperature or field variables:
   a. Toggle on **Use temperature-dependent data** to define behavior data that vary with temperature. A column labeled **Temp** appears in the data table.
   b. To define behavior data that depend on field variables, click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables. Field variable columns appear in the data table.
10. Enter the appropriate damage evolution law data in the table. You can enter data into the table using the keyboard. Alternatively, you can click mouse button 3 anywhere in the table to view a list of options for specifying tabular data. For detailed information on each option, see *Entering tabular data*.
11. To modify the behavior settings for the regularization (Abaqus/Explicit analyses only) or the extrapolation of the data, use the procedure described in *Specifying behavior settings for tabular data*.

Additional information

- *Connector Damage Behavior*
- *Connector section editors*
- *Creating connector sections*
- *Defining elasticity*
- *Defining plasticity*
- *Defining damage*

Defining a stop

You can limit values of the admissible range of motion for one or more available components of relative motion. For more information, see *Connector Stops and Locks*.

1. Display the connector section editor using one of the following methods:
   - To create a new connector section, follow the procedure outlined in *Creating connector sections*.
   - To edit an existing connector section, select **Connector->Section->Manager** from the main menu bar, select the connector section from the list that appears, and click **Edit**.
2. In the **Edit Connector Section** dialog box, do one of the following:
   - To define a new stop option, click **Add** and select **Stop** from the option menu that appears.
   - To edit an existing stop option, select the option from the **Behavior Options** list to display the associated data fields for that option.
3. In the **Components** field, toggle on all of the available components of relative motion for which you are defining a stop. If you want to specify different limits for different components, you must specify multiple stop options.
4. In the **Admissible Positions at Stop** portion of the editor, enter the limits for the admissible positions of the available components of relative motion that will trigger the stop.
5. Select one of the following:
   - If you want to continue defining behavior options, click **Add**, select the desired behavior option, and continue the connector section definition. For instructions on defining other behavior options, see *Using the connector section editors*.
   - If you want to view or edit an existing behavior option, select the option from the **Behavior Options** list. For instructions on editing behavior options, see *Using the connector section editors*.
   - If you want to save your connector section definition and exit the editor, click **OK.**

Additional information

- *Connector Stops and Locks*
- *Connector section editors*
- *Creating connector sections*

Defining a lock

You can specify locking criteria for any component of relative motion. The locking criteria may depend on the motions of the available components of relative motion and on the forces/moments in both available and constrained components of relative motion. The locking occurs when any one of the criteria are met, as opposed to when all of the criteria are met. For more information, see *Connector Stops and Locks*.

1. Display the connector section editor using one of the following methods:
   - To create a new connector section, follow the procedure outlined in *Creating connector sections*.
   - To edit an existing connector section, select **Connector->Section->Manager** from the main menu bar, select the connector section from the list that appears, and click **Edit**.
2. In the **Edit Connector Section** dialog box, do one of the following:
   - To define a new lock option, click **Add** and select **Lock** from the option menu that appears.
   - To edit an existing lock option, select the option from the **Behavior Options** list to display the associated data fields for that option.
3. In the **Components** field, toggle on the components of relative motion to be used to define locking criteria. If you want to specify different limits for different components, you must define multiple lock options.
4. Click the arrow to the right of the **Lock** field, and select an option from the list that appears:
   - Select **All** to lock all components of relative motion when any of the locking criteria are satisfied.
   - Select **Specify** to choose the available component of relative motion to lock when any of the locking criteria are satisfied.
5. To define locking criteria based on motion, in the **Position Locking Criteria** portion of the editor, enter the limits for the relative positions of the available components of relative motion that will trigger the lock.
6. To define locking criteria based on forces/moments, in the **Force/Moment Locking Criteria** portion of the editor, enter the limits for the forces/moments of the available or constrained components of relative motion that will trigger the lock.
7. Select one of the following:
   - If you want to continue defining behavior options, click **Add**, select the desired behavior option, and continue the connector section definition. For instructions on defining other behavior options, see *Using the connector section editors*.
   - If you want to view or edit an existing behavior option, select the option from the **Behavior Options** list. For instructions on editing behavior options, see *Using the connector section editors*.
   - If you want to save your connector section definition and exit the editor, click **OK.**

Additional information

- *Connector Stops and Locks*
- *Connector section editors*
- *Creating connector sections*

Defining failure

For an Abaqus/Standard analysis, you can specify failure criteria for any available components of relative motion. For an Abaqus/Explicit analysis, the failure criteria may depend on the motions of the available components of relative motion and on the forces/moments in both available and constrained components of relative motion. The failure occurs when any of the criteria are met, as opposed to when all of the criteria are met. For more information, see *Connector Failure Behavior*.

When you define failure criteria that depends on forces/moments, the sum of the forces/moments from all of the behavior options is compared to the failure criteria. In an Abaqus/Standard analysis, for the failure criteria to be valid, you must define a behavior option, such as elasticity, that generates a force/moment for the available components of relative motion used to define the failure criteria.

1. Display the connector section editor using one of the following methods:
   - To create a new connector section, follow the procedure outlined in *Creating connector sections*.
   - To edit an existing connector section, select **Connector->Section->Manager** from the main menu bar, select the connector section from the list that appears, and click **Edit**.
2. In the **Edit Connector Section** dialog box, do one of the following:
   - To define a new failure option, click **Add** and select **Failure** from the option menu that appears.
   - To edit an existing failure option, select the option from the **Behavior Options** list to display the associated data fields for that option.
3. In the **Components** field, toggle on the components of relative motion to be used to define failure criteria. If you want to specify different limits for different components, you must define multiple failure options.
4. Click the arrow to the right of the **Release** field, and select an option from the list that appears:
   - Select **All** to release all of the components of relative motion when any of the failure criteria are satisfied. The connector will have no effect on the analysis beyond that point.
   - Select **Specify** to choose the component of relative motion to release when any of the failure criteria are satisfied.
5. To define failure criteria based on motion, in the **Position Failure Criteria** portion of the editor, enter the limits for the relative positions of the available components of relative motion that will cause failure.
6. To define failure criteria based on forces/moments, in the **Force/Moment Failure Criteria** portion of the editor, enter the limits for the forces/moments of the available components of relative motion that will cause failure. In an Abaqus/Explicit analysis, you can also enter the limits for the forces/moments of the constrained components of relative motion that will cause failure.
7. Select one of the following:
   - If you want to continue defining behavior options, click **Add**, select the desired behavior option, and continue the connector section definition. For instructions on defining other behavior options, see *Using the connector section editors*.
   - If you want to view or edit an existing behavior option, select the option from the **Behavior Options** list. For instructions on editing behavior options, see *Using the connector section editors*.

- If you want to save your connector section definition and exit the editor, click **OK.**

Additional information

• *Connector Behavior*
• *Connector section editors*
• *Creating connector sections*

Defining a reference length

You can define the translational or angular positions at which constitutive forces and moments are zero for the available components of relative motion. Reference lengths/angles are subtracted from the components of relative motion before being used in elasticity and friction behavior. You can define only one reference length option. For more information, see *Connector Behavior*.

1. Display the connector section editor using one of the following methods:
   - To create a new connector section, follow the procedure outlined in *Creating connector sections*.
   - To edit an existing connector section, select **Connector->Section->Manager** from the main menu bar, select the connector section from the list that appears, and click **Edit**.
2. In the **Edit Connector Section** dialog box, do one of the following:
   - To define a new reference length option, click **Add** and select **Reference Length** from the option menu that appears.
   - To edit an existing reference length option, select the option from the **Behavior Options** list to display the associated data fields for that option.
3. In the **Constitutive Reference Length and Angle** portion of the editor, enter the reference lengths and reference angles associated with the available components of relative motion. If you do not enter a value, the reference lengths and reference angles are determined by the initial configuration of the connector.
4. Select one of the following:
   - If you want to continue defining behavior options, click **Add**, select the desired behavior option, and continue the connector section definition. For instructions on defining other behavior options, see *Using the connector section editors*.
   - If you want to view or edit an existing behavior option, select the option from the **Behavior Options** list. For instructions on editing behavior options, see *Using the connector section editors*.
   - If you want to save your connector section definition and exit the editor, click **OK.**

Additional information

- *Connector Behavior*
- *Connector section editors*
- *Creating connector sections*

Defining time integration

You can specify implicit or explicit time integration for elasticity, damping, and friction in an Abaqus/Explicit analysis. By default, implicit time integration is used. You can define only one integration option. For more information, see *Connector Behavior*.

1. Display the connector section editor using one of the following methods:
   - To create a new connector section, follow the procedure outlined in *Creating connector sections*.
   - To edit an existing connector section, select **Connector->Section->Manager** from the main menu bar, select the connector section from the list that appears, and click **Edit**.
2. In the **Edit Connector Section** dialog box, do one of the following:
   - To define a new integration option, click **Add** and select **Integration** from the option menu that appears.
   - To edit an existing integration option, select the option from the **Behavior Options** list to display the associated data fields for that option.
3. Click the arrow to the right of the **Integration** field and select an option from the list that appears:
   - Select **Implicit** to use implicit time integration.
   - Select **Explicit** to use explicit time integration.
4. Select one of the following:
   - If you want to continue defining behavior options, click **Add**, select the desired behavior option, and continue the connector section definition. For instructions on defining other behavior options, see *Using the connector section editors*.
   - If you want to view or edit an existing behavior option, select the option from the **Behavior Options** list. For instructions on editing behavior options, see *Using the connector section editors*.
   - If you want to save your connector section definition and exit the editor, click **OK.**

Additional information

- *Connector section editors*
- *Creating connector sections*

Specifying behavior settings for tabular data

You can specify behavior settings for the regularization (Abaqus/Explicit analyses only) and the extrapolation of tabular data that you use to define elasticity, damping, user-defined friction, plasticity, and damage behavior options and connector derived component terms. You can also specify settings for the evaluation of rate-dependent data in an Abaqus/Explicit analysis for selected behavior options. For more information, see *Defining Connector Behavior Using Tabular Data*.

You can modify the behavior settings for all of the behavior options in a connector section, or you can specify the behavior settings for individual behavior options. Behavior settings for individual behavior options take precedence over the connector section behavior settings. You specify behavior settings for all of the behavior options in a connector section on the **Table Options** tabbed page of the connector section editor. For more information, see *Creating connector sections*.

To display context-sensitive help for options in the **Edit Table Options** dialog box, you must select the option of interest and then press **[F1]**. (The **Help** menu in the main menu bar is unavailable while the dialog box is displayed.)

1. Display the **Edit Table Options** dialog box.
   - For elasticity, damping, user-defined friction, plasticity, or damage behavior using tabular data, click **Table Options** on the **Behavior Options** tabbed page of the connector section editor. For more information, see the following sections:
     - *Defining elasticity*
     - *Defining damping*
     - *Specifying predefined friction parameters or contact forces*
     - *Defining plasticity*
     - *Defining damage*
     - *Defining damage evolution*
   - For connector derived component terms, click **Table Options** from the **Edit Derived Component Term** dialog box. For more information, see *Specifying connector derived components*.
2. In the **Regularization** portion of the dialog box, specify the settings for the regularization of data in an Abaqus/Explicit analysis.
   a. Specify which regularization behavior settings to use for this behavior option.
   - Toggle on **Use behavior settings** to use the regularization behavior settings that apply to all of the behavior options in the connector section.
   - Toggle off **Use behavior settings** to use the regularization behavior settings that you specify in this dialog box.

   b. By default, Abaqus/Explicit regularizes the data into tables that are defined in terms of even intervals of the independent variables.
   - Toggle on **Regularize data** to regularize tabular data.
   - Toggle off **Regularize data** to turn off regularization of the tabular data and use the data that you define directly.

   c. If you want to regularize tabular data, specify the error tolerance.
   - Choose **Use default** to use the default value of 0.03.
   - Choose **Specify**, and enter a value for the error tolerance.

3. The **Rate Options** portion of the dialog box is available if you are defining plasticity behavior that includes isotropic hardening or damage initiation behavior. You can specify settings for the evaluation of rate-dependent data in an Abaqus/Explicit analysis. These settings apply only for plasticity behavior that includes isotropic hardening using a **Tabular** definition (the force-constitutive motion data are specified directly in tabular form) or damage behavior with plastic motion–based initiation criteria.
   a. Specify the value of the rate filter factor, ω.
      - Choose **Use default** to use the default value of 0.9.
      - Choose **Specify**, and enter a value ($0 < \omega \leq 1$). A value of $\omega = 1$ provides no filtering and should be used with caution.
   b. Specify the interpolation method.
      - Choose **Linear** to use linear intervals for the equivalent relative plastic motion rate while interpolating rate-dependent damage initiation data.
      - Choose **Logarithmic** to use logarithmic intervals for the equivalent relative plastic motion rate while interpolating rate-dependent damage initiation data.
4. In the **Extrapolation** portion of the dialog box, specify the settings for the extrapolation of data.
   a. Specify which extrapolation behavior settings to use for this behavior option.
      - Toggle on **Use behavior settings** to use the extrapolation behavior settings that apply to all of the behavior options in the connector section.
      - Toggle off **Use behavior settings** to use the extrapolation behavior settings that you specify in this dialog box.
   b. Specify the method for the extrapolation of tabular data. The data points that you enter make up a nonlinear curve in the constitutive space. By default, Abaqus extrapolates the dependent variables as constant values that correspond to the end points of the curve outside the specified range of the independent variables.
      - Choose **Constant** to use constant extrapolation of the dependent variables outside the specified range of the independent variables.
      - Choose **Linear** to use linear extrapolation of the dependent variables outside the specified range of the independent variables.
5. Click **OK** to save your behavior settings and to return to the connector section editor.

Additional information

- *Connector section editors*
- *Creating connector sections*

Specifying connector derived components

You can create a connector derived component to specify the friction-generating normal force in connectors as a complex combination of connector forces and moments or to use as an intermediate result in a connector potential function. For more information on connector derived components, see *Connector Functions for Coupled Behavior*.

To display context-sensitive help for options in the derived component editor or the **Edit Derived Component Term** dialog box, you must select the option of interest and then press **[F1]**. (The **Help** menu in the main menu bar is unavailable while the editor and dialog box are displayed.)

1. To display the connector derived component editor, click  from the connector section editor when you are defining a user-defined friction model or from potential contribution editors. For more information, see *Specifying predefined friction parameters or contact forces*, and *Specifying potential terms*.
2. In the **Edit Derived Component** dialog box you can add, edit, and delete derived component terms as follows:

Adding terms

Click  to display the **Edit Derived Component Term** dialog box.

Modifying terms

In the **Derived Component Terms** list, select the term whose data you want to change, and click  to display the **Edit Derived Component Term** dialog box.

Deleting terms

In the **Derived Component Terms** list, select the terms that you want to delete, and click .

3. In the **Edit Derived Component Term** dialog box, do the following:
   a. Select a **Term operator** to specify the method used to compute the derived component term.

Square root of sum of squares

Abaqus computes the derived component term as the square root of the sum of the squares of each intrinsic component contribution.

Direct sum

Abaqus computes the derived component term as the direct sum of the intrinsic component contributions.

Macauley sum

Abaqus computes the derived component term as the sum of the intrinsic component contributions with a Macauley bracket function applied to each contribution.

   b. Choose the **Overall term sign**.

Positive

Select a positive sign for the derived component term.

Negative

Select a negative sign for the derived component term.

c. Choose the intrinsic components to be used in the definition of the derived component, and enter the scaling factor (α_1) for each component in the data table.

d. If desired, toggle on **Use local directions**, choose **Independent position components** or **Independent constitutive motion components**, and select the available components of relative position or constitutive motion to be used as independent variables in the definition of the connector derived component. Enter the connector relative position or constitutive motion in the direction specified by the independent component in the corresponding field of the table. For more information, see *Defining Nonlinear Connector Behavior Properties to Depend on Relative Positions or Constitutive Displacements/Rotations*.

e. If desired, toggle on **Use temperature-dependent data** to define data that vary with temperature. A column labeled **Temp** appears in the data table.

f. If desired, click the arrows to the right of the **Number of field variables** field to increase or decrease the number of field variables to define data that depend on field variables. Field variable columns appear in the data table.

4. To modify the behavior settings for the regularization (Abaqus/Explicit analyses only) or the extrapolation of the data, use the procedure described in *Specifying behavior settings for tabular data*.

5. Click **OK** to save the data and to exit the editor.

Additional information

- *Understanding connector sections and functions*
- *Connector section editors*
- *Specifying predefined friction parameters or contact forces*
- *Specifying potential terms*

Specifying potential terms

Connector potentials are user-defined mathematical functions that represent yield surfaces, limiting surfaces, or magnitude measures in the space spanned by components of relative motion in a connector.
You use potentials to define coupled friction, plasticity, or damage behavior options. For more information, see *Connector Functions for Coupled Behavior*.

To display context-sensitive help for options in the potential contribution editor, you must select the option of interest and then press **[F1]**. (The **Help** menu in the main menu bar is unavailable while the editor is displayed.)

1. Display the potential tabbed page.
   - For friction behavior, use the procedure outlined in *Defining friction* to display the **Force Potential** tabbed page.
   - For plasticity behavior, use the procedure outlined in *Defining plasticity* to display the **Force Potential** tabbed page.
   - For damage behavior, use the procedures outlined in *Defining damage* and *Defining damage evolution* to display the **Initiation Potential** and **Evolution Potential** tabbed pages.
2. Choose the **Operator**.

Sum

Define the potential as the sum of the contributions.

Maximum

Define the potential as the contribution that yields the maximum value.

3. If you selected **Sum** in the **Operator** field, enter a positive value in the **Exponent** field to specify the inverse of the overall exponent in the potential definition, β, that defines a general elliptical form of the potential. The default value of `2` defines a quadratic form of the potential.
4. In the **Potential Contributions** portion of the tabbed page, select one of the following options:
   - To define a contribution to the potential, P_i, click .

     The potential contribution editor appears.
   - To edit an existing contribution, select a contribution from the list, and click .

     The potential contribution editor appears.
   - To delete an existing contribution, select a contribution from the list, and click .
5. In the potential contribution editor, do the following:
   a. Specify the component to use in the potential contribution.

Specify component

Choose an available component of relative motion to define the potential contribution.

Specify derived component

Click  to specify a connector derived component to define the potential contribution. For more information, see *Specifying connector derived components*.

b. Choose the **Sign**.

Positive

Select a positive sign for the potential contribution.

Negative

Select a negative sign for the potential contribution.

c. Enter the following data:

Scaling factor

Enter the nonzero scaling factor R. The default value is 1.

Positive exponent

Enter a value for the positive exponent α. The positive exponent value is ignored if you selected **Maximum** in the **Operator** field.

Shift factor

Enter the shift factor a. The default value is 0.

H-function

Select the function H to be used to generate the contribution. The default value is **ABS**.

- **ABS**. Use the absolute value function to generate the contribution.
- **MACAULEY**. Use the Macauley bracket ($\langle X \rangle = 0 \quad \text{if} \quad X \leq 0 \quad \text{and} = X \quad \text{if} \quad X > 0$) to generate the contribution.
- **IDENTITY**. Select the identity function only if the following is true:
  - **Positive exponent** (α) = **Exponent** (β) = 1

Additional information

- *Defining friction*
- *Defining plasticity*
- *Defining damage*

Using the Query toolset to obtain connector assignment information

You can use the Query toolset to display detailed information about connector section assignments.

1. From the main menu bar, select **Tools->Query**.

    **Tip:** You can also query the model by clicking the  tool in the Query toolset.

   Abaqus/CAE displays the **Query** dialog box.

   You can request either a general query or a module-specific query. For a discussion of the information displayed by general queries, see *Obtaining general information about the model*. The **Connector assignments** query is specific to the Interaction module.

2. From the **Interaction Module Queries** list, select **Connector assignments**.

   A summary of connector section assignments appears.

3. Select the wires or attachment lines in the viewport that you want to query. (For more information, see *Selecting objects within the viewport*.)

4. Click **Done** or click mouse button 2 to display detailed information about the connector section assignment for the selected wires or attachment lines.

5. To exit the querying procedure, click the cancel button  in the prompt area.

Additional information

- *Creating and modifying connector section assignments*
- *Understanding the role of the Query toolset*

The Load module

You use the Load module to define and manage the following prescribed conditions:

- Loads
- Boundary conditions
- Predefined fields
- Load cases (see *Load cases*)

For information on modeling a bolt load, see *Bolt loads*.

In this section:

- *Understanding the role of the Load module*
- *Entering and exiting the Load module*
- *Managing prescribed conditions*
- *Creating and modifying prescribed conditions*
- *Understanding symbols that represent prescribed conditions*
- *Transferring results between Abaqus analyses*
- *Using the Load module toolbox*
- *Using the Load module*
- *Using the load editors*
- *Using the boundary condition editors*
- *Using the predefined field editors*

Understanding the role of the Load module

Prescribed conditions in Abaqus/CAE are step-dependent objects, which means that you must specify the analysis steps in which they are active. You can use the load, boundary condition, and predefined field managers to view and manipulate the stepwise history of prescribed conditions. You can also use the **Step** list located in the context bar to specify the steps in which new loads, boundary conditions, and predefined fields become active by default.

You can use the Amplitude toolset in the Load module to specify complicated time or frequency dependencies that can be applied to prescribed conditions. The Set and Surface toolsets in the Load module allow you to define and name regions of your model to which you would like to apply prescribed conditions. The Analytical Field toolset and the Discrete Field toolset allow you to create fields that you can use to define spatially varying parameters for selected prescribed conditions.

Load cases are sets of loads and boundary conditions used to define a particular loading condition. You can create load cases in static perturbation and steady-state dynamic, direct steps. For information on load cases, see *Load cases*.

Additional information

- *About Prescribed Conditions*
- *Multiple Linear Load Case Analysis*
- *The Amplitude toolset*
- *The Analytical Field toolset*
- *The Discrete Field toolset*
- *The Set and Surface toolsets*

Entering and exiting the Load module

You can enter the Load module at any time during an Abaqus/CAE session by clicking **Load** in the **Module** list located in the context bar. The **Load**, **BC**, **Predefined Field**, **Load Case**, **Feature**, and **Tools** menus appear on the main menu bar. A **Step** list appears in the context bar.

To exit the Load module, specify another module in the **Module** list in the context bar. You need not take any specific action to save your prescribed conditions before exiting the module; they are saved automatically when you save the entire model by selecting **File->Save** or **File->Save As** from the main menu bar.

Managing prescribed conditions

Prescribed condition managers are dialog boxes that you use to organize and manipulate the prescribed conditions associated with a given model. Each kind of prescribed condition that you can define in the Load module has a separate manager. You access the managers by selecting **Manager** from the appropriate menus on the main menu bar. The Load module provides the following managers:

- **Load Manager**
- **Boundary Condition Manager**
- **Predefined Field Manager**

Prescribed condition managers contain alphabetical lists of all the prescribed conditions of a certain type that you have created. For example, the **Load Manager** shown in *Figure 1* contains a list of loads.

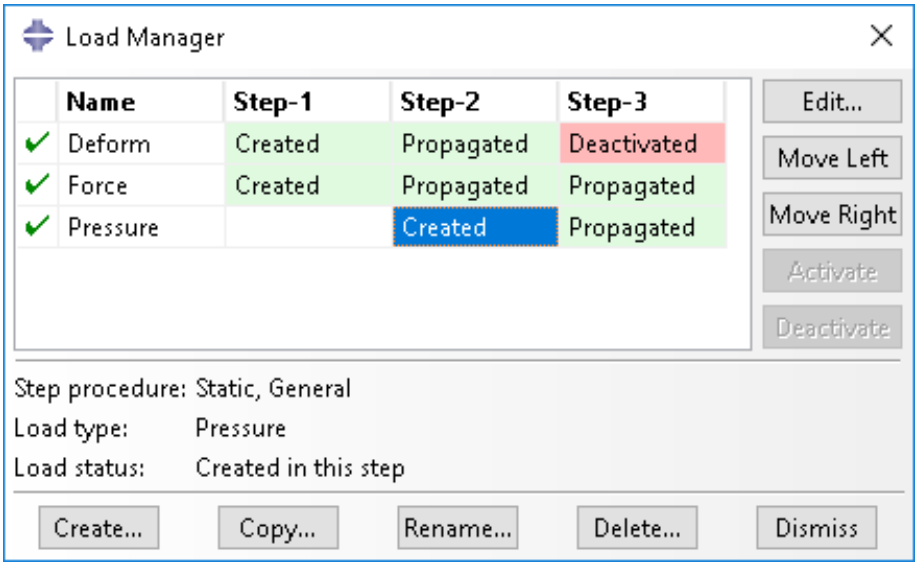

Figure 1: The Load Manager.

The **Create**, **Edit**, **Copy**, **Rename**, and **Delete** buttons in the managers allow you to create new prescribed conditions or to edit, copy, rename, and delete existing ones. You can also initiate the create, edit, copy, rename, and delete procedures by using the **Load**, **BC**, and **Predefined Field** menus in the main menu bar. After you select a management operation from the main menu bar, the procedure is exactly the same as if you had clicked the corresponding button inside the manager dialog box.

The prescribed condition managers are step-dependent managers, which means that they contain additional information concerning the history of each load, boundary condition, and predefined field in the model. You can use the icons in the column along the left side of the managers to suppress prescribed conditions or to resume previously suppressed prescribed conditions for an analysis. The suppress and resume procedures are also available from the **Load**, **BC**, and **Predefined Field** menus in the main menu bar. For more information, see *Suppressing and resuming objects*.

You can use the **Copy** button in manager dialog boxes, the corresponding menu command, or the Model Tree to copy a load, boundary condition, or predefined field. You can copy these objects from any step to any valid step, with some restrictions. For more details, see *Copying step-dependent objects using manager dialog boxes*.

The **Move Left**, **Move Right**, **Activate**, and **Deactivate** buttons allow you to manipulate the stepwise history of prescribed conditions. For more information, see *Modifying the history of a step-dependent object*.

Note:

The **Activate** and **Deactivate** buttons are not available in the **Predefined Field Manager**.

For detailed instructions on creating, editing, and manipulating prescribed conditions, see the following sections:

- *Using the Load module*
- *Using the load editors*
- *Using the boundary condition editors*
- *Using the predefined field editors*

Additional information

- *Managing objects*
- *What are step-dependent managers?*
- *Changing the status of an object in a step*

Creating and modifying prescribed conditions

To create a load, boundary condition, or predefined field, select **Create** from the appropriate menu in the main menu bar. A **Create** dialog box will appear in which you can provide a name for the prescribed condition and choose the type of the prescribed condition that you want to create.

When you click **Continue** in the **Create** dialog box, you are prompted to select the region to which you want to apply the prescribed condition, unless the prescribed condition is applied to the whole model. You can apply connector loads and connector boundary conditions (displacement, velocity, and acceleration) only to wires that are associated with a connector section assignment. If you are select multiple wires, the connector sections assigned to the wires in the connector section assignments must have the available components of relative motion for which you are defining loads and boundary conditions. You can apply connector material flow boundary conditions only to endpoints of wires that are associated with a connector section assignment. Once you have selected the region, an editor appears in which you can specify additional information about the prescribed condition, such as its magnitude.

The top panel of each prescribed condition editor displays the name and type of the prescribed condition, the analysis step you are currently in, and the region of the model to which the prescribed condition will be applied. If you are editing a prescribed condition in the step in which it was first created, an **Edit Region** ( ) button appears next to the **Region** field; this button allows you to edit the region to which the prescribed condition is applied. If editing the region requires a complete redefinition of the prescribed condition (for example, if the prescribed condition is applied to the whole model or refers to subregions within the originally selected region), the **Edit Region** button does not appear. For more information, see *Editing the region to which a prescribed condition is applied*.

The format of the rest of the editor depends on the type of prescribed condition you are defining and on the step specified at the top of the editor. For example, the editor for concentrated forces is shown in *Figure 1*.

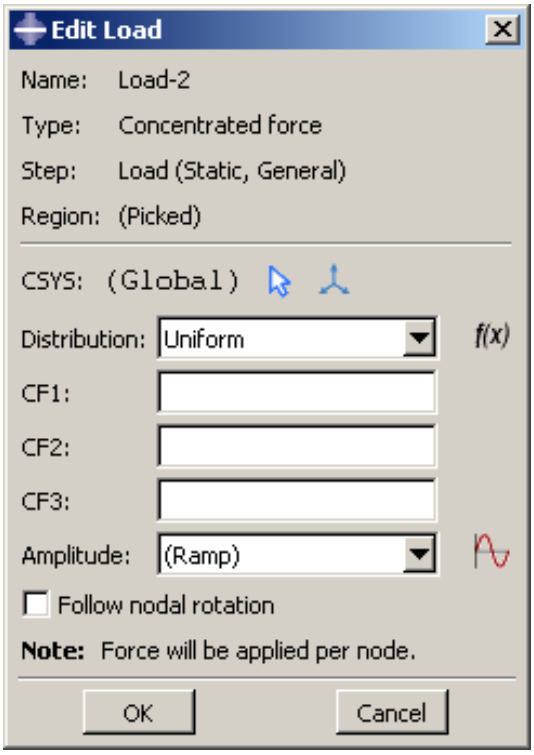

Figure 1: The editor for concentrated forces.

This editor contains special text fields in which you can specify the components of the force in the 1-, 2-, and 3-directions. The editor also contains an **Amplitude** text field that allows you to vary the magnitude of the prescribed condition as

a function of time. You can accept the default amplitude, select an amplitude that you have defined using the Amplitude toolset, or click  to define a new amplitude. (For more information, see *The Amplitude toolset*.)

You can specify the coordinate system in which you will apply the following loads or boundary conditions:

Loads

- Concentrated force
- Moment
- General and shear surface traction
- General shell edge load
- Inertia relief
- Current density

Boundary conditions

- Symmetry/antisymmetry/encastre
- Displacement/rotation
- Velocity/angular velocity
- Acceleration/rotational acceleration
- Eulerian mesh motion
- Magnetic vector potential

All other prescribed conditions use the global coordinate system, with the exception of pressures, which are applied normal to the selected surfaces.

If the load or boundary condition allows you to specify the coordinate system, you can select an existing datum coordinate system or you can accept the global coordinate system. If the desired datum coordinate system does not exist, you can create it using the Datum toolset. (For more information, see *Creating datum coordinate systems*.) Alternatively, you can refer to an Abaqus/Standard user subroutine that defines the coordinate system (see *ORIENT*).

Note:

If you delete or suppress the datum coordinate system, the orientation of the load or boundary condition reverts to the global coordinate system.

The rules for creating and modifying predefined fields vary depending on the predefined field type:

- Some predefined fields require that you specify only the initial conditions. You can create and edit this type of predefined field only in the initial step. Abaqus computes subsequent values for the predefined field as the analysis progresses. The predefined fields of this type are initial velocity specifications, hardening specifications, and material assignments (for Eulerian analyses). For more information, see *Initial Conditions*.
- You can create predefined temperature fields for any step in the analysis. You can define the temperatures for the current model either by entering the values for the desired steps or by reading the temperature values computed by Abaqus in a previous analysis with thermal components. For more information, see “Temperature,” in *Predefined Fields*.

Note:

If you do not define initial values for a predefined field, that field is assumed to have a value of zero at the start of the analysis.

Once you have created a prescribed condition, you can modify the prescribed condition in the following ways:

- You can modify some or all of the data that you entered in the editor when you created the prescribed condition.
- You can use the managers to modify the stepwise history of the prescribed condition. (For more information, see *What are step-dependent managers?*.)

To display help on a particular manager or editor feature, select **Help->On Context** from the main menu bar and then click the feature of interest.

Additional information

- *What are step-dependent managers?*
- *Using the load editors*
- *Using the boundary condition editors*
- *Using the predefined field editors*
- *The Datum toolset*
- *The Amplitude toolset*

Understanding symbols that represent prescribed conditions

This section explains how to interpret the symbols that represent prescribed conditions.

When you apply prescribed conditions to a region, you can choose to display symbols in the viewport that indicate the following:

- The regions to which you applied the prescribed condition.
- The type of the prescribed condition.
- If applicable, the degrees of freedom to which you applied the prescribed condition.
- If applicable, the direction (negative or positive) in which you applied the prescribed condition.
- If applicable, the spatial variation of the prescribed condition.

For information about controlling the visibility of these symbols, see *Controlling the display of attributes*.

In this section:

- *Understanding prescribed condition symbol type, color, and size*
- *What do single-headed and double-headed arrows represent?*
- *Understanding symbol location and direction*

Understanding prescribed condition symbol type, color, and size

The type, color, and size of the symbols that represent prescribed conditions can vary with

- the type of prescribed condition that the symbols represent,
- the degrees of freedom to which you apply the prescribed condition, and
- the spatial variation of the prescribed condition (for analytical field distributions).

Refer to *Symbols used to represent prescribed conditions*, for summaries of the significance of the symbol types and colors.

For example, *Figure 1* displays a concentrated force applied to vertices. All of the arrows that represent the different components of the concentrated force are yellow.

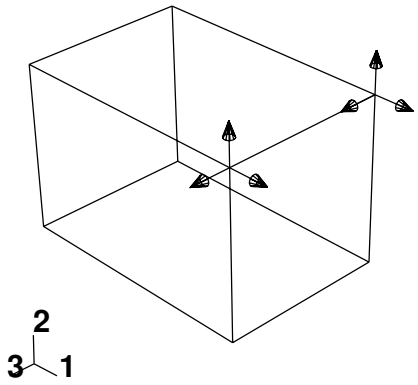

Figure 1: A concentrated force.

On the other hand, *Figure 2* shows a **Velocity/Angular Velocity** boundary condition that is applied to both translational and rotational degrees of freedom. The sandy brown arrows represent components of the boundary condition that are applied to translational degrees of freedom. The magenta arrows represent components of the boundary condition that are applied to rotational degrees of freedom.

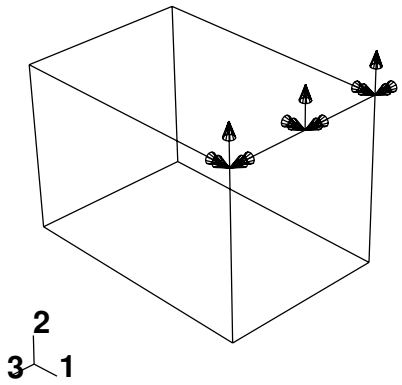

Figure 2: A boundary condition applied to an edge.

Note:

When a boundary condition fixes a degree of freedom in place, the arrow representing that component lacks a stem.

Figure 3 displays a uniform temperature field applied to a face.

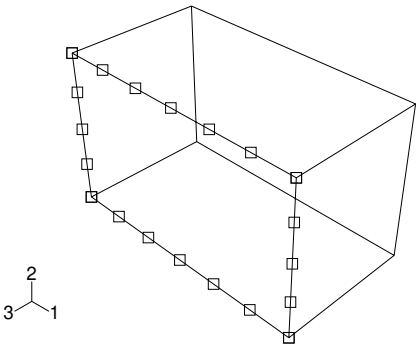

Figure 3: A uniform temperature field.

In general, the size of the symbols is uniform and unrelated to the magnitude of the prescribed condition. For prescribed conditions that use analytical field distributions, the symbols are scaled based on the analytical field value. *Figure 4* shows a pressure load that uses an analytical field to specify a spatially varying magnitude.

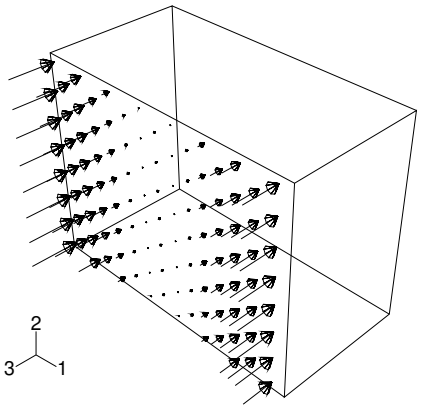

Figure 4: Variation of a pressure load over a face.

In addition, for symbols other than arrows, a plus sign (+) or a minus sign (−) is displayed inside each symbol to indicate whether the magnitude of the prescribed condition is positive or negative at that location.*Figure 5* shows a temperature boundary condition. For clarity, the symbol size has been increased.

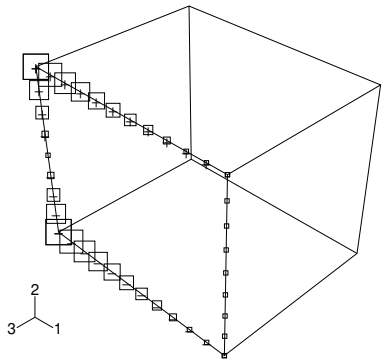

Figure 5: A temperature boundary condition using an analytical field distribution.

For information on controlling symbol size and scaling, see *Controlling the display of attributes*.

In some circumstances Abaqus/CAE displays scaled-down symbols for prescribed conditions, such as when a specified prescribed condition has no effect on the analysis or when an analytical field evaluates to zero for a portion of its region. These scaled-down symbols are noticeably smaller than the default symbol size. For example, if you specify a shear surface traction load with a direction vector normal to the surface, Abaqus/CAE cannot apply this type of load normal to the reference surface and displays very small arrow symbols to represent the load in the viewport.

Additional information

- *Displaying symbols for interactions and prescribed conditions that use analytical fields*
- *Controlling the display of attributes*
- *Symbols used to represent prescribed conditions*

What do single-headed and double-headed arrows represent?

In many cases Abaqus/CAE uses arrows to represent prescribed conditions in the viewport. These arrows represent each component of the prescribed condition (except for fluid boundary conditions, in which case the arrows represent the resultant direction). For example, the arrows that appear in *Figure 1* represent the three components of a concentrated force that is applied to two vertices.

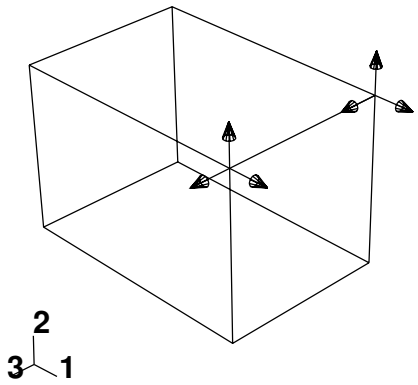

Figure 1: A concentrated force with three components.

An arrow with a single arrowhead represents a component of a prescribed condition that is applied to a translational degree of freedom. For example, the three components of the concentrated force in *Figure 1* are applied to degrees of freedom 1 through 3; therefore, each arrow in the figure has a single arrowhead.

When a component of a prescribed condition is applied to a rotational degree of freedom, that component appears as a double-headed arrow. The arrows in *Figure 2* indicate that a **Velocity/Angular Velocity** boundary condition is applied to degrees of freedom 4 and 6 of the vertices.

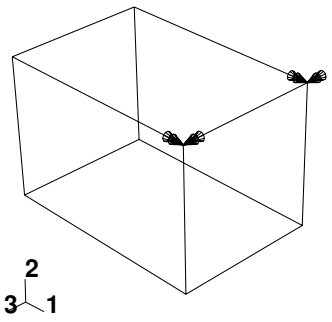

Figure 2: A boundary condition applied to rotational degrees of freedom.

A magnified view of the double-headed arrows appears in *Figure 3*.

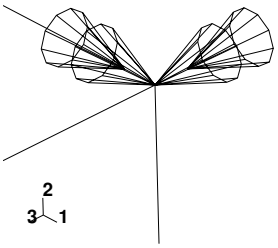

Figure 3: Magnified double-headed arrows.

If you apply a prescribed condition to both translational and rotational degrees of freedom, both the single-headed and the double-headed arrows appear. For example, a **Velocity/Angular Velocity** boundary condition is applied to degrees of freedom 1, 3, 4, and 6 of the vertex in *Figure 4*.

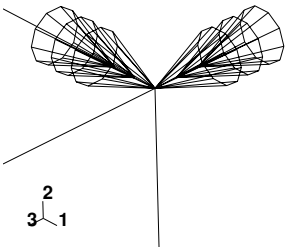

Figure 4: Magnified view of a boundary condition applied to translational and rotational degrees of freedom.

In this figure the single-headed arrows are sandy brown and indicate that degrees of freedom 1 and 3 of the vertex are fixed.The double-headed arrows are magenta and appear directly behind the single-headed arrows; the double-headed arrows indicate that degrees of freedom 4 and 6 of the vertex are fixed.

For information on arrow color, see *Understanding prescribed condition symbol type, color, and size*. For information on when to expect arrows to point toward or away from a region, see *Understanding symbol location and direction*.

Additional information

- *Understanding symbols that represent prescribed conditions*
- *Controlling the display of attributes*

Understanding symbol location and direction

The placement of symbols on a model can depend on the type of prescribed condition that the symbols represent and the type of region to which the prescribed condition is applied. *Table 1* indicates where symbols appear on geometric models, and *Table 2* indicates where symbols appear on meshed models.

Table 1: Symbol location on geometry.

Region type to which the prescribed condition is applied	Location of symbols on the model
Vertex	At the vertex
Edge	Equally spaced along the edge
Assembly-level wire	At the midpoint of the wire
Face	Equally spaced over the interior of the face for directional prescribed conditions (e.g., pressure load)
	Equally spaced along the edges of the face for nondirectional prescribed conditions (e.g., surface charge and boundary conditions)
Cell	Equally spaced along each edge of the cell
Whole model	At the point required to define the rigid body motion (inertia relief load only); otherwise, at the triad indicating the origin and orientation of the global coordinate system

Table 2: Symbol location on meshes.

Region type to which the prescribed condition is applied	Location of symbols on the model
Node	At the node
Element edge (for two-dimensional meshes)	At the midpoint of the element edge
Element face (for three-dimensional meshes)	At the centroid of the element face
Assembly-level wire	At the midpoint of the wire

For example, *Figure 1* shows a concentrated force applied to two vertices and a boundary condition applied to a surface of a geometric model.

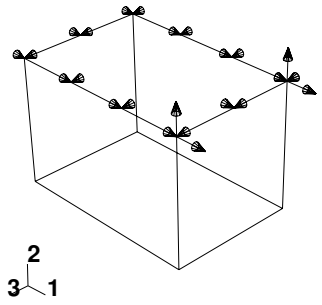

Figure 1: A concentrated force and a boundary condition.

Figure 2 shows a boundary condition applied to four nodes and a pressure load applied to several element faces of a mesh.

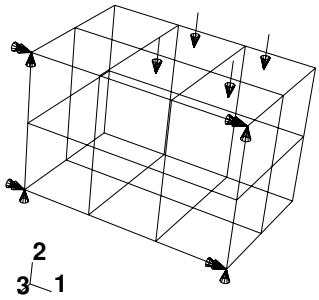

Figure 2: A pressure load and a boundary condition.

Note:

If you apply a pressure load to a planar geometry face where the surface area is small compared to the enclosed area (such as a ring formed by two concentric circles), the load symbols may not be distributed evenly, regardless of the symbol density settings in the **Assembly Display Options** dialog box.

When a boundary condition fixes a degree of freedom in place, the arrow representing that component points into the region and lacks a stem. For example, the boundary condition in *Figure 3* fixes degrees of freedom 1, 2, and 3 in place.

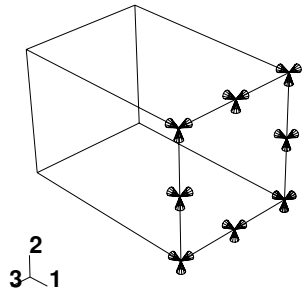

Figure 3: A boundary condition fixing degrees of freedom in place.

Likewise, if a positive pressure load or an Eulerian inflow boundary condition is applied to a region, the arrows representing that pressure load or boundary condition point into the region, as illustrated in *Figure 4*.

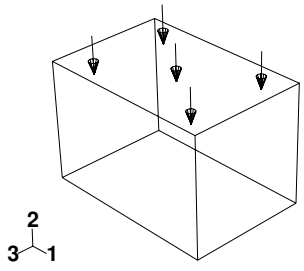

Figure 4: A positive pressure load.

If a load is defined to have a complex magnitude and the real and imaginary parts have different signs (for example, $2 - 3i$), the load will appear as an arrow with two ends. Similarly, an Eulerian boundary condition that includes both inflow and outflow components will appear as an arrow with two ends.

In all other cases, arrows representing components of a prescribed condition point out from the region.

Note:

When a component of a concentrated force is zero, no arrow appears for that component. Likewise, when a boundary condition leaves a degree of freedom unconstrained, no arrow appears for that component.

Transferring results between Abaqus analyses

You can select part instances from your model and associate an initial state field with the instances. An initial state field applies a deformed mesh and its associated material state to the instances using data imported from a previous Abaqus/Standard or Abaqus/Explicit analysis. Abaqus/CAE allows you to select the job name corresponding to the analysis from which the initial state field is imported. You can also specify the particular step and increment of the analysis from which to import data. Abaqus/CAE imports data from several of the files created by the previous analysis. As a result, the files from the analysis must reside in the directory from which you started the current Abaqus/CAE session.

You can use this capability to drive an Abaqus/Explicit analysis with the results of an Abaqus/Standard analysis and vice versa. This is useful if your problem can be broken down into different stages; for example, you can use Abaqus/Explicit to analyze a metal forming problem and Abaqus/Standard to analyze the following springback. You can also use this capability to change the model definition between steps. For more information, see *About Transferring Results between Abaqus Analyses*.

You can also transfer results and model information from an Abaqus/Standard analysis to a new Abaqus/Standard analysis, where you can specify additional model definitions before continuing the analysis. For example, you might first study the local behavior of a particular component during an assembly process and then study the behavior of the assembled product. You can start by analyzing the local behavior of the component in an Abaqus/Standard analysis. You can then transfer the model information and results from this analysis to a second Abaqus/Standard analysis, where you can specify additional model definitions for the other components and analyze the behavior of the entire product.

Abaqus/CAE always imports the material state along with the deformed mesh. If you want to import only the deformed mesh, you can import a mesh from a selected step and increment of an output database. For more information, see *What kinds of files can be imported and exported from Abaqus/CAE?*.

Abaqus uses the imported information when you submit a job for analysis; however, Abaqus/CAE does not update the shape of the selected instances to reflect the applied deformed mesh. As a result, you should be careful when adding new instances to the assembly and positioning them relative to existing part instances. For example, a new part instance may appear to touch one of the instances associated with the initial state field; however, when the analysis applies the imported deformed mesh, the instances may become separated or overclosed.

To avoid this mismatch between the undeformed state and the imported state, you may want to import the deformed mesh from the analysis instead of working with the undeformed part instance. Even if you import the deformed mesh, you must take care that the frame from which you imported the mesh is the same as the step and increment specified in the initial state field. For more information, see *Importing a part from an output database*. Alternatively, you can create the current model by copying it from the model that generated the previous Abaqus/Standard or Abaqus/Explicit analysis. For more information, see *Manipulating models within a model database*.

The reference configuration is the configuration of the model from which displacements (and associated strains) are calculated. By default, Abaqus/CAE does not use the imported data to update the reference configuration. As a result, displacements and strains are calculated as total values relative to the reference configuration at the start of the original analysis, and the values will be continuous between analyses. You can change the default behavior and configure Abaqus/CAE to update the reference configuration to be the imported configuration. Abaqus/CAE now calculates displacements and strains relative to the new imported reference configuration; for example, for a springback analysis.

Abaqus imposes many restrictions when you try to create an initial state field. For a detailed discussion of these limitations, see *About Transferring Results between Abaqus Analyses*. For example, the mesh of the part instances that you select from the current model must match the mesh of the part instances that you are importing. You can then, for example, change the material definition, add loads and boundary conditions, and change from an Abaqus/Standard to an Abaqus/Explicit step. However, you cannot perform an operation that will change the mesh of a selected part instance; for example, you cannot partition the part instance.

You can transfer results between analyses only if the original analysis used one of the following steps:

- Static stress

- Dynamic stress
- Steady-state transport

In addition, if you are importing data from one Abaqus/Standard analysis to another, the original analysis can use a coupled temperature-displacement step. You cannot import data from a linear perturbation step.

In addition, Abaqus/CAE applies the following limitations:

- The selected part instances and the instances from the previous analysis must have the same name.
- After you define the initial state field, Abaqus/CAE will continue to show the undeformed shape of the model.
- You cannot use the Assembly module position and constraint tools, such as **Translate** and **Face to Face**, to move a part instance associated with an initial field.
- Abaqus/CAE imports only the mesh and the material state from the previous analysis. As a result, you must redefine sets, surfaces, and all of the prescribed conditions (loads, boundary conditions, predefined fields, interactions, connectors, etc.) at the assembly level of the current model. You should not redefine any of these components in the part definitions of the current model.
- Abaqus/CAE checks that the files exist that contain data from the previous Abaqus/Standard or Abaqus/Explicit analysis; however, it does not check that the specified step and increment number have been written to the files. The job submission fails if the data for the specified step or increment do not exist.
- You cannot modify a part instance associated with an initial field (or the part from which you created the instance). In addition, you cannot modify the mesh of a part instance associated with an initial field (or the mesh of the part from which you created the instance).
- You cannot assign new sections, material orientations, normals, or beam orientations to the part from which you created the instance associated with an initial field. Similarly, you cannot assign mass or inertia. However, you can edit the material definition (which Abaqus/CAE imports along with the mesh). The imported material definitions will overwrite any existing material definitions.

Using the Load module toolbox

You can access all the Load module tools through either the main menu bar or the Load module toolbox. *Figure 1* shows the icons for all the load tools in the Load module toolbox.

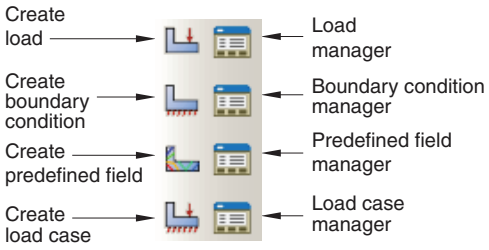

Figure 1: The Load module toolbox.

Using the Load module

This section provides general information on defining loads, boundary conditions, and predefined fields.

For information on other Load module topics, see the following sections:

- *What are step-dependent managers?*
- *Bolt loads*
- *Load cases*

In this section:

- *Creating loads*
- *Creating boundary conditions*
- *Creating predefined fields*
- *Editing the region to which a prescribed condition is applied*

Creating loads

When you create a load, you must specify the name of the load, the step in which to activate the load, the type of load, and the region of the assembly to which you want to apply the load.

1. From the main menu bar, select **Load->Create**.

   A **Create Load** dialog box appears with a default name displayed in the **Name** text field.

    **Tip:** You can also create a load using the  tool in the Load module toolbox.

2. Type a name for the load. For more information on naming objects, see *Using basic dialog box components*.
3. Select the step in which to activate the load. Click the arrow next to the **Step** text field, and select from the list that appears. Loads can be created only in an analysis step; you cannot create a load in the initial step.
4. From the **Category** list on the left side of the dialog box, choose the desired category. The **Category** choices available are dependent upon the type of analysis procedures you are performing.

   The **Types for Selected Step** list on the right side of the dialog box changes to a list of all the available load types.
5. From the **Types for Selected Step** list, select the load type and click **Continue**.
6. If you are creating a gravity load or an inertia relief load, the load editor appears.
7. If you are creating a connector force or connector moment using assembled fasteners, you can click **Done** in the prompt area to select a wire set from the template model.

   The load editor appears.

   a. Click the arrow next to the **Assembled fastener** field, and select from the list that appears.

      The template model name associated with the assembled fastener is displayed in the editor. The **Template set** list is populated with the wire sets that are associated with the referenced template model.

   b. Select a wire set from the **Template set** list. You must ensure that the wire set has a section assignment that has the available components of relative motion for which you want to define forces.

      The appropriate fields for the available components of relative motion are displayed.

8. For all other load types, select the region to which you want to apply the load.

   If you are creating a connector force or connector moment, you must select wires that are associated with a connector section assignment. The best approach for selecting wires is to use the default geometry set name for the wire feature (see *Creating or modifying wire features for multiple connectors*, for more information). If you select multiple wires, you must ensure that the connector sections assigned to the wires in the connector section assignments have the available components of relative motion for which you want to define forces or moments. If there are insufficient available components of relative motion for the connector force or connector moment, a message appears asking you to select different wires or to change the connection type.

   Use one of the following methods to select the region for the load:

   - Select a region in the viewport. You can use the angle method to select a group of faces or edges from geometry or a group of element faces from a mesh. For more information, see *Using the angle and feature edge method to select multiple objects*. When you have finished selecting, click mouse button 2.

Tip: You can limit the types of objects that you can select in the viewport by specifying filtering options in the Selection toolbar. See *Using the selection options*, for more information.

If the model contains a combination of mesh and geometry, click one of the following from the prompt area:

- Click **Geometry** to apply the load to geometry or to a reference point.
- Click **Mesh** to apply the load to a native or orphan mesh selection.

By default, for most load types a set or surface is created that contains the selected objects. You can change this behavior by toggling off the option to create a set or surface in the prompt area. A default name is provided in the prompt area, but you can enter a new name.

- To select from a list of existing sets or surfaces, do the following:

  1. Click **Sets** or **Surfaces** on the right side of the prompt area. (The name of the button depends on the type of object you are creating. For example, if you are creating a pressure load, a **Surfaces** button appears.)

     Abaqus/CAE displays the **Region Selection** dialog box containing a list of available sets or surfaces.

  2. Select the set or surface of interest and click **Continue**.

Note:

The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** or **Surfaces** on the right side of the prompt area.

The load editor appears. The region to which you are applying the load is highlighted in the viewport.

9. Enter all of the data necessary to define the load and click **OK**.

Note:

If you create a connector force or connector moment that exceeds the failure criteria for a connector, the connector force or connector moment will still be applied.

For detailed information on a particular feature of the editor, select **Help->On Context** from the main menu bar and then click the feature of interest or see *Using the load editors*.

Symbols appear in the viewport that represent the load that you just created. For more information, see *Understanding symbols that represent prescribed conditions*.

Additional information

- *Understanding and using toolboxes and toolbars*
- *What are step-dependent managers?*
- *Selecting objects within the viewport*
- *Using the load editors*
- *Connectors*
- *About assembled fasteners*
- *Creating assembled fasteners*

- *The Set and Surface toolsets*

Creating boundary conditions

When you create a boundary condition, you must specify the name of the boundary condition, the step in which to activate the boundary condition, the type of boundary condition, and the region of the assembly to which you want to apply the boundary condition.

1. From the main menu bar, select **BC->Create**.

   A **Create Boundary Condition** dialog box appears with a default name displayed in the **Name** text field.

   Tip: You can also create a boundary condition using the  tool in the Load module toolbox.

2. Type a name for the boundary condition. For more information on naming objects, see *Using basic dialog box components*.
3. Select the step in which to activate the boundary condition. Click the arrow next to the **Step** text field, and select from the list that appears.
4. From the **Category** list on the left side of the dialog box, choose the desired category. The **Category** choices available are dependent upon the type of analysis procedures you are performing.

   The **Types for Selected Step** list on the right side of the dialog box changes to a list of all the available boundary condition types.
5. From the **Types for Selected Step** list, select the boundary condition type and click **Continue**.
6. If you are creating a connector boundary condition using assembled fasteners, you can click **Done** in the prompt area to select a wire set from the template model.

   The boundary condition editor appears.

   a. Click the arrow next to the **Assembled fastener** field, and select from the list that appears.

      The template model name associated with the assembled fastener is displayed in the editor. The **Template set** list is populated with the wire sets that are associated with the referenced template model.

   b. Select a wire set from the **Template set** list. You must ensure that the wire set has a section assignment that has the available components of relative motion for which you want to define velocity.

      The appropriate fields for the available components of relative motion are displayed.

7. For all other boundary condition types, select the region to which you want to apply the boundary condition.

   If you are creating a connector displacement, connector velocity, or connector acceleration boundary condition, you must select wires that are associated with a connector section assignment. The best approach for selecting wires is to use the default geometry set name for the wire feature (see *Creating or modifying wire features for multiple connectors*, for more information). If you select multiple wires, you must ensure that the connector sections assigned to the wires in the connector section assignments have the available components of relative motion for which you want to define displacement, velocity, or acceleration. If there are insufficient available components of relative motion for the connector boundary condition, a message appears asking you to select different wires or to change the connection type.

   If you are creating a connector material flow boundary condition, you must select endpoints of wires that are associated with a connector section assignment.

If you are creating an Eulerian mesh motion boundary condition, select an Eulerian part instance in the viewport. Otherwise, use one of the following methods to select the region for the boundary condition:

- Select a region in the viewport. You can use the angle method to select a group of faces or edges from geometry or a group of element faces from a mesh. For more information, see *Using the angle and feature edge method to select multiple objects*. When you have finished selecting, click mouse button 2.

  Tip: You can limit the types of objects that you can select in the viewport by specifying filtering options in the Selection toolbar. See *Using the selection options*, for more information.

  If the model contains a combination of mesh and geometry, you must choose the type of region to which you want to apply the boundary condition. From the prompt area, select one of the following:

  - Click **Geometry** to apply the boundary condition to geometry or to a reference point.
  - Click **Mesh** to apply the boundary condition to a native or orphan mesh selection.

  By default, a set or surface is created that contains the selected objects. You can change this behavior by toggling off the option to create a set or surface in the prompt area. A default name is provided in the prompt area, but you can enter a new name.

- To select from a list of existing sets or surfaces, do the following:

  1. Click **Sets** or **Surfaces** on the right side of the prompt area. (The name of the button depends on the type of object you are creating. For example, if you are creating a pressure load, a **Surfaces** button appears.)

     Abaqus/CAE displays the **Region Selection** dialog box containing a list of available sets or surfaces.

  2. Select the set or surface of interest and click **Continue**.

     Note:

     The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** or **Surfaces** on the right side of the prompt area.

The boundary condition editor appears. The region to which you are applying the boundary condition is highlighted in the viewport.

8. Enter all of the data necessary to define the boundary condition and click **OK**.

   Note:

   If you create a connector displacement boundary condition that exceeds the failure criteria for a connector, the connector displacement will be ignored.

   For detailed information on a particular feature of the editor, select **Help->On Context** from the main menu bar and then click the feature of interest or see *Using the boundary condition editors*.

Symbols appear in the viewport that represent the boundary condition that you just created. For more information, see *Understanding symbols that represent prescribed conditions*.

Additional information

- *Creating assembled fasteners*
- *The Set and Surface toolsets*

Creating predefined fields

When you create a predefined field, you must specify the name of the field, the step in which to activate the field, the type of field, and the region of the assembly to which you want to apply the field.

Note:

The process for creating temperature fields is described separately; see *Defining a temperature field*.

1. From the main menu bar, select **Predefined Field->Create**.

   A **Create Predefined Field** dialog box appears with a default name displayed in the **Name** text field.

   Tip: You can also create a predefined field using the tool in the Load module toolbox.

2. Type a name for the predefined field. For more information on naming objects, see *Using basic dialog box components*.
3. Select the step in which to activate the predefined field. Click the arrow next to the **Step** text field, and select from the list that appears.
4. From the **Category** list on the left side of the dialog box, choose the desired category. The **Category** choices available are dependent upon the type of analysis procedures you are performing.

   The **Types for Selected Step** list on the right side of the dialog box changes to a list of all the available predefined field types.
5. From the **Types for Selected Step** list, select the predefined field type and click **Continue**.
6. If the model contains a combination of mesh and geometry, you must choose the type of region to which you want to apply the predefined field. From the prompt area, select one of the following:

   - Click **Geometry** to apply the predefined field to geometry or to a reference point.
   - Click **Mesh** to apply the predefined field to a native or orphan mesh selection.

7. Select the region to which you want to apply the predefined field.

   If you are creating a material assignment field or an initial state field, use the mouse to select a part instance in the viewport. For all other predefined fields, select a region using one of the following methods:

   - Use the mouse to select a region in the viewport. You can use the angle method to select a group of faces or edges from geometry or a group of element faces or nodes from a mesh. For more information, see *Using the angle and feature edge method to select multiple objects*. When you have finished selecting, click mouse button 2.

     Tip: You can limit the types of objects that you can select in the viewport by specifying filtering options in the Selection toolbar. See *Using the selection options*, for more information.

     By default, a set is created that contains the selected objects. You can change this behavior by toggling off the option to create a set in the prompt area. A default name is provided in the prompt area, but you can enter a new name.
   - To select from a list of existing sets, do the following:

     1. Click **Sets** on the right side of the prompt area.

Abaqus/CAE displays the **Region Selection** dialog box containing a list of available sets.

2. Select the set of interest and click **Continue**.

Note:

The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

The predefined field editor appears. The region to which you are applying the predefined field is highlighted in the viewport.

8. Enter all of the data necessary to define the predefined field and click **OK**. For detailed information on a particular feature of the editor, select **Help->On Context** from the main menu bar and then click the feature of interest or see *Using the predefined field editors*.

   Symbols appear in the viewport that represent the predefined field that you just created. For more information, see *Understanding symbols that represent prescribed conditions*.

Additional information

- *Understanding and using toolboxes and toolbars*
- *What are step-dependent managers?*
- *Selecting objects within the viewport*
- *Using the predefined field editors*
- *The Set and Surface toolsets*

Editing the region to which a prescribed condition is applied

You can edit the region to which a prescribed condition is applied in the step in which the load, boundary condition, or predefined field was created.
You cannot edit the region if the definition of the prescribed condition refers to subregions within the original region (a material assignment predefined field, for example).

Note: Gravity loads can be applied to regions in your model, but they cannot be applied to individual point masses in Abaqus/CAE.

1. From the **Load**, **BC**, or **Predefined Field** menu in the main menu bar, select **Manager** to display the **Load Manager**, **Boundary Condition Manager**, or **Predefined Field Manager**.
2. Click the cell located in the row of the prescribed condition that you want to modify and in the column of the step of interest, and click **Edit**. Alternatively, you can just double-click the cell.

   Tip: You can also initiate this procedure by clicking the step in which the prescribed condition was created in the **Step** list located in the context bar. From the **Load**, **BC**, or **Predefined Field** menu in the main menu bar, select **Edit->*prescribed condition***. For example, to edit a load you would select **Load->Edit->*load of your choice***.

   An editor appears.

3. In the top part of the editor, click  to edit the region selection.
4. Edit the region using one of the following methods:

   - Select and unselect objects in the viewport. When you have finished editing the region, click mouse button 2. (For more information, see *Selecting objects within the viewport*.)

     Tip: You can limit the types of objects that you can select in the viewport by specifying filtering options in the Selection toolbar. See *Using the selection options*, for more information.

   - To select from a list of existing sets or surfaces, do the following:

     1. Click **Sets** or **Surfaces** on the right side of the prompt area. (The name of the button depends on the type of object you are editing. For example, if you are editing a pressure load, a **Surfaces** button appears.)

        Abaqus/CAE displays the **Region Selection** dialog box containing a list of available sets or surfaces.

     2. Select the set or surface of interest and click **Continue**.

     Note:

     The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** or **Surfaces** on the right side of the prompt area.

5. In the editor, finish editing the prescribed condition definition as desired and then click **OK**.

The symbols representing the prescribed condition in the viewport change to appear on the newly edited region.

Using the load editors

This section explains how to enter data in the load editor to define specific types of loads.

The following topics are covered in *Modeling techniques*:

- *Bolt loads*
- *Creating the submodel load*

In this section:

- *Defining a concentrated force*
- *Defining a moment*
- *Defining a pressure load*
- *Defining a shell edge load*
- *Defining a surface traction load*
- *Defining a pipe pressure load*
- *Defining a body force*
- *Defining a line load*
- *Defining a gravity load*
- *Defining a generalized plane strain load*
- *Defining a rotational body force*
- *Defining a Coriolis force*
- *Defining a connector force*
- *Defining a connector moment*
- *Defining a substructure load definition to activate a substructure load case*
- *Defining an inertia relief load*
- *Defining a surface heat flux*
- *Defining a body heat flux*
- *Defining a concentrated heat flux*
- *Defining an inward volume acceleration*
- *Defining a concentrated pore fluid flow*
- *Defining a surface pore fluid flow*
- *Defining a concentrated current*
- *Defining a surface current*
- *Defining a body current*
- *Defining a surface current density*
- *Defining a body current density*
- *Defining a concentrated charge*
- *Defining a surface charge*
- *Defining a body charge*
- *Defining a concentrated concentration flux*
- *Defining a surface concentration flux*
- *Defining a body concentration flux*
- *Defining a fluid pressure penetration load*
- *Defining a distributed ion concentration body flux*
- *Defining an ion concentration flux*

- *Defining a fluid surface current*

Defining a concentrated force

You can apply a concentrated force load to a vertex or node.

1. Display the concentrated force load editor using one of the following methods:
   - To create a new concentrated force load, follow the procedure outlined in *Creating loads* (**Category**: `Mechanical`; **Types for Selected Step**: `Concentrated force`).
   - To edit an existing concentrated force load using menus or managers, see *Editing step-dependent objects*. To edit the region to which the load is applied, see *Editing the region to which a prescribed condition is applied*.
2. Click the arrow to the right of the **Distribution** field, and select the option of your choice from the list that appears:
   - Select **Uniform** to define a load that is uniform over the region.
   - Select an analytical field to define a spatially varying load. Only analytical fields that are valid for this load type are displayed in the selection list. Alternatively, you can click  to create a new analytical field. (See *The Analytical Field toolset* for more information.)
3. In the **CF1**, **CF2**, and **CF3** text fields, enter the components of the concentrated force in each direction (units F):

   If you leave a text field blank, a force of zero is assigned to that direction automatically. However, you must enter at least one nonzero component in the editor to define the load.
4. If desired, click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)
5. If desired, toggle on **Follow nodal rotation** to make the direction of the load rotate with the rotation at this node.

   Follow nodal rotation affects only nodes that have rotational degrees of freedom and steps in which the **Nlgeom** setting is turned on.
6. If you want to change the coordinate system (**CSYS**) for the concentrated force load, click  and use one of the following methods:
   - Select an existing datum coordinate system in the viewport.
   - Select an existing datum coordinate system by name.
     1. From the prompt area, click **Datum CSYS List** to display a list of datum coordinate systems.
     2. Select a name from the list, and click **OK**.
   - Click **Use Global CSYS** from the prompt area to revert to the global coordinate system.

   This coordinate system editing option is available only in the step in which the concentrated force load is created. By default, the global coordinate system is used to define the load.
7. Click **OK** to save your data and to exit the editor.

Additional information

- *Creating and modifying prescribed conditions*

- *Understanding symbols that represent prescribed conditions*
- *Using analytical expression fields*
- *Creating expression fields*
- *Concentrated Loads*

Defining a moment

You can create a moment load to define rotation at a vertex or node.

1. Display the moment load editor using one of the following methods:
   - To create a new moment load, follow the procedure outlined in *Creating loads* (**Category**: `Mechanical`; **Types for Selected Step**: `Moment`).
   - To edit an existing moment load using menus or managers, see *Editing step-dependent objects*. To edit the region to which the load is applied, see *Editing the region to which a prescribed condition is applied*.
2. Click the arrow to the right of the **Distribution** field, and select the option of your choice from the list that appears:
   - Select **Uniform** to define a load that is uniform over the region.
   - Select an analytical field to define a spatially varying load. Only analytical fields that are valid for this load type are displayed in the selection list. Alternatively, you can click $f(x)$ to create a new analytical field. (See *The Analytical Field toolset* for more information.)
3. In the **CM1**, **CM2**, and **CM3** text fields, enter the components of the moment about each axis (units FL).

   If you leave a text field blank, a moment of zero is assigned to that direction automatically. However, you must enter at least one nonzero component in the editor to define the load.
4. If desired, click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)
5. If desired, toggle on **Follow nodal rotation** to make the direction of the load rotate with the rotation at this node.

   Follow nodal rotation affects only nodes that have rotational degrees of freedom and steps in which the **Nlgeom** setting is turned on.
6. If you want to change the coordinate system (**CSYS**) for the moment, click  and use one of the following methods:
   - Select an existing datum coordinate system in the viewport.
   - Select an existing datum coordinate system by name.
     1. From the prompt area, click **Datum CSYS List** to display a list of datum coordinate systems.
     2. Select a name from the list, and click **OK**.

      **Note:**

     You should not apply a moment load at the origin of a cylindrical coordinate system; doing so would make the radial and tangential loads indeterminate.
   - Click **Use Global CSYS** from the prompt area to revert to the global coordinate system.

   This coordinate system editing option is available only in the step in which the moment is created. By default, the global coordinate system is used to define the moment.

7. Click **OK** to save your data and to exit the editor.

Additional information

- *Creating and modifying prescribed conditions*
- *Understanding symbols that represent prescribed conditions*
- *Using analytical expression fields*
- *Creating expression fields*
- *Concentrated Loads*

Defining a pressure load

You can create a pressure load to define a pressure over a surface.

1. Display the pressure load editor using one of the following methods:
   - To create a new pressure load, follow the procedure outlined in *Creating loads* (**Category**: `Mechanical`; **Types for Selected Step**: `Pressure`).
   - To edit an existing pressure load using menus or managers, see *Editing step-dependent objects*. To edit the region to which the load is applied, see *Editing the region to which a prescribed condition is applied*.

2. Click the arrow to the right of the **Distribution** field, and select the option of your choice from the list that appears:
   - Select **Uniform** to define a pressure that is uniformly distributed over the surface. For this option, the magnitude you provide must be the force per unit area.
   - Select **Total Force** to define a pressure that is uniformly distributed over the surface. For this option, the magnitude you provide must be the total magnitude of the force applied to the surface (instead of force per unit area).
   - Select **Hydrostatic** to define a hydrostatic pressure applied to the surface. (This option is valid only for Abaqus/Standard analyses.)
   - Select **Stagnation** to define a stagnation pressure applied to the surface. (This option is valid only for Abaqus/Explicit analyses.)
   - Select **Viscous** to define a viscous pressure applied to the surface. (This option is valid only for Abaqus/Explicit analyses.)
   - Select **User-defined** to define the magnitude of the load in user subroutine *DLOAD* (for Abaqus/Standard) or *VDLOAD* (for Abaqus/Explicit). See the following sections for more information:
     - *Specifying general job settings*
     - *DLOAD*
     - *VDLOAD*
   - Select an analytical field, labeled with an (A), or a discrete field, labeled with a (D), to define a spatially varying pressure. Only analytical fields and discrete fields that are valid for this load type are displayed in the selection list.

     Alternatively, you can click $f(x)$ to create a new analytical field. (See *The Analytical Field toolset* for more information.)

3. If you selected the **Uniform**, **Total Force**, analytical field, or discrete field distribution option, perform the following steps:
   a. In the **Magnitude** text field, enter the pressure magnitude.

      For a **Uniform** distribution, enter the total force magnitude divided by the surface area over which the force is applied (units FL^{-2}).

      For a **Total Force** distribution, enter the total magnitude of the force (units F). Based on the undeformed model geometry, Abaqus/CAE calculates a constant uniform surface pressure from the force magnitude entered. In a large-displacement analysis, however, the actual total force may change during the analysis due to the deformation of the loaded surface.

b. If desired, click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)

c. Click **OK** to save your data and to exit the editor.

4. If you selected the **Hydrostatic** distribution option, perform the following steps:

a. In the **Magnitude** text field, enter the pressure magnitude (units FL^{-2}).

b. In the **Zero pressure height** field, enter the *Z*-coordinate (if you are working in three-dimensional or axisymmetric space) or the *Y*-coordinate (if you are working in two-dimensional space) of the height at which the pressure is zero.

c. In the **Reference pressure height** field, enter the *Z*-coordinate (if you are working in three-dimensional or axisymmetric space) or the *Y*-coordinate (if you are working in two-dimensional space) of the height at which the pressure is the magnitude specified in the **Magnitude** field.

(For more information, see *Hydrostatic Pressure Loads on Two-Dimensional, Three-Dimensional, and Axisymmetric Elements in Abaqus/Standard*.)

d. If desired, click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)

5. If you selected the **Stagnation** or **Viscous** distribution option, perform the following steps:

a. In the **Magnitude** text field, enter the pressure magnitude (units FL^{-2}).

b. If desired, click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)

c. If desired, toggle on **Determine velocity from reference point** to subtract the velocity of a reference node from the velocity of the surface where the pressure is applied.

d. Click  to select a reference point using one of the following methods:

- Select a point from the viewport.
- Click **Points** in the prompt area, and select a named set.

Note:

The set that you select must contain a single node or vertex.

e. Click **OK** to save your data and to exit the editor.

6. If you selected the **User-defined** distribution option, perform the following steps:

a. If desired, enter the pressure magnitude in the **Magnitude** field (units FL^{-2}). Magnitude data that you enter in the editor are passed into the user subroutine in an Abaqus/Standard analysis but are ignored in an Abaqus/Explicit analysis.

b. Click **OK** to save your data and to exit the editor.

c. Enter the Job module and display the job editor for the analysis job of interest. (For more information, see *Creating, editing, and manipulating jobs*.)

d. In the job editor, click the **General** tab, and specify the file containing the user subroutine that defines the load magnitude. For more information, see *Specifying general job settings*.

Note:

You can specify only one user subroutine file in the job editor; if your analysis involves more than one user subroutine, you must combine the user subroutines into one file and then specify that file.

Additional information

- *Creating and modifying prescribed conditions*
- *Understanding symbols that represent prescribed conditions*
- *Using analytical expression fields*
- *Creating expression fields*
- *Creating discrete fields*
- *Distributed Loads*

Defining a shell edge load

You can create a shell edge load to define a general, shear, normal, or transverse traction or a moment along a shell edge.

1. Display the shell edge load editor using one of the following methods:
   - To create a new shell edge load, follow the procedure outlined in *Creating loads* (**Category**: `Mechanical`; **Types for Selected Step**: `Shell edge load`).
   - To edit an existing shell edge load using menus or managers, see *Editing step-dependent objects*. To edit the region to which the load is applied, see *Editing the region to which a prescribed condition is applied*.

2. Click the arrow to the right of the **Distribution** field, and select the option of your choice from the list that appears:
   - Select **Uniform** to define a load that is uniform over the shell edge.
   - Select **User-defined** to define the magnitude of the load in user subroutine *UTRACLOAD* (for Abaqus/Standard). See the following sections for more information:
     - *Specifying general job settings*
     - *UTRACLOAD*
   - Select an analytical field to define a spatially varying load. Only analytical fields that are valid for this load type are displayed in the selection list. Alternatively, you can click $f(x)$ to create a new analytical field. (See *The Analytical Field toolset* for more information.)

3. Click the arrow to the right of the **Traction** field, and select the option of your choice from the list that appears:
   - Select **Normal** to define a normal shell edge traction.
   - Select **Transverse** to define a transverse shell edge traction.
   - Select **Shear** to define a shear shell edge traction.
   - Select **Moment** to define a shell edge moment.
   - Select **General** to define a general shell edge traction.

4. If you selected the **General** traction type, specify the load direction.
   a. Click  next to **Vector** to specify the coordinates of the direction vector.
   b. By default, the traction components are specified with respect to the global axes. To refer to a local coordinate system for the direction components of the traction:
      - Select **CSYS: Picked** and click  to pick a previously defined local coordinate system.
      - Select **CSYS: User-defined** and enter the name of a user subroutine that defines a local coordinate system.
   c. If you selected **CSYS: Picked**, you can define an additional rotation about one of the axes. Click the arrow to the right of the **Additional rotation about axis** field, select the axis about which the other two axes will be rotated, and enter a value for the additional rotation angle.

5. In the **Magnitude** text field, enter the shell edge load magnitude (units FL^{-1}).

6. If desired, click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)
7. If desired, click the arrow to the right of the **Traction is defined per unit** field, and select **deformed area** to define the shell edge load with respect to the current (deformed) area or **undeformed area** to define the shell edge load with respect to the reference (original) area.
8. If you selected the **General** traction type, you can toggle off **Follow rotation** to define a non-follower load (i.e., the load always acts in a fixed global direction rather than rotating with the shell edge in a geometrically nonlinear analysis).
9. Click **OK** to save your data and to exit the editor.

Additional information

- *Creating and modifying prescribed conditions*
- *Understanding symbols that represent prescribed conditions*
- *Using analytical expression fields*

- *Distributed Loads*

Defining a surface traction load

You can create a surface traction load to define a general or shear traction over a surface.

1. Display the surface traction load editor using one of the following methods:
   - To create a new surface traction load, follow the procedure outlined in *Creating loads* (**Category**: `Mechanical`; **Types for Selected Step**: `Surface traction`).
   - To edit an existing surface traction load using menus or managers, see *Editing step-dependent objects*. To edit the region to which the load is applied, see *Editing the region to which a prescribed condition is applied*.
2. Click the arrow to the right of the **Distribution** field, and select the option of your choice from the list that appears:
   - Select **Uniform** to define a load that is uniform over the surface.
   - Select **User-defined** to define the magnitude of the load in user subroutine *UTRACLOAD* (for Abaqus/Standard). See the following sections for more information:
     - *Specifying general job settings*
     - *UTRACLOAD*
   - Select an analytical field to define a spatially varying load. Only analytical fields that are valid for this load type are displayed in the selection list. Alternatively, you can click $f(x)$ to create a new analytical field. (See *The Analytical Field toolset* for more information.)
3. Click the arrow to the right of the **Traction** field, and select the option of your choice from the list that appears:
   - Select **Shear** to define a shear surface traction.
   - Select **General** to define a general surface traction.
4. Specify the load direction.
   a. Click  next to **Vector** or **Vector before projection** to specify the coordinates of the direction vector.
   b. By default, the traction components are specified with respect to the global axes. To refer to a local coordinate system for the direction components of the traction:
      - Select **CSYS: Picked** and click  to pick a previously defined local coordinate system.
      - Select **CSYS: User-defined** and enter the name of a user subroutine that defines a local coordinate system.
   c. If you selected **CSYS: Picked**, you can define an additional rotation about one of the axes. Click the arrow to the right of the **Additional rotation about axis** field, select the axis about which the other two axes will be rotated, and enter a value for the additional rotation angle.
5. In the **Magnitude** text field, enter the surface traction magnitude (units FL^{-2}).

6. If desired, click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)
7. If desired, click the arrow to the right of the **Traction is defined per unit** field, and select **deformed area** to define the surface traction with respect to the current (deformed) area or **undeformed area** to define the surface traction with respect to the reference (original) area.
8. If you selected the **General** traction type, you can toggle off **Follow rotation** to define a non-follower load in a geometrically nonlinear analysis (i.e., the load always acts in a fixed global direction rather than rotating with the surface).
9. Click **OK** to save your data and to exit the editor.

Additional information

- *Creating and modifying prescribed conditions*
- *Understanding symbols that represent prescribed conditions*
- *Using analytical expression fields*
- *Creating expression fields*
- *Distributed Loads*

Defining a pipe pressure load

You can create this type of load to prescribe internal or external pressure in a pipe or elbow.

1. Display the pipe pressure load editor using one of the following methods:
   - To create a new pipe pressure load, follow the procedure outlined in *Creating loads* (**Category**: `Mechanical`; **Types for Selected Step**: `Pipe pressure`).
   - To edit an existing pipe pressure load using menus or managers, see *Editing step-dependent objects*. To edit the region to which the load is applied, see *Editing the region to which a prescribed condition is applied*.
2. Select the **Side** option of your choice:
   - Select **Internal** to prescribe an internal pressure within the pipe.
   - Select **External** to prescribe an external pressure on the pipe.
3. In the **Effective diameter** field, enter the appropriate pipe diameter:
   - Enter the inner diameter of the pipe if you selected **Internal** in the previous step.
   - Enter the outer diameter of the pipe if you selected **External** in the previous step.

   Note:

   The effective diameter that you enter remains constant throughout the analysis. It is not scaled as the pipe expands or contracts under the pressure, even when the **Nlgeom** setting is turned on. (For more information on the **Nlgeom** setting, see *Accounting for geometric nonlinearity*.)
4. Click the arrow to the right of the **Distribution** field, and select the option of your choice from the list that appears:
   - Select **Uniform** to define a load that is uniform over the pipe surface.
   - Select **Hydrostatic** to define a hydrostatic pressure on or within the pipe.
   - Select **User-defined** to define the magnitude of the load in user subroutine *DLOAD*. See the following sections for more information:
     - *Specifying general job settings*
     - *DLOAD*
   - Select an analytical field to define a spatially varying load. Only analytical fields that are valid for this load type are displayed in the selection list. Alternatively, you can click $f(x)$ to create a new analytical field. (See *The Analytical Field toolset* for more information.)
5. If you selected the **Uniform** or analytical field distribution option, perform the following steps:
   a. In the **Magnitude** text field, enter the pressure magnitude (units FL^{-2}).
   b. If desired, click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click to create a new amplitude. (See *The Amplitude toolset* for more information.)
   c. Click **OK** to save your data and to exit the editor.
6. If you selected the **Hydrostatic** distribution option, perform the following steps:

a. In the **Magnitude** text field, enter the pressure magnitude (units FL^{-2}).

b. In the **Zero pressure height** field, enter the *Z*-coordinate of the height at which the pressure is zero.

c. In the **Reference pressure height** field, enter the *Z*-coordinate of the height at which the pressure is the magnitude specified in the **Magnitude** field.

(For more information, see *Hydrostatic Pressure Loads on Two-Dimensional, Three-Dimensional, and Axisymmetric Elements in Abaqus/Standard*.)

d. If desired, click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)

7. If you selected the **User-defined** distribution option, perform the following steps:

a. If desired, enter the pressure magnitude in the **Magnitude** field (units FL^{-2}). Magnitude data that you enter in the editor are passed into the user subroutine.

b. Click **OK** to save your data and to exit the editor.

c. Enter the Job module and display the job editor for the analysis job of interest. (For more information, see *Creating, editing, and manipulating jobs*.)

d. In the job editor, click the **General** tab, and specify the file containing the user subroutine *DLOAD*. For more information, see *Specifying general job settings*.

Note:

You can specify only one user subroutine file in the job editor; if your analysis involves more than one user subroutine, you must combine the user subroutines into one file and then specify that file.

Additional information

- *Creating and modifying prescribed conditions*
- *Understanding symbols that represent prescribed conditions*
- *Using analytical expression fields*
- *Creating expression fields*
- *Distributed Loads*

Defining a body force

You can define a body force to prescribe loading per unit volume over a body.

1. Display the body force load editor using one of the following methods:
   - To create a new body force load, follow the procedure outlined in *Creating loads* (**Category**: `Mechanical`; **Types for Selected Step**: `Body force`).
   - To edit an existing body force load using menus or managers, see *Editing step-dependent objects*. To edit the region to which the load is applied, see *Editing the region to which a prescribed condition is applied*.

2. If the **Distribution** field appears in the editor, click the arrow to the right of the field, and select the option of your choice from the list that appears:
   - Select **Uniform** to define a load that is uniform over the body.
   - Select **User-defined** to define the magnitude of the load in user subroutine *DLOAD* (for Abaqus/Standard) or *VDLOAD* (for Abaqus/Explicit). See the following sections for more information:
     - *Specifying general job settings*
     - *DLOAD*
     - *VDLOAD*
   - Select an analytical field to define a spatially varying load. Only analytical fields that are valid for this load type are displayed in the selection list. Alternatively, you can click **Create** to create a new analytical field. (See *The Analytical Field toolset* for more information.)

3. If you selected the **Uniform** or analytical field distribution option, perform the following steps:
   a. In the **Component 1**, **Component 2**, and (if you are working in three-dimensional space) **Component 3** fields, enter the body force per unit volume in each direction (units FL^{-3}):
      - If you are working in three-dimensional or two-dimensional space, the **Component 1**, **Component 2**, and **Component 3** fields correspond to the 1-, 2-, and (if applicable) 3-directions.
      - If you are working in axisymmetric space, **Component 1** corresponds to the radial direction and **Component 2** corresponds to the axial direction.

   b. If desired, click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)
   c. Click **OK** to save your data and to exit the editor.

4. If you selected the **User-defined** distribution option, perform the following steps:
   a. If desired, in the **Component 1**, **Component 2**, and (if applicable) **Component 3** fields enter the body force per unit volume in each direction (units FL^{-3}).

      Load magnitude data that you enter in the editor are passed into the user subroutine in an Abaqus/Standard analysis but are ignored in an Abaqus/Explicit analysis.
   b. Click **OK** to save your data and to exit the editor.
   c. Enter the Job module and display the job editor for the analysis job of interest. (For more information, see *Creating, editing, and manipulating jobs*.)

d. In the job editor, click the **General** tab, and specify the file containing the user subroutine that defines the load magnitude. For more information, see *Specifying general job settings*.

Note:

You can specify only one user subroutine file in the job editor; if your analysis involves more than one user subroutine, you must combine the user subroutines into one file and then specify that file.

Additional information

- *Creating and modifying prescribed conditions*
- *Understanding symbols that represent prescribed conditions*
- *Using analytical expression fields*
- *Creating expression fields*
- *Distributed Loads*

Defining a line load

You can create a line load to prescribe the force per unit length over a beam.

1. Display the line load editor using one of the following methods:
   - To create a new line load, follow the procedure outlined in *Creating loads* (**Category**: `Mechanical`; **Types for Selected Step**: `Line load`).
   - To edit an existing line load using menus or managers, see *Editing step-dependent objects*. To edit the region to which the load is applied, see *Editing the region to which a prescribed condition is applied*.

2. Click the arrow to the right of the **System** field, and from the list that appears select the coordinate system in which you want to define the load:
   - Select **Global** if you want to specify the load components in the global 1-, 2-, and (if you are working in three-dimensional space) 3-directions.
   - Select **Local** if you want to specify the load components in the beam local 1-direction (if you are working in three-dimensional space) and the beam local 2-direction. (For more information, see *Assigning a beam orientation*.)

3. Click the arrow to the right of the **Distribution** field, and select the option of your choice from the list that appears:
   - Select **Uniform** to define a load that is uniform over the region.
   - Select **User-defined** to define the magnitude of the load in user subroutine *DLOAD* (for Abaqus/Standard) or *VDLOAD* (for Abaqus/Explicit). See the following sections for more information:
     - *Specifying general job settings*
     - *DLOAD*
     - *VDLOAD*
   - Select an analytical field to define a spatially varying load. Only analytical fields that are valid for this load type are displayed in the selection list. Alternatively, you can click $f(x)$ to create a new analytical field. (See *The Analytical Field toolset* for more information.)

4. If you selected the **Uniform** or analytical field distribution option, perform the following steps:
   a. In the **Component** fields, enter the body force per unit length in each direction (units FL^{-1}):
      - If you selected the **Global** system, the **Component 1**, **Component 2**, and **Component 3** fields correspond to the 1-, 2-, and 3-directions.
      - If you selected the **Local** system, the **Component 1** field corresponds to the beam local 1-direction, and the **Component 2** field corresponds to the beam local 2-direction.

   b. If desired, click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)
   c. Click **OK** to save your data and to exit the editor.

5. If you selected the **User-defined** distribution option, perform the following steps:

a. If desired, in the **Component** fields enter the force per unit length in each direction (units FL^{-1}).

Entering load magnitude data in the editor is optional for user-defined loads. Any data you enter are passed to the user subroutine in an Abaqus/Standard analysis but are ignored in an Abaqus/Explicit analysis.

b. Click **OK** to save your data and to exit the editor.

c. Enter the Job module, and display the job editor for the analysis job of interest. (For more information, see *Creating, editing, and manipulating jobs*.)

d. In the job editor, click the **General** tab, and specify the file containing the user subroutine that defines the load magnitude. For more information, see *Specifying general job settings*.

Note:

You can specify only one user subroutine file in the job editor; if your analysis involves more than one user subroutine, you must combine the user subroutines into one file and then specify that file.

Additional information

- *Creating and modifying prescribed conditions*
- *Understanding symbols that represent prescribed conditions*
- *Using analytical expression fields*
- *Creating expression fields*

Defining a gravity load

You can create a gravity load to define a uniform acceleration in a fixed direction. Abaqus calculates the loading using the acceleration magnitude that you enter in the gravity load definition and the density specified in the material definition.

1. Display the gravity load editor using one of the following methods:
   - To create a new gravity load, follow the procedure outlined in *Creating loads* (**Category**: `Mechanical`; **Types for Selected Step**: `Gravity`).
   - To edit an existing gravity load using menus or managers, see *Editing step-dependent objects*.
2. By default, a gravity load is applied to the whole model. If desired, you can apply a gravity load to particular regions of a model:
   a. Click .
   b. Select the region to which you want to apply the load, as described in *Creating loads*.
   c. Click **Done** in the prompt area.

   Note:

   You cannot apply gravity loads to individual point masses. To include point masses in a gravity load, apply the load to the whole model.
3. Click the arrow to the right of the **Distribution** field, if available; and select the option of your choice from the list that appears:
   - Select **Uniform** to define a load that is uniform over the region.
   - Select an analytical field to define a spatially varying load. Only analytical fields that are valid for this load type are displayed in the selection list. Alternatively, you can click  to create a new analytical field. (See *The Analytical Field toolset* for more information.)
4. In the **Component 1**, **Component 2**, and (if you are working with a model in three-dimensional space) **Component 3** text fields, enter the components of the acceleration in each direction:
   - If you are working in three-dimensional or two-dimensional space, the **Component 1**, **Component 2**, and **Component 3** fields correspond to the 1-, 2-, and (if applicable) 3-directions.
   - If you are working in axisymmetric space, only the **Component 2** text field is available. **Component 2** corresponds to the axial direction.

   If you leave a text field blank, a value of zero is assigned to that direction automatically. However, you must enter at least one nonzero component in the editor to define the load.
5. If desired, click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)
6. Click **OK** to save your data and to exit the editor.

Additional information

- *Creating and modifying prescribed conditions*
- *Understanding symbols that represent prescribed conditions*
- *Using analytical expression fields*

- *Creating expression fields*
- *Distributed Loads*

Defining a generalized plane strain load

You can create a generalized plane strain load to define an axial load applied to the reference point of a region modeled with generalized plane strain elements.
A generalized plane strain load cannot be defined for a coupled temperature-displacement analysis.

1. Display the generalized plane strain load editor using one of the following methods:
   - To create a new generalized plane strain load, follow the procedure outlined in *Creating loads* (**Category**: `Mechanical`; **Types for Selected Step**: `Generalized plane strain`).
   - To edit an existing generalized plane strain load using menus or managers, see *Editing step-dependent objects*. To edit the region to which the load is applied, see *Editing the region to which a prescribed condition is applied*.
2. Click the arrow to the right of the **Distribution** field, and select the option of your choice from the list that appears:
   - Select **Uniform** to define a load that is uniform over the region.
   - Select an analytical field to define a spatially varying load. Only analytical fields that are valid for this load type are displayed in the selection list. Alternatively, you can click $f(x)$ to create a new analytical field. (See *The Analytical Field toolset* for more information.)
3. In the **Axial force** text field, enter the axial force (units F).
4. In the **Moment about X** field, enter the moment applied at the reference point about the *X*-axis.
5. In the **Moment about Y** field, enter the moment applied at the reference point about the *Y*-axis.
6. If desired, click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)
7. Click **OK** to save your data and to exit the editor.

Additional information

- *Creating expression fields*
- *Adding unsupported keywords to your Abaqus/CAE model*
- *Generalized Plane Strain Elements*

Defining a rotational body force

You can create a rotational body force load to define loads resulting from the rotation of the model.

You can specify angular velocity, rotary acceleration, or rotordynamic load. Abaqus defines the load by using the square of the angular velocity or by using the acceleration directly. In any case the load definition must include an axis of rotation, which is defined as follows:

- If you are working in three-dimensional space, you define the location and direction of the axis by entering the global coordinates of two points.
- If you are working in two-dimensional space, you specify the location of the axis by entering the coordinates of a point in the plane. The direction of the axis is always out of the plane.
- If you are working in axisymmetric space, the axis is always in the location and direction of the positive global z-axis.

 **Note:** You can define a rotary acceleration force only in two- or three-dimensional space.

1. Display the rotational body force load editor using one of the following methods:
   - To create a new rotational body force load, follow the procedure outlined in *Creating loads* (**Category**: `Mechanical`; **Types for Selected Step**: `Rotational body force`).

     If you are working in two- or three-dimensional space, enter in the prompt area the required information concerning the location and, if applicable, the direction of the axis of rotation.
   - To edit an existing rotational body force load using menus or managers, see *Editing step-dependent objects*. To edit the region to which the load is applied, see *Editing the region to which a prescribed condition is applied*.

     If you are editing a load in the step in which it was created, an **Edit** () button appears next to each point you specified in the load editor. Click  if you want to change the coordinates that determine the location and, if applicable, direction of the axis of rotation. (This option applies only if you are working in two- or three-dimensional space.)
2. Select the force type of your choice:
   - Toggle **Centrifugal** if you want to define a centrifugal force.
   - Toggle **Rotary acceleration** if you want to define a rotary acceleration force.
   - Toggle **Rotordynamic load** if you want to define a rotordynamic load.
3. Click the arrow to the right of the **Distribution** field, and select the option of your choice from the list that appears:
   - Select **Uniform** to define a load that is uniform over the body.
   - Select an analytical field to define a spatially varying load. Only analytical fields that are valid for this load type are displayed in the selection list. Alternatively, you can click  to create a new analytical field. (See *The Analytical Field toolset* for more information.)
4. In the text field that appears, enter the appropriate value:
   - If you are defining a centrifugal force, enter the angular velocity in radians/time.
   - If you are defining a rotary acceleration force, enter the rotary acceleration in radians/time^2.
   - If you are defining a rotordynamic load, enter the rotordynamic load in radians/time.

5. If desired, click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)

   For centrifugal loading, the amplitude is applied to the calculated load, not the angular velocity.

6. Click **OK** to save your data and to exit the editor.

Additional information

- *Creating and modifying prescribed conditions*
- *Understanding symbols that represent prescribed conditions*
- *Using analytical expression fields*
- *Creating expression fields*

Defining a Coriolis force

You can create a Coriolis force load to define loads resulting from rotation of the model. You must specify the force as the product of the material density (mass per unit volume) for solid and shell elements or the mass per unit length for beam elements and the angular velocity in radians per time. The load definition must include an axis of rotation, which is defined as follows:

- If you are working in three-dimensional space, you define the location and direction of the axis by entering the global coordinates of two points.
- If you are working in two-dimensional space, you specify the location of the axis by entering the coordinates of a point in the plane. The direction of the axis is always out of the plane.
- If you are working in axisymmetric space, the axis is always in the location and direction of the positive global *Z*-axis.

1. Display the Coriolis force load editor using one of the following methods:
   - To create a new rotational body force load, follow the procedure outlined in *Creating loads* (**Category**: `Mechanical`; **Types for Selected Step**: `Coriolis force`).

     If you are working in two- or three-dimensional space, enter in the prompt area the required information concerning the location and, if applicable, direction of the axis of rotation.
   - To edit an existing Coriolis force load using menus or managers, see *Editing step-dependent objects*. To edit the region to which the load is applied, see *Editing the region to which a prescribed condition is applied*.

     If you are editing a load in the step in which it was created, an **Edit** () button appears next to each point you specified in the load editor. Click  if you want to change the coordinates that determine the location and, if applicable, direction of the axis of rotation. (This option applies only if you are working in two- or three-dimensional space.)
2. Click the arrow to the right of the **Distribution** field, and select the option of your choice from the list that appears:
   - Select **Uniform** to define a load that is uniform over the body.
   - Select an analytical field to define a spatially varying load. Only analytical fields that are valid for this load type are displayed in the selection list. Alternatively, you can click  to create a new analytical field. (See *The Analytical Field toolset* for more information.)
3. In the **Coriolis force** field, enter the magnitude of the force.
4. If desired, click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)
5. Click **OK** to save your data and to exit the editor.

Additional information

- *Creating and modifying prescribed conditions*
- *Understanding symbols that represent prescribed conditions*
- *Using analytical expression fields*

- *Creating expression fields*
- *Specifying Loads due to Rotation of the Model in Abaqus/Standard*

Defining a connector force

You can create a connector force to apply a concentrated force to the available components of relative motion of connectors.

1. Display the connector force load editor using one of the following methods:
   - To create a new connector force, follow the procedure outlined in *Creating loads* (**Category**: `Mechanical`; **Types for Selected Step**: `Connector force`).
   - To edit an existing connector force using menus or managers, see *Editing step-dependent objects*. To edit the region to which the connector force is applied, see *Editing the region to which a prescribed condition is applied*.
2. In the available **F1**, **F2**, and **F3** text fields, enter the components of the concentrated force for each available translational component of relative motion (units F). Only components common to all of the selected wires are available in the editor.

   If you leave a text field blank, a force of zero is assigned to that component of relative motion automatically. However, you must enter at least one nonzero component in the editor to define the load.

   Warning: The connector force will be applied regardless of whether the connector force exceeds the failure criteria for the connector.
3. If desired, click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)
4. Click **OK** to save your data and to exit the editor.

Additional information

- *Creating and modifying prescribed conditions*
- *Understanding symbols that represent prescribed conditions*
- *About Connectors*

Defining a connector moment

You can create a connector moment to apply a concentrated moment to the available components of relative motion of connectors.

1. Display the connector moment load editor using one of the following methods:
   - To create a new connector moment, follow the procedure outlined in *Creating loads* (**Category**: `Mechanical`; **Types for Selected Step**: `Connector moment`).
   - To edit an existing connector moment using menus or managers, see *Editing step-dependent objects*. To edit the region to which the connector moment is applied, see *Editing the region to which a prescribed condition is applied*.
2. In the available **M1**, **M2**, and **M3** text fields, enter the components of the moment for each available rotational component of relative motion (units FL). Only components common to all of the selected wires are available in the editor.

   If you leave a text field blank, a moment of zero is assigned to that component of relative motion automatically. However, you must enter at least one nonzero component in the editor to define the load.

   Warning: The connector moment will be applied regardless of whether the connector moment exceeds the failure criteria for the connector.
3. If desired, click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)
4. Click **OK** to save your data and to exit the editor.

Additional information

- *Creating and modifying prescribed conditions*
- *Understanding symbols that represent prescribed conditions*
- *About Connectors*

Defining a substructure load definition to activate a substructure load case

You can create a substructure load definition in a substructure usage model to activate a substructure load case for one or more substructures in your analysis.

The activation process enables you to change the magnitude of substructure load case loads and boundary conditions using two options:

- The magnitude multiplier option applies a scaling value to the specified substructure load case loads and boundary conditions. To reproduce the loading conditions defined during substructure generation exactly, accept the default magnitude of 1.0.
- The amplitude selection enables you to apply a variable multiplying factor to the substructure load case loads and boundary conditions.

For more information about load cases in Abaqus/CAE, see *Load cases*.

1. Display the substructure load editor using one of the following methods:
   - To create a new substructure load, follow the procedure outlined in *Creating loads* (**Category**: `Mechanical`; **Types for Selected Step**: `Substructure load`).
   - To edit an existing substructure load using menus or managers, see *Editing step-dependent objects*.
2. Do the following:
   a. Click  to open the **Select Substructure Load Cases** dialog box.
   b. Toggle on check boxes for each substructure load case that you want to activate.
   c. Click **OK** to close the **Select Substructure Load Cases** dialog box.
3. In the **Magnitude multiplier** text field, enter the value by which you want to scale the specified substructure load case loads and boundary conditions. The default value is 1.0, which provides no scaling. You can enter only real values for the magnitude multiplier. To specify complex values, you must use the **Keywords Editor**, as described in *Adding unsupported keywords to your Abaqus/CAE model*.
4. If desired, click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)
5. Click **OK** to save your data and to exit the editor.

Additional information

- *Creating and modifying prescribed conditions*
- *Defining a load case*
- *Using Substructures*

Defining an inertia relief load

You can create an inertia relief load to balance externally applied forces on a free or partially free body. An inertia relief load is applied to the whole model. You can apply only one active inertia relief load for each general analysis step. For detailed information about inertia relief loads, see *Inertia Relief*.

Note:

You cannot apply inertia relief loads in submodels. For submodels Abaqus ignores the inertia relief effect computed by including an inertia relief load in the global model.

1. Display the inertia relief load editor using one of the following methods:
   - To create a new inertia relief load, follow the procedure outlined in *Creating loads* (**Category**: `Mechanical`; **Types for Selected Step**: `Inertia relief`).
   - To edit an existing inertia relief load using menus or managers, see *Editing step-dependent objects*.
2. If a **Method** field appears toward the top of the editor, click the arrow to the right of the field, and select one of the following:
   - Select **Compute loading** to continue to compute loading for the specified directions.
   - Select **Fix at current loading** to fix the loading at the magnitude and direction from the previous step.

   The **Method** option is unavailable in the step in which the inertia relief load is created.
3. Toggle on a degree of freedom to define a free direction along which you want to apply the inertia relief load. The degrees of freedom displayed are dependent on the modeling space.
4. If you want to change the coordinate system (**CSYS**) for the inertial relief load, click  and use one of the following methods:
   - Select an existing datum coordinate system in the viewport.
   - Select an existing datum coordinate system by name.
     1. From the prompt area, click **Datum CSYS List** to display a list of datum coordinate systems.
     2. Select a name from the list, and click **OK**.
   - Click **Use Global CSYS** from the prompt area to revert to the global coordinate system.

   This coordinate system editing option is available only in the step in which the inertia relief load is created. By default, the global coordinate system is used to define the load.
5. If **X**, **Y**, and **Z** text fields appear at the bottom of the editor, enter the coordinates of the additional point that is required to define the rigid body motion. You must define an additional point for certain combinations of free directions. For more information, see *Inertia Relief*.
6. Click **OK** to save your data and to exit the editor.

Additional information

- *Creating and modifying prescribed conditions*
- *Understanding symbols that represent prescribed conditions*
- *Inertia Relief*

Defining a surface heat flux

You can create a surface heat flux load to define surface-based heat fluxes.

1. Display the surface heat flux load editor using one of the following methods:
   - To create a new surface heat flux load, follow the procedure outlined in *Creating loads* (**Category**: `Thermal`; **Types for Selected Step**: `Surface heat flux`).
   - To edit an existing surface heat flux load using menus or managers, see *Editing step-dependent objects*. To edit the region to which the load is applied, see *Editing the region to which a prescribed condition is applied*.

2. Click the arrow to the right of the **Distribution** field, and select the option of your choice from the list that appears:
   - Select **Uniform** to define a load that is uniform over the surface. For this option, the magnitude you provide must be the flux per unit area.
   - Select **User-defined** to define the magnitude of the load in user subroutine *DFLUX*. (This option is valid only in Abaqus/Standard analyses.) See the following sections for more information:
     - *Specifying general job settings*
     - *DFLUX*
   - Select **Total Flux** to define a load that is uniform over the surface. For this option, the magnitude you provide must be the total magnitude of the flux applied to the surface (instead of flux per unit area).
   - Select an analytical field, labeled with an (A), or a discrete field, labeled with a (D), to define a spatially varying surface heat flux. Only analytical fields and discrete fields that are valid for this load type are displayed in the selection list.

     Alternatively, you can click $f(x)$ to create a new analytical field. (See *The Analytical Field toolset* for more information.)

3. If you selected the **Uniform**, **Total Flux**, analytical field, or discrete field distribution option, perform the following steps:
   a. In the **Magnitude** text field, enter the surface heat flux magnitude. A positive magnitude indicates heat flow into the surface.

      For a **Uniform** distribution, enter the total flux magnitude divided by the surface area over which the flux is applied (units $JT^{-1}L^{-2}$).

      For a **Total Flux** distribution, enter the total magnitude of the flux (units JT^{-1}). Abaqus/CAE calculates a constant uniform surface flux from the flux magnitude entered.

   b. If desired, click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)
   c. Click **OK** to save your data and to exit the editor.

4. If you selected the **User-defined** distribution option, perform the following steps:
   a. If desired, enter the surface heat flux magnitude in the **Magnitude** field (units $JT^{-1}L^{-2}$). A positive magnitude indicates heat flow into the surface.

      Magnitude data that you enter in the editor are passed into the user subroutine.

b. Click **OK** to save your data and to exit the editor.

c. Enter the Job module and display the job editor for the analysis job of interest. (For more information, see *Creating, editing, and manipulating jobs*.)

d. In the job editor, click the **General** tab, and specify the file containing the user subroutine that defines the load magnitude. For more information, see *Specifying general job settings*.

Note:

You can specify only one user subroutine file in the job editor; if your analysis involves more than one user subroutine, you must combine the user subroutines into one file and then specify that file.

Defining a body heat flux

You can create a body heat flux load to define distributed heat fluxes over a volume.

1. Display the body heat flux load editor using one of the following methods:
   - To create a new body heat flux load, follow the procedure outlined in *Creating loads* (**Category**: `Thermal`; **Types for Selected Step**: `Body heat flux`).
   - To edit an existing body heat flux load using menus or managers, see *Editing step-dependent objects*. To edit the region to which the load is applied, see *Editing the region to which a prescribed condition is applied*.

2. Click the arrow to the right of the **Distribution** field, and select the option of your choice from the list that appears:
   - Select **Uniform** to define a load that is uniform over the body.
   - Select **User-defined** to define the magnitude of the load in user subroutine *DFLUX*. (This option is valid only in Abaqus/Standard analyses.) See the following sections for more information:
     - *Specifying general job settings*
     - *DFLUX*
   - Select an analytical field, labeled with an (A), or a discrete field, labeled with a (D), to define a spatially varying load. Only analytical fields and discrete fields that are valid for this load type are displayed in the selection list.

     Alternatively, you can click $f(x)$ to create a new analytical field. (See *The Analytical Field toolset* for more information.)

3. If you selected the **Uniform**, analytical field, or discrete field distribution option, perform the following steps:
   a. In the **Magnitude** text field, enter the body heat flux magnitude (units $JT^{-1}L^{-3}$). A positive magnitude indicates heat flow into the body.
   b. If desired, click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)
   c. Click **OK** to save your data and to exit the editor.

4. If you selected the **User-defined** distribution option, perform the following steps:
   a. If desired, enter the body heat flux magnitude in the **Magnitude** field (units $JT^{-1}L^{-3}$). A positive magnitude indicates heat flow into the body.

   Magnitude data that you enter in the editor are passed into the user subroutine.
   b. Click **OK** to save your data and to exit the editor.
   c. Enter the Job module and display the job editor for the analysis job of interest. (For more information, see *Creating, editing, and manipulating jobs*.)
   d. In the job editor, click the **General** tab, and specify the file containing the user subroutine that defines the load magnitude. For more information, see *Specifying general job settings*.

Note: You can specify only one user subroutine file in the job editor; if your analysis involves more than one user subroutine, you must combine the user subroutines into one file and then specify that file.

Defining a concentrated heat flux

You can apply a concentrated heat flux to a vertex or node.

1. Display the concentrated heat flux load editor using one of the following methods:
   - To create a new concentrated heat flux load, follow the procedure outlined in *Creating loads* (**Category**: `Thermal`; **Types for Selected Step**: `Concentrated heat flux`).
   - To edit an existing concentrated heat flux load using menus or managers, see *Editing step-dependent objects*. To edit the region to which the load is applied, see *Editing the region to which a prescribed condition is applied*.
2. Click the arrow to the right of the **Distribution** field, and select the option of your choice from the list that appears:
   - Select **Uniform** to define a load that is uniform over the region.
   - Select an analytical field to define a spatially varying load. Only analytical fields that are valid for this load type are displayed in the selection list. Alternatively, you can click $f(x)$ to create a new analytical field. (See *The Analytical Field toolset* for more information.)
3. In the **Magnitude** field, enter the concentrated heat flux magnitude (units JT^{-1}). A positive magnitude indicates heat flow into the body at the vertex or node.
4. If desired, click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)
5. If you are working with shell elements and want to apply the heat flux to a degree of freedom other than 11, enter the desired degree of freedom in the **Degree of freedom** field. Otherwise, accept the default degree of freedom.

   You can enter any number between 11 and 31 in the **Degree of freedom** field. If you prefer, you can use the arrows on the right side of the field to scroll through the range of valid degrees of freedom.

   For more information, see “Specifying concentrated heat fluxes,” in *Thermal Loads*.
6. Click **OK** to save your data and to exit the editor.

Defining an inward volume acceleration

You can create an inward volume acceleration load to specify a volume acceleration at a vertex or node on the boundary of an acoustic medium. (For more information, see "Loads," in *Coupled Acoustic-Structural Analysis*.)

1. Display the inward volume acceleration load editor using one of the following methods:
   - To create a new inward volume acceleration load, follow the procedure outlined in *Creating loads* (**Category**: `Acoustic`; **Types for Selected Step**: `Inward volume acceleration`).
   - To edit an existing inward volume acceleration load using menus or managers, see *Editing step-dependent objects*. To edit the region to which the load is applied, see *Editing the region to which a prescribed condition is applied*.
2. Click the arrow to the right of the **Distribution** field, and select the option of your choice from the list that appears:
   - Select **Uniform** to define a load that is uniform over the region.
   - Select an analytical field to define a spatially varying load. Only analytical fields that are valid for this load type are displayed in the selection list. Alternatively, you can click $f(x)$ to create a new analytical field. (See *The Analytical Field toolset* for more information.)
3. In the **Magnitude** field, enter the volume acceleration (units L^3T^{-2}).
4. If desired, click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)
5. Click **OK** to save your data and to exit the editor.

Defining a concentrated pore fluid flow

You can create a concentrated pore fluid flow load to define concentrated pore fluid flow at a vertex or node in soils analyses.

1. Display the concentrated pore fluid flow load editor using one of the following methods:
   - To create a new concentrated pore fluid flow load, follow the procedure outlined in *Creating loads* (**Category**: `Fluid`; **Types for Selected Step**: `Concentrated pore fluid`).
   - To edit an existing concentrated pore fluid flow load using menus or managers, see *Editing step-dependent objects*. To edit the region to which the load is applied, see *Editing the region to which a prescribed condition is applied*.
2. Click the arrow to the right of the **Distribution** field, and select the option of your choice from the list that appears:
   - Select **Uniform** to define a load that is uniform over the region.
   - Select an analytical field to define a spatially varying load. Only analytical fields that are valid for this load type are displayed in the selection list. Alternatively, you can click $f(x)$ to create a new analytical field. (See *The Analytical Field toolset* for more information.)
3. In the **Magnitude** field, enter the flow rate (units L^3T^{-1}). A positive magnitude indicates fluid flow out of the body at the vertex or node.
4. If desired, click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)
5. Click **OK** to save your data and to exit the editor.

Defining a surface pore fluid flow

You can create a surface pore fluid flow load to define pore fluid flow velocities normal to surfaces in soils analyses.

1. Display the surface pore fluid flow load editor using one of the following methods:
   - To create a new surface pore fluid flow load, follow the procedure outlined in *Creating loads* (**Category**: `Fluid`; **Types for Selected Step**: `Surface pore fluid`).
   - To edit an existing surface pore fluid flow load using menus or managers, see *Editing step-dependent objects*. To edit the region to which the load is applied, see *Editing the region to which a prescribed condition is applied*.

2. Click the arrow to the right of the **Distribution** field, and select the option of your choice from the list that appears:
   - Select **Uniform** to define a load that is uniform over the surface.
   - Select **User-defined** to define the magnitude of the load in user subroutine *DFLOW*. See the following sections for more information:
     - *Specifying general job settings*
     - *DFLOW*
   - Select an analytical field, labeled with an (A), or a discrete field, labeled with a (D), to define a spatially varying load. Only analytical fields and discrete fields that are valid for this load type are displayed in the selection list.

     Alternatively, you can click $f(x)$ to create a new analytical field. (See *The Analytical Field toolset* for more information.)

3. If you selected the **Uniform**, analytical field, or discrete field distribution option, perform the following steps:
   a. In the **Magnitude** text field, enter the flow velocity (units LT^{-1}). A positive magnitude indicates fluid flow into the surface.
   b. If desired, click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)
   c. Click **OK** to save your data and to exit the editor.

4. If you selected the **User-defined** distribution option, perform the following steps:
   a. If desired, enter the flow velocity in the **Magnitude** field (units LT^{-1}). A positive magnitude indicates fluid flow into the surface.

      Magnitude data that you enter in the editor are passed into the user subroutine.
   b. Click **OK** to save your data and to exit the editor.
   c. Enter the Job module and display the job editor for the analysis job of interest. (For more information, see *Creating, editing, and manipulating jobs*.)
   d. In the job editor, click the **General** tab, and specify the file containing the user subroutine that defines the load magnitude. For more information, see *Specifying general job settings*.

Note:

You can specify only one user subroutine file in the job editor; if your analysis involves more than one user subroutine, you must combine the user subroutines into one file and then specify that file.

Defining a concentrated current

You can create a concentrated current load to define a concentrated current at a vertex or node in a coupled thermal-electrical analysis.

1. Display the concentrated current load editor using one of the following methods:
   - To create a new concentrated current load, follow the procedure outlined in *Creating loads* (**Category**: `Electrical/Magnetic`; **Types for Selected Step**: `Concentrated current`).
   - To edit an existing concentrated current load using menus or managers, see *Editing step-dependent objects*. To edit the region to which the load is applied, see *Editing the region to which a prescribed condition is applied*.
2. Click the arrow to the right of the **Distribution** field, and select the option of your choice from the list that appears:
   - Select **Uniform** to define a load that is uniform over the region.
   - Select an analytical field to define a spatially varying load. Only analytical fields that are valid for this load type are displayed in the selection list. Alternatively, you can click  to create a new analytical field. (See *The Analytical Field toolset* for more information.)
3. In the **Magnitude** field, enter the current magnitude (units CT^{-1}). A positive magnitude indicates current flow into the body at the vertex or node.
4. If desired, click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)
5. Click **OK** to save your data and to exit the editor.

Additional information

Defining a surface current

You can create a surface current load to define current densities over a surface in a coupled thermal-electrical analysis.

1. Display the surface current load editor using one of the following methods:
   - To create a new surface current load, follow the procedure outlined in *Creating loads* (**Category**: `Electrical/Magnetic`; **Types for Selected Step**: `Surface current`).
   - To edit an existing surface current load using menus or managers, see *Editing step-dependent objects*. To edit the region to which the load is applied, see *Editing the region to which a prescribed condition is applied*.
2. Click the arrow to the right of the **Distribution** field, and select the option of your choice from the list that appears:
   - Select **Uniform** to define a load that is uniform over the surface.
   - Select an analytical field to define a spatially varying load. Only analytical fields that are valid for this load type are displayed in the selection list. Alternatively, you can click $f(x)$ to create a new analytical field. (See *The Analytical Field toolset* for more information.)
3. In the **Magnitude** text field, enter the current density (units $C\,L^{-2}T^{-1}$). A positive magnitude indicates current flow into the surface.
4. If desired, click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)
5. Click **OK** to save your data and to exit the editor.

Defining a body current

You can create a body current load to define current densities over a body in a coupled thermal-electrical analysis.

1. Display the body current load editor using one of the following methods:
   - To create a new body current load, follow the procedure outlined in *Creating loads* (**Category**: `Electrical/Magnetic`; **Types for Selected Step**: `Body current`).
   - To edit an existing body current load using menus or managers, see *Editing step-dependent objects*. To edit the region to which the load is applied, see *Editing the region to which a prescribed condition is applied*.
2. Click the arrow to the right of the **Distribution** field, and select the option of your choice from the list that appears:
   - Select **Uniform** to define a load that is uniform over the body.
   - Select an analytical field to define a spatially varying load. Only analytical fields that are valid for this load type are displayed in the selection list. Alternatively, you can click $f(x)$ to create a new analytical field. (See *The Analytical Field toolset* for more information.)
3. In the **Magnitude** text field, enter the current density (units C $L^{-3}T^{-1}$). A positive magnitude indicates current flow into the body.
4. If desired, click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)
5. Click **OK** to save your data and to exit the editor.

Additional information

Defining a surface current density

You can create a surface current density load to define current density over a surface in an eddy current analysis. The surface current density load is available only in an electromagnetic model.

1. Display the surface current density load editor using one of the following methods:
   - To create a new surface current density load, follow the procedure outlined in *Creating loads* (**Category**: `Electrical/Magnetic`; **Types for Selected Step**: `Surface current density`).
   - To edit an existing surface current density load using menus or managers, see *Editing step-dependent objects*. To edit the region to which the load is applied, see *Editing the region to which a prescribed condition is applied*.

2. Click the arrow to the right of the **Distribution** field, and select the option of your choice from the list that appears:
   - Select **Uniform** to define a load that is uniform over the surface.
   - Select **User-defined** to define the magnitude and direction of the load in user subroutine *UDSECURRENT*. See the following sections for more information:
     - *Specifying general job settings*
     - *UDSECURRENT*

3. If you selected the **Uniform** distribution option, perform the following steps:
   a. In the **Component 1**, **Component 2**, and (if applicable) **Component 3** fields, enter the real (in-phase) and imaginary (out-of-phase) parts of the surface current density vector.

      Abaqus/CAE calculates the magnitude and direction of the surface current density vector.
   b. If desired, click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)
   c. Click **OK** to save your data and to exit the editor.

4. If you selected the **User-defined** distribution option, perform the following steps:
   a. If desired, in the **Component 1**, **Component 2**, and (if applicable) **Component 3** fields enter the real (in-phase) and imaginary (out-of-phase) parts of the surface current density vector.

      Abaqus/CAE calculates the magnitude and direction of the surface current density vector and that information is passed into the user subroutine.
   b. Click **OK** to save your data and to exit the editor.
   c. Enter the Job module and display the job editor for the analysis job of interest. (For more information, see *Creating, editing, and manipulating jobs*.)
   d. In the job editor, click the **General** tab, and specify the file containing the user subroutine that defines the magnitude and direction of the load. For more information, see *Specifying general job settings*.

Note:

You can specify only one user subroutine file in the job editor; if your analysis involves more than one user subroutine, you must combine the user subroutines into one file and then specify that file.

Additional information

Defining a body current density

You can create a body current density load to define current density over a volume in an eddy current analysis. The body current density load is available only in an electromagnetic model.

1. Display the body current density load editor using one of the following methods:
   - To create a new body current density load, follow the procedure outlined in *Creating loads* (**Category**: `Electrical/Magnetic`; **Types for Selected Step**: `Body current density`).
   - To edit an existing body current density load using menus or managers, see *Editing step-dependent objects*. To edit the region to which the load is applied, see *Editing the region to which a prescribed condition is applied*.

2. Click the arrow to the right of the **Distribution** field, and select the option of your choice from the list that appears:
   - Select **Uniform** to define a load that is uniform over the volume.
   - Select **User-defined** to define the magnitude and direction of the load in user subroutine *UDECURRENT*. See the following sections for more information:
     - *Specifying general job settings*
     - *UDECURRENT*

3. If you selected the **Uniform** distribution option, perform the following steps:
   a. In the **Component 1**, **Component 2**, and (if applicable) **Component 3** fields, enter the real (in-phase) and imaginary (out-of-phase) parts of the body current density vector.

      Abaqus/CAE calculates the magnitude and direction of the body current density vector.
   b. If desired, click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)
   c. Click **OK** to save your data and to exit the editor.

4. If you selected the **User-defined** distribution option, perform the following steps:
   a. If desired, in the **Component 1**, **Component 2**, and (if applicable) **Component 3** fields enter the real (in-phase) and imaginary (out-of-phase) parts of the body current density vector.

      Abaqus/CAE calculates the magnitude and direction of the body current density vector and that information is passed into the user subroutine.
   b. Click **OK** to save your data and to exit the editor.
   c. Enter the Job module and display the job editor for the analysis job of interest. (For more information, see *Creating, editing, and manipulating jobs*.)
   d. In the job editor, click the **General** tab, and specify the file containing the user subroutine that defines the magnitude and direction of the load. For more information, see *Specifying general job settings*.

Note:

You can specify only one user subroutine file in the job editor; if your analysis involves more than one user subroutine, you must combine the user subroutines into one file and then specify that file.

Defining a concentrated charge

You can create a concentrated charge load to apply an electric charge to a vertex or node in a piezoelectric analysis.

1. Display the concentrated charge load editor using one of the following methods:
   - To create a new concentrated charge load, follow the procedure outlined in *Creating loads* (**Category**: `Electrical/Magnetic`; **Types for Selected Step**: `Concentrated charge`).
   - To edit an existing concentrated charge load using menus or managers, see *Editing step-dependent objects*. To edit the region to which the load is applied, see *Editing the region to which a prescribed condition is applied*.
2. Click the arrow to the right of the **Distribution** field, and select the option of your choice from the list that appears:
   - Select **Uniform** to define a load that is uniform over the region.
   - Select an analytical field to define a spatially varying load. Only analytical fields that are valid for this load type are displayed in the selection list. Alternatively, you can click  to create a new analytical field. (See *The Analytical Field toolset* for more information.)
3. In the **Magnitude** field, enter the charge magnitude (units C).
4. If desired, click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)

   Note:

   The amplitude field appears only if amplitudes are valid for the type of perturbation step in which you are creating the load. For more information, see “Linear perturbation analysis steps,” in *General and Perturbation Procedures*.
5. Click **OK** to save your data and to exit the editor.

Additional information

Defining a surface charge

You can create a surface charge load to apply a distributed electric charge to a surface in a piezoelectric analysis.

1. Display the surface charge load editor using one of the following methods:
   - To create a new surface charge load, follow the procedure outlined in *Creating loads* (**Category**: `Electrical/Magnetic`; **Types for Selected Step**: `Surface charge`).
   - To edit an existing surface charge load using menus or managers, see *Editing step-dependent objects*. To edit the region to which the load is applied, see *Editing the region to which a prescribed condition is applied*.
2. Click the arrow to the right of the **Distribution** field, and select the option of your choice from the list that appears:
   - Select **Uniform** to define a load that is uniform over the surface.
   - Select an analytical field to define a spatially varying load. Only analytical fields that are valid for this load type are displayed in the selection list. Alternatively, you can click  to create a new analytical field. (See *The Analytical Field toolset* for more information.)
3. In the **Magnitude** field, enter the charge density (units CL^{-2}).
4. If desired, click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)

   Note:

   The amplitude field appears only if amplitudes are valid for the type of perturbation step in which you are creating the load. For more information, see “Linear perturbation analysis steps,” in *General and Perturbation Procedures*.
5. Click **OK** to save your data and to exit the editor.

Additional information

Defining a body charge

You can create a body charge load to apply an electric charge to a body in a piezoelectric analysis.

1. Display the body charge load editor using one of the following methods:
   - To create a new body charge load, follow the procedure outlined in *Creating loads* (**Category**: `Electrical/Magnetic`; **Types for Selected Step**: `Body charge`).
   - To edit an existing body charge load using menus or managers, see *Editing step-dependent objects*. To edit the region to which the load is applied, see *Editing the region to which a prescribed condition is applied*.
2. Click the arrow to the right of the **Distribution** field, and select the option of your choice from the list that appears:
   - Select **Uniform** to define a load that is uniform over the body.
   - Select an analytical field to define a spatially varying load. Only analytical fields that are valid for this load type are displayed in the selection list. Alternatively, you can click $f(x)$ to create a new analytical field. (See *The Analytical Field toolset* for more information.)
3. In the **Magnitude** field, enter the charge density (units CL^{-3}).
4. If desired, click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)

   Note:

   The amplitude field appears only if amplitudes are valid for the type of perturbation step in which you are creating the load. For more information, see “Linear perturbation analysis steps,” in *General and Perturbation Procedures*.
5. Click **OK** to save your data and to exit the editor.

Additional information

Defining a concentrated concentration flux

You can create a concentrated concentration flux load to define a concentrated concentration flux at a vertex or node in a mass diffusion analysis.

1. Display the concentrated concentration flux load editor using one of the following methods:
   - To create a new concentrated concentration flux load, follow the procedure outlined in *Creating loads* (**Category**: `Mass diffusion`; **Types for Selected Step**: `Concentrated concentration flux`).
   - To edit an existing concentrated concentration flux load using menus or managers, see *Editing step-dependent objects*. To edit the region to which the load is applied, see *Editing the region to which a prescribed condition is applied*.
2. Click the arrow to the right of the **Distribution** field, and select the option of your choice from the list that appears:
   - Select **Uniform** to define a load that is uniform over the region.
   - Select an analytical field to define a spatially varying load. Only analytical fields that are valid for this load type are displayed in the selection list. Alternatively, you can click $f(x)$ to create a new analytical field. (See *The Analytical Field toolset* for more information.)
3. In the **Magnitude** field, enter the concentration flux magnitude (units PL^3T^{-1}). A positive magnitude indicates concentration flow into the body at the vertex or node.
4. If desired, click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)
5. Click **OK** to save your data and to exit the editor.

Additional information

- *Creating and modifying prescribed conditions*
- *Understanding symbols that represent prescribed conditions*
- *Using analytical expression fields*
- *Creating expression fields*
- *Mass Diffusion Analysis*

Defining a surface concentration flux

You can create a surface concentration flux load to define a concentration flux over a surface in a mass diffusion analysis.

1. Display the surface concentration flux load editor using one of the following methods:
   - To create a new surface concentration flux load, follow the procedure outlined in *Creating loads* (**Category**: `Mass diffusion`; **Types for Selected Step**: `Surface concentration flux`).
   - To edit an existing surface concentration flux load using menus or managers, see *Editing step-dependent objects*. To edit the region to which the load is applied, see *Editing the region to which a prescribed condition is applied*.

2. Click the arrow to the right of the **Distribution** field, and select the option of your choice from the list that appears:
   - Select **Uniform** to define a load that is uniform over the surface.
   - Select **User-defined** to define the magnitude of the load in user subroutine *DFLUX*. See the following sections for more information:
     - *Specifying general job settings*
     - *DFLUX*
   - Select an analytical field, labeled with an (A), or a discrete field, labeled with a (D), to define a spatially varying load. Only analytical fields and discrete fields that are valid for this load type are displayed in the selection list.

     Alternatively, you can click  to create a new analytical field. (See *The Analytical Field toolset* for more information.)

3. If you selected the **Uniform**, analytical field, or discrete field distribution option, perform the following steps:
   a. In the **Magnitude** text field, enter the concentration flux density (units PLT^{-1}). A positive magnitude indicates concentration flow into the surface.
   b. If desired, click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)
   c. Click **OK** to save your data and to exit the editor.

4. If you selected the **User-defined** distribution option, perform the following steps:
   a. If desired, enter the concentration flux density in the **Magnitude** field (units PLT^{-1}). A positive magnitude indicates concentration flow into the surface.

      Magnitude data that you enter in the editor are passed into the user subroutine.
   b. Click **OK** to save your data and to exit the editor.
   c. Enter the Job module and display the job editor for the analysis job of interest. (For more information, see *Creating, editing, and manipulating jobs*.)
   d. In the job editor, click the **General** tab, and specify the file containing the user subroutine that defines the load magnitude. For more information, see *Specifying general job settings*.

Note:

You can specify only one user subroutine file in the job editor; if your analysis involves more than one user subroutine, you must combine the user subroutines into one file and then specify that file.

Defining a body concentration flux

You can create a body concentration flux load to define a concentration flux over a body in a mass diffusion analysis.

1. Display the body concentration flux load editor using one of the following methods:
   - To create a new body concentration flux load, follow the procedure outlined in *Creating loads* (**Category**: `Mass diffusion`; **Types for Selected Step**: `Body concentration flux`).
   - To edit an existing body concentration flux load using menus or managers, see *Editing step-dependent objects*. To edit the region to which the load is applied, see *Editing the region to which a prescribed condition is applied*.
2. Click the arrow to the right of the **Distribution** field, and select the option of your choice from the list that appears:
   - Select **Uniform** to define a load that is uniform over the body.
   - Select **User-defined** to define the magnitude of the load in user subroutine *DFLUX*. See the following sections for more information:
     - *Specifying general job settings*
     - *DFLUX*
   - Select an analytical field, labeled with an (A), or a discrete field, labeled with a (D), to define a spatially varying load. Only analytical fields and discrete fields that are valid for this load type are displayed in the selection list.

     Alternatively, you can click $f(x)$ to create a new analytical field. (See *The Analytical Field toolset* for more information.)
3. If you selected the **Uniform**, analytical field, or discrete field distribution option, perform the following steps:
   a. In the **Magnitude** text field, enter the concentration flux density (units PT^{-1}). A positive magnitude indicates concentration flow into the body.
   b. If desired, click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)
   c. Click **OK** to save your data and to exit the editor.
4. If you selected the **User-defined** distribution option, perform the following steps:
   a. If desired, enter the concentration flux density in the **Magnitude** field (units PT^{-1}). A positive magnitude indicates concentration flow into the body.

      Magnitude data that you enter in the editor are passed into the user subroutine.
   b. Click **OK** to save your data and to exit the editor.
   c. Enter the Job module and display the job editor for the analysis job of interest. (For more information, see *Creating, editing, and manipulating jobs*.)
   d. In the job editor, click the **General** tab, and specify the file containing the user subroutine that defines the load magnitude. For more information, see *Specifying general job settings*.

Note:

You can specify only one user subroutine file in the job editor; if your analysis involves more than one user subroutine, you must combine the user subroutines into one file and then specify that file.

Defining a fluid pressure penetration load

You can create a fluid pressure penetration load to define a fluid pressure over a surface.

1. Display the fluid pressure load editor using one of the following methods:
   - To create a new fluid pressure load, follow the procedure outlined in *Creating loads* (**Category**: `Mechanical`; **Types for Selected Step**: `Fluid pressure penetration`).
   - To edit an existing fluid pressure load using menus or managers, see *Editing step-dependent objects*. To edit the region to which the load is applied, see *Editing the region to which a prescribed condition is applied*.
2. In the **Magnitude** text field, enter the fluid pressure magnitude (units FL^{-2}).
3. If desired, click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears.
4. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)
5. In the **Critical pressure** text field, enter the critical pressure.
6. In the **Time period** text field, enter the time period.

   This field is supported only for Abaqus/Standard analyses (linear perturbation analyses are not supported).
7. Click the arrow to the right of the **Wetting type** field, and select the option of your choice from the list that appears:
   - Select **LOCAL** to define the algorithm for controlling the evolution region.
   - Select **WETTING ADVANCE** to define the algorithm for controlling the evolution region in Abaqus/Explicit analyses.
8. If you selected **WETTING ADVANCE** in the **Wetting type** field, perform the following steps to define the evolution regions in the table.
   a. In the **Evolutions region** column, double-click the cell of the table or right-click and select **Edit region**.
   b. Select a region in the viewport.

      A default name is provided in the prompt area, but you can enter a new name.
   c. To select from a list of existing sets, do the following:
      1. Click **Sets** on the right side of the prompt area.
      2. Select the set or surface of interest, and click **Continue**.
9. Click **OK** to save your data and to exit the editor.

Defining a distributed ion concentration body flux

You can create a body ion flux load to define distributed ion concentration fluxes over a volume.

1. Display the distributed ion concentration body flux load editor using one of the following methods:
   - To create a new distributed ion concentration body flux load, follow the procedure outlined in *Creating loads* (**Category**: `Coupled Thermal Electro-Chemical`; **Types for Selected Step**: `Distributed ion concentration body flux`).
   - To edit an existing distributed ion concentration body flux load using menus or managers, see *Editing step-dependent objects*. To edit the region to which the load is applied, see *Editing the region to which a prescribed condition is applied*.

2. Click the arrow to the right of the **Distribution** field, and select the option of your choice from the list that appears:
   - Select **Uniform** to define a load that is uniform over the body.
   - Select **User-defined** to define the magnitude of the load in user subroutine *DFLUX*. (This option is valid only in Abaqus/Standard analyses.) See the following sections for more information:
     - *Specifying general job settings*
     - *DFLUX*
   - Select an analytical field, labeled with an (A), or a discrete field, labeled with a (D), to define a spatially varying load. Only analytical fields and discrete fields that are valid for this load type are displayed in the selection list.

     Alternatively, you can click $f(x)$ to create a new analytical field. (See *The Analytical Field toolset* for more information.)

3. If you selected the **Uniform**, analytical field, or discrete field distribution option, perform the following steps:
   a. In the **Magnitude** text field, enter the body ion flux magnitude (units mol $T^{-1}L^{-3}$). A positive magnitude indicates ion flow into the body.
   b. If desired, click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)
   c. Click **OK** to save your data and to exit the editor.

4. If you selected the **User-defined** distribution option, perform the following steps:
   a. If desired, enter the body ion flux magnitude in the **Magnitude** field (units mol $T^{-1}L^{-3}$). A positive magnitude indicates ion flow into the body.

      Magnitude data that you enter in the editor are passed into the user subroutine.
   b. Click **OK** to save your data and to exit the editor.
   c. Enter the Job module and display the job editor for the analysis job of interest. (For more information, see *Creating, editing, and manipulating jobs*.)
   d. In the job editor, click the **General** tab, and specify the file containing the user subroutine that defines the load magnitude. For more information, see *Specifying general job settings*.

Note: You can specify only one user subroutine file in the job editor; if your analysis involves more than one user subroutine, you must combine the user subroutines into one file and then specify that file.

Defining an ion concentration flux

You can apply an ion concentration flux to a vertex or node.

1. Display the ion concentration flux load editor using one of the following methods:
   - To create a new ion concentration flux load, follow the procedure outlined in *Creating loads* (**Category**: `Coupled Thermal Electro-Chemical`; **Types for Selected Step**: `Ion concentration flux`).
   - To edit an existing ion concentration flux load using menus or managers, see *Editing step-dependent objects*. To edit the region to which the load is applied, see *Editing the region to which a prescribed condition is applied*.
2. Click the arrow to the right of the **Distribution** field, and select the option of your choice from the list that appears:
   - Select **Uniform** to define a load that is uniform over the region.
   - Select an analytical field to define a spatially varying load. Only analytical fields that are valid for this load type are displayed in the selection list. Alternatively, you can click $f(x)$ to create a new analytical field. (See *The Analytical Field toolset* for more information.)
3. In the **Magnitude** field, enter the concentrated ion flux magnitude (units mol T^{-1}). A positive magnitude indicates ion flow into the body at the vertex or node.
4. **Optional:** If desired, click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)
5. Click **OK** to save your data and to exit the editor.

Defining a fluid surface current

You can create a fluid surface current load to define fluid current densities over a surface in a coupled thermal-electro-chemical analysis.

1. Display the fluid surface current load editor using one of the following methods:
   - To create a new fluid surface current load, follow the procedure outlined in *Creating loads* (**Category**: `Coupled Thermal Electro-Chemical`; **Types for Selected Step**: `Fluid surface current`).
   - To edit an existing fluid surface current load using menus or managers, see *Editing step-dependent objects*. To edit the region to which the load is applied, see *Editing the region to which a prescribed condition is applied*.
2. Click the arrow to the right of the **Distribution** field, and select the option of your choice from the list that appears:
   - Select **Uniform** to define a load that is uniform over the surface.
   - Select an analytical field to define a spatially varying load. Only analytical fields that are valid for this load type are displayed in the selection list. Alternatively, you can click $f(x)$ to create a new analytical field. (See *The Analytical Field toolset* for more information.)
3. In the **Magnitude** text field, enter the current density (units C $L^{-2}T^{-1}$). A positive magnitude indicates current flow into the surface.
4. If desired, click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)
5. Click **OK** to save your data and to exit the editor.

Using the boundary condition editors

This section explains how to define specific types of boundary conditions.

The following topic is covered in *Modeling techniques*:

- *Creating the submodel boundary condition*

In this section:

- *Defining a symmetry/antisymmetry/encastre boundary condition*
- *Defining a displacement/rotation boundary condition*
- *Defining a velocity/angular velocity boundary condition*
- *Defining an acceleration/angular acceleration boundary condition*
- *Defining a connector displacement boundary condition*
- *Defining a connector velocity boundary condition*
- *Defining a connector acceleration boundary condition*
- *Defining a base motion boundary condition*
- *Defining a secondary base motion boundary condition*
- *Defining a retained nodal DOFs boundary condition*
- *Specifying temperature*
- *Defining a pore pressure boundary condition*
- *Defining a fluid cavity pressure boundary condition*
- *Defining an electric potential boundary condition*
- *Defining a magnetic vector potential boundary condition*

Defining a symmetry/antisymmetry/encastre boundary condition

You can define a boundary condition by selecting one of the common types listed in the symmetry/antisymmetry/encastre boundary condition editor.

1. Display the symmetry/antisymmetry/encastre boundary condition editor using one of the following methods:
   - To create a new symmetry/antisymmetry/encastre boundary condition, follow the procedure outlined in *Creating boundary conditions* (**Category**: `Mechanical`; **Types for Selected Step**: `Symmetry/Antisymmetry/Encastre`).
   - To edit an existing symmetry/antisymmetry/encastre boundary condition using menus or managers, see *Editing step-dependent objects*. You can edit the symmetry/antisymmetry/encastre boundary condition only in the step in which it was created.
2. If you are creating the boundary condition in a buckling step, select the **Use BC for** option that specifies the calculations for which you want the boundary condition used. For more information, see "Boundary conditions," in *Eigenvalue Buckling Prediction*.
3. By default, the global coordinate system is used to define the boundary condition. To change the coordinate system in which the boundary condition is applied, click  for the **CSYS** option and do one of the following:
   - Select an existing datum coordinate system in the viewport.
   - Select an existing datum coordinate system by name.
     1. From the prompt area, click **Datum CSYS List** to display a list of datum coordinate systems.
     2. Select a name from the list, and click **OK**.
   - Click **Use Global CSYS** from the prompt area to revert to the global coordinate system.
4. Select one of the following options:

XSYMM

Symmetry about a plane X = constant (U1 = UR2 = UR3 = 0).

YSYMM

Symmetry about a plane Y = constant (U2 = UR1 = UR3 = 0).

ZSYMM

Symmetry about a plane Z = constant (U3 = UR1 = UR2 = 0).

XASYMM

Antisymmetry about a plane with X = constant (U2 = U3 = UR1 = 0;Abaqus/Standard only).

YASYMM

Antisymmetry about a plane with Y = constant (U1 = U3 = UR2 = 0;Abaqus/Standard only).

ZASYMM

Antisymmetry about a plane with Z = constant (U1 = U2 = UR3 = 0;Abaqus/Standard only).

PINNED

Pinned (U1 = U2 = U3 = 0).

ENCASTRE

Fully built-in (U1 = U2 = U3 = UR1 = UR2 = UR3 = 0).

5. Click **OK** to save your data and to exit the editor.

Additional information

- *Using the Load module*
- *Creating and modifying prescribed conditions*
- *Boundary Conditions*

Defining a displacement/rotation boundary condition

You can create a displacement/rotation boundary condition to constrain the movement of the selected degrees of freedom to zero or to prescribe the displacement or rotation for each selected degree of freedom.

Note: If you apply the boundary condition to a two-dimensional planar region, only the **U1**, **U2**, and **UR3** degrees of freedom are available. If you model the part with generalized plane strain elements, you must use the **Keywords Editor** to apply boundary conditions on the active degrees of freedom (**U3**, **UR1**, and **UR2**) at the reference node of these elements (see *Adding unsupported keywords to your Abaqus/CAE model*).

1. Display the displacement/rotation boundary condition editor using one of the following methods:
   - To create a new displacement/rotation boundary condition, follow the procedure outlined in *Creating boundary conditions* (**Category**: `Mechanical`; **Types for Selected Step**: `Displacement/Rotation`).
   - To edit an existing displacement/rotation boundary condition using menus or managers, see *Editing step-dependent objects*. To edit the region to which the boundary condition is applied, see *Editing the region to which a prescribed condition is applied*.
2. If you are creating the boundary condition in a buckling step, select the **Use BC for** option that specifies the calculations for which you want the boundary condition used. For more information, see "Boundary conditions," in *Eigenvalue Buckling Prediction*.
3. By default, the global coordinate system is used to define the boundary condition. To change the coordinate system in which the boundary condition is applied, click  for the **CSYS** option and do one of the following:
   - Select an existing datum coordinate system in the viewport.
   - Select an existing datum coordinate system by name.
     1. From the prompt area, click **Datum CSYS List** to display a list of datum coordinate systems.
     2. Select a name from the list, and click **OK**.
   - Click **Use Global CSYS** from the prompt area to revert to the global coordinate system.

   This coordinate system editing option is available only in the step in which the boundary condition is created.
4. If a **Method** field appears toward the top of the editor, click the arrow to the right of the field, and select one of the following:
   - Select **Specify Constraints** if you want to specify values for particular degrees of freedom.
   - Select **Fixed at Current Position** if you want to fix the degrees of freedom at their final values from the previous general step.

   The **Method** option appears in the editor only if both methods are valid for the selected step.
5. Click the arrow to the right of the **Distribution** field, if available, and do the following:
   - Select **Uniform** to define a uniform boundary condition.
   - Select **User-defined** to define the boundary condition in user subroutine *DISP*. See the following sections for more information:
     - *Specifying general job settings*

- *DISP*

- Select an analytical field, labeled with an (A), or a discrete field, labeled with a (D), to define a spatially varying boundary condition. Only analytical fields and discrete fields that are valid for this boundary condition type are displayed in the selection list.

  Alternatively, you can click $f(x)$ to create a new analytical field. (See *The Analytical Field toolset* for more information.)

The **Distribution** option appears in the editor only if you are creating the boundary condition or editing the boundary condition in the step in which it was created. This option is unavailable if you select the **Fixed at Current Position** method.

6. If you selected the **Uniform**, analytical field, or discrete field distribution option, perform the following steps:
   a. Use the appropriate method to define the boundary condition:

If no text fields appear next to each degree of freedom:

- Toggle on a degree of freedom to fix the value either at zero (if you are defining a degree of freedom in the initial step) or at its final value at the end of the previous analysis step (if you are defining the degree of freedom in the second analysis step or in a later step.)
- Toggle off a degree of freedom to leave the degree of freedom unconstrained.

If text fields appear next to each degree of freedom:

- Toggle on a degree of freedom to constrain the degree of freedom. The text field becomes available in which you can specify a value for the degree of freedom. If you are creating the boundary condition in this step, a default value of zero appears in the text field. If you are modifying the boundary condition in this step, the value propagated from the previous step appears in the text field.
- Toggle off a degree of freedom to leave the degree of freedom unconstrained. If you toggle off a degree of freedom after modifying the default or propagated value in the text field, the modified value is lost. If you toggle that degree of freedom back on, the default or propagated value reappears in the text field.
- If an **Amplitude** appears at the bottom of the editor, click the arrow to the right of the field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)

   b. Click **OK** to save your data and to exit the editor.

7. If you selected the **User-defined** distribution option, perform the following steps:
   a. If desired, use the following techniques to define displacement:

   - Toggle on a degree of freedom to constrain the degree of freedom. If you are in the initial step, that degree of freedom is set to zero. If you are in any step other than the initial step, a text field becomes available in which you can specify a value for the degree of freedom.
   - Toggle off a degree of freedom to leave the degree of freedom unconstrained.

   Data that you enter in the editor for particular degrees of freedom are passed into the user subroutine.

b. Click **OK** to save your data and to exit the editor.

c. Enter the Job module and display the job editor for the analysis job of interest. (For more information, see *Creating, editing, and manipulating jobs*.)

d. In the job editor, click the **General** tab, and specify the file containing the user subroutine that defines the boundary condition. For more information, see *Specifying general job settings*.

Note:

You can specify only one user subroutine file in the job editor; if your analysis involves more than one user subroutine, you must combine the user subroutines into one file and then specify that file.

Additional information

- *Creating and modifying prescribed conditions*

- *Boundary Conditions*

Defining a velocity/angular velocity boundary condition

You can create a velocity/angular velocity boundary condition to prescribe a velocity for the selected degrees of freedom of the selected region's nodes.

Note:

To fix the velocity of a region at zero you must define a specific displacement for that region (see *Defining a displacement/rotation boundary condition*).

1. Display the velocity/angular velocity boundary condition editor using one of the following methods:
   - To create a new velocity/angular velocity boundary condition, follow the procedure outlined in *Creating boundary conditions* (**Category**: `Mechanical`; **Types for Selected Step**: `Velocity/Angular velocity`).
   - To edit an existing velocity/angular velocity boundary condition using menus or managers, see *Editing step-dependent objects*. To edit the region to which the boundary condition is applied, see *Editing the region to which a prescribed condition is applied*.
2. By default, the global coordinate system is used to define the boundary condition. To change the coordinate system in which the boundary condition is applied, click  for the **CSYS** option and do one of the following:
   - Select an existing datum coordinate system in the viewport.
   - Select an existing datum coordinate system by name.
     1. From the prompt area, click **Datum CSYS List** to display a list of datum coordinate systems.
     2. Select a name from the list, and click **OK**.
   - Click **Use Global CSYS** from the prompt area to revert to the global coordinate system.

   This coordinate system editing option is available only in the step in which the boundary condition is created.
3. If a **Distribution** field appears in the editor, click the arrow to the right of the field, and select one of the following:
   - Select **Uniform** to define a uniform boundary condition.
   - Select **User-defined** to define the boundary condition in user subroutine *DISP*. See the following sections for more information:
     - *Specifying general job settings*
     - *DISP*
   - Select an analytical field to define a spatially varying boundary condition. Only analytical fields that are valid for this boundary condition type are displayed in the selection list. Alternatively, you can click  to create a new analytical field. (See *The Analytical Field toolset* for more information.)

   The **Distribution** option appears in the editor only if you are creating the boundary condition or editing the boundary condition in the step in which it was created. In addition, this option is unavailable if you are performing an Abaqus/Explicit analysis.

4. If you selected the **Uniform** or analytical field distribution option, perform the following steps:
   a. Use the appropriate method to define the boundary condition:

If no text fields appear next to each degree of freedom:

You can use the following techniques to define the boundary condition:

- Toggle on a degree of freedom to fix the value at zero.
- Toggle off a degree of freedom to leave the degree of freedom unconstrained.

If text fields appear next to each degree of freedom:

You can use the following techniques to define the boundary condition:

- Toggle on a degree of freedom to constrain the degree of freedom. The text field becomes available in which you can specify a value for the degree of freedom. If you are creating the boundary condition in this step, a default value of zero appears in the text field. If you are modifying the boundary condition in this step, the value propagated from the previous step appears in the text field.
- Toggle off a degree of freedom to leave the degree of freedom unconstrained. If you toggle off a degree of freedom after modifying the default or propagated value in the text field, the modified value is lost. If you toggle that degree of freedom back on, the default or propagated value reappears in the text field.
- Click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)

   b. Click **OK** to save your data and to exit the editor.

5. If you selected the **User-defined** distribution option, perform the following steps:
   a. If desired, use the following techniques to define the velocity:

   - Toggle on a degree of freedom to constrain the degree of freedom. If you are in the initial step, that degree of freedom is set to zero. If you are in any step other than the initial step, a text field becomes available in which you can specify a value for the degree of freedom.
   - Toggle off a degree of freedom to leave the degree of freedom unconstrained.

   Data that you enter in the editor for specific degrees of freedom are passed into the user subroutine.

   b. Click **OK** to save your data and to exit the editor.
   c. Enter the Job module and display the job editor for the analysis job of interest. (For more information, see *Creating, editing, and manipulating jobs*.)
   d. In the job editor, click the **General** tab, and specify the file containing the user subroutine that defines the boundary condition. For more information, see *Specifying general job settings*.

Note: You can specify only one user subroutine file in the job editor; if your analysis involves more than one user subroutine, you must combine the user subroutines into one file and then specify that file.

Defining an acceleration/angular acceleration boundary condition

You can create an acceleration/angular acceleration boundary condition to prescribe an acceleration for the selected degrees of freedom of the selected region's nodes.

Note:

To fix the acceleration of a region at zero you must define a specific displacement for that region (see *Defining a displacement/rotation boundary condition*).

1. Display the acceleration/angular acceleration boundary condition editor using one of the following methods:
   - To create a new acceleration/angular acceleration boundary condition, follow the procedure outlined in *Creating boundary conditions* (**Category**: `Mechanical`; **Types for Selected Step**: `Acceleration/Angular acceleration`).
   - To edit an existing acceleration/angular acceleration boundary condition using menus or managers, see *Editing step-dependent objects*. To edit the region to which the boundary condition is applied, see *Editing the region to which a prescribed condition is applied*.
2. By default, the global coordinate system is used to define the boundary condition. To change the coordinate system in which the boundary condition is applied, click for the **CSYS** option and do one of the following:
   - Select an existing datum coordinate system in the viewport.
   - Select an existing datum coordinate system by name.
     1. From the prompt area, click **Datum CSYS List** to display a list of datum coordinate systems.
     2. Select a name from the list, and click **OK**.
   - Click **Use Global CSYS** from the prompt area to revert to the global coordinate system.

   This coordinate system editing option is available only in the step in which the boundary condition is created.
3. If a **Distribution** field appears in the editor, click the arrow to the right of the field, and select one of the following:
   - Select **Uniform** to define a uniform boundary condition.
   - Select **User-defined** to define the boundary condition in user subroutine *DISP*. See the following sections for more information:
     - *Specifying general job settings*
     - *DISP*
   - Select an analytical field to define a spatially varying boundary condition. Only analytical fields that are valid for this boundary condition type are displayed in the selection list. Alternatively, you can click $f(x)$ to create a new analytical field. (See *The Analytical Field toolset* for more information.)

The **Distribution** option appears in the editor only if you are creating the boundary condition or editing the boundary condition in the step in which it was created. In addition, this option is unavailable if you are performing an Abaqus/Explicit analysis.

4. If you selected the **Uniform** or analytical field distribution option, perform the following steps:
   a. Use the appropriate method to define the boundary condition:

If no text fields appear next to each degree of freedom:

You can use the following techniques to define the boundary condition:

- Toggle on a degree of freedom to fix the value at zero.
- Toggle off a degree of freedom to leave the degree of freedom unconstrained.

If text fields appear next to each degree of freedom:

You can use the following techniques to define the boundary condition:

- Toggle on a degree of freedom to constrain the degree of freedom. The text field becomes available in which you can specify a value for the degree of freedom. If you are creating the boundary condition in this step, a default value of zero appears in the text field. If you are modifying the boundary condition in this step, the value propagated from the previous step appears in the text field.
- Toggle off a degree of freedom to leave the degree of freedom unconstrained. If you toggle off a degree of freedom after modifying the default or propagated value in the text field, the modified value is lost. If you toggle that degree of freedom back on, the default or propagated value reappears in the text field.
- Click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)

   b. Click **OK** to save your data and to exit the editor.

5. If you selected the **User-defined** distribution option, perform the following steps:
   a. If desired, use the following techniques to define the acceleration:

   - Toggle on a degree of freedom to constrain the degree of freedom. If you are in the initial step, that degree of freedom is set to zero. If you are in any step other than the initial step, a text field becomes available in which you can specify a value for the degree of freedom.
   - Toggle off a degree of freedom to leave the degree of freedom unconstrained.

   Data that you enter in the editor for specific degrees of freedom are passed into the user subroutine.

   b. Click **OK** to save your data and to exit the editor.
   c. Enter the Job module and display the job editor for the analysis job of interest. (For more information, see *Creating, editing, and manipulating jobs*.)
   d. In the job editor, click the **General** tab, and specify the file containing the user subroutine that defines the boundary condition. For more information, see *Specifying general job settings*.

Note:

You can specify only one user subroutine file in the job editor; if your analysis involves more than one user subroutine, you must combine the user subroutines into one file and then specify that file.

Defining a connector displacement boundary condition

You can create a connector displacement boundary condition to prescribe a displacement for the available components of relative motion of connectors. If the connector displacement boundary condition exceeds the failure criteria for a connector, the connector displacement will be ignored.

1. Display the connector displacement boundary condition editor using one of the following methods:
   - To create a new connector displacement boundary condition, follow the procedure outlined in *Creating boundary conditions* (**Category**: `Mechanical`; **Types for Selected Step**: `Connector displacement`).
   - To edit an existing connector displacement/rotation boundary condition using menus or managers, see *Editing step-dependent objects*. To edit the region to which the boundary condition is applied, see *Editing the region to which a prescribed condition is applied*.
2. If you are creating the boundary condition in a buckling step, select the **Use BC for** option that specifies the calculations for which you want the boundary condition used. For more information, see "Boundary conditions," in *Eigenvalue Buckling Prediction*.
3. If a **Method** field appears toward the top of the editor, click the arrow to the right of the field, and select one of the following:
   - Select **Specify Constraints** if you want to specify values for particular components of relative motion.
   - Select **Fixed at Current Position** if you want to fix the components of relative motion at their final values from the previous general step.

   The **Method** option appears in the editor only if both methods are valid for the selected step.
4. If a **Distribution** field appears in the editor, click the arrow to the right of the field, and select one of the following:
   - Select **Uniform** to define a uniform boundary condition.
   - Select **User-defined** to define the boundary condition in user subroutine *DISP*. See the following sections for more information:
     - *Specifying general job settings*
     - *DISP*

   The **Distribution** option appears in the editor only if you are creating the boundary condition or editing the boundary condition in the step in which it was created. This option is unavailable if you select the **Fixed at Current Position** method or if you are performing an Abaqus/Explicit analysis.
5. If you are defining the boundary condition directly in the editor (and not in user subroutine *DISP*), perform the following steps:
   a. Use the appropriate method to define the boundary condition. Only components common to all of the selected wires are available in the editor.

If no text fields appear next to each component of relative motion:

- Toggle on a component of relative motion to fix the value either at zero (if you are defining a component of relative motion in the initial step) or at its final value at the end of the previous analysis step (if you are defining the component of relative motion in the second analysis step or in a later step.)

- Toggle off a component of relative motion to leave the component of relative motion unconstrained.

If text fields appear next to each component of relative motion:

- Toggle on a component of relative motion to constrain the component of relative motion. The text field becomes available in which you can specify a value for the component of relative motion. If you are creating the boundary condition in this step, a default value of zero appears in the text field. If you are modifying the boundary condition in this step, the value propagated from the previous step appears in the text field.
- Toggle off a component of relative motion to leave the component of relative motion unconstrained. If you toggle off a component of relative motion after modifying the default or propagated value in the text field, the modified value is lost. If you toggle that component of relative motion back on, the default or propagated value reappears in the text field.
- Click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)

b. Click **OK** to save your data and to exit the editor.

6. If you are defining the boundary condition in user subroutine *DISP*, perform the following steps:

a. If desired, use the following techniques to define displacement. Only components common to all of the selected wires are available in the editor.

- Toggle on a component of relative motion to constrain the component of relative motion. If you are in the initial step, that component of relative motion is set to zero. If you are in any step other than the initial step, a text field becomes available in which you can specify a value for the component of relative motion.
- Toggle off a component of relative motion to leave the component of relative motion unconstrained.

Data that you enter in the editor for particular degrees of freedom are passed into the user subroutine.

b. Click **OK** to save your data and to exit the editor.

c. Enter the Job module and display the job editor for the analysis job of interest. (For more information, see *Creating, editing, and manipulating jobs*.)

d. In the job editor, click the **General** tab, and specify the file containing the user subroutine that defines the boundary condition. For more information, see *Specifying general job settings*.

Note: You can specify only one user subroutine file in the job editor; if your analysis involves more than one user subroutine, you must combine the user subroutines into one file and then specify that file.

Additional information

Defining a connector velocity boundary condition

You can create a connector velocity boundary condition to prescribe a velocity for the available components of relative motion of connectors.

1. Display the connector velocity boundary condition editor using one of the following methods:
   - To create a new connector velocity boundary condition, follow the procedure outlined in *Creating boundary conditions* (**Category**: `Mechanical`; **Types for Selected Step**: `Connector velocity`).
   - To edit an existing connector velocity boundary condition using menus or managers, see *Editing step-dependent objects*. To edit the region to which the boundary condition is applied, see *Editing the region to which a prescribed condition is applied*.

2. If a **Distribution** field appears in the editor, click the arrow to the right of the field, and select one of the following:
   - Select **Uniform** to define a uniform boundary condition.
   - Select **User-defined** to define the boundary condition in user subroutine *DISP*. See the following sections for more information:
     - *Specifying general job settings*
     - *DISP*

   The **Distribution** option appears in the editor only if you are creating the boundary condition or editing the boundary condition in the step in which it was created. In addition, this option is unavailable if you are performing an Abaqus/Explicit analysis.

3. If you are defining the boundary condition directly in the editor (and not in user subroutine *DISP*), perform the following steps:
   a. Use the appropriate method to define the boundary condition. Only components common to all of the selected wires are available in the editor.

If no text fields appear next to each component of relative motion:

You can use the following techniques to define the boundary condition:

- Toggle on a component of relative motion to fix the component of relative motion at zero.
- Toggle off a component of relative motion to leave the component of relative motion unconstrained.

If text fields appear next to each component of relative motion:

You can use the following techniques to define the boundary condition:

- Toggle on a component of relative motion to constrain the component of relative motion. The text field becomes available in which you can specify a value for the component of relative motion. If you are creating the boundary condition in this step, a default value of zero appears in the text field. If you are modifying the boundary condition in this step, the value propagated from the previous step appears in the text field.

- Toggle off a component of relative motion to leave the component of relative motion unconstrained. If you toggle off a component of relative motion after modifying the default or propagated value in the text field, the modified value is lost. If you toggle that component of relative motion back on, the default or propagated value reappears in the text field.
- Click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)

b. Click **OK** to save your data and to exit the editor.

4. If you are defining the boundary condition in user subroutine *DISP*, perform the following steps:

a. If desired, use the following techniques to define the velocity. Only components common to all of the selected wires are available in the editor.

- Toggle on a component of relative motion to constrain the component of relative motion. If you are in the initial step, that component of relative motion is set to zero. If you are in any step other than the initial step, a text field becomes available in which you can specify a value for the component of relative motion.
- Toggle off a component of relative motion to leave the component of relative motion unconstrained.

Data that you enter in the editor for specific degrees of freedom are passed into the user subroutine.

b. Click **OK** to save your data and to exit the editor.

c. Enter the Job module and display the job editor for the analysis job of interest. (For more information, see *Creating, editing, and manipulating jobs*.)

d. In the job editor, click the **General** tab, and specify the file containing the user subroutine that defines the boundary condition. For more information, see *Specifying general job settings*.

Note: You can specify only one user subroutine file in the job editor; if your analysis involves more than one user subroutine, you must combine the user subroutines into one file and then specify that file.

Defining a connector acceleration boundary condition

You can create a connector acceleration boundary condition to prescribe an acceleration for the available components of relative motion of connectors.

1. Display the connector acceleration boundary condition editor using one of the following methods:
   - To create a new connector acceleration boundary condition, follow the procedure outlined in *Creating boundary conditions* (**Category**: `Mechanical`; **Types for Selected Step**: `Connector acceleration`).
   - To edit an existing connector acceleration boundary condition using menus or managers, see *Editing step-dependent objects*. To edit the region to which the boundary condition is applied, see *Editing the region to which a prescribed condition is applied*.

2. If a **Distribution** field appears in the editor, click the arrow to the right of the field, and select one of the following:
   - Select **Uniform** to define a uniform boundary condition.
   - Select **User-defined** to define the boundary condition in user subroutine *DISP*. See the following sections for more information:
     - *Specifying general job settings*
     - *DISP*

   The **Distribution** option appears in the editor only if you are creating the boundary condition or editing the boundary condition in the step in which it was created. In addition, this option is unavailable if you are performing an Abaqus/Explicit analysis.

3. If you are defining the boundary condition directly in the editor (and not in user subroutine *DISP*), perform the following steps:
   a. Use the appropriate method to define the boundary condition. Only components common to all of the selected wires are available in the editor.

If no text fields appear next to each component of relative motion:

You can use the following techniques to define the boundary condition:

- Toggle on a component of relative motion to fix the value at zero.
- Toggle off a component of relative motion to leave the component of relative motion unconstrained.

If text fields appear next to each component of relative motion:

You can use the following techniques to define the boundary condition:

- Toggle on a component of relative motion to constrain the component of relative motion. The text field becomes available in which you can specify a value for the component of relative motion. If you are creating the boundary condition in this step, a default value of zero appears in the text field. If you are modifying the boundary condition in this step, the value propagated from the previous step appears in the text field.
- Toggle off a component of relative motion to leave the component of relative motion unconstrained. If you toggle off a component of relative motion after modifying the

default or propagated value in the text field, the modified value is lost. If you toggle that component of relative motion back on, the default or propagated value reappears in the text field.

- Click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)

b. Click **OK** to save your data and to exit the editor.

4. If you are defining the boundary condition in user subroutine *DISP*, perform the following steps:

a. If desired, use the following techniques to define the acceleration. Only components common to all of the selected wires are available in the editor.

- Toggle on a component of relative motion to constrain the component of relative motion. If you are in the initial step, that component of relative motion is set to zero. If you are in any step other than the initial step, a text field becomes available in which you can specify a value for the component of relative motion.
- Toggle off a component of relative motion to leave the component of relative motion unconstrained.

Data that you enter in the editor for specific degrees of freedom are passed into the user subroutine.

b. Click **OK** to save your data and to exit the editor.

c. Enter the Job module and display the job editor for the analysis job of interest. (For more information, see *Creating, editing, and manipulating jobs*.)

d. In the job editor, click the **General** tab, and specify the file containing the user subroutine that defines the boundary condition. For more information, see *Specifying general job settings*.

Note:

You can specify only one user subroutine file in the job editor; if your analysis involves more than one user subroutine, you must combine the user subroutines into one file and then specify that file.

Additional information

- *Creating and modifying prescribed conditions*
- *Understanding symbols that represent prescribed conditions*
- *Connector Actuation*

Defining a base motion boundary condition

You can create a base motion boundary condition to specify the motion of nodes in a modal dynamic step, steady-state dynamic (mode-based or subspace-based) step, or random response step. The base motion can be acceleration, velocity, or displacement.

For more information on base motion, see the boundary conditions discussions in the following sections:

- *Transient Modal Dynamic Analysis*
- *Mode-Based Steady-State Dynamic Analysis*
- *Subspace-Based Steady-State Dynamic Analysis*
- *Random Response Analysis*

1. Display the boundary condition editor using one of the following methods:
   - To create a new displacement base motion boundary condition, follow the procedure outlined in *Creating boundary conditions* (**Category**: `Mechanical`; **Types for Selected Step**: `Acceleration base motion` or `Velocity base motion` or `Displacement base motion`).
   - To edit an existing base motion boundary condition using menus or managers, see *Editing step-dependent objects*.
2. In the **Basic** tab, select the **Degree-of-freedom** to specify the direction for which the base motion is being defined. This direction is always a global direction: **U1**, **U2**, **U3**, **UR1**, **UR2**, or **UR3**.
3. For a modal dynamic step or steady-state dynamic (mode-based or subspace-based) step, specify the following options:
   a. If the base motion is to be applied to a secondary base, toggle on **Secondary base** and choose the name of the secondary base boundary condition defined previously in the eigenfrequency extraction step.
   b. Choose an **Amplitude** curve that defines the time history (modal dynamic step) or frequency spectrum (steady-state dynamic step) of the base motion.
   c. Enter a new value for the **Amplitude scale factor**, if desired. The default value is 1.0.
   d. Base motions are always specified in global directions, regardless of the use of nodal transformations. You specify the global direction (**Degree-of-freedom**) for which the base motion is being defined. If a rotation is specified about an origin that is not the origin of the coordinates, you must specify the **Center of rotation** by clicking  and picking a point in the viewport or entering the coordinates.
   e. For a steady-state dynamic step, you can toggle on **Define imaginary (out-of-phase) portion given by amplitude** if the specified amplitude curve defines the imaginary part of the base motion (instead of the real, in-phase portion).
4. For a random response step, click the **Correlation** tab and toggle on **Specify correlation** to define the cross-correlation as part of the definition of random loading. See *Defining the Correlation*, for complete information about correlation options. To define a correlation, fill out the cells in a row of the table as follows:
   a. Click in the **Approach** column, and select one of the following approaches:
      - Select **Correlated** if all terms in the correlation matrix should be included.
      - Select **Uncorrelated** if only diagonal terms should be used.

- Select **User** to indicate that user subroutine *UCORR* will be called to obtain the scaling factors for the correlation matrix.

b. Click in the **PSD** column cell, and select the PSD definition amplitude that you defined previously. This amplitude represents the power spectral density function for the random noise source.

c. In the **Real** and **Imaginary** columns, enter the real and imaginary parts of the scaling factor. These scaling factors specify whether the real and imaginary terms will be included in the spatial correlation matrix.

You can add rows in the table to create additional correlations to define the random loading.

5. Click **OK** to save your data and to exit the editor.

Additional information

- *Creating and modifying prescribed conditions*
- *Understanding symbols that represent prescribed conditions*

Defining a secondary base motion boundary condition

You can create a secondary base motion boundary condition in a frequency extraction step. If a subsequent modal dynamic or steady-state dynamic (mode-based or subspace-based) step has more than one independent base motion, the driven nodes must be grouped together into secondary bases in addition to the primary base. See *Defining Primary and Secondary Bases for Modal Superposition Procedures*, for a complete discussion of base motion boundary conditions.

1. Display the boundary condition editor using one of the following methods:
   - To create a new secondary base boundary condition, follow the procedure outlined in *Creating boundary conditions* (**Category**: `Mechanical`; **Types for Selected Step**: `Secondary base`).
   - To edit an existing boundary condition using menus or managers, see *Editing step-dependent objects*.
2. Select the region to which you want to apply the boundary condition. Double-click in the empty table cell under the **Region** column and use one of the following methods:
   - Select a region in the viewport. You can use the angle method to select a group of faces or edges from geometry or a group of element faces from a mesh. For more information, see *Using the angle and feature edge method to select multiple objects*. When you have finished selecting, click mouse button 2.

     Tip: You can limit the types of objects that you can select in the viewport by specifying filtering options in the Selection toolbar. See *Using the selection options*, for more information.

     If the model contains a combination of mesh and geometry, you must choose the type of region to which you want to apply the boundary condition. From the prompt area, select one of the following:
     - Click **Geometry** to apply the boundary condition to geometry or to a reference point.
     - Click **Mesh** to apply the boundary condition to a native or orphan mesh selection.
   - To select from a list of existing sets, do the following:
     1. Click **Sets** on the right side of the prompt area.

        Abaqus/CAE displays the **Region Selection** dialog box containing a list of available sets.
     2. Select the set of interest, and click **Continue**.

        Note:

        The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.
3. Select the **Constrained-degrees-of-freedom** in the table by clicking one or more checkboxes.
4. Click **OK** to save your data and to exit the editor.

Additional information

- *Creating and modifying prescribed conditions*
- *Understanding symbols that represent prescribed conditions*

Defining a retained nodal DOFs boundary condition

You can create a retained nodal degrees of freedom (DOFs) boundary condition to specify the degrees of freedom that are to be retained as external to a substructure. This boundary condition can be created only in a **Substructure generation** step.

1. Display the retained nodal DOFs boundary condition editor using one of the following methods:
   - To create a new retained nodal DOFs boundary condition, follow the procedure outlined in *Creating boundary conditions* (**Category**: `Mechanical`; **Types for Selected Step**: `Retained nodal dofs`).
   - To edit an existing retained nodal DOFs boundary condition using menus or managers, see *Editing step-dependent objects*. To edit the region to which the boundary condition is applied, see *Editing the region to which a prescribed condition is applied*.
2. Toggle on any of the following options:

U1

Nodal freedom in the 1-direction.

U2

Nodal freedom in the 2-direction.

U3

Nodal freedom in the 3-direction.

UR1

Rotation about the 1-axis.

UR2

Rotation about the 2-axis.

UR3

Rotation about the 3-axis.

3. Click **OK** to save your data and to exit the editor.

Additional information

- *Creating and modifying prescribed conditions*
- *Understanding symbols that represent prescribed conditions*
- *Configuring a substructure generation procedure*
- *Defining the Retained Nodal Degrees of Freedom*

Specifying temperature

You can create a temperature boundary condition to specify a temperature for the selected region.

1. Display the temperature boundary condition editor using one of the following methods:
   - To create a new temperature boundary condition, follow the procedure outlined in *Creating boundary conditions* (**Category**: `Other`; **Types for Selected Step**: `Temperature`).
   - To edit an existing temperature boundary condition using menus or managers, see *Editing step-dependent objects*. To edit the region to which the boundary condition is applied, see *Editing the region to which a prescribed condition is applied*.
2. If a **Method** field appears toward the top of the editor, click the arrow to the right of the field, and select one of the following:
   - Select **Specify magnitude** if you want to specify a value for the temperature.
   - Select **Fixed at current magnitude** if you want to fix the temperature magnitude at its final value from the previous general step.

   The **Method** option appears in the editor only if both methods are valid for the selected step.
3. If a **Distribution** field appears in the editor, click the arrow to the right of the field, and select one of the following:
   - Select **Uniform** to define a uniform boundary condition.
   - Select **User-defined** to define the boundary condition in user subroutine *DISP*. See the following sections for more information:
     - *Specifying general job settings*
     - *DISP*
   - Select an analytical field to define a spatially varying boundary condition. Only analytical fields that are valid for this boundary condition type are displayed in the selection list. Alternatively, you can click $f(x)$ to create a new analytical field. (See *The Analytical Field toolset* for more information.)

   The **Distribution** option appears in the editor only if you are creating the boundary condition or editing the boundary condition in the step in which it was created. This option is unavailable if you select the **Fixed at current magnitude** method.
4. If you selected the **Uniform** or analytical field distribution option, perform the following steps:
   a. If applicable, enter the temperature magnitude in the **Magnitude** field.
   b. If applicable, click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)

   Note:

   The **Magnitude** and **Amplitude** fields are unavailable if you are creating the boundary condition in the initial step (in which case the magnitude is always zero) or are fixing the magnitude at its final value from the previous analysis step.

5. If you selected the **User-defined** distribution option, perform the following steps:
   a. If desired, enter the temperature magnitude in the **Magnitude** field. Magnitude data that you enter in the editor are passed into the user subroutine.

      (The **Magnitude** field is unavailable if you are creating the boundary condition in the initial step.)
   b. Click **OK** to save any entered data and to exit the editor.
   c. Enter the Job module, and display the job editor for the analysis job of interest. (For more information, see *Creating, editing, and manipulating jobs*.)
   d. In the job editor, click the **General** tab, and specify the file containing the user subroutine that defines the boundary condition. For more information, see *Specifying general job settings*.

      Note:

      You can specify only one user subroutine file in the job editor; if your analysis involves more than one user subroutine, you must combine the user subroutines into one file and then specify that file.

6. If a shell region is selected, enter the temperature degrees of freedom that you want to specify in the **Degrees of freedom** field. For information on how shell temperature degrees of freedom are labeled, see either "Heat transfer shell elements" or "Coupled temperature-displacement shell elements" in *Choosing a Shell Element*.

   You can enter multiple degrees of freedom, from 11 to 31, inclusive, by separating each number with a comma. For example, if you want to specify degrees of freedom 11, 12, and 13, you must enter the following:`11,12,13`
7. Click **OK** to save your data and to exit the editor.

Defining a pore pressure boundary condition

You can create a pore pressure boundary condition to specify the excess or total pore pressure in a porous medium. If no gravity load exists in the model, you must specify excess pore pressure. If the model contains any gravity load, you must specify total pore pressure. (For more information, see "Boundary conditions," in *Coupled Pore Fluid Diffusion and Stress Analysis*.)

1. Display the pore pressure boundary condition editor using one of the following methods:
   - To create a new pore pressure boundary condition, follow the procedure outlined in *Creating boundary conditions* (**Category**: `Other`; **Types for Selected Step**: `Pore pressure`).
   - To edit an existing pore pressure boundary condition using menus or managers, see *Editing step-dependent objects*. To edit the region to which the boundary condition is applied, see *Editing the region to which a prescribed condition is applied*.

2. If a **Method** field appears toward the top of the editor, click the arrow to the right of the field, and select one of the following:
   - Select **Specify magnitude** if you want to specify a value for the excess or total pore pressure.
   - Select **Fixed at current magnitude** if you want to fix the excess or total pore pressure magnitude at its final value from the previous general step.

   The **Method** option appears in the editor only if both methods are valid for the selected step.

3. If a **Distribution** field appears in the editor, click the arrow to the right of the field, and select one of the following:
   - Select **Uniform** to define a uniform boundary condition.
   - Select **User-defined** to define the boundary condition in user subroutine *DISP*. See the following sections for more information:
     - *Specifying general job settings*
     - *DISP*
   - Select an analytical field to define a spatially varying boundary condition. Only analytical fields that are valid for this boundary condition type are displayed in the selection list. Alternatively, you can click $f(x)$ to create a new analytical field. (See *The Analytical Field toolset* for more information.)

   The **Distribution** option appears in the editor only if you are creating the boundary condition or editing the boundary condition in the step in which it was created. This option is unavailable if you select the **Fixed at current magnitude** method.

4. If you selected the **Uniform** or analytical field distribution option, perform the following steps:
   a. If applicable, enter the magnitude of the excess or total pore pressure in the **Magnitude** field.
   b. If applicable, click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)

Note:

The **Magnitude** and **Amplitude** fields are unavailable if you are creating the boundary condition in the initial step (in which case the magnitude is always zero) or are fixing the magnitude at its final value from the previous general step.

c. Click **OK** to save your data and to exit the editor.

5. If you selected the **User-defined** distribution option, perform the following steps:

a. If desired, enter the pore pressure magnitude in the **Magnitude** field. Magnitude data that you enter in the editor are passed into the user subroutine.

(The **Magnitude** field is unavailable if you are creating the boundary condition in the initial step.)

b. Click **OK** to save any entered data and to exit the editor.

c. Enter the Job module, and display the job editor for the analysis job of interest. (For more information, see *Creating, editing, and manipulating jobs*.)

d. In the job editor, click the **General** tab, and specify the file containing the user subroutine that defines the boundary condition. For more information, see *Specifying general job settings*.

Note: You can specify only one user subroutine file in the job editor; if your analysis involves more than one user subroutine, you must combine the user subroutines into one file and then specify that file.

Defining a fluid cavity pressure boundary condition

You can create a fluid cavity pressure boundary condition to control the pressure in a cavity throughout the analysis. The fluid cavity pressure is associated with a fluid cavity interaction. It is used to determine flow for a fluid exchange interaction. You can change the fluid cavity pressure throughout the analysis by assigning a new value for the step and an amplitude to define the rate of change from the previous value. (For more information, see *Initial Conditions*.)

1. Display the fluid cavity pressure boundary condition editor using one of the following methods:
   - To create a new fluid cavity pressure boundary condition, follow the procedure outlined in *Creating boundary conditions* (**Category**: `Other`; **Types for Selected Step**: `Fluid cavity pressure`).
   - To edit an existing fluid cavity pressure boundary condition using menus or managers, see *Editing step-dependent objects*.
2. If a **Method** field appears toward the top of the editor, click the arrow to the right of the field, and select one of the following:
   - Select **Specify pressure** if you want to specify a value for the fluid cavity pressure.
   - Select **Fixed at current pressure** if you want to fix the fluid cavity pressure magnitude at its final value from the previous general step.

   The **Method** option appears in the editor only if both methods are valid for the selected step.
3. If a **Fluid cavity interaction** field appears, click the arrow to the right of the field, and select the interaction to which the pressure applies.

   The **Fluid cavity interaction** option appears in the editor only if you are creating a new boundary condition or if you are editing the fluid pressure boundary condition in the step in which it was created. The interaction cannot be changed when editing the boundary condition in a propagated step.
4. If a **Fluid cavity pressure** field appears, enter a value for the current step.
5. If applicable, click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)

    **Note:**

   The **Amplitude** field is unavailable if you are creating the boundary condition in the initial step (in which case the magnitude is always zero) or are fixing the magnitude at its final value from the previous general step (such as when editing a frequency step).
6. Click **OK** to save your data and to exit the editor.

Additional information

Defining an electric potential boundary condition

You can create an electric potential boundary condition to prescribe an electrical potential on a region.
(For more information, see "Boundary conditions," in *Coupled Thermal-Electrical Analysis* and *Piezoelectric Analysis*.)

1. Display the electric potential boundary condition editor using one of the following methods:
   - To create a new electric potential boundary condition, follow the procedure outlined in *Creating boundary conditions* (**Category**: `Electrical/Magnetic/Electrochemical`; **Types for Selected Step**: `Electric potential`).
   - To edit an existing electric potential boundary condition using menus or managers, see *Editing step-dependent objects*. To edit the region to which the boundary condition is applied, see *Editing the region to which a prescribed condition is applied*.
2. If a **Method** field appears toward the top of the editor, click the arrow to the right of the field, and select one of the following:
   - Select **Specify magnitude** if you want to specify a value for the electric potential.
   - Select **Fixed at current magnitude** if you want to fix the electric potential magnitude at its final value from the previous general step.

   The **Method** option appears in the editor only if both methods are valid for the selected step.
3. If a **Distribution** field appears in the editor, click the arrow to the right of the field, and select one of the following:
   - Select **Uniform** to define a uniform boundary condition.
   - Select **User-defined** to define the boundary condition in user subroutine *DISP*. See the following sections for more information:
     - *Specifying general job settings*
     - *DISP*
   - Select an analytical field to define a spatially varying boundary condition. Only analytical fields that are valid for this boundary condition type are displayed in the selection list. Alternatively, you can click $f(x)$ to create a new analytical field. (See *The Analytical Field toolset* for more information.)

   The **Distribution** option appears in the editor only if you are creating the boundary condition or editing the boundary condition in the step in which it was created. This option is unavailable if you select the **Fixed at current magnitude** method.
4. If you selected the **Uniform** or analytical field distribution option, perform the following steps:
   a. If applicable, enter the magnitude of the electric potential in the **Magnitude** field.
   b. If applicable, click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)

   Note:

   The **Magnitude** and **Amplitude** fields are unavailable if you are creating the boundary condition in the initial step (in which case the magnitude is always zero) or are fixing the magnitude at its final value from the previous general step.

c. Click **OK** to save your data and to exit the editor.

5. If you selected the **User-defined** distribution option, perform the following steps:
   a. If desired, enter the electric potential magnitude in the **Magnitude** field. Magnitude data that you enter in the editor are passed into the user subroutine.

      (The **Magnitude** field is unavailable if you are creating the boundary condition in the initial step.)
   b. Click **OK** to save any entered data and to exit the editor.
   c. Enter the Job module, and display the job editor for the analysis job of interest. (For more information, see *Creating, editing, and manipulating jobs*.)
   d. In the job editor, click the **General** tab, and specify the file containing the user subroutine that defines the boundary condition. For more information, see *Specifying general job settings*.

      Note:

      You can specify only one user subroutine file in the job editor; if your analysis involves more than one user subroutine, you must combine the user subroutines into one file and then specify that file.

Defining a magnetic vector potential boundary condition

You can create a magnetic vector potential boundary condition to prescribe magnetic vector potential on a surface. (For more information, see *Boundary Conditions*.) The magnetic vector potential boundary condition is available only in an electromagnetic model.

1. Display the magnetic vector potential boundary condition editor using one of the following methods:
   - To create a new magnetic vector potential boundary condition, follow the procedure outlined in *Creating boundary conditions* (**Category**: `Electrical/Magnetic`; **Types for Selected Step**: `Magnetic vector potential`).
   - To edit an existing magnetic vector potential boundary condition using menus or managers, see *Editing step-dependent objects*. To edit the region to which the boundary condition is applied, see *Editing the region to which a prescribed condition is applied*.

2. Click the arrow to the right of the **Distribution** field, and select the option of your choice from the list that appears:
   - Select **Uniform** to define a boundary condition that is uniform over the surface.
   - Select **User-defined** to define the magnitude and direction of the boundary condition in user subroutine *UDEMPOTENTIAL*. See the following sections for more information:
     - *Specifying general job settings*
     - *UDEMPOTENTIAL*

3. If you selected the **Uniform** distribution option, perform the following steps:
   a. In the **Component 1**, **Component 2**, and (if applicable) **Component 3** fields, enter the real (in-phase) and imaginary (out-of-phase) parts of the magnetic vector potential.

      Abaqus/CAE calculates the magnitude and direction of the magnetic vector potential.
   b. If desired, click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)
   c. Click **OK** to save your data and to exit the editor.

4. If you selected the **User-defined** distribution option, perform the following steps:
   a. If desired, in the **Component 1**, **Component 2**, and (if applicable) **Component 3** fields enter the real (in-phase) and imaginary (out-of-phase) parts of the magnetic vector potential.

      Abaqus/CAE calculates the magnitude and direction of the magnetic vector potential and that information is passed into the user subroutine.
   b. Click **OK** to save your data and to exit the editor.
   c. Enter the Job module and display the job editor for the analysis job of interest. (For more information, see *Creating, editing, and manipulating jobs*.)
   d. In the job editor, click the **General** tab, and specify the file containing the user subroutine that defines the magnitude and direction of the boundary condition. For more information, see *Specifying general job settings*.

Note: You can specify only one user subroutine file in the job editor; if your analysis involves more than one user subroutine, you must combine the user subroutines into one file and then specify that file.

Additional information

Defining a normalized concentration boundary condition

You can create a normalized concentration boundary condition to prescribe values of normalized concentration for a region in a mass diffusion analysis. (For more information, see Boundary conditions in *Mass Diffusion Analysis*.)

1. Display the normalized concentration boundary condition editor using one of the following methods:
   - To create a new normalized concentration boundary condition, follow the procedure outlined in *Creating boundary conditions* (**Category**: `Other`; **Types for Selected Step**: `Normalized concentration`).
   - To edit an existing normalized concentration boundary condition using menus or managers, see *Editing step-dependent objects*. To edit the region to which the boundary condition is applied, see *Editing the region to which a prescribed condition is applied*.
2. If a **Method** field appears toward the top of the editor, click the arrow to the right of the field, and select one of the following:
   - Select **Specify magnitude** if you want to specify a value for the normalized concentration.
   - Select **Fixed at current magnitude** if you want to fix the normalized concentration magnitude at its final value from the previous general step.

   The **Method** option appears in the editor only if both methods are valid for the selected step.
3. If a **Distribution** field appears in the editor, click the arrow to the right of the field, and select one of the following:
   - Select **Uniform** to define a uniform boundary condition.
   - Select **User-defined** to define the boundary condition in user subroutine *DISP*. See the following sections for more information:
     - *Specifying general job settings*
     - *DISP*
   - Select an analytical field to define a spatially varying boundary condition. Only analytical fields that are valid for this boundary condition type are displayed in the selection list. Alternatively, you can click  to create a new analytical field. (See *The Analytical Field toolset* for more information.)

   The **Distribution** option appears in the editor only if you are creating the boundary condition or editing the boundary condition in the step in which it was created. This option is unavailable if you select the **Fixed at current magnitude** method.
4. If you selected the **Uniform** or analytical field distribution option, perform the following steps:
   a. If applicable, enter the normalized concentration magnitude in the **Magnitude** field.
   b. If applicable, click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)

   Note:

   The **Magnitude** and **Amplitude** fields are unavailable if you are creating the boundary condition in the initial step (in which case the magnitude is always zero) or are fixing the magnitude at the final value from the previous general step.

c. Click **OK** to save your data and to exit the editor.

5. If you selected the **User-defined** distribution option, perform the following steps:

a. If desired, enter the normalized concentration magnitude in the **Magnitude** field. Magnitude data that you enter in the editor are passed into the user subroutine.

(The **Magnitude** field is unavailable if you are creating the boundary condition in the initial step.)

b. Click **OK** to save any entered data and to exit the editor.

c. Enter the Job module, and display the job editor for the analysis job of interest. (For more information, see *Creating, editing, and manipulating jobs*.)

d. In the job editor, click the **General** tab, and specify the file containing the user subroutine that defines the boundary condition. For more information, see *Specifying general job settings*.

Note:

You can specify only one user subroutine file in the job editor; if your analysis involves more than one user subroutine, you must combine the user subroutines into one file and then specify that file.

Defining an acoustic pressure boundary condition

You can create an acoustic pressure boundary condition to specify the pressure for the selected region of an acoustic medium. (For more information, see Boundary Conditions in *Coupled Acoustic-Structural Analysis*.)

1. Display the acoustic pressure boundary condition editor using one of the following methods:
   - To create a new acoustic pressure boundary condition, follow the procedure outlined in *Creating boundary conditions* (**Category**: `Other`; **Types for Selected Step**: `Acoustic pressure`).
   - To edit an existing acoustic pressure boundary condition using menus or managers, see *Editing step-dependent objects*. To edit the region to which the boundary condition is applied, see *Editing the region to which a prescribed condition is applied*.
2. If a **Method** field appears toward the top of the editor, click the arrow to the right of the field, and select one of the following:
   - Select **Specify magnitude** if you want to specify a value for the acoustic pressure.
   - Select **Fixed at current magnitude** if you want to fix the acoustic pressure magnitude at its final value from the previous general step.

   The **Method** option appears in the editor only if both methods are valid for the selected step.
3. If a **Distribution** field appears in the editor, click the arrow to the right of the field, and select one of the following:
   - Select **Uniform** to define a uniform boundary condition.
   - Select **User-defined** to define the boundary condition in user subroutine *DISP*. See the following sections for more information:
     - *Specifying general job settings*
     - *DISP*
   - Select an analytical field to define a spatially varying boundary condition. Only analytical fields that are valid for this boundary condition type are displayed in the selection list. Alternatively, you can click $f(x)$ to create a new analytical field. (See *The Analytical Field toolset* for more information.)

   The **Distribution** option appears in the editor only if you are creating the boundary condition or editing the boundary condition in the step in which it was created. This option is unavailable if you select the **Fixed at current magnitude** method.
4. If you selected the **Uniform** or analytical field distribution option, perform the following steps:
   a. If applicable, enter the magnitude of the acoustic pressure in the **Magnitude** field.
   b. If applicable, click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)

Note:

The **Magnitude** and **Amplitude** fields are unavailable if you are creating the boundary condition in the initial step (in which case the magnitude is always zero) or are fixing the magnitude at its final value from the previous analysis step.

c. Click **OK** to save your data and to exit the editor.

5. If you selected the **User-defined** distribution option, perform the following steps:

a. If desired, enter the acoustic pressure magnitude in the **Magnitude** field. Magnitude data that you enter in the editor are passed into the user subroutine.

(The **Magnitude** field is unavailable if you are creating the boundary condition in the initial step.)

b. Click **OK** to save any entered data and to exit the editor.

c. Enter the Job module, and display the job editor for the analysis job of interest. (For more information, see *Creating, editing, and manipulating jobs*.)

d. In the job editor, click the **General** tab, and specify the file containing the user subroutine that defines the boundary condition. For more information, see *Specifying general job settings*.

Note:

You can specify only one user subroutine file in the job editor; if your analysis involves more than one user subroutine, you must combine the user subroutines into one file and then specify that file.

Additional information

Defining a connector material flow boundary condition

You can create a connector material flow boundary condition to constrain the material flow at the endpoints of a connector.

1. Display the connector material flow boundary condition editor using one of the following methods:
   - To create a new connector material flow boundary condition, follow the procedure outlined in *Creating boundary conditions* (**Category**: `Other`; **Types for Selected Step**: `Connector material flow`).
   - To edit an existing connector material flow boundary condition using menus or managers, see *Editing step-dependent objects*. To edit the region to which the boundary condition is applied, see *Editing the region to which a prescribed condition is applied*.
2. If a **Method** field appears toward the top of the editor, click the arrow to the right of the field and select one of the following:
   - Select **Specify magnitude** if you want to specify a value for the connector material flow.
   - Select **Fixed at current magnitude** if you want to fix the connector material flow magnitude at its final value from the previous general step.

   The **Method** option appears in the editor only if both methods are valid for the selected step.
3. If a **Distribution** field appears in the editor, click the arrow to the right of the field and select one of the following:
   - Select **Uniform** to define a uniform boundary condition.
   - Select **User-defined** to define the boundary condition in user subroutine *DISP* (for Abaqus/Standard). See the following sections for more information:
     - *Specifying general job settings*
     - *DISP*
   - Select an analytical field to define a spatially varying boundary condition. Only analytical fields that are valid for this boundary condition type are displayed in the selection list. Alternatively, you can click  to create a new analytical field. (See *The Analytical Field toolset* for more information.)

   The **Distribution** option appears in the editor only if you are creating the boundary condition or editing the boundary condition in the step in which it was created. This option is unavailable if you select the **Fixed at current magnitude** method.
4. If you selected the **Uniform** or analytical field distribution option, perform the following steps:
   a. If applicable, enter the magnitude of the connector material flow in the **Magnitude** field.
   b. If applicable, click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)

       **Note:**

      The **Magnitude** and **Amplitude** fields are unavailable if you are creating the boundary condition in the initial step (in which case the magnitude is always zero) or are fixing the magnitude at its final value from the previous general step.

c. Click **OK** to save your data and to exit the editor.

5. If you selected the **User-defined** distribution option, perform the following steps:

a. If desired, enter the connector material flow magnitude in the **Magnitude** field. Magnitude data that you enter in the editor are passed into the user subroutine.

(The **Magnitude** field is unavailable if you are creating the boundary condition in the initial step.)

b. Click **OK** to save any entered data and to exit the editor.

c. Enter the Job module, and display the job editor for the analysis job of interest. (For more information, see *Creating, editing, and manipulating jobs*.)

d. In the job editor, click the **General** tab, and specify the file containing the user subroutine that defines the boundary condition. For more information, see *Specifying general job settings*.

Note:

You can specify only one user subroutine file in the job editor; if your analysis involves more than one user subroutine, you must combine the user subroutines into one file and then specify that file.

Defining an Eulerian boundary condition

You can create an Eulerian boundary condition to control the flow of materials into and out of an Eulerian region. Eulerian boundary conditions should be applied only to parts with an Eulerian section assignment, and they cannot be applied in the initial step of an analysis.

1. Display the Eulerian boundary condition editor using one of the following methods:
   - To create a new Eulerian boundary condition, follow the procedure outlined in *Creating boundary conditions* (**Category**: `Other`; **Types for Selected Step**: `Eulerian boundary`).
   - To edit an existing Eulerian boundary condition using menus or managers, see *Editing step-dependent objects*. To edit the region to which the boundary condition is applied, see *Editing the region to which a prescribed condition is applied*.
2. Specify the **Flow type** that the boundary condition will control:
   - **Inflow** controls the flow of Eulerian material into the region across the selected surface.
   - **Outflow** controls the flow of Eulerian material out of the region across the selected surface.
   - **Both** allows you to specify controls for inflow and outflow conditions in the same boundary condition definition.
3. If you selected **Inflow** (or **Both**) as the **Flow type**, select the **Inflow** condition:
   - Select **Free** to allow any new material to flow freely into the Eulerian region. The material that flows into the region is based on the material that currently occupies the region: as Eulerian material inside the region moves away from the boundary surface, the same material flows across the boundary to replace it.
   - Select **None** to prevent inflow of any new Eulerian material (including void) across the boundary surface. Eulerian material inside the region can move tangentially along the boundary surface, but it cannot separate from the boundary surface.
   - Select **Void** to allow only void to flow into the Eulerian region. As Eulerian material inside the region moves away from the boundary surface, void flows across the boundary to replace it.
4. If you selected **Outflow** (or **Both**) as the **Flow type**, select the **Outflow** condition:
   - Select **Zero pressure** to allow material to flow out of the Eulerian region while also enforcing a condition of zero net pressure across the boundary surface using artificial traction forces.
   - Select **Free** to allow material to flow freely out of the Eulerian region without any artificial traction forces.
   - Select **Nonreflecting** to allow material to flow out of the Eulerian region while also minimizing the reflection of dilatational and shear wave energy back into the region using artificial traction forces.
   - Select **Equilibrium** to allow material to flow out of the Eulerian region while also enforcing a condition of zero-order continuous stress across the boundary surface using artificial traction forces.

Additional information

- *Creating and modifying prescribed conditions*
- *Using the Load module*
- *Defining Eulerian Boundaries*

Defining an Eulerian mesh motion boundary condition

Eulerian mesh motion allows an Eulerian mesh—which is usually rigid and undeformable—to expand, contract, and translate during an analysis. As part of the mesh motion definition you identify an object to follow, which can be either a Lagrangian surface or an Eulerian material instance; the Eulerian mesh resizes and moves during the analysis so that it always surrounds this object.

Eulerian mesh motion is calculated based on a rectangular "bounding box" that is constructed by Abaqus. The bounding box cannot be visualized in Abaqus/CAE, but it typically corresponds relatively closely to the Eulerian mesh. The creation and behavior of the bounding box is described in *Eulerian Mesh Motion*. You can set restraints and restrictions on the contraction, expansion, and translation of this bounding box as part of the mesh motion boundary condition definition. These restrictions may prevent the Eulerian mesh from completely encompassing the specified object to follow at all times during the analysis.

Eulerian mesh motion boundary conditions can be applied only to parts with an Eulerian section assignment, and they cannot be applied in the initial step of an analysis.

1. Display the Eulerian mesh motion boundary condition editor using one of the following methods:
   - To create a new Eulerian mesh motion boundary condition, follow the procedure outlined in *Creating boundary conditions* (**Category**: `Other`; **Types for Selected Step**: `Eulerian mesh motion`).
   - To edit an existing Eulerian mesh motion boundary condition using menus or managers, see *Editing step-dependent objects*. To edit the part instance to which the mesh motion definition applies, see *Editing the region to which a prescribed condition is applied*.

2. Specify the **Object to Follow**:
   - To follow a Lagrangian surface, choose **Surface region** and click  to select a surface:
     - Select a surface in the viewport. You can use the angle method to select a group of faces from geometry or a group of element faces from a mesh. For more information, see *Using the angle and feature edge method to select multiple objects*. When you have finished selecting, click mouse button 2.
     - To select from a list of existing surfaces, do the following:
       1. Click **Surfaces** on the right side of the prompt area.

          Abaqus/CAE displays the **Region Selection** dialog box containing a list of available surfaces.
       2. Select the surface of interest, and click **Continue**.

           **Note:**

          The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Surfaces** on the right side of the prompt area.

   - To follow an Eulerian material, choose **Eulerian material instance** and select an instance.

3. By default, the global coordinate system is used to construct the mesh bounding box. To change the coordinate system in which the mesh bounding box is constructed, click  for the **CSYS** option and do one of the following:
   - Select an existing datum coordinate system in the viewport.

- Select an existing datum coordinate system by name.
  1. From the prompt area, click **Datum CSYS List** to display a list of datum coordinate systems.
  2. Select a name from the list, and click **OK**.
- Click **Use Global CSYS** from the prompt area to revert to the global coordinate system.

Alternatively, click  to define a new datum coordinate system.

This coordinate system editing option is available only in the step in which the boundary condition is created.

4. On the **Controls** tabbed page, specify general constraints and limitations on the motion of the mesh bounding box:
   a. To prevent the mesh from contracting during the analysis, toggle off **Allow mesh contraction**. This option is toggled on by default.
   b. Specify an **Aspect ratio limit** for the maximum change allowed in the length to width ratio in any of the three bounding box directions. The value must be greater than or equal to one.
   c. Specify the **Mesh velocity factor**. This factor defines the maximum velocity of the Eulerian mesh as a fraction of the velocity of the object being followed. The value must be greater than or equal to zero.
   d. If the object being followed is an Eulerian material, specify a **Volume fraction threshold**. Elements whose Eulerian material volume fraction are less than this threshold are considered empty for the purposes of mesh motion, and the mesh does not expand or move to account for the material in these elements. The value must be greater than zero and less than or equal to one.
   e. Specify the **Buffer size**, which preserves some distance between the object being tracked and the Eulerian mesh boundary:
      - Select **Specify**, and enter a value to define a buffer equal to the given value times the maximum Eulerian element size. The value must be greater than or equal to zero.
      - Select **Initial** to define a buffer equal to the initial distance between the object and the mesh boundary.
5. On each of the **Axis** tabbed pages, specify limits on the motion of the bounding box in each of its three directions:
   a. Choose whether the original **Center position** is **Free** or **Fixed** along the selected axis.
   b. Choose whether the original **Positive plane position** is **Free** or **Fixed**. The positive plane is the face of the bounding box whose normal is aligned with the positive direction of the selected axis.
   c. Choose whether the original **Negative plane position** is **Free** or **Fixed**. The negative plane is the face of the bounding box whose normal is aligned with the negative direction of the selected axis.
   d. Specify the **Expansion ratio** along the selected axis:
      - Choose **Unlimited** to allow infinite scaling of the bounding box if necessary.
      - Choose **Specify maximum**, and enter a value to define a maximum scaling ratio. The value must be greater than or equal to one.
   e. Specify the minimum **Contraction ratio** along the selected axis. The value must be greater than or equal to zero and less than or equal to one.

Defining an electric potential electrolyte boundary condition

You can create an electric potential electrolyte boundary condition to prescribe an electrical potential of electrolyte on a region. (For more information, see "Boundary conditions," in *Coupled Thermal-Electrochemical Analysis*, *Fully Coupled Thermal-Electrochemical-Structural Analysis* and *Fully Coupled Thermal-Electrochemical-Structural–Pore Pressure Analysis* .)

1. Display the electric potential electrolyte boundary condition editor using one of the following methods:
   - To create a new electric potential electrolyte boundary condition, follow the procedure outlined in *Creating boundary conditions* (**Category**: `Electrical/Magnetic/Electrochemical`; **Types for Selected Step**: `Electric potential electrolyte`).
   - To edit an existing electric potential electrolyte boundary condition using menus or managers, see *Editing step-dependent objects*. To edit the region to which the boundary condition is applied, see *Editing the region to which a prescribed condition is applied*.
2. If a **Method** field appears toward the top of the editor, click the arrow to the right of the field, and select one of the following:
   - Select **Specify magnitude** if you want to specify a value for the electric potential electrolyte.
   - Select **Fixed at current magnitude** if you want to fix the electric potential electrolyte magnitude at its final value from the previous general step.

   The **Method** option appears in the editor only if both methods are valid for the selected step.
3. If a **Distribution** field appears in the editor, click the arrow to the right of the field, and select one of the following:
   - Select **Uniform** to define a uniform boundary condition.
   - Select **User-defined** to define the boundary condition in user subroutine *DISP*. See the following sections for more information:
     - *Specifying general job settings*
     - *DISP*
   - Select an analytical field to define a spatially varying boundary condition. Only analytical fields that are valid for this boundary condition type are displayed in the selection list. Alternatively, you can click  to create a new analytical field. (See *The Analytical Field toolset* for more information.)

   The **Distribution** option appears in the editor only if you are creating the boundary condition or editing the boundary condition in the step in which it was created. This option is unavailable if you select the **Fixed at current magnitude** method.
4. If you selected the **Uniform** or analytical field distribution option, perform the following steps:
   a. If applicable, enter the magnitude of the electric potential electrolyte in the **Magnitude** field.
   b. If applicable, click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)

Note:

The **Magnitude** and **Amplitude** fields are unavailable if you are creating the boundary condition in the initial step (in which case the magnitude is always zero) or are fixing the magnitude at its final value from the previous general step.

c. Click **OK** to save your data and to exit the editor.

5. If you selected the **User-defined** distribution option, perform the following steps:

a. If desired, enter the electric potential electrolyte magnitude in the **Magnitude** field. Magnitude data that you enter in the editor are passed into the user subroutine.

(The **Magnitude** field is unavailable if you are creating the boundary condition in the initial step.)

b. Click **OK** to save any entered data and to exit the editor.

c. Enter the Job module, and display the job editor for the analysis job of interest. (For more information, see *Creating, editing, and manipulating jobs*.)

d. In the job editor, click the **General** tab, and specify the file containing the user subroutine that defines the boundary condition. For more information, see *Specifying general job settings*.

Note:

You can specify only one user subroutine file in the job editor; if your analysis involves more than one user subroutine, you must combine the user subroutines into one file and then specify that file.

Defining an ion concentration boundary condition

You can create an ion concentration boundary condition to prescribe an ion concentration on a region. (For more information, see “Boundary conditions,” in *Coupled Thermal-Electrochemical Analysis*, *Fully Coupled Thermal-Electrochemical-Structural Analysis* and *Fully Coupled Thermal-Electrochemical-Structural–Pore Pressure Analysis* .)

1. Display the ion concentration boundary condition editor using one of the following methods:
   - To create a new ion concentration boundary condition, follow the procedure outlined in *Creating boundary conditions* (**Category**: `Electrical/Magnetic/Electrochemical`; **Types for Selected Step**: `Ion concentration`).
   - To edit an existing ion concentration boundary condition using menus or managers, see *Editing step-dependent objects*. To edit the region to which the boundary condition is applied, see *Editing the region to which a prescribed condition is applied*.
2. If a **Method** field appears toward the top of the editor, click the arrow to the right of the field, and select one of the following:
   - Select **Specify magnitude** if you want to specify a value for the ion concentration.
   - Select **Fixed at current magnitude** if you want to fix the ion concentration magnitude at its final value from the previous general step.

   The **Method** option appears in the editor only if both methods are valid for the selected step.
3. If a **Distribution** field appears in the editor, click the arrow to the right of the field, and select one of the following:
   - Select **Uniform** to define a uniform boundary condition.
   - Select **User-defined** to define the boundary condition in user subroutine *DISP*. See the following sections for more information:
     - *Specifying general job settings*
     - *DISP*
   - Select an analytical field to define a spatially varying boundary condition. Only analytical fields that are valid for this boundary condition type are displayed in the selection list. Alternatively, you can click $f(x)$ to create a new analytical field. (See *The Analytical Field toolset* for more information.)

   The **Distribution** option appears in the editor only if you are creating the boundary condition or editing the boundary condition in the step in which it was created. This option is unavailable if you select the **Fixed at current magnitude** method.
4. If you selected the **Uniform** or analytical field distribution option, perform the following steps:
   a. If applicable, enter the magnitude of the ion concentration in the **Magnitude** field.
   b. If applicable, click the arrow to the right of the **Amplitude** field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.)

Note:

The **Magnitude** and **Amplitude** fields are unavailable if you are creating the boundary condition in the initial step (in which case the magnitude is always zero) or are fixing the magnitude at its final value from the previous general step.

c. Click **OK** to save your data and to exit the editor.

5. If you selected the **User-defined** distribution option, perform the following steps:

a. If desired, enter the ion concentration magnitude in the **Magnitude** field. Magnitude data that you enter in the editor are passed into the user subroutine.

(The **Magnitude** field is unavailable if you are creating the boundary condition in the initial step.)

b. Click **OK** to save any entered data and to exit the editor.

c. Enter the Job module, and display the job editor for the analysis job of interest. (For more information, see *Creating, editing, and manipulating jobs*.)

d. In the job editor, click the **General** tab, and specify the file containing the user subroutine that defines the boundary condition. For more information, see *Specifying general job settings*.

Note:

You can specify only one user subroutine file in the job editor; if your analysis involves more than one user subroutine, you must combine the user subroutines into one file and then specify that file.

Using the predefined field editors

This section explains how to define or initialize specific types of predefined fields.

In this section:

- *Defining an initial velocity field*
- *Defining a hardening field*
- *Defining an initial stress*
- *Defining a geostatic initial stress field*
- *Defining a temperature field*
- *Defining values for predefined field variables*
- *Defining a material assignment field*
- *Defining an initial state field*
- *Defining a saturation field*
- *Defining an initial void ratio field*
- *Defining a pore pressure field in a porous medium*
- *Defining a fluid cavity pressure field*
- *Defining a fluid electric potential field*
- *Defining a solid electric potential field*
- *Defining an ion concentration field*

Defining an initial velocity field

You can create this type of predefined field to define the initial velocity of the selected region. For more information, see *Initial Conditions*.

1. Display the velocity field editor using one of the following methods:
   - To create a new velocity field, follow the procedure outlined in *Creating predefined fields* (**Category**: `Mechanical`; **Types for Selected Step**: `Velocity`).
   - To edit an existing velocity field using menus or managers, see *Editing step-dependent objects*.

   Note:

   You can create or edit an initial velocity only in the initial step.

2. Click the arrow to the right of the **Distribution** field, and select the option of your choice from the list that appears:
   - Select **Uniform** to define an initial velocity that is uniform over the region.
   - Select an analytical field to define a spatially varying initial velocity. Alternatively, you can click  to create a new analytical field. (See *The Analytical Field toolset* for more information.)

3. Click the arrow to the right of the **Definition** field, and select the option of your choice from the list that appears:
   - Select **Translational only** to define an initial translational velocity only.
   - Select **Rotational only** to define an initial rotational velocity only.
   - Select **Translational & rotational** to define both an initial translational velocity and an initial rotational velocity.

4. If you selected the **Translational only** definition option, enter the magnitudes for the initial translational velocities in the 1-, 2-, and (if you are working in three-dimensional space) 3-directions in the **V1**, **V2**, and (if applicable) **V3** text fields. (If you leave a text field blank, an initial translational velocity of zero is assigned to that degree of freedom by default; the velocity must be defined in at least one direction.)
5. If you selected the **Rotational only** definition option:
   a. Enter the magnitude of the angular velocity (in radians/time) in the **Angular velocity** text field.
   b. Define the axis of rotation.
      - For three-dimensional models, enter the *x*-, *y*-, and *z*-coordinates, separated by commas, of the points in the **Axis point 1** and **Axis point 2** text fields.
      - For two-dimensional models, enter the *x*- and *y*-coordinates, separated by a comma, of the point in the **Axis point** text field. Rotation is assumed to be about the positive *z*-axis at the specified point.
      - For axisymmetric models, enter the radius in the **Axis radius** text field. Rotation is assumed to be about the positive *z*-axis at the specified radius.

6. If you selected the **Translational & rotational** definition option, follow the instructions in both Steps 3 and 4.

7. Click **OK** to save your data and to exit the editor.

Additional information

- *Using analytical expression fields*
- *Creating expression fields*
- *Initial Conditions*

Defining a hardening field

You can create a hardening field to define initial values of state variables for plastic hardening. For more information, see *Initial Conditions*.

1. Display the hardening field editor using one of the following methods:
   - To create a new hardening field, follow the procedure outlined in *Creating predefined fields* (**Category**: `Mechanical`; **Types for Selected Step**: `Hardening`).
   - To edit an existing hardening field using menus or managers, see *Editing step-dependent objects*.

   Note:

   You can create or edit a hardening field only in the initial step.

2. Click the arrow to the right of the **Distribution** field, and select the option of your choice from the list that appears:
   - Select **Uniform** to define initial values that are uniform over the region.
   - Select an analytical field to define spatially varying initial values. Alternatively, you can click $f(x)$ to create a new analytical field. (See *The Analytical Field toolset* for more information.)

3. Click the arrow to the right of the **Definition** field, and select the option of your choice from the list that appears:
   - Select **Kinematic hardening** to specify an initial equivalent plastic strain and the initial backstress tensors for kinematic hardening material models.
   - Select **Crushable foam** to specify an initial volumetric compacting plastic strain for the crushable foam material model.
   - Select **Rebar** to specify an initial equivalent plastic strain and the initial backstress tensors for rebar layers. (This option is valid only for Abaqus/Standard analyses.)
   - Select **Section points** to specify an initial equivalent plastic strain and the initial backstress tensors at section points through the thickness of shell elements.
   - Select **User-defined** to specify the initial equivalent plastic strain and, if relevant, the initial backstress tensors in user subroutine *HARDINI*. (This option is valid only in Abaqus/Standard analyses.) See the following sections for more information:
     - *Specifying general job settings*
     - *HARDINI*

4. If applicable, click the arrows to the right of the **Number of backstresses** field to specify the number of backstresses to include in the model. The default number of backstresses is 1. The maximum number of backstresses allowed is 10.

   Additional columns appear in the **Data** table to specify multiple backstress tensors.

5. In the **Data** table, enter the data relevant to your **Definition** selection (not all of the following parameters will apply):

Equiv Plast Strain

Initial equivalent plastic strain, $\bar{\varepsilon}^{pl}\big|_0$.

Vol Plast Strain

Initial volumetric compacting plastic strain, $-\varepsilon_{\text{vol}}^{pl}$.

Rebar Layer Name

Name of rebar layer.

Section Point Number

Section point number.

Alpha 1_11, Alpha 1_22, etc.

Values for each component of the initial first backstress tensor, $\boldsymbol{\alpha 1^0}$.

Alpha k_11, Alpha k_22, etc.

Values for each component of the initial k^{th} backstress tensor, $\boldsymbol{\alpha k^0}$.

6. Click **OK** to save your data and to exit the editor.

Additional information

- *Creating predefined fields*
- *Understanding symbols that represent prescribed conditions*
- *Using analytical expression fields*
- *Creating expression fields*
- *Initial Conditions*

Defining an initial stress

You can create an initial stress field for a region of your model. You can create or modify an initial stress field only in the initial step. For more information, see *Initial Conditions*.

1. Display the stress field editor using one of the following methods:
   - To create a new stress field, follow the procedure outlined in *Creating predefined fields* (**Category**: `Mechanical`; **Types for Selected Step**: `Stress`).
   - To edit an existing stress field using menus or managers, see *Editing step-dependent objects*.

   Note:

   You can create or edit a stress field only in the initial step.

2. Click the arrow to the right of the **Specification** field, and select the option of your choice from the list that appears:
   - Select **Direct specification**, then specify stress components in the data table. You can specify up to six component values.
   - Select **From output database file** to specify stress values from a user-specified output database file.

3. If you are specifying initial stress from an output database file, do the following:
   a. Specify the file name from which you want to import stress values.
   b. From the **Step** and **Increment** fields, specify the step name and increment number from which you want to import stress values.
4. Click **OK** to create the initial stress field and to close the dialog box.

   Blue circles appear on the model representing the initial stress field that you just created.

Additional information

- *Creating predefined fields*
- *Understanding symbols that represent prescribed conditions*
- *Initial Conditions*

Defining a geostatic initial stress field

When a geostatic stress field is prescribed for a particular region, the stress in the vertical direction (assumed to be the *z*-direction in three-dimensional and axisymmetric models and the *y*-direction in two-dimensional models) is assumed to vary (piecewise) linearly with this vertical coordinate. Geostatic stress fields are applicable only to continuum elements. For more information, see *Initial Conditions*. For Abaqus/Explicit analyses, elevation-dependent initial stresses cannot be specified for beams and shells.

1. Display the geostatic stress field editor using one of the following methods:
   - To create a new geostatic stress field, follow the procedure outlined in *Creating predefined fields* (**Category**: `Mechanical`; **Types for Selected Step**: `Geostatic stress`).
   - To edit an existing geostatic stress field using menus or managers, see *Editing step-dependent objects*.

   Note:

   You can create or edit a geostatic stress field only in the initial step.

2. In the **Stress magnitude 1** field, specify the vertical component of (effective) stress at the first location in the region.
3. In the **Vertical coordinate 1** field, specify the vertical coordinate corresponding to the first location in the region.
4. In the **Stress magnitude 2** field, specify the vertical component of (effective) stress at the second location in the region.
5. In the **Vertical coordinate 2** field, specify the vertical coordinate corresponding to the second location in the region.
6. In the **Lateral coefficient 1** field, specify the first coefficient of lateral stress. This coefficient defines the *x*-direction stress component.
7. If desired, toggle on **Specify** for the **Lateral coefficient 2** setting and specify the second coefficient of lateral stress. This coefficient defines the *y*-direction stress component in three-dimensional cases and the thickness or hoop direction component in plane or axisymmetric cases. If this value is omitted, it is assumed to be the same as the first lateral stress coefficient.
8. Click **OK** to save your data and to exit the editor.

   Light blue circles appear on the model representing the initial geostatic stress field that you just created.

Additional information

- *Creating predefined fields*
- *Understanding symbols that represent prescribed conditions*
- *Initial Conditions*

Defining a temperature field

You can define the magnitude and time variation of the temperature of the selected region for each analysis step; Abaqus will interpolate the temperatures to the material points. Alternatively, you can use the temperature values that Abaqus computed during a previous analysis with thermal components to define the temperatures in the current model.

1. Display the temperature field editor using one of the following methods:
   - To create a new temperature field, follow the procedure outlined in *Creating predefined fields* (**Category**: `Other`; **Types for Selected Step**: `Temperature`).

     Note:

     If you want to specify the temperature variation directly in the temperature field editor, in user subroutine *UTEMP*, or using an analytical field or discrete field, you must select a region for the temperature field. If you want to specify any other temperature distribution, you may click **Done** in the prompt area to use a calculated temperature.

   - To edit an existing temperature field using menus or managers, see *Editing step-dependent objects*.

2. If you are editing a temperature field in any general analysis step other than the one in which the field was created, click the arrow to the right of the **Status** field, and select the option of your choice from the list that appears:
   - Select **Propagated** to indicate that the temperature field is active in the current step with temperatures values held constant from the previous step. No data can be specified; click **OK** to exit the editor. If you change the status of the current step from **Modified** to **Propagated** and click **OK**, all modifications to the current step are removed.
   - Select **Modified** to edit the field definition for the current step. Continue with Step 3.
   - Select **Reset to initial** to reset the field definition to the one that was prescribed in the initial step. No data can be specified; click **OK** to reset the field and to exit the editor.

3. If you are creating a new temperature field, click the arrow to the right of the **Distribution** field, and select the option of your choice from the list that appears.

   Note:

   If you are creating a temperature field in the initial step, only the **Direct specification**, **From results or output database file**, analytical field, and discrete field distribution options are available.

   - Select **Direct specification** to specify the temperature variation over the selected region in the temperature field editor.
   - Select **From results or output database file** to read temperature values from the results or output database file of a previous Abaqus analysis with thermal components.
   - Select **User-defined** to define temperature values in user subroutine *UTEMP*. This option is available only for Abaqus/Standard analyses. See the following sections for more information:
     - *Specifying general job settings*
     - *UTEMP*

- Select **From results or output database file and user-defined** to read temperature values from the results or output database file of a previous Abaqus analysis with thermal components and modify them in user subroutine *UTEMP*. This option is available only for Abaqus/Standard analyses.
- Select an analytical field, labeled with an (A), or a discrete field, labeled with a (D), to define a spatially varying temperature. The selection list contains all analytical fields and only discrete fields that are valid for temperature fields.

  Alternatively, you can click $f(x)$ to create a new analytical field. (See *The Analytical Field toolset* for more information.)

4. If you selected the **Direct specification**, analytical field, or discrete field distribution option, perform the following steps:
   a. Click the arrow to the right of the **Section variation** field, and select an option from the list that appears. Only options that are valid for the selected region appear in the list. Beam and shell gradient values are not affected by an analytical field or a discrete field. You should select an option that is consistent with the temperature variation method defined in the section definition associated with the region selected for this field as follows:
      - Select **Constant through region** to define a constant temperature over a section.

        In the **Magnitude** text field, enter the magnitude of the temperature across the section.
      - Select **Gradient through shell section** to define a temperature variation through a shell section. The **Temperature variation** method in the shell section editor must specify **Linear through thickness**.

        In the **Reference magnitude** text field, enter the magnitude of the temperature at the reference surface. In the **Thickness gradient** text field, enter the temperature gradient through the section.
      - Select **Gradient through beam section** to define a temperature variation through a beam section. (This method is not available for axisymmetric models.) The **Temperature variation** method in the beam section editor must specify **Linear by gradients**.

        In the **Reference magnitude** text field, enter the magnitude of the temperature at the cross-section origin. In the **N1 gradient** and **N2 gradient** text fields, enter the temperature gradients through the section in the $\mathbf{n_1}$- and $\mathbf{n_2}$-directions of the beam, respectively. For beams in a plane only the temperature magnitude and the **N2 gradient** must be specified.
      - Select **Defined at shell/beam temperature points** to define a piecewise linear temperature variation through a shell or beam section. The **Temperature variation** method in the shell section editor must specify **Piecewise linear over *n* values**. The **Temperature variation** method in the beam section editor must specify **Interpolated from temperature points**.

        Select the number of temperature points to be specified by either typing an integer in the **Temperature points** text field or using the arrows to the right of the text field to select a number, and enter the magnitude of the temperature at each point in the **Section Data** table. The number of values in the section definition should be less than or equal to the number of temperature data points given for this field. If the number of values is less, the last value will be repeated to match the number of temperature data points.

   b. If desired (for all steps other than the initial step), click the arrow to the right of the **Amplitude** text field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.) Beam and shell gradient values will be modified by the amplitude definition.
   c. Click **OK** to save your data and to exit the editor.

5. If you selected the **From results or output database file** distribution option, perform the following steps:
   a. In the **File name** text field, enter the name of the results or output database file from which temperature data are to be read; or click  to display the **Select Results or Output Database File** dialog box and select the file of your choice. (See *Using file selection dialog boxes* for more information.)
   b. If you are creating a temperature field in the initial step:
      - In the **Step** text field, enter the step number of the analysis whose results or output database file is being used as input from which the field data should be read.
      - In the **Increment** text field, enter the increment number of the analysis whose results or output database file is being used as input from which the field data should be read.
   c. Optionally, if you are creating a temperature field in an analysis step other than the initial step:
      - In the **Begin step** text field, enter the step number of the analysis whose results or output database file is being used as input that begins the field data to be read. By default, the first step available in the results or output database file will be used.
      - In the **Begin increment** text field, enter the increment number of the analysis whose results or output database file is being used as input that begins the field data to be read. By default, the first increment available in the results or output database file will be used.
      - In the **End step** text field, enter the step number of the analysis whose results or output database file is being used as input that ends the field data to be read. By default, the **Begin step** value will be used.
      - In the **End increment** text field, enter the increment number of the analysis whose results or output database file is being used as input that ends the field data to be read. By default, the last increment available for the **End step** value in the results or output database file will be used.
   d. Choose the **Mesh compatibility**.
      - Select **Compatible** if the meshes in the original analysis and the current analysis are the same or differ only in the element order.

        If the original and current meshes differ only in the element order, you must indicate that midside node temperatures in second-order elements are to be interpolated from corner node temperatures by toggling on **Interpolate midside nodes**.
      - Select **Incompatible** if the meshes in the original analysis and the current analysis are dissimilar. This option is valid only if the temperature values are being read from an output database file.
   e. If the original and current meshes are dissimilar, you can specify a value for the **Exterior tolerance**.
      - Specify the **absolute** value by which nodes of the current model may lie outside the region of the elements of the original model. If this value is not specified or is 0.0, the **relative** tolerance will apply.
      - Specify the **relative** fraction of the average element size by which nodes of the current model may lie outside the region of the elements of the original model.

      If both tolerances are specified, Abaqus uses the tighter tolerance.
   f. Click **OK** to save your data and to exit the editor.
6. If you selected the **User-defined** distribution option, perform the following steps:

a. Click **OK** to exit the editor.

b. Enter the Job module, and display the job editor for the analysis job of interest. (For more information, see *Creating, editing, and manipulating jobs*.)

c. In the job editor, click the **General** tab, and specify the file containing the user subroutine that defines the temperature field. For more information, see *Specifying general job settings*.

Note:

You can specify only one user subroutine file in the job editor; if your analysis involves more than one user subroutine, you must combine the user subroutines into one file and then specify that file.

7. If you selected the **From results or output database file and user-defined** distribution option, follow the procedures outlined in Steps 5 and 6 for the **From results or output database file** and **User-defined** distribution options.

Defining values for predefined field variables

You can define the initial value and the magnitude and time variation of a field variable over a selected region for each analysis step; Abaqus interpolates the values to the material points.

1. Display the predefined field variable editor using one of the following methods:
   - To create a new predefined field variable, follow the procedure outlined in *Creating predefined fields* (**Category**: `Other`; **Types for Selected Step**: `Field`).

     Note:

     If you want to specify the field variable variation directly in the editor, in user subroutine *UFIELD* or *VUFIELD*, or using an analytical field or discrete field, you must select a region for the field variable. If you want to specify any other field distribution, you can click **Done** in the prompt area to use calculated fields.

   - To edit an existing field variable using menus or managers, see *Editing step-dependent objects*.

2. If you are editing a field variable in any general analysis step other than the one in which the field variable was created, click the arrow to the right of the **Status** field, and select the option of your choice from the list that appears:
   - Select **Propagated** to indicate that the field variable is active in the current step with field variable values held constant from the previous step. No data can be specified; click **OK** to exit the editor. If you change the status of the current step from **Modified** to **Propagated** and click **OK**, all modifications to the current step are removed.
   - Select **Modified** to edit the field variable definition for the current step. Continue with Step 3.
   - Select **Reset to initial** to reset the field variable definition to the one that was prescribed in the initial step. No data can be specified; click **OK** to reset the field and to exit the editor.

3. If you are creating a new field variable, click the arrow to the right of the **Distribution** field, and select the option of your choice from the list that appears.

   Note:

   If you are creating a field variable in the initial step, only the **Direct specification**, **From results or output database file**, analytical field, and discrete field distribution options are available.

   - Select **Direct specification** to specify the field variable variation over the selected region in the field editor.
   - Select **From results or output database file** to read field variable values from the results or output database file of a previous Abaqus analysis.
   - Select **User-defined** to define field variable values in user subroutine *UFIELD* for Abaqus/Standard analyses or user subroutine *VUFIELD* for Abaqus/Explicit analyses. See *Specifying general job settings* for more information.
   - Select **From results or output database file and user-defined** to read field variable values from the results or output database file of a previous Abaqus analysis and modify them in user subroutine *UFIELD* or *VUFIELD*.
   - Select an analytical field, labeled with an (A), or a discrete field, labeled with a (D), to define a spatially varying field variable. The selection list contains all analytical fields and only discrete fields that are valid for the field variable.

Alternatively, you can click $f(x)$ to create a new analytical field. (See *The Analytical Field toolset* for more information.)

4. If you selected the **Direct specification**, analytical field, or discrete field distribution option, perform the following steps:
   a. Click the arrows to right of the **Field variable number** field to indicate the number of the field variable you are defining.
   b. Click the arrow to the right of the **Section variation** field, and select an option from the list that appears. Only options that are valid for the selected region appear in the list. Beam and shell gradient values are not affected by an analytical field or a discrete field. You should select an option that is consistent with the field variable variation method defined in the section definition associated with the region selected for this field variable as follows:
      - Select **Constant through region** to define a constant field variable value over a section.

        In the **Magnitude** text field, enter the magnitude of the field variable across the section.
      - Select **Gradient through beam section** to define the field variable variation through a beam section. (This method is not available for axisymmetric models.)

        In the **Reference magnitude** text field, enter the magnitude of the field variable at the cross-section origin. In the **N2 gradient** text field, enter the field variable gradients through the section in the $\mathbf{n_2}$-direction of the beam.
      - Select **Defined at shell/beam field points** to define a piecewise linear field variable variation through a shell or beam section.

        Select the number of field points to be specified by either typing an integer in the **Field points** text field or using the arrows to the right of the text field to select a number, and enter the magnitude of the field variable at each point in the **Section Data** table. The number of values in the section definition should be less than or equal to the number of field variable data points given for this field. If the number of values is less, the last value will be repeated to match the number of field variable data points.

   c. If desired (for all steps other than the initial step), click the arrow to the right of the **Amplitude** text field, and select the amplitude of your choice from the list that appears. Alternatively, you can click  to create a new amplitude. (See *The Amplitude toolset* for more information.) Beam and shell gradient values will be modified by the amplitude definition.
   d. Click **OK** to save your data and to exit the editor.
5. If you selected the **From results or output database file** distribution option, perform the following steps:
   a. Click the arrows to the right of the **Field variable number** field to indicate the number of the field variable you are defining. The default is field variable number 1. To define more than one field variable, you can create additional predefined fields. You must number the field variables consecutively starting from 1.
   b. In the **File name** text field, enter the name of the results or output database file from which field variable data are to be read; or click  to display the **Select Results or Output Database File** dialog box and select the file of your choice. (See *Using file selection dialog boxes* for more information.)
   c. If you are reading results from an output database in an Abaqus/Standard analysis, you can specify a scalar nodal output variable to be read and used to initialize the field variable.
   d. If you are creating a field variable in the initial step:

- In the **Step** text field, enter the step number of the analysis whose results or output database file is being used as input from which the field variable data should be read.
- In the **Increment** text field, enter the increment number of the analysis whose results or output database file is being used as input from which the field variable data should be read.

e. Optionally, if you are creating a field variable in an analysis step other than the initial step:

- In the **Begin step** text field, enter the step number of the analysis whose results or output database file is being used as input that begins the field variable data to be read. By default, the first step available in the results or output database file is used.
- In the **Begin increment** text field, enter the increment number of the analysis whose results or output database file is being used as input that begins the field variable data to be read. By default, the first increment available in the results or output database file is used.
- In the **End step** text field, enter the step number of the analysis whose results or output database file is being used as input that ends the field variable data to be read. By default, the **Begin step** value is used.
- In the **End increment** text field, enter the increment number of the analysis whose results or output database file is being used as input that ends the field variable data to be read. By default, the last increment available for the **End step** value in the results or output database file is used.

f. Choose the **Mesh compatibility**.

- Select **Compatible** if the meshes in the original analysis and the current analysis are the same or differ only in the element order.
- Select **Incompatible** if the meshes in the original analysis and the current analysis are dissimilar. This option is valid only if the field variable values are being read from an output database file.

g. Click **OK** to save your data and to exit the editor.

6. If you selected the **User-defined** distribution option, perform the following steps:

a. Click **OK** to exit the editor.

b. Enter the Job module, and display the job editor for the analysis job of interest. (For more information, see *Creating, editing, and manipulating jobs*.)

c. In the job editor, click the **General** tab, and specify the file containing the user subroutine that defines the field variable values. For more information, see *Specifying general job settings*.

Note:

You can specify only one user subroutine file in the job editor; if your analysis involves more than one user subroutine, you must combine the user subroutines into one file and then specify that file.

7. If you selected the **From results or output database file and user-defined** distribution option, follow the procedures outlined in Steps 5 and 6 for the **From results or output database file** and **User-defined** distribution options.

Defining a material assignment field

A material assignment field is used to specify the geometric composition of different materials in the initial state of an Eulerian part instance.
The available materials that can be assigned depend on the material instances defined in the Eulerian section assigned to the part. For a general overview of material assignments for Eulerian parts, see *Assigning materials to Eulerian part instances*.

Each Eulerian part instance in a model can have only one material assignment field applied to it. Conversely, a material assignment field can be applied to only one Eulerian part instance; if you have multiple Eulerian part instances in your model, you must create a material assignment field for each instance.

Materials are assigned by selecting a region of the Eulerian part instance, then specifying the material instances that are present in that region. Each material instance is assigned a percentage indicating the volume fraction occupied by the material instance within the selected region. If the material instance percentages within a region do not add up to 100%, the remaining volume fraction in the region is occupied by a void with no material properties. A void is also assigned by default to any regions within the part instance for which a material assignment is not explicitly specified. For a detailed discussion of how Abaqus interprets material volume fractions, refer to *Eulerian Analysis*.

1. Display the material assignment field editor using one of the following methods:
   - To create a new material assignment field, follow the procedure outlined in *Creating predefined fields* (**Category**: `Other`; **Types for Selected Step**: `Material assignment`). You can create a material assignment field only during the initial step.
   - To edit an existing material assignment field using menus or managers, see *Editing step-dependent objects*. You can modify a material assignment field only during the initial step, and you cannot edit the region to which the material assignment field is applied.

2. Specify the method you are using to define volume fractions for each material instance:
   - Choose **Uniform** to define volume fractions that are uniform across each region.
   - Choose **Discrete fields** to define the volume fractions using discrete fields. Discrete fields can be used to define volume fractions that are spatially varying across a region.

3. Select a region for the material assignment. The region must be contained within the part instance that was selected in Step 1. If the Eulerian part consists of a single cell (there are no interior partitions), Abaqus/CAE automatically selects the whole part.
   a. Click mouse button 3 in the **Region** column of the **Volume Fractions** table, and select **Edit Region** from the menu that appears. Alternatively, you can double-click mouse button 1 in the **Region** column.
   b. Select cells in the part instance using one of the following methods:
      - Select and unselect cells in the viewport. When you have finished selecting the cells, click mouse button 2. (For more information, see *Selecting objects within the viewport*.)
      - To select from a list of existing sets, click **Sets** on the right side of the prompt area, select the set of interest in the **Region Selection** dialog box, and click **Continue**.

Note:

The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

4. The remaining columns in the **Volume Fractions** table correspond to the material instances in the Eulerian section. The material instance name is appended to the part instance name in the column headings (for example, a column labeled **Bottle-1.Water** corresponds to a material instance named `Water` in a part instance named `Bottle-1`). If you are defining uniform volume fractions, a **Void** column also appears; you cannot edit values in the **Void** column. In the columns corresponding to each material instance, enter the appropriate volume fraction for the region:

   - If you are defining uniform volume fractions, enter the volume fraction for each material instance as a percentage in decimal form. For example, enter `0.45` for a volume fraction of 45%. Values greater than `1` are automatically reset to `1`. To assign all material instances equally to a region, click mouse button 3 anywhere in the **Volume Fractions** table, and select **Equalize Rows** from the menu that appears.

     Note:

     As you enter material volume fractions, Abaqus/CAE automatically adjusts the value in the **Void** column so that all values in the table row sum to one. If the sum of the entered values is greater than one, Abaqus/CAE automatically sets **Void** to zero and normalizes the remaining values so that they sum to one.

   - If you are defining the volume fractions using discrete fields, click in the material instance columns; then click the arrow that appears and select a name from the list of available discrete fields. If the discrete field has not been defined, click mouse button 3 anywhere in the **Volume Fractions** table, and select **Create Discrete Field** from the menu that appears to access the Discrete Field toolset (see *Creating discrete fields*). Volume fractions in the discrete field definition should be specified as percentages in decimal form; for example, enter `0.45` for a volume fraction of 45%. Data in the discrete field definition for elements that are not within the selected region are ignored.

     Warning:

     Because discrete fields are mesh-dependent, subsequent modifications to the Eulerian part mesh will invalidate a material assignment based on discrete fields.

5. To clear all material volume fraction values from a row, click mouse button 3 anywhere in the row, and select **Clear Rows** from the menu that appears.
6. To define material volume fractions in another region of the part instance, click mouse button 3 in the **Volume Fractions** table, and select **Add Row** from the menu that appears.

   Abaqus/CAE adds a new row to the **Volume Fractions** table. Repeat the above steps to define a new region and its associated material volume fractions.
7. Once material instances have been appropriately assigned to all regions of the part instance, click **OK** to save your data and to exit the material assignment field editor. If material instances are not assigned to some regions of the part instance, those regions are initially assigned a void with no material properties.

Additional information

- *Creating Eulerian sections*
- *Creating predefined fields*
- *Eulerian analyses*

Defining an initial state field

You can select part instances from your model and associate an initial state field with the instances. An initial state field defines a deformed mesh and its associated material state using data imported from a previous Abaqus/Standard or Abaqus/Explicit analysis. You can create an initial state field only during the initial step. For more information, see *Transferring results between Abaqus analyses*, and *About Transferring Results between Abaqus Analyses*.

1. Display the initial state field editor using one of the following methods:
   - To create a new initial field, follow the procedure outlined in *Creating predefined fields* (**Category**: `Other`; **Types for Selected Step**: `Initial state`). You can create an initial state field only during the initial step.
   - To edit an existing initial state field using menus or managers, see *Editing step-dependent objects*. You can modify an initial state field only during the initial step.
2. In the **Job name** field of the editor, enter the name of the job from which Abaqus/CAE will import the deformed mesh and material state. Abaqus/CAE imports data from several of the files created by the original analysis. As a result, the files from the analysis must reside in the directory from which you started the current Abaqus/CAE session.
3. Choose the step from which to import. Do one of the following:
   - Choose **Last step** to import data from the last step of the previous analysis.
   - Choose **Specify**, and enter an integer specifying the step from which to import data from the previous analysis. A value of 1 specifies the first step.
4. Choose the frame from which to import. Do one of the following:
   - Choose **Last** to import data from the last frame of the specified step.
   - Choose **Specify**, and enter an integer specifying the frame of the specified step. A value of 1 specifies the first frame.
5. By default, Abaqus/CAE does not use the imported data to update the reference configuration. As a result, displacements and strains are calculated as total values relative to the reference configuration at the start of the analysis and will be continuous from the start of the analysis. Toggle on **Update reference configuration** to reset the reference configuration to be the imported configuration. Displacements and strains are now calculated relative to the new imported configuration.
6. Click **OK** to create the initial state field and to close the dialog box.

   Yellow circles appear on the model representing the initial field that you just created. For more information, see *Understanding symbols that represent prescribed conditions*. Although Abaqus/CAE checks that the files from the previous analysis exist when you create the initial state field, it imports the deformed mesh and the material state from the specified step and increment only when you analyze the model in the Job module. As a result, you will not see any other changes in the current model after you create the initial state field; for example, Abaqus/CAE does not update the mesh of the current model.

Defining a saturation field

You can define the initial saturation, *s*, for a region in a coupled pore fluid diffusion/stress analysis (see *Coupled Pore Fluid Diffusion and Stress Analysis*). You can create an initial saturation field only during the initial step.

1. Display the saturation field editor using one of the following methods:
   - To create a new saturation field, follow the procedure outlined in *Creating predefined fields* (**Category**: `Other`; **Types for Selected Step**: `Saturation`).
   - To edit an existing saturation field using menus or managers, see *Editing step-dependent objects*.
2. Click the arrow to the right of the **Distribution** field, and select the option of your choice from the list that appears:
   - Select **Uniform** to define an initial saturation that is uniform over the region.
   - Select an analytical field to define a spatially varying initial saturation. Alternatively, you can click $f(x)$ to create a new analytical field. (See *The Analytical Field toolset* for more information.)
3. From the **Saturation** field, specify an initial saturation value for the region between `0.0` (for no saturation) and `1.0` (for full saturation).
4. Click **OK** to create the saturation field and to close the dialog box.

   Green squares appear on the model representing the initial saturation field that you just created.

Defining an initial void ratio field

For Abaqus/Standard analyses you can specify the initial values of the void ratio, *e*, at the nodes of a porous medium (see *Coupled Pore Fluid Diffusion and Stress Analysis*). The initial void ratio can be defined directly as an elevation-dependent function, by interpolation from the output database file of a previous Abaqus analysis, or by user subroutine *VOIDRI*. For more information, see *Initial Conditions*. You can create or modify an initial void ratio field only during the initial step.

1. Display the initial void ratio field editor using one of the following methods:
   - To create a new initial void ratio field, follow the procedure outlined in *Creating predefined fields* (**Category**: `Other`; **Types for Selected Step**: `Void ratio`).
   - To edit an existing initial void ratio field using menus or managers, see *Editing step-dependent objects*.

2. Click the arrow to the right of the **Point 1 distribution** field, and select the option of your choice from the list that appears:
   - Select **Uniform** to define a void ratio that is uniform for the selected region.
   - Select **From output database file** to read void ratio values from the output database file of a previous Abaqus analysis with void ratio components.
   - Select **User-defined** to specify void ratio using options in user subroutine *VOIDRI*. See the following sections for more information:
     - *Specifying general job settings*
     - *VOIDRI*
   - Select an analytical field to define a spatially varying initial void ratio. Alternatively, you can click $f(x)$ to create a new analytical field. (See *The Analytical Field toolset* for more information.)

3. For uniform distributions, do the following:
   a. From the **Elevation distribution** options, select either **Linear** or **Constant**.
   b. In the **Void ratio 1** field, specify the initial void ratio in the first region in your model.
   c. If you selected an elevation distribution that varies linearly, specify the following options:
      - In the **Vertical coordinate 1** field, specify the vertical position of the first location in your model for which you are specifying initial void ratio.
      - In the **Point 2 distribution** field, specify either a **Uniform** distribution for void ratio at the second elevation or select an analytical field to define a spatially varying initial void ratio at the second elevation. If you select **Uniform**, specify the void ratio and vertical position of the second location in your model.

4. If you are specifying void ratio output from an output database file, do the following:
   a. Specify the file name from which you want to import void ratio values.
   b. From the **Step** options, either select **Last** to read void ratio output from the last step of the output database or select **Specify** and enter the number of the step from which you want to read void ratio data.
   c. From the **Increment** options, either select **Last** to read void ratio output from the last increment of the selected step or select **Specify** and enter the number of the increment from which you want to read void ratio data.
   d. Toggle on **Interpolate midside nodes** to interpolate void ratio values between dissimilar meshes.

5. For user-defined void ratio distributions, do the following:
   a. Enter the Job module, and display the job editor for the analysis job of interest. (For more information, see *Creating, editing, and manipulating jobs*.)
   b. In the job editor, click the **General** tab, and specify the file containing the user subroutine that defines the predefined field. For more information, see *Specifying general job settings*.

   Note:

   You can specify only one user subroutine file in the job editor; if your analysis involves more than one user subroutine, you must combine the user subroutines into one file and then specify that file.

6. Click **OK** to create the initial void ratio field and to close the dialog box.

   Sandy brown squares appear on the model representing the initial void ratio field that you just created.

Additional information

- *Understanding symbols that represent prescribed conditions*
- *Creating predefined fields*

Defining a pore pressure field in a porous medium

For Abaqus/Standard analyses you can define the initial pore pressure field, u_w, for nodes in a coupled pore fluid diffusion/stress analysis (see *Coupled Pore Fluid Diffusion and Stress Analysis*). The initial pore pressure can be defined directly as an elevation-dependent function, by interpolation from the output database file of a previous Abaqus analysis, or by user subroutine *UPOREP*. You can create or modify a pore pressure field only during the initial step. For more information, see *Initial Conditions*.

1. Display the pore pressure field editor using one of the following methods:
   - To create a new pore pressure field, follow the procedure outlined in *Creating predefined fields* (**Category**: `Other`; **Types for Selected Step**: `Pore pressure`). You can create a pore pressure field only during the initial step.
   - To edit an existing pore pressure field using menus or managers, see *Editing step-dependent objects*. You can modify a pore pressure field only during the initial step.

2. Click the arrow to the right of the **Point 1 distribution** field, and select the option of your choice from the list that appears:
   - Select **Uniform** to define a pore pressure that is uniform for the selected region.
   - Select **From output database file** to read pore pressure values from the output database file of a previous Abaqus analysis with pore pressure components.
   - Select **User-defined** to specify pore pressure output using options in user subroutine *UPOREP*. See the following sections for more information:
     - *Specifying general job settings*
     - *UPOREP*
   - Select an analytical field to define a spatially varying initial pore pressure. Alternatively, you can click $f(x)$ to create a new analytical field. (See *The Analytical Field toolset* for more information.)

3. For uniform distributions, do the following:
   a. From the **Elevation distribution** options, select either **Linear** or **Constant**.
   b. In the **Pore pressure 1** field, specify the initial pore pressure in the first region in your model.
   c. If you selected an elevation distribution that varies linearly, specify the following options:
      - In the **Vertical coordinate 1** field, specify the vertical position of the first location in your model for which you are specifying initial pore pressure.
      - In the **Point 2 distribution** field, specify either a **Uniform** distribution for pore pressure at the second elevation or select an analytical field to define a spatially varying initial pore pressure at the second elevation. If you select **Uniform**, specify the pore pressure and vertical position of the second location in your model.

4. If you are specifying pore pressure output from an output database file, do the following:
   a. Specify the file name from which you want to import pore pressure values.
   b. From the **Step** options, either select **Last** to read pore pressure output from the last step of the output database or select **Specify** and enter the number of the step from which you want to read pore pressure data
   c. From the **Increment** options, either select **Last** to read pore pressure output from the last increment of the selected step or select **Specify** and enter the number of the increment from which you want to read pore pressure data.

d. Toggle on **Interpolate midside nodes** to interpolate pore pressure values between dissimilar meshes.

5. For user-defined pore pressure distributions, do the following:

a. Enter the Job module, and display the job editor for the analysis job of interest. (For more information, see *Creating, editing, and manipulating jobs*.)

b. In the job editor, click the **General** tab, and specify the file containing the user subroutine that defines the predefined field. For more information, see *Specifying general job settings*.

Note:

You can specify only one user subroutine file in the job editor; if your analysis involves more than one user subroutine, you must combine the user subroutines into one file and then specify that file.

6. Click **OK** to create the pore pressure field and to close the dialog box.

Magenta squares appear on the model representing the initial pore pressure field that you just created.

Defining a fluid cavity pressure field

You can define the initial fluid cavity pressure for fluid-filled cavities (see *About Surface-Based Fluid Cavities*). You can create or modify a fluid cavity pressure field only during the initial step. For more information, see *Initial Conditions*. To modify fluid cavity pressure in a step other than the initial step, you must define a fluid cavity pressure boundary condition (for more information, see *Defining a fluid cavity pressure boundary condition*).

1. Display the fluid cavity pressure field editor using one of the following methods:
   - To create a new fluid cavity pressure field, follow the procedure outlined in *Creating predefined fields* (**Category**: `Other`; **Types for Selected Step**: `Fluid cavity pressure`). You can create a fluid cavity pressure field only during the initial step.
   - To edit an existing fluid cavity pressure field using menus or managers, see *Editing step-dependent objects*. You can modify a fluid cavity pressure field only during the initial step.
2. Click the arrow to the right of the **Fluid cavity interaction** field, and select the interaction to which the fluid cavity pressure applies.
3. Enter the **Fluid cavity pressure**.
4. Click **OK** to create the fluid cavity pressure field and to close the dialog box.

   A green diamond appears at the fluid cavity reference point representing the initial fluid cavity pressure field that you just created.

Defining a fluid electric potential field

You can define the initial fluid electric potential, for a region in an electrochemical analysis procedures (see *About Electrochemical Analysis Procedures*).

1. Display the fluid electric potential field editor using one of the following methods:
   - To create a new fluid electric potential field, follow the procedure outlined in *Creating predefined fields* (**Category**: `Other`; **Types for Selected Step**: `Fluid Electric potential`).
   - To edit an existing fluid electric potential field using menus or managers, see *Editing step-dependent objects*.
2. Click the arrow to the right of the **Distribution** field, and select the option of your choice from the list that appears:
   - Select **Uniform** to define an initial fluid electric potential that is uniform over the region.
   - Select an analytical field to define a spatially varying initial fluid electric potential. Alternatively, you can click $f(x)$ to create a new analytical field. (See *The Analytical Field toolset* for more information.)
3. From the **Fluid Electric Potential** field, specify an initial fluid electric potential value for the region.
4. Click **OK** to create the fluid electric potential field and to close the dialog box.

   Green squares appear on the model representing the initial fluid electric potential field that you just created.

Defining a solid electric potential field

You can define the initial solid electric potential, for a region in an electrochemical analysis procedures (see *About Electrochemical Analysis Procedures*).

1. Display the solid electric potential field editor using one of the following methods:
   - To create a new solid electric potential field, follow the procedure outlined in *Creating predefined fields* (**Category**: `Other`; **Types for Selected Step**: `Solid Electric potential`).
   - To edit an existing solid electric potential field using menus or managers, see *Editing step-dependent objects*.
2. Click the arrow to the right of the **Distribution** field, and select the option of your choice from the list that appears:
   - Select **Uniform** to define an initial solid electric potential that is uniform over the region.
   - Select an analytical field to define a spatially varying initial solid electric potential. Alternatively, you can click $f(x)$ to create a new analytical field. (See *The Analytical Field toolset* for more information.)
3. From the **Solid Electric Potential** field, specify an initial solid electric potential value for the region.
4. Click **OK** to create the solid electric potential field and to close the dialog box.

   Green squares appear on the model representing the initial solid electric potential field that you just created.

Defining an ion concentration field

You can define the initial ion concentration, for a region in an electrochemical analysis procedures (see *About Electrochemical Analysis Procedures*).

1. Display the ion concentration field editor using one of the following methods:
   - To create a new ion concentration field, follow the procedure outlined in *Creating predefined fields* (**Category**: `Other`; **Types for Selected Step**: `Ion Concentration`).
   - To edit an existing ion concentration field using menus or managers, see *Editing step-dependent objects*.
2. Click the arrow to the right of the **Distribution** field, and select the option of your choice from the list that appears:
   - Select **Uniform** to define an initial ion concentration that is uniform over the region.
   - Select an analytical field to define a spatially varying initial ion concentration. Alternatively, you can click $f(x)$ to create a new analytical field. (See *The Analytical Field toolset* for more information.)
3. From the **Ion Concentration** field, specify an initial ion concentration value for the region.
4. Click **OK** to create the ion concentration field and to close the dialog box.
   Green squares appear on the model representing the initial ion concentration field that you just created.

The Mesh module

The Mesh module contains tools that allow you to generate meshes on parts and assemblies created within Abaqus/CAE. In addition, the Mesh module contains functions that verify an existing mesh.

For information on editing orphan nodes and elements, see *What can I do with the Edit Mesh toolset?*.

In this section:

- *Obtaining mesh information and statistics*
- *Creating a mesh part*
- *Controlling adaptive remeshing*

Understanding the role of the Mesh module

The Mesh module allows you to generate meshes on parts and assemblies created within Abaqus/CAE. Various levels of automation and control are available so that you can create a mesh that meets the needs of your analysis. As with creating parts and assemblies, the process of assigning mesh attributes to the model—such as seeds, mesh techniques, and element types—is feature based. As a result you can modify the parameters that define a part or an assembly, and the mesh attributes that you specified within the Mesh module are regenerated automatically.

The Mesh module provides the following features:

- Tools for prescribing mesh density at local and global levels.
- Model coloring that indicates the meshing technique assigned to each region in the model.
- A variety of mesh controls, such as:
  - Element shape
  - Meshing technique
  - Meshing algorithm
  - Adaptive remeshing rule
- A tool for assigning Abaqus/Standard or Abaqus/Explicit element types to mesh elements. The elements can belong either to a model that you created or to an orphan mesh.
- A tool for verifying mesh quality.
- Tools for refining the mesh and for improving the mesh quality.
- A tool for saving the meshed assembly or selected part instances as a mesh part.

Entering and exiting the Mesh module

You can enter the Mesh module at any time during an Abaqus/CAE session by clicking **Mesh** in the **Module** list located in the context bar. Upon entering the **Mesh** module, the Abaqus/CAE interface changes in the following ways:

- The **Seed**, **Mesh**, **Feature**, and **Tools** menus appear on the main menu bar.
- The **Object** field that appears in the context bar allows you to display either a part or the assembly.
- Abaqus/CAE may change the color of the part instances in the assembly displayed in the viewport. These color cues describe the meshability and dependence of each instance. Independent instances appear in a color that describes their meshability, while dependent intances appear blue in the Assembly context and white in the Part context. See *Meshing independent and dependent part instances*.

Note:

Part instances are color coded according to their meshability and dependence only when the **Mesh defaults** color mapping is selected. If you displayed the default color mapping in a different module, Abaqus/CAE applies the **Mesh defaults** color mapping automatically upon your entry to the Mesh module. If you selected a non-default color mapping such as **Materials** in a different module, Abaqus/CAE continues color coding according to that color mapping (in this case, by material type) when you enter the Mesh module.

To exit the Mesh module, select any other module from the **Module** list. You need not save your mesh before exiting the module; it will be saved automatically when you save the entire model by selecting **File->Save** or **File->Save As** from the main menu bar.

Mesh module basics

This section provides brief explanations of terms and concepts that you must understand to use the Mesh module effectively. It gives you an overview of the functions available and describes the role that each function plays in the mesh creation process.

In this section:

- *The meshing process*
- *Mesh attributes and controls*
- *Mesh generation*
- *Top-down meshing*
- *Bottom-up meshing*
- *Mesh technique color coding*
- *Mesh refinement*
- *Mesh optimization*
- *Mesh verification*
- *Meshing independent and dependent part instances*
- *Displaying a native mesh*

The meshing process

To create an acceptable mesh, you use the following process:

Assign mesh attributes and set mesh controls

The Mesh module provides a variety of tools that allow you to specify different mesh characteristics, such as mesh density, element shape, and element type.

Generate the mesh

The Mesh module uses a variety of techniques to generate meshes. The different mesh techniques provide you with different levels of control over the mesh.

Refine the mesh

The Mesh module provides a variety of tools that allow you to refine the mesh:

- The seeding tools allow you to adjust the mesh density in selected regions.
- The Partition toolset allows you to partition complex models into simpler subregions.
- The Virtual Topology toolset allows you to simplify your model by combining small faces and edges with adjacent faces and edges.
- The Edit Mesh toolset allows you to make minor adjustments to your mesh.

Optimize the mesh

You can assign remeshing rules to regions of your model. Remeshing rules enable successive refinement of your mesh where each refinement is based on the results of an analysis.

Verify the mesh

The verification tools provide you with information concerning the quality of the elements used in a mesh.

Mesh attributes and controls

Abaqus/CAE provides you with a variety of tools for controlling mesh characteristics:

- You can specify the density of a mesh by creating seeds along the edges of the model to indicate where the corner nodes of the elements should be located. For example, *Figure 1* displays a model with biased seeding along the top and left edges.

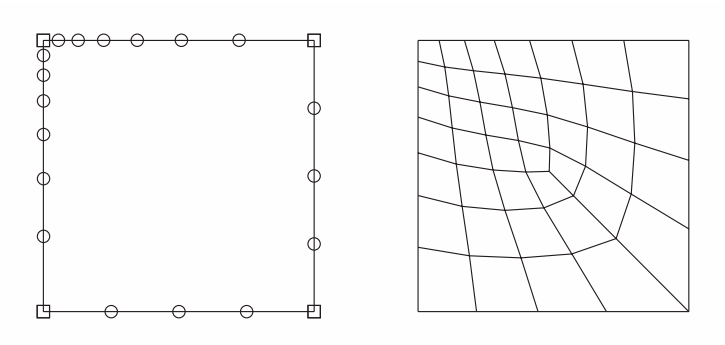

Figure 1: A model with biased seeding.

For more information, see *Understanding seeding*.

- You can select the shape of the mesh elements. For example, *Figure 2* shows a model that has been meshed first with quadrilateral elements and then with triangular elements.

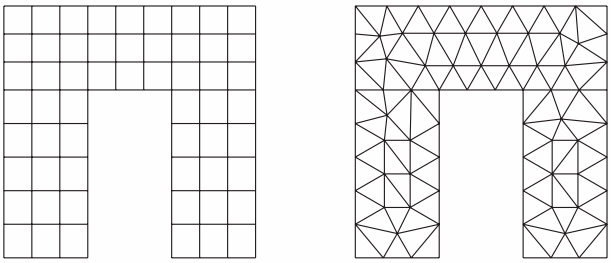

Figure 2: Two meshes with different element shapes.

For more information, see *Assigning Abaqus element types*.

- You can choose the meshing technique—free, structured, or swept—and, where applicable, you can choose the meshing algorithm—medial axis or advancing front. For more information, see *Mesh generation*.
- You can select the element type that is assigned to the mesh by choosing the element family, geometric order, and shape along with specific element controls, such as hourglassing. For more information, see *Understanding mesh generation*.

Additional information

- *Understanding seeding*
- *Assigning Abaqus element types*
- *Verifying and improving meshes*

Mesh generation

Abaqus/CAE can use a variety of meshing techniques to mesh models of different topologies. In some cases you can choose the technique used to mesh a model or model region. In other cases only one technique is valid. The different meshing techniques provide varying levels of automation and user control. There are two meshing methodologies available in Abaqus/CAE: top-down and bottom-up.

Top-down meshing generates a mesh by working down from the geometry of a part or region to the individual mesh nodes and elements. You can use top-down meshing techniques to mesh one-, two-, or three-dimensional geometry using any available element type. The resulting mesh exactly conforms to the original geometry. The rigid conformance to geometry makes top-down meshing predominantly an automated process but may make it difficult to produce a high-quality mesh on regions with complex shapes.

Bottom-up meshing generates a mesh by working up from two-dimensional entities (geometric faces, element faces, or two-dimensional elements) to create a three-dimensional mesh. You can use bottom-up meshing techniques to mesh only solid three-dimensional geometry using all—or nearly all—hexahedral elements. Generating a mesh using the bottom-up meshing technique is a manual process, and the resulting mesh may vary significantly from the original geometry. However, allowing the mesh to vary from geometry may allow you to produce a high quality hexahedral mesh on regions with complex shapes.

Additional information

- *Top-down meshing*
- *Bottom-up meshing*

Top-down meshing

Top-down meshing relies on the geometry of a part to define the outer bounds of the mesh. The top-down mesh matches the geometry; you may need to simplify and/or partition complex geometry so that Abaqus/CAE recognizes basic shapes that it can use to generate a high-quality mesh. In some cases top-down methods may not allow you to mesh portions of a complex part with the desired type of elements. The top-down techniques—structured, swept, and free meshing—and their geometry requirements are well-defined, and loads and boundary conditions applied to a part are associated automatically with the resulting mesh.

Structured meshing

Structured meshing is the top-down technique that gives you the most control over your mesh because it applies preestablished mesh patterns to particular model topologies. Most unpartitioned solid models are too complex to be meshed using preestablished mesh patterns. However, you can often partition complex models into simple regions with topologies for which structured meshing patterns exist. *Figure 1* shows an example of a structured mesh. For more information, see *Structured meshing and mapped meshing*.

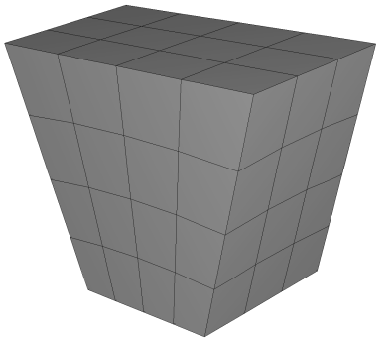

Figure 1: A structured mesh.

Swept meshing

Abaqus/CAE creates swept meshes by internally generating the mesh on an edge or face and then sweeping that mesh along a sweep path. The result can be either a two-dimensional mesh created from an edge or a three-dimensional mesh created from a face. Like structured meshing, swept meshing is a top-down technique limited to models with specific topologies and geometries. *Figure 2* shows an example of a swept mesh. For more information, see *Swept meshing*.

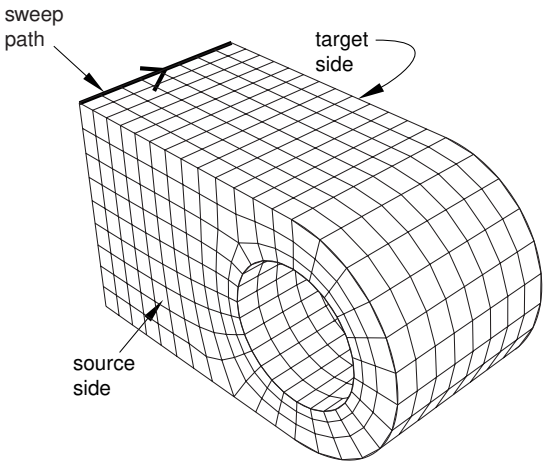

Figure 2: A swept mesh.

Free meshing

The free meshing technique is the most flexible top-down meshing technique. It uses no preestablished mesh patterns and can be applied to almost any model shape. However, free meshing provides you with the least control over the mesh since there is no way to predict the mesh pattern. *Figure 3* shows an example of a free mesh. For more information, see *Free meshing*.

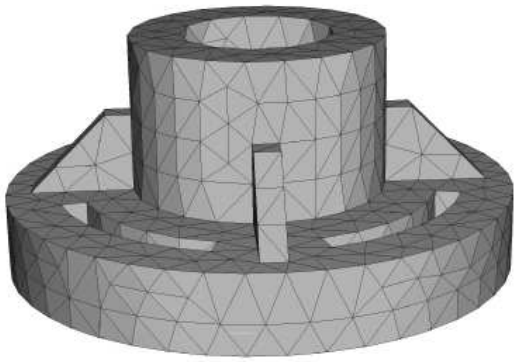

Figure 3: A free mesh generated with tetrahedral elements.

Additional information

- *Bottom-up meshing*
- *Understanding mesh generation*
- *Assigning Abaqus element types*
- *Verifying and improving meshes*

Bottom-up meshing

Bottom-up meshing uses the part geometry as a guideline for the outer bounds of the mesh, but the mesh is not required to conform to the geometry. Removing this restriction gives you greater control over the mesh and allows you to create a hexahedral or hexahedral-dominated mesh on geometry that is too complex for the structured or swept meshing techniques. Bottom-up meshing can be applied to any solid model shape. It provides you with the most control over the mesh, since you select the method and the parameters that drive the mesh. However, you must also decide whether the resulting mesh is a suitable approximation of the geometry. If it is not, you can delete the mesh and try a different bottom-up meshing method or partition the region and mesh the resulting smaller regions with either bottom-up or top-down meshing techniques.

To mesh a single bottom-up region, you may have to apply several successive bottom-up meshes. For example, you may use an extruded bottom-up mesh to generate part of a region, then use the element faces of the extruded mesh as a starting point to generate a swept mesh for features that the extruded mesh did not include.

Loads and boundary conditions are applied to geometry. Unlike a top-down mesh, a bottom-up mesh may not be fully associated with geometry. Therefore, you should check that the mesh is correctly associated with the geometry in areas where loads or boundary conditions are applied. Proper mesh-geometry association will ensure that the loads and boundary conditions are correctly transferred to the mesh during the analysis. (For more information, see *Mesh-geometry association*.) Because of the extra effort required by the user to create a satisfactory mesh compared to the automated top-down meshing processes, bottom-up meshing is recommended for use only when top-down meshing cannot generate a suitable mesh.

Figure 1 shows an example of a bottom-up meshed part. Although this part is relatively simple, it requires two regions and four bottom-up meshes to completely mesh the part. Abaqus/CAE displays bottom-up meshed regions using a mixture of the region geometry color (light tan) and the mesh color (light blue) to emphasize that the geometry and mesh may not be associated. Displaying both the geometry and the mesh allows you to view and edit the mesh-geometry associativity.

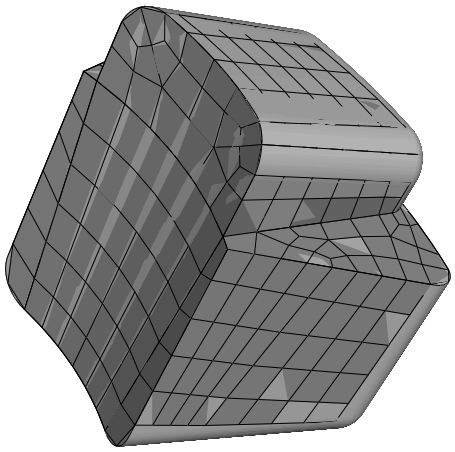

Figure 1: A bottom-up hexahedral meshed part.

Additional information

- *Top-down meshing*
- *Understanding mesh generation*
- *Assigning Abaqus element types*
- *Verifying and improving meshes*

• *Bottom-up meshing*

Mesh technique color coding

When the **Mesh defaults** color mapping is selected, Abaqus/CAE uses different colors to indicate which meshing technique, if any, is currently assigned to a region. For example, if a solid region is meshable using the structured meshing technique, the region turns green when you enter the Mesh module; the green color indicates that the structured meshing technique is assigned to that region. Yellow indicates that the sweep meshing technique is applied to a region. If a region is unmeshable using the currently assigned element shape, the region turns orange when you enter the Mesh module. Regions that are pink or light tan have been assigned the free and bottom-up meshing techniques, respectively.

Note:

You must use the **Mesh Controls** dialog box to assign the bottom-up meshing technique to a region. Abaqus/CAE does not automatically assign the bottom-up meshing technique and will not indicate whether a region that is assigned the bottom-up technique can also be meshed using a top-down technique. (For more information, see *Assigning mesh controls*.)

You can change the applicable meshing techniques by partitioning the region into smaller regions with simpler topology, by changing the element shape assigned to the region, or by using the Virtual Topology toolset.

Additional information

- *Determining which regions are meshable*
- *Color coding geometry and mesh elements*

Mesh refinement

The Mesh module provides a set of tools that allow you to refine a mesh.

- You can use the Partition toolset to divide geometric regions into smaller regions. The resulting partitions introduce new edges that you can seed; therefore, you can combine partitioning and seeding to gain additional control over the mesh generation process. You can also use partitioning to create regions to which you can assign different element types. For example, you might want to assign reduced-integration elements to some portions of your model and fully integrated elements to others. For more information, see *The Partition toolset*.
- In some cases the geometry contains details such as very small faces and edges. The Virtual Topology toolset allows you to remove these small details by combining a small face with an adjacent face or by combining a small edge with an adjacent edge. Introducing virtual topology is a convenient method for creating a clean, well-formed mesh. For more information, see *The Virtual Topology toolset*.
- You can use the Edit Mesh toolset to make minor adjustments to your mesh. For more information, see *What can I do with the Edit Mesh toolset?*.

Mesh optimization

You can assign remeshing rules to regions of your model. Remeshing rules enable successive refinement of your mesh based on solution results. After each analysis, the Mesh module adjusts your mesh with the aim of reducing selected error indicators in the solution results. For more information, see *Understanding adaptive remeshing*, *Advanced meshing techniques*, and *Creating, editing, and manipulating adaptivity processes*.

Mesh verification

The Mesh module provides a set of tools that allow you to verify a mesh and to obtain mesh statistics and mesh information. The Mesh module also provides geometry diagnostic tools that will help you determine why Abaqus/CAE cannot mesh a region. For more information, see *Verifying your mesh*, *Querying your mesh*, and *Using the geometry diagnostic tools*.

Meshing independent and dependent part instances

The approach to meshing independent and dependent instances is different. For more information, see *What is the difference between a dependent and an independent part instance?*.

Independent

To mesh an independent instance, use the context bar to change the **Object** to **Assembly** and mesh the instance directly. You cannot mesh a part that you have used to create an independent instance.

Dependent

To mesh a dependent instance, use the context bar to change the **Object** to **Part** and select the part with which the dependent instance is associated. You can then mesh the part, and Abaqus/CAE applies the same mesh to each dependent instance in the assembly. Dependent instances are convenient when you have a linear or radial pattern of part instances. You can mesh the original part, and Abaqus/CAE applies the same mesh to each instance of the part in the pattern.

Displaying a native mesh

You can switch between displaying the geometry of the part instance and the meshed representation of the same instance.

Click the **Show native mesh**  icon located in the **Visible Objects** toolbar.

You can use the **Show native mesh** tool in any of the assembly-related modules to switch between displaying the geometry of the assembly and a meshed representation of the assembly. Abaqus/CAE displays the meshed representation of both independent and dependent part instances in the assembly (assuming that you have created the appropriate meshes).

Toggling between the geometry of a part and its meshed representation using the **Show native mesh** tool allows you to see how closely the mesh follows the geometry. The tool also allows you to see how Abaqus/CAE incorporated virtual topology into the mesh. In addition, you may find it useful to click on the **Show native mesh** tool in the Job module. You can then confirm that the entire assembly has been meshed correctly before you submit a job for analysis.

The display of any orphan elements in the model is unaffected by this tool; orphan elements are displayed regardless of whether you display the geometry or elements for the native portion of part instances.

Understanding seeding

This section explains the concept of seeding and how to use seeding to improve meshes.

In this section:

- *What are mesh seeds?*
- *Can I seed a face or a cell?*
- *Controlling the seed density*
- *Applying curvature control to your seeding*
- *Constraining seeds*
- *Minimizing seed repositioning*
- *What is the relationship between vertices and nodes?*

What are mesh seeds?

Seeds are markers that you place along the edges of a region to specify the target mesh density in that region. Both the mesh density along the boundary of the region and the mesh density in the interior of the region are determined by the seeds along the edges of the region.

You can create and control seeds using the **Seed** menu in the Mesh module main menu bar. Abaqus/CAE generates meshes that match your seeds as closely as possible. Abaqus/CAE can use the following methods to control the distribution of the seeds:

- Position the seeds uniformly along all the edges of a part or part instance
- Position the seeds uniformly along an edge
- Position the seeds with a bias such that the mesh density increases toward one end of the edge
- Position the seeds with a bias such that the mesh density increases from each end toward the center of the edge
- Position the seeds with a bias such that the mesh density increases from the center toward each end of the edge

Figure 1 shows a combination of uniform seeding and bias seeding.

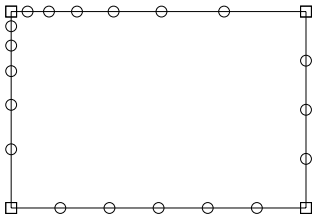

Figure 1: A model with uniform and bias seeding.

You should apply seeds to all edges. If a uniform seed distribution is sufficient, the recommended approach is to seed the entire part or part instance. If you want more control over the mesh, you can partition the region and then provide seeds along the partitions you have created. This technique is described in greater detail in *Verifying and improving meshes*.

Mesh seeds specify only a target mesh density. If you are using hexahedral or quadrilateral elements, Abaqus/CAE often changes the element distribution so that the mesh can be generated successfully. You can prevent such adjustments by constraining the number of seeds along an edge. When you constrain seeds, you are prescribing mainly the number of elements along the edge, and, to a lesser extent, the precise locations of the nodes; if necessary, Abaqus/CAE adjusts the locations of the nodes to reduce element distortion. In addition, you should use such constraints with care, since they can make it more difficult for the mesh generator to obtain a mesh.

By default, Abaqus/CAE displays seeds on a part or assembly only when you are defining or modifying seed placement. You can enable persistent seed display if you want the seeds to appear while you perform other operations in the Mesh module; toggle on  in the **Visible Objects** toolbar to maintain seed display.

Can I seed a face or a cell?

You can select edges, faces, or cells to seed; however, Abaqus/CAE creates seeds only along edges. When you select faces or cells to seed, Abaqus/CAE creates seeds only along the edges of the faces or cells. In addition, you can select a set or surface to seed; as a result, Abaqus/CAE creates seeds along the edges of the geometry contained in the set or surface.

When you are applying uniform seeds, you can use a combination of the following methods to select the region to which Abaqus/CAE will apply the seeds:

Individually/By angle

You can select edges, faces, or cells individually; or you can use the angle method to select a group of edges or faces. For example, if you choose the angle method and select an edge, Abaqus/CAE then selects every adjacent edge until the angle between the edges is equal to or exceeds the angle that you entered. For more information, see *Using the angle and feature edge method to select multiple objects*.

Selection filters

You can use filters to choose the type of object to select—**Edges**, **Faces**, **Cells**, or **All**. By default, Abaqus/CAE allows you to select all types of object. The option to select by angle becomes available only after you select **Edges** or **Faces** from the selection filters. For more information, see *Filtering your selection based on the type of object*.

Sets or surfaces

By default, Abaqus/CAE allows you to apply seeds to edges, faces, and cells that you select from the viewport. Alternatively, you can click **Sets/Surfaces** on the right of the prompt area and select from eligible sets (or surfaces). When you select a set (or surface), Abaqus/CAE applies seeds to every edge in the set (or surface), including every edge of all the cells and faces. Abaqus/CAE ignores any vertices in the set (or surface).

Controlling the seed density

You can use the following methods to control the seed density along selected edges:

- Specify the average element size for every edge of the entire part or part instance.
- Specify the number of elements desired along an edge.
- Specify the average element size along an edge. (If the edge length is not an integer multiple of the element length, Abaqus/CAE will change the element length slightly to obtain an integer number of elements along the edge.)
- Specify a nonuniform distribution of elements along an edge. The element density can increase from one end of the edge to the other (single bias), or the element density can vary from the center of the edge to each end (double bias). For a nonuniform distribution you can specify either of the following:
  - The number of elements desired along an edge and a bias ratio. The bias ratio is the ratio of the largest element to the smallest element.
  - The size of the smallest element and the size of the largest element.

If you select edges that you previously seeded using a combination of these methods, Abaqus/CAE provides an **As Is** option that allows you to retain the seeding method. Abaqus/CAE provides a similar option if you select edges with a mixture of curvature controls or seed constraints.

For detailed instructions on prescribing seed density, see the following sections:

- *Defining seed density for an entire part or part instance*
- *Seeding an edge by prescribing the number of elements*
- *Seeding an edge by prescribing element size*
- *Prescribing biased seeding along an edge*
- *Applying constraints to edge seeds*
- *Seeding previously meshed parts, part instances, or regions*
- *Deleting part or instance seeds*
- *Deleting edge seeds*

Seeds created by specifying an average element size for the entire part or part instance are called part seeds or instance seeds, respectively, and appear in white; seeds created using the other methods are called edge seeds and appear in magenta. Edge seeds always override part or instance seeds; therefore, when you specify the average element size for the entire part or part instance, part or instance seeds appear only on edges of the region that do not already have edge seeds. New edges created by partitioning are given part or instance seeds by default.

When you seed an edge of a region that is assigned the swept or revolved mesh technique, the edge seeding tools automatically propagate seeds from the selected edge to the matching edges in the region. In other words, the seeds on the face or edge at the beginning of the sweep path are propagated automatically to the face or edge at the end of the sweep path. Likewise, the seeds created on one edge along the sweep path are propagated automatically to the other edges along the sweep path. As a result, even though you select a single edge of a face to seed, Abaqus/CAE will propagate the seeds to additional edges and faces. For more information, see *What is swept meshing?*.

Applying curvature control to your seeding

The part seeding tool allows you to specify a target element size when you are seeding a part, a part instance, or multiple edges. If the geometry is relatively regular, specifying a single target element size can result in an acceptable mesh. However, if you specify a single target element size and the geometric features that make up the part or edges vary in size, the resulting mesh may be too coarse to adequately represent any small features, as shown in *Figure 1*.

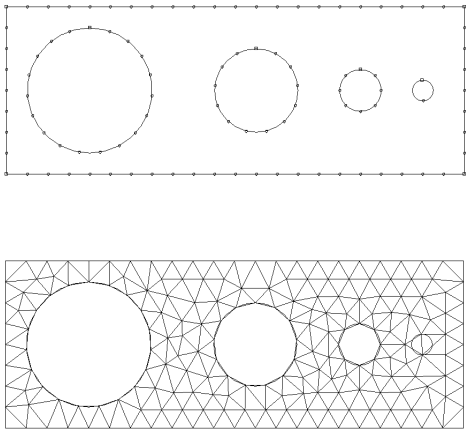

Figure 1: Seeding and the resulting mesh with no curvature control.

To avoid the problem of inadequate seeding around small curved features, Abaqus/CAE applies curvature control when it seeds a part, a part instance, or edges. Curvature control allows Abaqus/CAE to calculate the seed distribution based on the curvature of the edge along with the target element size. *Figure 2* shows the same part seeded and meshed with curvature control enabled.

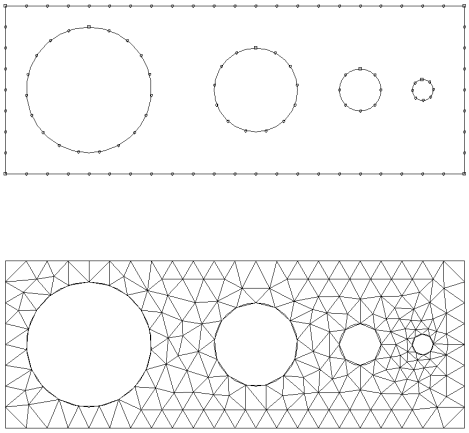

Figure 2: Seeding and the resulting mesh with curvature control enabled.

You can configure the following to specify how curvature control will influence the seeding:

Deviation factor

The deviation factor is a measure of how much the element edges deviate from the original geometry, as shown in *Figure 3*.

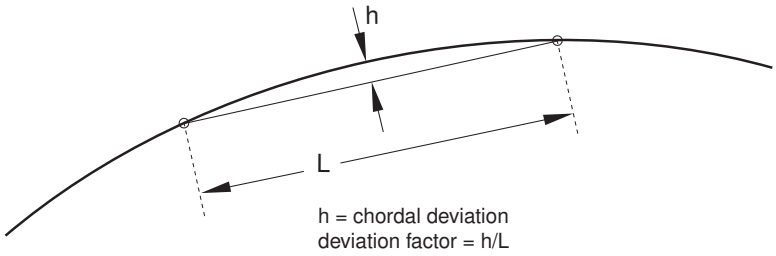

Figure 3: Deviation factor.

To help you visualize the deviation factor, Abaqus/CAE displays the approximate number of elements it would create around a circle corresponding to the setting that you enter. As you reduce the deviation factor, the number of elements that Abaqus/CAE would create around a circle increases. This number is only a visual aid; for example, if you are seeding a spline or an ellipse, Abaqus/CAE creates a different number of elements, depending on the local curvature along the edge.

Specify minimum size factor

Specifying a minimum size factor prevents Abaqus/CAE from creating very fine meshes in areas of high curvature that you have no interest in modeling; for example, kinks in spline curves or fillets with a very small radius. The number that you enter representing the minimum size is the fraction of the global seed size. As a result, if you change the global seed size, you do not have to change the minimum size factor.

For detailed instructions on applying curvature control, see *Defining seed density for an entire part or part instance*.

Constraining seeds

By default, mesh seeds prescribe only a target mesh density. Abaqus/CAE generally matches the mesh seeds exactly when you are using the free meshing technique to generate triangular- or tetrahedral-shaped elements. However, in other cases Abaqus/CAE may alter the element distribution so that it can successfully generate the mesh. If you want to prevent Abaqus/CAE from altering the element distribution, you can fix a specific number of elements along an edge by constraining the seeds along that edge. You can constrain only edge seeds, not part or instance seeds.

You can assign any one of the following three states to a group of seeds along an edge:

Unconstrained

This is the default setting. The number of elements along an edge can either increase or decrease so that the mesh can become denser or coarser than is specified by the seeds. Unconstrained seeds appear as open circles.

Partially constrained

The number of elements along an edge may be increased during mesh generation but cannot be decreased. This constraint allows the mesh to become denser than is specified by the seeds but no coarser. Partially constrained seeds appear as upward-pointing triangles.

Fully constrained

The number of elements specified by constrained seeds along an edge cannot be altered by the mesh generation process. When the seeds are fully constrained, the mesh generation will attempt to allow the location of the nodes to correspond exactly to the location of the seeds. However, an exact match between the seeds and the nodal positions is not guaranteed. Fully constrained seeds appear as squares.

Abaqus/CAE always creates a fully constrained seed at each geometric vertex of a region to indicate that a finite element node will be positioned at each vertex.

In many cases the mesh generator must redistribute elements (and deviate from the number and location of the seeds) to generate a mesh successfully. For the greatest likelihood of meshing success, leave seeds unconstrained or at least avoid fully constraining large numbers of seeds in a given part or part instance so that the mesh generator has as much freedom to redistribute seeds as possible.

For detailed instructions on constraining edge seeds, see the following sections :

- *Applying constraints to edge seeds*
- *Relaxing constraints using the error dialog box*

Minimizing seed repositioning

During the mesh generation process Abaqus/CAE uses the seeds that you create as target locations for nodes along the edges of the mesh. However, if you are using quadrilateral- or hexahedral-shaped elements, a close match between your seeds and nodes depends heavily on the following:

The element shapes you allow in transition regions

You will obtain a better match between your seeds and the nodes of the mesh if you allow triangular elements in transition regions. The seeds and the nodes are less likely to match if you restrict your mesh to including only quadrilateral elements.

The mesh transition setting

You will obtain a better match between your seeds and the nodes of the mesh if you allow for mesh transition.

The meshing technique

The mesh generated using the advancing front meshing algorithm matches your seeding better than the mesh generated using the medial axis algorithm.

The seed constraints

Fully constrained seeds closely match the generated nodes in both number and position. However, you must fully constrain only a few edges of a part or part instance; otherwise, Abaqus/CAE will not be able to generate a mesh.

How neighboring regions are seeded

When meshing multiple regions, Abaqus/CAE often redistributes the elements so that the mesh is compatible between regions. Even though a single region's seed arrangement may be adequate for generating a mesh on that one region, the seed arrangement may need to be changed since the number of elements must be compatible with neighboring regions along shared edges.

Note:

Mesh compatibility between part instances is not guaranteed. In some simple cases seeding can help achieve part-to-part mesh compatibility. Techniques for obtaining compatible meshes are described in *Compatible meshes between part instances*.

Abaqus/CAE tries to adhere as closely as possible to the number and location of seeds that you specified when balancing the element redistribution for the entire model. If given a choice between making a large change along a single seeded edge and making a small change to many edges, Abaqus/CAE will make many small changes.

What is the relationship between vertices and nodes?

When you seed a model, Abaqus/CAE automatically places fully constrained seeds wherever vertices appear along the model's edges. Fully constrained seeds that appear at vertices always indicate that nodes will appear at those vertices. (Fully constrained seeds that appear at other locations along an edge of a region do not indicate the exact location of nodes; they indicate only the number of nodes along that edge.) Therefore, when you sketch a part, you should keep in mind that the location of vertices in the part influences the quality of the mesh that Abaqus/CAE can generate. (For information about altering vertex locations, see *Dragging Sketcher objects*.)

For example, *Figure 1* shows a sketch of a two-dimensional part.

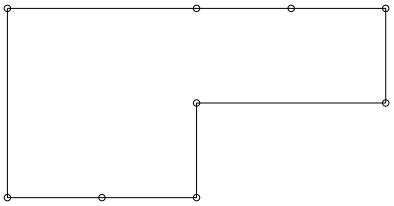

Figure 1: Vertices on a two-dimensional part.

Note the locations of the nine vertices. These vertices were created by sketching several line segments along the top and bottom edges rather than one continuous line segment along each edge.

When that part or an instance of the part is seeded, square-shaped, fully constrained seeds appear at each vertex, as shown in *Figure 2*.

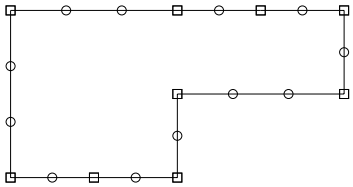

Figure 2: Fully constrained seeds appear at each vertex.

When the model is meshed, Abaqus/CAE always places nodes at the location of the fully constrained seeds that are located at vertices, as shown in *Figure 3*.

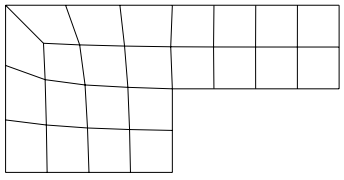

Figure 3: Nodes appear at the vertices.

Likewise, *Figure 4* shows the sketch of two concentric circles that will be extruded to form a hollow cylinder.

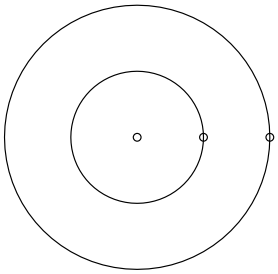

Figure 4: Concentric circles with aligned vertices.

Note the location of the vertices, which the Sketcher creates at the locations you click to define the circles' perimeters.

When the cylinder is seeded, square-shaped, fully constrained seeds appear at each vertex, as shown in *Figure 5*.

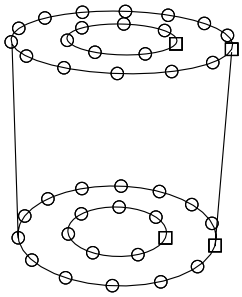

Figure 5: Fully constrained seeds appear at each vertex.

When the model is meshed, nodes always appear at the location of the fully constrained seeds that are located at vertices, as shown in *Figure 6*.

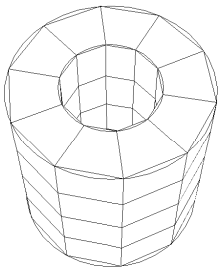

Figure 6: Nodes appear at the vertices.

If you do not align the two vertices when you sketch the cylinder, you risk generating a distorted mesh. For example, the vertices of the two concentric circles are not aligned in *Figure 7*.

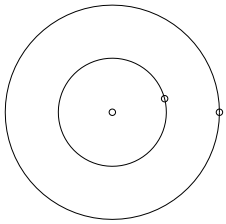

Figure 7: Concentric circles whose vertices are not aligned.

As a result, the mesh is slightly distorted on the right side, as shown in *Figure 8*.

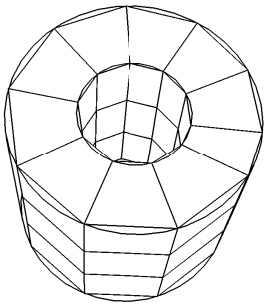

Figure 8: A distorted mesh.

Assigning Abaqus element types

This section explains how to assign Abaqus/Standard and Abaqus/Explicit element types to geometric regions and to orphan elements.

In this section:

- *How do mesh elements correspond to Abaqus elements?*
- *What kinds of elements must be generated outside the Mesh module?*
- *Element type assignment*
- *Preferred element types list*

How do mesh elements correspond to Abaqus elements?

The Mesh module can generate meshes containing the following element shapes.

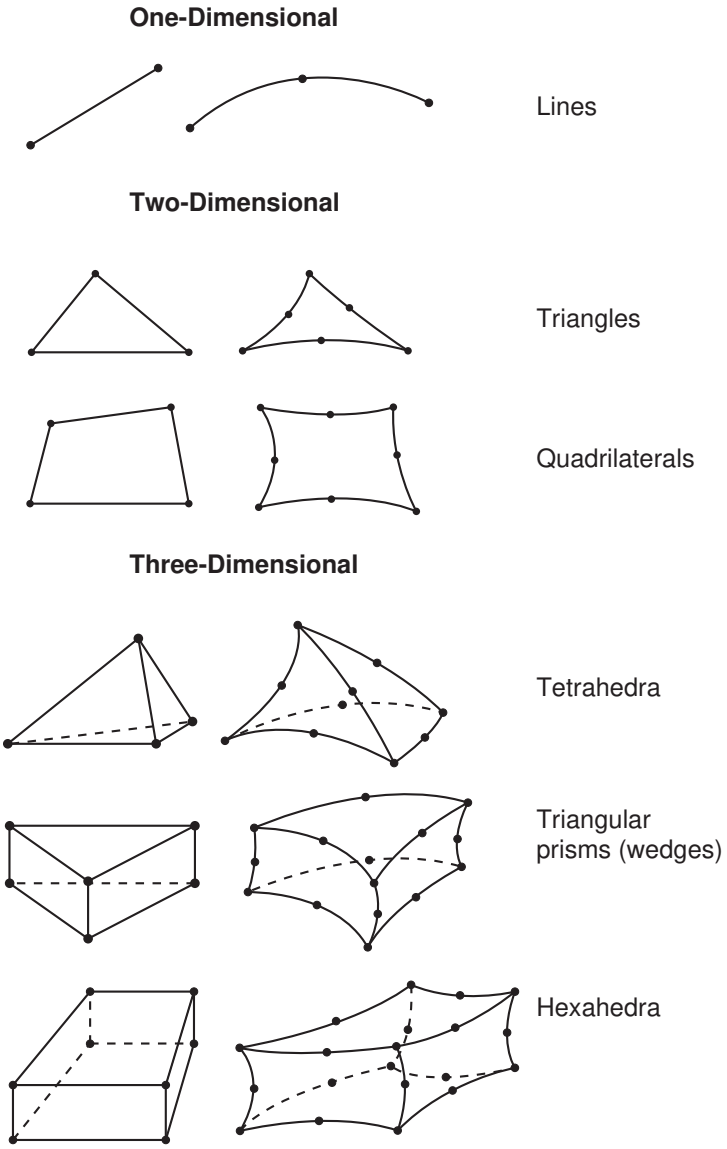

Figure 1: Element shapes.

Most elements in Abaqus/Standard and Abaqus/Explicit correspond to one of the shapes shown; that is, they are topologically equivalent to these shapes. For example, although the elements CPE4, CAX4R, and S4R are used for stress analysis, DC2D4 is used for heat transfer analysis, and AC2D4 is used for acoustic analysis, all five elements are topologically equivalent to a linear quadrilateral.

Every mesh region has one or more Abaqus element types assigned to it by default. Each element type corresponds to an element shape that can be used in the region. For example, a shell mesh region typically has a quadrilateral and a triangular element type assigned to it by default. However, you can change the element assignment for any Abaqus element that is topologically equivalent to the element shape assigned to the region. As a result, you can choose to mesh a shell region with only all triangular elements, and Abaqus/CAE ignores the quadrilateral element assignment.

To change the element assignment to an Abaqus element that is topologically equivalent to the element shape assigned to the region, select **Mesh->Element Type** from the main menu bar. Similarly, you can select **Mesh->Controls** to select the element shape for meshing.

However, since no element type checking is done until you submit the analysis, it is possible to choose an element that is inappropriate for the analysis you will be conducting. For example, Abaqus/CAE does not prevent you from specifying heat transfer elements such as DC2D4, even though you may be conducting a stress analysis.

What kinds of elements must be generated outside the Mesh module?

Abaqus/CAE provides support for most of the elements that are used by Abaqus/Standard and Abaqus/Explicit. However, some elements are not supported and must be generated outside the Mesh module.

The following list describes the elements that are not supported by Abaqus/CAE. If you want to assign these element types to a model, you must use a text editor to add them to the input file generated in the Job module. For information on generating the input file, see *Basic steps for analyzing a model*.

- Acoustic interface element (ASI1)
- Coupled thermal-electrical-structural elements (Q3D4, Q3D6, etc.)
- Distributing coupling elements (DCOUP2D and DCOUP3D)
- Drag chain elements (DRAG2D and DRAG3D)
- Elastic-plastic joint elements (JOINT2D and JOINT3D)
- Frame elements (FRAME2D and FRAME3D)
- Gap elements, coupled temperature-displacement and heat transfer (GAPUNIT and DGAP)
- Infinite elements (CIN3D8, CINAX4, etc.)
- Line spring elements (LS3S and LS6)
- Membrane elements, 9-node quadrilateral (M3D9 and M3D9R)
- Membrane elements, cylindrical (MCL6 and MCL9)
- Particle element (PC3D)
- Pipe-soil interaction elements (PSI24, PSI34, etc.)
- Slide line elements (ISL21A and ISL22A)
- Stress/displacement variable node elements (C3D15V, C3D27, etc.)

  Note:

  After you submit the analysis for execution, Abaqus/Standard automatically converts any C3D20*(R)(H)* element that is adjacent to a secondary surface in a contact pair into the corresponding C3D27*(R)(H)* element. (Neither element is available in Abaqus/Explicit.) Otherwise, there is no way to generate variable node hexahedra with Abaqus/CAE.

- Surface elements, cylindrical (SFMCL6 and SFMCL9)
- Thin shell element, 9-node doubly curved (S9R5)
- Tube-to-tube contact elements (ITT21 and ITT31)
- Poroelastic acoustic elements (C3D4A, C3D6A, and C3D8A)

Some pyramid elements, such as C3D5 and AC3D5, are supported by Abaqus/CAE in that they can be imported from and written to input files. However, Abaqus/CAE has no meshing algorithms that generate a pyramid shape. You can assign a different pyramid element type to existing pyramid elements in the Mesh module.

You cannot assign some elements, such as CONN2D2 and SPRING1 in the Mesh module; however, you can create equivalent connectors in the Interaction module or engineering features in the Property module or Interaction module as shown in *Table 1*. These elements are written to the input file.

Table 1: Abaqus/CAE support for connectors and engineering features.

Elements	Abaqus/CAE support
CONN2D2, CONN3D2	Equivalent connector in Interaction module
DASHPOTA, DASHPOT1, DASHPOT2	Engineering feature in Property module or Interaction module (linear behavior independent of field variables)
	Equivalent connector in Interaction module
GAPCYL, GAPSPHER, GAPUNI	Equivalent connector in Interaction module
HEATCAP	Engineering feature in Property module or Interaction module
ITSCYL, ITSUNI	Equivalent connector in Interaction module
JOINTC	Equivalent connector in Interaction module
MASS	Engineering feature in Property module or Interaction module
ROTARYI	Engineering feature in Property module or Interaction module
SPRINGA, SPRING1, SPRING2	Engineering feature in Property module or Interaction module (linear behavior independent of field variables)
	Equivalent connector in Interaction module

For more information, see *Understanding connectors*, *Inertia*, and *Springs and dashpots*.

Element type assignment

You can assign element types to geometric regions and to orphan mesh elements.

Element types can be assigned to the following:

- A region selected from geometry-based parts or part instances. The part instances must have come from parts that you created in the Part module or from parts that you imported.
- A set that refers to a region selected from geometry-based parts or part instances. The set can also refer to a skin reinforcement.
- An orphan element or element set.

All regions from geometry-based parts or part instances have default element type assignments. These assignments depend on the kind of part to which the region or element belongs. You can also specify a list of preferred element types for element type assignment (see *Preferred element types list*, for more information).

You can view and change the Abaqus element types that are assigned using the **Element Type** dialog box, which you can display by selecting **Mesh->Element Type**. For example, the **Element Type** dialog box for a two-dimensional structural region is shown in *Figure 1*.

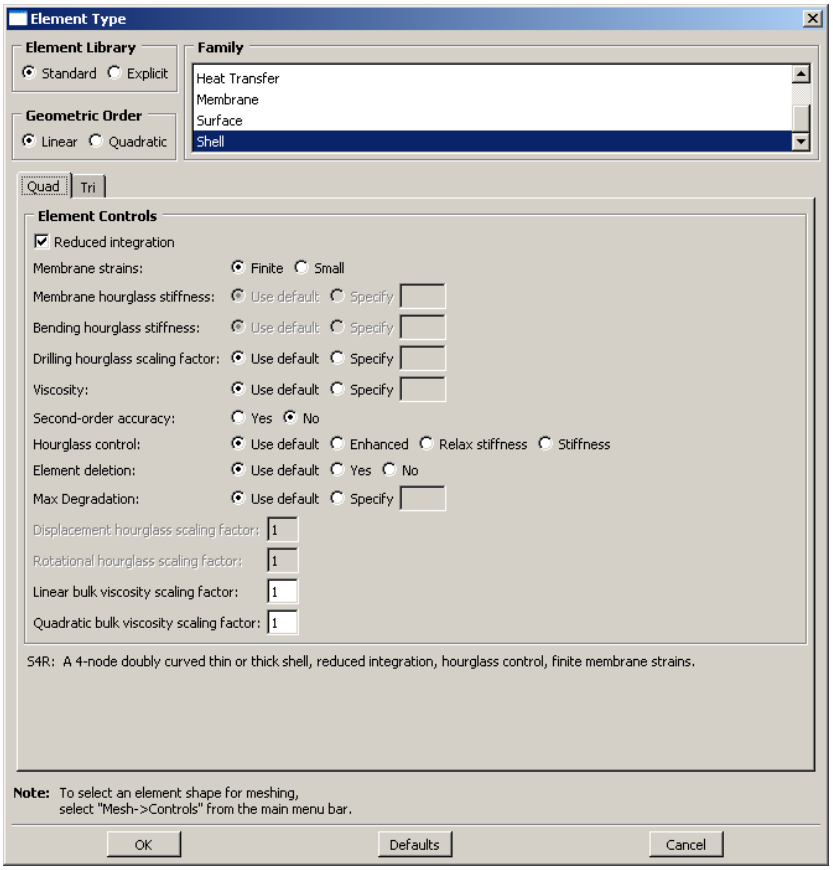

Figure 1: The Element Type dialog box for a two-dimensional structural region in an Abaqus/Standard model.

At the top of the dialog box, you enter your preferences for element library, geometric order, and family. Then, you select a specific element type by clicking the tabs in the bottom half of the dialog box and choosing from the options that appear. For more information on the element control options, see *Section Controls*.

The dialog box can contain from one to three tabs depending on the dimensionality of the selected region or regions:

- The **Line** tab allows you to choose an applicable element type and assign it to one-dimensional mesh elements in the region.
- The **Quad** and **Tri** tabs allow you to choose an applicable element type and assign it to two-dimensional mesh elements in the region.
- The **Hex**, **Wedge**, and **Tet** tabs allow you to assign three-dimensional element types to the three-dimensional mesh elements in the region.

For example, in *Figure 1* the options for a linear shell element from the Abaqus/Standard element library are selected. After clicking the **Quad** tab, reduced integration and finite membrane strains are selected. The name and a brief description of the quadrilateral shell element that meets all of these criteria appear at the bottom of the tabbed page.

The **Tri** tab in this dialog box is shown in *Figure 2*. The name and a brief description of the triangular shell element that meets all of the criteria specified in the dialog box appear at the bottom of the **Tri** tabbed page in *Figure 2*. If the selected region in this example happens to contain a combination of triangular and quadrilateral mesh elements:

- The quadrilateral mesh elements are assigned the S4R element type.
- The triangular mesh elements are assigned the S3 element type.

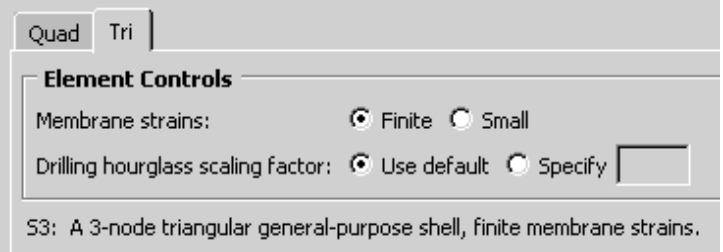

Figure 2: The Tri tab.

If the region contains only quadrilateral elements, all of the elements are assigned the S4R element type.

For detailed, step-by-step instructions for assigning element types to a mesh region, see *Associating Abaqus elements with mesh regions*. For lists of the element types that are available, see the *Abaqus/Standard Element Index* and the *Abaqus/Explicit Element Index*. You can select most of these elements through the **Element Type** dialog box. *What kinds of elements must be generated outside the Mesh module?* describes the elements that cannot be selected.

Preferred element types list

You can specify a list of preferred element types for element type assignment.

Abaqus/CAE must be run interactively to use preferred element types. The list must be created prior to loading the Mesh module in Abaqus/CAE.

When a part or part instance that has never been assigned an element type is meshed, the preferred element type list is consulted. If an element type appropriate to the geometry is found in the list, it is assigned to the geometry. Multiple element types representing different shapes (for example, triangles and quadrilaterals) can be assigned in combination, but only element types that are compatible with each other are used. When more than one appropriate element type is found in the list, the first element type encountered takes precedence.

The list is also consulted when populating the **Element Type** dialog box such that preferred element types are selected by default for a region not previously assigned any element types. If you click **Defaults** in the dialog box, the default element types (not the preferred element types) are displayed.

You can specify the preferred element types list in either the `abaqus_v6.env` or the `custom_v6.env` environment file. It is recommended that you specify the list of preferred element types in the `onCaeStartup()` function in the environment file. For example:

```
def onCaeStartup():
    import mesh
    prefElems=(mesh.C3D8T, mesh.C3D10MT, mesh.S8R)
    session.defaultMesherOptions.setValues(guiPreferredElements=prefElems)
```

• *Using the Abaqus environment files*

Verifying and improving meshes

This section explains how you use the tools in the Mesh module to verify your mesh quality, to control mesh generation, and to improve the mesh quality.

In this section:

- *Verifying your mesh*
- *Querying your mesh*
- *Why partition in the Mesh module?*
- *How are seeds and other attributes affected by partitioning?*
- *Regenerating partitions after modifying geometry*
- *Using virtual topology to improve your mesh*
- *Using adaptive remeshing to improve your mesh*

Verifying your mesh

Upon completion of a meshing operation, Abaqus/CAE highlights any bad elements in the mesh. Abaqus/CAE also provides a set of tools in the Mesh module that allow you to verify the quality of your mesh and to obtain information about the nodes and elements in the mesh. You can use these tools to isolate regions where the mesh quality is poor and to guide you if you need to refine your mesh. To verify the quality of the mesh, choose the **Object** from the context bar, and select **Mesh->Verify** from the main menu bar. You can then select the part, part instances, geometric regions, or element to verify. Abaqus/CAE allows you to choose between checking that your mesh will pass the quality tests in the analysis products and checking that your mesh passes individual quality checks, such as checking for elements with a large aspect ratio. Any elements that do not pass the specified criteria are highlighted in the viewport, and you can choose to create and save a set containing the highlighted elements or, if applicable, the cells, faces, or edges related to those elements. For detailed information on using the mesh verify tools, see *Verifying element quality*.

You can use the **Analysis checks** to verify that the elements in your mesh will pass the element quality checks that are included with the input file processor in Abaqus/Standard or Abaqus/Explicit. Abaqus/CAE highlights any elements that fail the mesh quality tests and displays the number of elements tested along with the number of errors and warnings in the message area. The mesh quality tests in the input file processor are extensive and specific to each element type. At a minimum, the mesh quality tests issue a warning for elements that seem inappropriately distorted, and the tests issue an error if the distortion is severe. Abaqus/CAE does not support analysis checks for beam, gasket, or cohesive elements.

You can use the **Shape metrics** to highlight elements of a selected shape that do not meet one of the following selection criteria:

Shape factor

Abaqus/CAE highlights elements with a normalized shape factor smaller than a specified value. The shape factor criterion is available only for triangular and tetrahedral elements. The shape factor ranges from 0 to 1, with 1 indicating the optimal element shape and 0 indicating a degenerate element.

- For triangular elements the normalized shape factor is defined as

$$shape\ factor = \frac{element\ area}{optimal\ element\ area}.$$

  Optimal element area is the area of an equilateral triangle with the same circumradius as the element. (The circumradius is the radius of the circle passing through the three vertices of the triangle.)

- For tetrahedral elements the normalized shape factor is defined as

$$shape\ factor = \frac{element\ volume}{optimal\ element\ volume}.$$

  Optimal element volume is the volume of an equilateral tetrahedron with the same circumradius as the element. (The circumradius is the radius of the sphere passing through the four vertices of the tetrahedron.)

Small face corner angle

Abaqus/CAE highlights elements containing faces where two edges meet at an angle smaller than a specified angle.

Large face corner angle

Abaqus/CAE highlights elements containing faces where two edges meet at an angle larger than a specified angle.

Aspect ratio

Abaqus/CAE highlights elements with an aspect ratio larger than a specified value. The aspect ratio is the ratio between the longest and shortest edge of an element.

Table 1 shows the default limits for the selection criteria based on the element shape.

Table 1: Element shape selection criteria limits.

Selection criterion	Quadrilateral	Triangle	Hexahedra	Tetrahedra	Wedge
Shape factor	N/A	0.01	N/A	0.0001	N/A
Smaller face corner angle	10	5	10	5	10
Larger face corner angle	160	170	160	170	160
Aspect ratio	10	10	10	10	10

You can use the **Size metrics** to highlight elements that do not meet one of the following selection criteria:

Geometric deviation factor

Abaqus/CAE highlights elements with an edge whose geometric deviation factor is greater than the specified value. The geometric deviation factor is a measure of how much an element edge deviates from the original geometry, and Abaqus/CAE calculates this value by dividing the maximum gap between an element edge and its parent geometric face or edge by the length of the element edge. By default, Abaqus/CAE highlights elements whose geometric deviation factor is greater than 0.2.

Abaqus/CAE calculates the geometric deviation factor only for elements in a native mesh. If you select a part that contains no geometry, Abaqus/CAE disables this option in the **Verify Mesh** dialog box. If your selection includes both native and orphan elements, Abaqus/CAE considers only the native elements for calculations of geometric deviation factor.

Short edge

Abaqus/CAE highlights elements with an edge shorter than a specified value.

Long edge

Abaqus/CAE highlights elements with an edge longer than a specified value.

Stable time increment

Abaqus/CAE highlights elements with a calculated stable time increment less than the specified value. The stable time increment calculation requires a suitable material definition and section assignment and is meaningful only for Abaqus/Explicit analyses.

The stable time increment calculation in Abaqus/CAE is an approximation of the initial stable time increment calculation made by Abaqus/Explicit for an element-by-element formulation. It does not account for any of the following conditions:

- Mass scaling
- Point mass
- Rotary inertia

- Nonstructural mass
- Reinforcement (rebar)

Material behaviors supported for the stable time increment calculation in Abaqus/CAE include elastic, hyperelastic, hyperfoam (without user-defined test data), and acoustic medium. Composite sections with multiple materials are not supported. For more information, see *Stability*.

Maximum allowable frequency for acoustic elements

Abaqus/CAE highlights finite acoustic elements that may not be valid for modal or steady-state dynamic analyses in Abaqus/Standard above the specified frequency value. The maximum allowable frequency calculation requires a suitable material definition and section assignment. The calculation is a guideline based on approximately 10 elements per wavelength:

$$f_{max} = \frac{PC_o}{10h},$$

where P is the interpolation order (1 or 2), h is the size of the element bounding box, and C_o is the speed of sound $\left(\sqrt{\frac{bulk\ modulus}{density}}\right)$.

In addition, for both shape and size metrics Abaqus/CAE displays the following information in the message area for each selected part, part instance, or region:

- The name of the part or part instance.
- The total number of elements of the selected shape in the part instance or in the selected regions.
- The number of highlighted elements and the percentage of the elements being verified that these elements comprise.
- The average value of the selection criterion. For the geometric deviation factor, Abaqus/CAE calculates the average value by considering only elements along a curve or face; solid elements in the center of a volume are excluded from this value.
- The “worst” value of the selection criterion—the value closest to the criterion if it is not exceeded or the value farthest beyond the criterion if it is exceeded.

Querying your mesh

The Query toolset in the Mesh module allows you to obtain information about the nodes and elements in the mesh. In addition, you can select **Tools->Query** from the main menu bar to request the following information about the mesh:

- The total number of nodes and elements in a selected part, part instance, or region along with the number of elements of each element shape.
- The type and connectivity of a selected element.
- The positive and negative sides of shell and membrane faces.
- The direction of beam and truss tangents.
- The mesh stack orientation.
- Whether any edges of boundary faces have incompatible interfaces, cracks, or gaps and whether any edges intersect other faces.
- The location of free or non-manifold edges—exterior shell or solid element edges that are not shared by exactly two exterior elements.
- The location of any unmeshed regions.

For detailed information on using the Query toolset, see *Obtaining mesh information*.

Why partition in the Mesh module?

You can use the Partition toolset to divide parts or independent part instances into smaller regions. There are three reasons to create partitions in the Mesh module:

- To divide a complex, three-dimensional part or instance into simpler regions that Abaqus/CAE can mesh using primarily hexahedral elements with the structured or swept meshing techniques. (Almost all three-dimensional parts are meshable using the free meshing technique, but three-dimensional free meshes can include only tetrahedral elements.)
- To gain more control over mesh generation.
- To obtain regions to which you can assign different element types.

See *The Partition toolset* for detailed information on how to use each tool in the Partition toolset.

You can partition only parts or independent part instances. If you need to partition a dependent instance, you can partition the original part from which the dependent instance was created. Alternatively, you can create a copy of the original part and then create an independent instance of the copy. You can then replace the dependent instance with the new independent instance and partition the independent instance. For more information, see *What is the difference between a dependent and an independent part instance?*.

By default, the free meshing technique with quadrilateral elements is applied to all two-dimensional parts and part instances. When you create the mesh using this default technique, Abaqus/CAE implicitly creates partitions that divide the part into regions that can be meshed using the structured meshing technique. (For more information, see *Free meshing with quadrilateral and quadrilateral-dominated elements*.) Therefore, all two-dimensional parts are meshable without any manual partitioning.

However, when a three-dimensional part or instance is unmeshable using hexahedral elements, you must take one of the following steps:

- Change the element shape from hexahedra to tetrahedra so that the free meshing technique can be applied.
- Partition into structured- or swept-meshable regions.

When the **Mesh defaults** color mapping is selected, Abaqus/CAE uses the color orange to indicate that a three-dimensional region is unmeshable using the currently assigned element shape. For example, *Figure 1* illustrates a part that cannot be meshed with hexahedral elements.

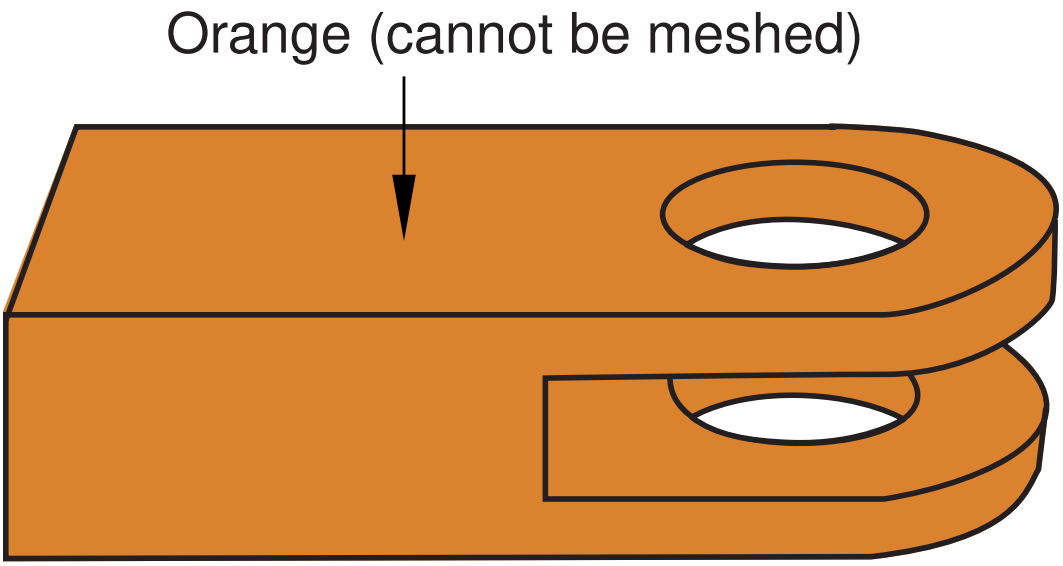

Figure 1: Unmeshable three-dimensional region.

With the addition of a partition, the part can be meshed with hexahedral elements, as shown in *Figure 2*; the green region can be meshed using the structured meshing technique, and the yellow regions can be meshed using the swept meshing technique.

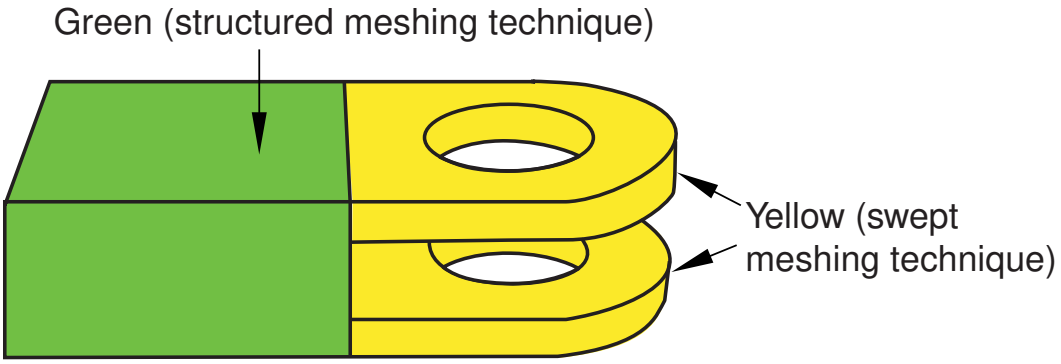

Figure 2: The model is partitioned into three regions.

Even when a part or instance can be meshed without partitioning, you may still want to partition to gain more control over mesh generation. Without partitions, the mesh is aligned only along the exterior edges; with partitions, the resulting mesh will have rows or grids of elements aligned along the partitions. That is, the mesh "flows" along the partitions. For example, in *Figure 3* the partition that divides the rectangle in two causes the mesh to flow at an angle along the partition.

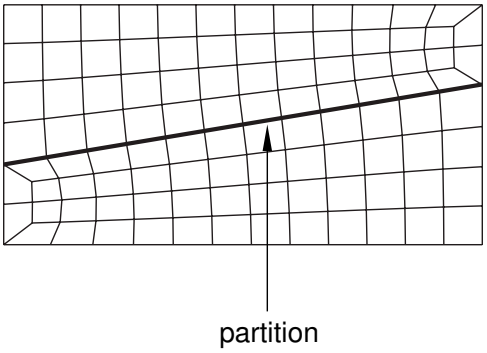

Figure 3: The mesh flows along the partition.

You can use the additional edges created by partitioning a face to control the mesh characteristics. For example, *Figure 4* illustrates how a partition and local mesh seeds allow you to control the mesh flow and density.

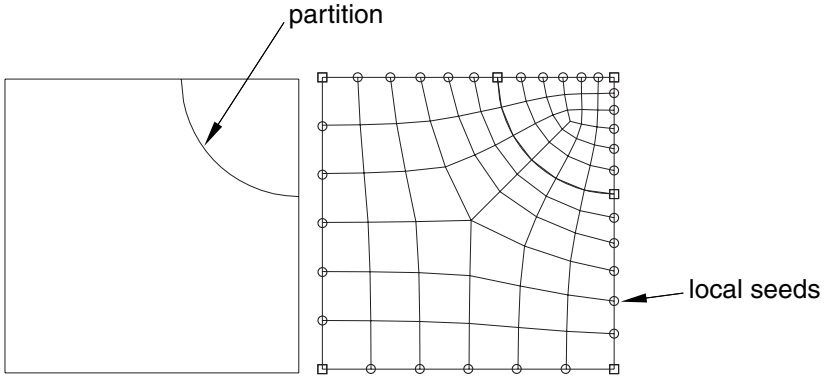

Figure 4: A partition and local mesh seeds allow you to control the mesh flow and density.

Similarly, *Figure 5* shows how partitioning and local mesh seeds allow you to refine the mesh in the area of a stress concentration.

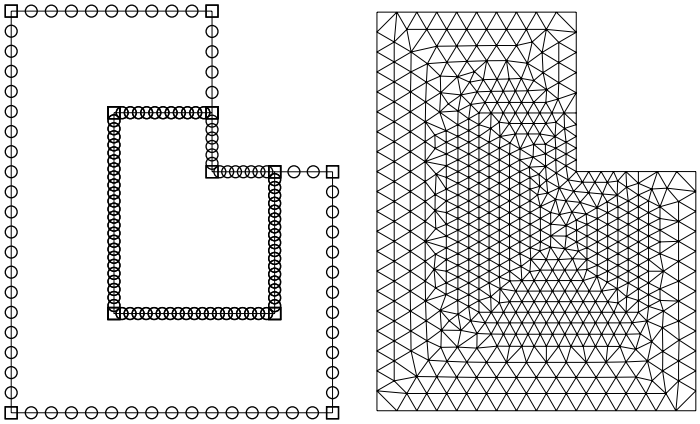

Figure 5: Partitioning and local mesh seeds allow you to refine the mesh in the area of a stress concentration.

In addition, you can apply different mesh controls, such as element shape, to the regions created by a partition.

When partitioning, remember that partitions will become element boundaries. Therefore, try to ensure that partitions make angles as close to 90° as possible with other partitions or edges. In addition, you should avoid creating unwanted short edges that will distort the mesh.

How are seeds and other attributes affected by partitioning?

Seed distributions along edges you have seeded may change during the partitioning process; Abaqus/CAE redistributes the seeds to accommodate any new vertices created by partitioning. For example, the left and right edges of the part instance in *Figure 1* are seeded with seven elements per edge.

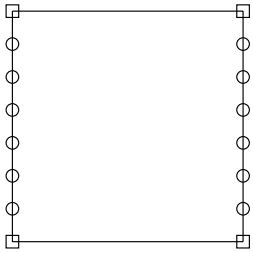

Figure 1: The left and right edges each have seven elements.

If you create a partition that splits the part instance into two regions, new vertices are created at the midpoints of both edges. In *Figure 2* you can see how Abaqus/CAE added seeds at the new vertices so that nodes will exist at the corners of each region.

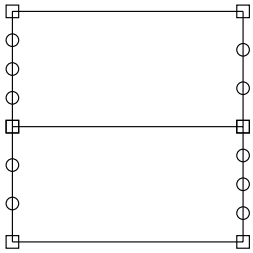

Figure 2: Redistribution of seeds.

Abaqus/CAE also redistributed the existing seeds to eliminate any overly small elements created by the new partition. However, this redistribution can result in seeds that are not aligned. The top region has one seed more on the left side than it does on the right, and the reverse is true for the bottom region. In this example you could change the number of elements along the right and left edges to an even number to ensure that the seeds align after partitioning.

Any other mesh attributes, such as element shape or element type, that you have applied are applied automatically to each new region that you create with a partition. However, once you have created the different regions, you can assign different mesh attributes to each region.

Regenerating partitions after modifying geometry

Partitions are features associated with the part or part instance; therefore, you can modify and regenerate them like any other feature.

For example, consider the partition on the right side of the part instance shown in *Figure 1*.

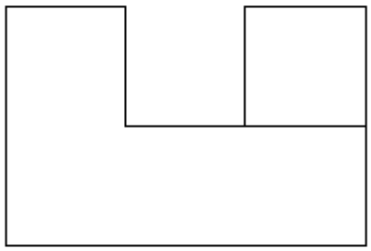

Figure 1: A partitioned part instance.

If you return to the Part module and widen the right side of the model, the partition also expands and continues to divide the face into two regions, as shown in *Figure 2*.

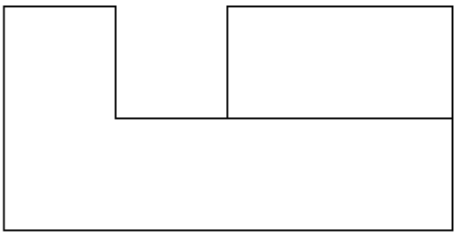

Figure 2: The partition is regenerated.

Sometimes regeneration of a partition creates unmeshable regions. In this situation simply add, modify, or delete partitions until the part instance becomes meshable again.

Using virtual topology to improve your mesh

In some cases parts or independent part instances contain details such as very small faces and edges. The Virtual Topology toolset allows you to remove these small details by combining a small face with an adjacent face or by combining a small edge with an adjacent edge. You can also ignore selected edges and vertices, which has the same effect as combining faces and edges. Introducing virtual topology is a convenient method for creating a clean, well-formed mesh. The Virtual Topology toolset is available only in the Mesh module.

However, adding virtual topology to a part instance can restrict your ability to subsequently mesh the part instance. For example, you cannot mesh regions that contain virtual topology using the following techniques:

- Two-dimensional free meshing with quadrilateral or quadrilateral-dominated elements using the medial axis algorithm.
- Three-dimensional swept meshing using the medial axis algorithm.
- Two-dimensional structured meshing if the region to be meshed is not bounded by four corners.
- Three-dimensional structured meshing if the region to be meshed is not bounded by six sides.

For more information, see *The Virtual Topology toolset*.

In addition, you can apply virtual topology only to independent instances. If you need to apply virtual topology to a dependent instance, you can create a copy of the original part and then create an independent instance of the copy. You can then replace the dependent instance with the new independent instance and apply virtual topology to the independent instance. For more information, see *What is the difference between a dependent and an independent part instance?*.

Using adaptive remeshing to improve your mesh

In many cases you will not know the adequacy of your mesh refinement for your particular solution goal until you have executed a number of analyses and evaluated the solution results. Mesh refinement studies are typically performed in these cases, where a mesh is successively refined and key solution results are confirmed to converge. You can automate this process by applying remeshing rules to regions of interest in your model and using the Abaqus/CAE adaptive remeshing process to automatically perform successive mesh refinement based on a series of executed analyses.

With a remeshing rule you can specify:

- The region where you want the mesh refined.
- The solution quality criteria (for example error indicators in the Mises stress) that mesh refinement is based on.
- The analysis step or steps that refinement is based on.
- Minimum and maximum element size constraints.
- A sizing algorithm and parameters appropriate to your simulation.

For more information, see *Advanced meshing techniques* and *Creating, editing, and manipulating adaptivity processes*.

Understanding mesh generation

This section explains basic concepts and terminology related to meshes and mesh generation.

In this section:

- *Generating a mesh*
- *Preserving the precision of nodal coordinates*
- *Determining which regions are meshable*
- *What should I do if a region fails to mesh?*
- *What is a mesh transition?*
- *What is the difference between the medial axis algorithm and the advancing front algorithm?*
- *What kinds of meshes cannot be generated automatically?*
- *When will Abaqus/CAE delete a mesh?*
- *Do I have to mesh the entire model in one operation?*
- *Can I change the geometric order of the elements in a mesh?*

Generating a mesh

Most meshing in Abaqus/CAE is completed in a “top-down” fashion.
This means that the mesh is created to conform exactly with the geometry of a region and works down to the element and node positions.

1. Abaqus/CAE follows these basic steps to generate a mesh:

   Generate a mesh on each top-down region using the meshing technique currently assigned to that region. By default, Abaqus/CAE generates meshes with first-order line, quadrilateral, or hexahedral elements throughout.

2. Merge the meshes of all regions into a single mesh. Typically, Abaqus/CAE merges the nodes along the common boundaries of neighboring regions into a single set of nodes. However, in certain cases Abaqus/CAE creates tied surface interactions instead of merging these nodes; for example, along the common interface between hexahedral and tetrahedral meshes. For more information, see *Meshing multiple three-dimensional solid regions*.

Top-down meshes generated by Abaqus/CAE conform to the geometry of the part or part instance they discretize, as shown in *Figure 1*:

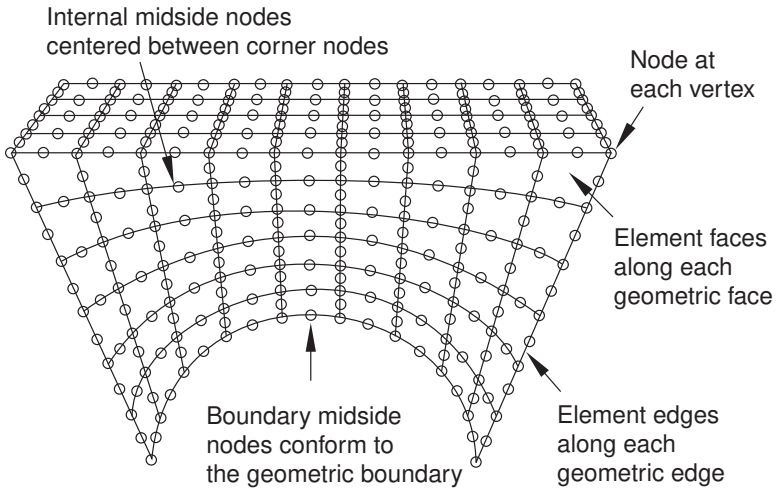

Figure 1: The mesh conforms to the geometry of the part instance.

- A node is generated at each geometric vertex.
- A connected set of element edges is generated along each geometric edge.
- A connected set of element faces is generated along each geometric face.
- Nodes that are on the boundary of the mesh (including the midside nodes of second-order elements) are also on the boundary of the geometry.
- Midside nodes of internal second-order elements are centered between the end nodes of the element edges.

For detailed, step-by-step instructions on creating a top-down mesh, see *Creating a mesh*.

Relying directly on the geometry to form the outer mesh boundaries can impact mesh quality as Abaqus/CAE creates elements to fill small details. In some cases you may not be able to implement a partitioning strategy that allows you to apply a top-down swept or structured meshing technique on a complex region. For solid regions, you can use the “bottom-up” meshing technique in place of the automated top-down meshing techniques to generate a hexahedral mesh. Bottom-up meshing is a manual, incremental meshing process that builds up a three-dimensional mesh from two-dimensional entities. You define the regions that will be meshed using the bottom-up technique, control the meshing process, decide whether the resulting mesh meets your needs, and—since the mesh is not required to conform to the geometry— control the associativity of the geometry to the mesh. For more information on bottom-up meshing, see *Bottom-up meshing*.

Preserving the precision of nodal coordinates

When you create a part in the Part module, it exists in its own coordinate system, independent of other parts in the model. In contrast, when you create an instance of the part in the Assembly module and position it relative to other part instances, you are working in the assembly's global coordinate system.

To preserve precision, the Mesh module separates the positioning information of a part instance from the geometry of the instance. As a result, when you generate a mesh, the nodal coordinates for the part instance are computed relative to the coordinate system of the original part. (When the Job module generates an input file, Abaqus/CAE writes the nodal coordinates for each instance relative to its own coordinate system and passes the instance positioning and orientation information to the analysis product via the **INSTANCE* keyword.)

The Mesh module stores these nodal coordinates in single precision. If the geometry of the part lies far from the origin of its coordinate system, some precision of the nodal coordinates will be lost. To prevent this loss of precision, you should try to position a part close to the origin of its coordinate system. For example, the origin of the coordinate system of an Abaqus/CAE native part is located at the origin of the sketch that defined the base feature. Therefore, if possible, you should position the sketch of the base feature over the origin of the sketcher grid.

Determining which regions are meshable

When the **Mesh defaults** color mapping is selected, the color of a region in the Mesh module indicates the meshing technique currently assigned to that region. The color coding is as follows:

- Structured meshing technique: green
- Free meshing technique: pink
- Swept meshing technique: yellow
- Unmeshable: orange
- Bottom-up meshing technique: light tan

See *Structured meshing and mapped meshing*, *Free meshing*, *Swept meshing*, and *Bottom-up meshing* for information about each meshing technique. See *Color coding geometry and mesh elements* for more information about color mappings.

In many cases Abaqus/CAE can use more than one technique to mesh a region; in these cases you can either accept the default technique, or you can use the **Mesh Controls** dialog box to select an alternative technique. In addition, you can change the meshing techniques that are valid for a region by adding partitions to the region or by assigning a different element shape to the region. For example, if you change the element shape assignment of an unmeshable three-dimensional part instance from hexahedra to tetrahedra, the part instance becomes meshable using the free-meshing technique. For more information, see *Why partition in the Mesh module?*.

Note:

You must use the **Mesh Controls** dialog box to assign the bottom-up meshing technique to a region. To unassign the bottom-up technique, you may select another technique or click **Defaults** in the **Mesh Controls** dialog box to allow Abaqus/CAE to use the default element shape and meshing technique for the region.

The default meshing technique for two-dimensional models is the free meshing technique. If you are not satisfied with the quality of the mesh generated by the free meshing technique, or if you prefer a more regular grid-like mesh pattern, you can assign structured meshing to the simpler regions of your model. However, if your model is large and complex, identifying the simple regions where structured meshing is applicable can be a time-consuming process. To make the process faster, you can apply the structured meshing technique to the entire model, and Abaqus/CAE will do the following:

- Determine if any faces are too complex to be structured meshed and ask if you wish to remove them from your selection.
- Determine if any faces are poorly shaped and will result in unacceptable mesh quality and ask if you wish to remove them from your selection.

If Abaqus/CAE removed any faces from your selection, they are colored pink to indicate that they will be meshed using free meshing. Remaining faces are colored green to indicate that Abaqus/CAE will mesh them using structured meshing.

For example, *Figure 1* shows a shell model of an electrical connector. The user attempted to assign structured meshing to the entire assembly, and Abaqus/CAE removed the indicated faces from their selection.

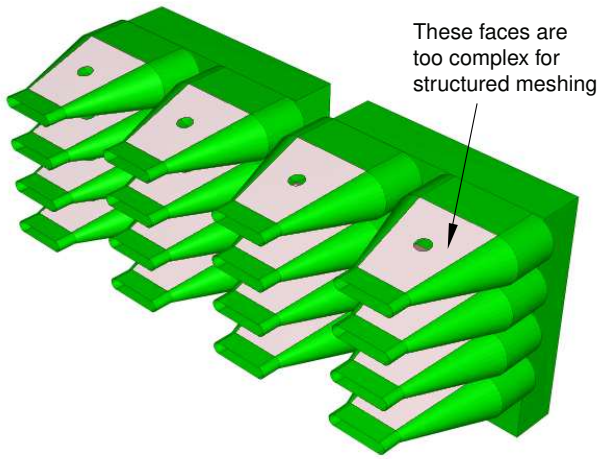

Figure 1: Faces that cannot be structured meshed are removed from the selection.

If you are meshing a solid model, you must select one or more cells and use the **Mesh Controls** dialog box to determine whether the structured technique can be applied to those cells. If you have a region that will be meshed using free tetrahedral meshing, you can select boundary faces and use the **Mesh Controls** dialog box to determine whether the structured technique can be applied to create a triangular boundary mesh prior to tetrahedral meshing of the solid.

For detailed information on controlling the mesh technique and element shape assigned to a region, see the following sections:

- *Bottom-up meshing*
- *Assigning mesh controls*
- *Choosing an element shape*
- *Selecting a meshing technique*
- *Changing mesh controls for previously meshed regions*

What should I do if a region fails to mesh?

If a region fails to mesh, Abaqus/CAE displays an **Error** dialog box that explains why the meshing failed. In most cases Abaqus/CAE highlights the region and allows you to save it in a set. You can create a display group from the set and use the display group to study the region that failed to mesh.

Some of the more common reasons why a region fails to mesh and the associated solutions are as follows:

Inadequate seeding

The region contains some small edges or the seed density is too coarse. You can use the Virtual Topology toolset to merge small edges. Alternatively, if you save the region that failed to mesh in a set, you can apply local seeds of a finer density to the saved set.

When you are creating a hexahedral mesh, a quadrilateral mesh, or a quadrilateral-dominated mesh using the medial axis algorithm, Abaqus may need to alter seeds to generate the mesh. In some cases, mesh generation may fail because the modified seeds density is too coarse. Meshing may succeed if you incrementally mesh the regions of the part in a different order, or, as described above, you can apply local seeds of a finer density and remesh the part.

Bad geometry

Bad geometry refers to small edges or faces or to part instances that are imprecise. You can use the Query toolset to check the geometry. For more information, see *Using the geometry diagnostic tools*.

Poor boundary triangles

When you are creating a free mesh with tetrahedral elements, Abaqus/CAE first creates a triangular mesh on the faces of the region and then uses those triangles as faces of the boundary tetrahedral elements. You can choose to preview the triangular mesh on the faces and decide if it is acceptable before continuing with the time-consuming process of generating tetrahedral elements through the interior of the region. For more information, see *What is a tetrahedral boundary mesh?*.

In some cases Abaqus/CAE cannot complete the conversion from triangles to tetrahedra and highlights the nodes on the boundary mesh that cannot be inserted into the tetrahedral mesh. The highlighted nodes serve as indicators of regions that require attention, and you can try the following:

- Use the seeding tools to increase the mesh density.
- Use the Virtual Topology toolset to combine small faces and edges with adjacent faces and edges.
- Use the Partition toolset to partition regions into simpler subregions.
- Use the Edit Mesh toolset to improve the tetrahedral boundary mesh.
- Use mesh controls to change the mesh technique applied to faces of the solid region.

Gasket regions

You can generate a gasket reinforcement mesh only on a region that contains a gasket mesh.

What is a mesh transition?

A mesh transition is an area where a mesh transitions from coarse (large elements) to fine (small elements), as shown in *Figure 1*.

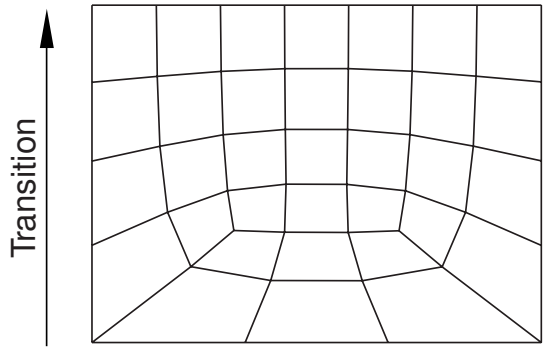

Figure 1: A mesh with a transition from coarse to fine elements.

Abaqus/CAE provides mesh transition controls for the following types of meshes:

- A two-dimensional, quadrilateral-only mesh that is created using the structured meshing technique or the free meshing technique with the medial axis algorithm.
- A three-dimensional, hexahedral-only mesh that is created by sweeping a two-dimensional mesh. For more information, see *What is swept meshing?*.

When transition controls are applicable to the type of mesh you are creating, a toggle button appears on the right side of the **Mesh Controls** dialog box that allows you to minimize the mesh transition. By default, Abaqus/CAE minimizes the mesh transition, which in some cases will reduce mesh distortion. Conversely, if you toggle off the option to minimize mesh transition, the mesh may move closer to the specified mesh seeds. To display the **Mesh Controls** dialog box, select **Mesh->Controls** from the main menu bar. For more information, see *Setting the mesh algorithm*.

What is the difference between the medial axis algorithm and the advancing front algorithm?

The medial axis algorithm and the advancing front algorithm are two meshing schemes that Abaqus/CAE can use to generate a mesh when you are doing the following:

- Meshing a surface with quadrilateral or quadrilateral-dominated elements using the free meshing technique.
- Meshing a solid region with hexahedral or hexahedral-dominated elements using the swept meshing technique. (Abaqus/CAE generates hexahedral and hexahedral-dominated meshes by sweeping the quadrilateral and quadrilateral-dominated elements generated by the two algorithms from the source side to the target side.)

The two algorithms are described as follows:

Medial axis

The medial axis algorithm first decomposes the region to be meshed into a group of simpler regions. The algorithm then uses structured meshing techniques to fill each simple region with elements. If the region being meshed is relatively simple and contains a large number of elements, the medial axis algorithm generates a mesh faster than the advancing front algorithm. Minimizing the mesh transition may improve the mesh quality. The mesh transition option is available only for quadrilateral and hexahedral meshing. For more information, see *What is a mesh transition?*.

Advancing front

The advancing front algorithm generates quadrilateral elements at the boundary of the region and continues to generate quadrilateral elements as it moves systematically to the interior of the region.

The elements generated by the advancing front algorithm will always follow the seeding exactly for quadrilateral-dominated and hexahedral-dominated meshes (except when you are creating a three-dimensional revolved mesh, and the profile being revolved touches the axis of revolution). For other meshes the elements generated by the advancing front algorithm will always follow the seeding more closely than those generated by the medial axis algorithm. If the region to be meshed contains virtual topology, you can use only the advancing front algorithm to generate the mesh.

If you select the advancing front algorithm, you can allow Abaqus/CAE to use mapped meshing where appropriate. (Mapped meshing is the same as structured meshing but applies to only four-sided regions.) For more information, see *What is mapped meshing?*, and *When can Abaqus/CAE apply mapped meshing?*.

You may have to experiment with the two algorithms to obtain the optimal mesh. *Figure 1* illustrates a simple shell region that was meshed with quadrilateral-dominated elements using the two meshing algorithms. In this example both algorithms generate an acceptable mesh.

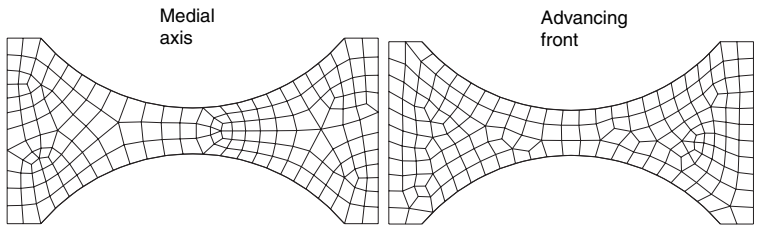

Figure 1: Both algorithms generate acceptable meshes.

Because the elements produced by the advancing front algorithm follow your seeds, the resulting mesh may include some skew in the elements in narrow regions. Element skew is illustrated in *Figure 2*.

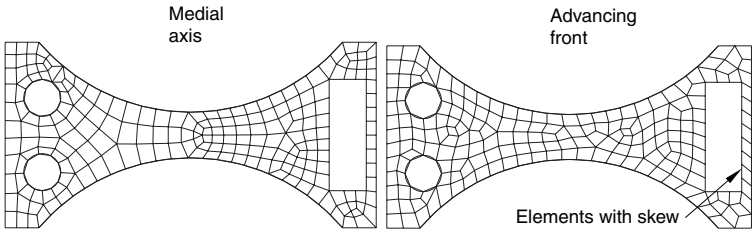

Figure 2: In some cases the advancing front algorithm generates elements with some skew.

In contrast, the advancing front algorithm may generate elements of a more uniform size with a more consistent aspect ratio, as shown in *Figure 3*. Uniform element size can play an important role in the analysis; for example, if you are creating a mesh for an Abaqus/Explicit analysis, small elements in the mesh can unduly control the size of the time step. In addition, if it is important that the elements follow your seeds, the advancing front algorithm is preferable.

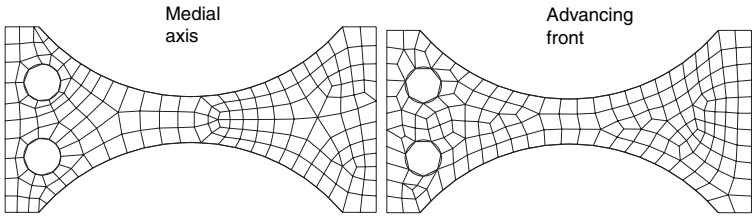

Figure 3: In some cases the advancing front algorithm produces a more uniform mesh.

In some cases, when you mesh multiple regions, Abaqus/CAE generates a mesh with sheared elements at the interface between regions. Nodes in one region may be positioned differently than nodes in an adjacent region, which results in shear at the common boundary when Abaqus/CAE merges the adjacent meshes. *Figure 4* shows multiple swept regions and the resulting mesh generated by the medial axis algorithm.

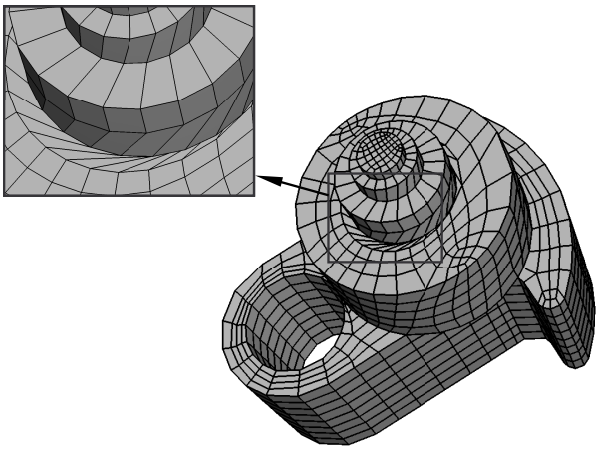

Figure 4: Mesh shear is significant between adjacent regions using the medial axis algorithm.

The advancing front algorithm positions the nodes on the source side at the same location as your seeds; as a result, the mesh shear will be reduced. *Figure 5* shows the same part meshed with the same seeding using the advancing front algorithm. However, as stated earlier, you may have to experiment with the two algorithms to obtain the optimal mesh.

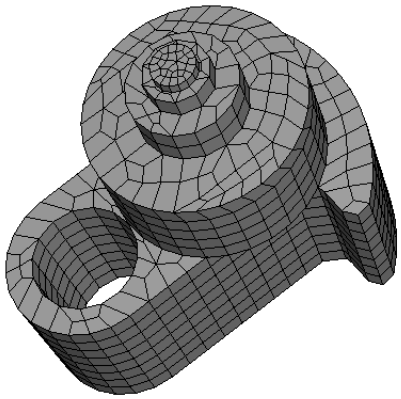

Figure 5: Mesh shear is reduced between adjacent regions using the advancing front algorithm.

Additional information

• *Setting the mesh algorithm*

What kinds of meshes cannot be generated automatically?

There are a few types of meshes that you cannot create using the mesh generator in the Mesh module:

Compatible meshes between part instances of the same assembly

Compatibility means that the element faces or element edges of the meshes of adjacent part instances share the same nodes and have the same topology at the common interface. You cannot prescribe mesh compatibility between instances. However, you can use the **Merge/Cut** tool in the Assembly module to merge multiple instances into a single part instance. You can then create a single compatible mesh from the single part instance. See *Compatible meshes between part instances*, for more information.

Symmetric meshes

You cannot ensure that Abaqus/CAE will generate a symmetric mesh for a symmetric part or part instance.

Bottom-up meshes

Bottom-up meshing is a manual process. You must set and apply the parameters to create the mesh for each region to which you have assigned the bottom-up meshing technique.

When will Abaqus/CAE delete a mesh?

The following attributes of a part, part instance, or region affect how the mesh will be generated:

- Seeding
- Element shape
- Meshing technique
- Meshing algorithm
- Logical corners of a two-dimensional structured region
- Transition control
- Sweep path of a swept region

If you change any of the attributes listed, the existing mesh will no longer be consistent with its attributes. As a result, Abaqus/CAE deletes the mesh, and you can recreate a new mesh that matches the new attributes. (Element order and element family are the only attributes that, when changed, do not require the mesh to be deleted and recreated.)

Whenever you make a change that will affect any of these attributes for a top-down meshed region, Abaqus/CAE displays a dialog box similar to the one shown in *Figure 1*.

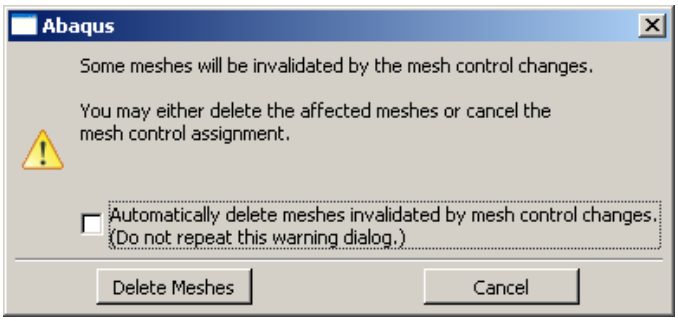

Figure 1: The warning dialog box.

You can delete the mesh by clicking the **Delete Meshes** button, or you can keep your mesh and exit the procedure by pressing the **Cancel** button.

You can also avoid this warning message for the remainder of the current session by toggling **Automatically delete meshes invalidated by mesh control changes**. The next time you attempt to change the attributes of a part, part instance, or region that already contains a mesh, the mesh will be deleted immediately without any warning being displayed.

If you save your model to a model database before you delete the mesh, you can revert back to that mesh if you are dissatisfied with later meshing attempts.

Since bottom-up meshes can be very time consuming to create, Abaqus/CAE attempts to preserve them in many circumstances that would cause a top-down mesh to be deleted. Bottom-up meshes are retained during changes to seeding, partitioning, and virtual topology. When you partition a region or create a virtual topology feature the mesh will be retained, but associativity with the geometry effected by the partition or virtual topology operation will be lost.

Warning:

There is no way to avoid deleting a top-down mesh when you change one of the meshing attributes listed above. Likewise, if you change the part geometry, Abaqus/CAE always deletes both top-down and bottom-up meshes without warning. Since remeshing can be time consuming for large or complex models, you should use caution when changing these attributes.

For detailed, step-by-step instructions on deleting a mesh, see *Deleting a mesh*.

Do I have to mesh the entire model in one operation?

Abaqus/CAE allows you to mesh the model in an incremental fashion, where each meshing operation meshes a different region of the model.
You can use incremental meshing to fine-tune the mesh in a selected region of your model without remeshing the entire model.

When you mesh a selected region, Abaqus/CAE tries to preserve the existing mesh in other regions of the model if possible. However, incremental meshing may force the nodes on the boundaries of the existing mesh to move and can reduce the mesh quality along the interfaces between the regions. If your part or part instance contains a seam crack, you must mesh the part or part instance in a single operation; incremental meshing is not supported.

In some cases Abaqus/CAE cannot proceed with an incremental meshing operation and must delete all the existing meshes before proceeding:

- Incremental meshing cannot proceed if the seeding between the existing mesh and the selected region cannot be honored. You must allow Abaqus/CAE to delete the existing mesh and remesh the original regions and the selected region.

  For example, consider the part instance in *Figure 1*.

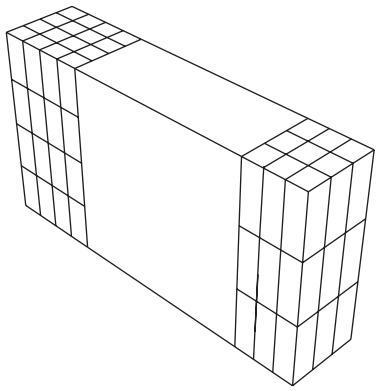

Figure 1: The central region cannot be meshed incrementally.

  The central region cannot be meshed incrementally because one end has a mesh with 4 × 4 mesh pattern and the opposite end has a mesh with a 3 × 3 mesh pattern. If you try to mesh only the central region, Abaqus/CAE will detect the problem and allow you to choose between the following:

  - Remesh the regions that are already meshed and the central region to generate a compatible mesh.
  - Cancel the operation to mesh the central region.

- Incremental meshing cannot proceed if the existing mesh needs to be derived from the mesh you are trying to create. For example, consider the part instance in *Figure 2*.

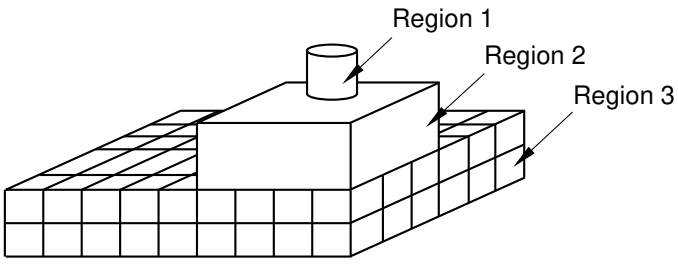

Figure 2: The regions must be meshed in the correct sequence.

To create a compatible mesh between region 1 and region 2, the mesh of region 2 is derived from the mesh of the cylinder in region 1. Similarly, the mesh of region 3 is derived from the mesh of region 2, which in turn was derived from the mesh of the cylinder in region 1. As a consequence, if you mesh region 3 first, Abaqus/CAE cannot incrementally mesh regions 1 and 2. You must allow Abaqus/CAE to mesh region 1 prior to remeshing regions that were already meshed.

If incremental meshing cannot proceed, Abaqus/CAE displays a warning message prior to deleting an existing mesh.

If you want to mesh the part or assembly incrementally, you can follow a strategy that will minimize the number of times Abaqus/CAE has to delete the existing mesh. The meshing strategy depends on the topology of the regions, the element shapes, the meshing technique, and the mesh seeding.

- Changes to the seeding always propagate out to the boundaries. As a result, you should start meshing from the interior of the part or part instance and continue out to the boundaries of the part or instance.
- However, if you can identify a set of adjacent three-dimensional regions that will be meshed using the swept method, you should start meshing on one side of the part or part instance and continue the mesh through the interior to the other side of the part or instance.
- Regions that are meshed by triangles or tetrahedral elements will never force the entire mesh to be deleted during incremental meshing. The same is also true for regions that are meshed by quadrilateral-dominated elements using the advancing front algorithm. Abaqus/CAE can always remesh these regions, and you can mesh them at any time.

Can I change the geometric order of the elements in a mesh?

If you have already meshed a part, a part instance, or a region, Abaqus/CAE allows you to change the element order without having to recreate the entire mesh. If you change between linear and quadratic elements, Abaqus/CAE simply adds or removes the midside nodes as required.

If the part or part instance contains orphan elements, you can change the order of all the elements or you can change the order of only selected elements. Orphan elements contain no underlying geometry information; therefore, you should take care when changing the order of the elements. If you change orphan elements from quadratic to linear, all information on the location of the midside nodes is lost. As a result, if you subsequently decide to change back from linear to quadratic elements, you will not be able to return to the original mesh. For more information, see *What kinds of files can be imported and exported from Abaqus/CAE?*.

Structured meshing and mapped meshing

This section describes the structured and mapped meshing techniques and the types of regions to which these techniques can be applied.

In this section:

- *What is structured meshing?*
- *What is mapped meshing?*
- *Two-dimensional structured meshing*
- *Three-dimensional structured meshing*
- *Using structured meshing near concave boundaries*
- *When can Abaqus/CAE apply mapped meshing?*

What is structured meshing?

The structured meshing technique generates structured meshes using simple predefined mesh topologies. Abaqus/CAE transforms the mesh of a regularly shaped region, such as a square or a cube, onto the geometry of the region you want to mesh. For example, *Figure 1* illustrates how simple mesh patterns for triangles, squares, and pentagons are applied to more complex shapes.

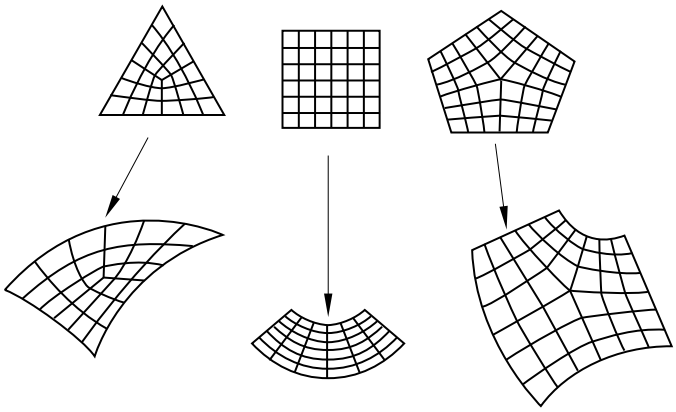

Figure 1: Two-dimensional structured mesh patterns.

You can apply the structured meshing technique to simple two-dimensional regions (planar or curved) or to simple three-dimensional regions that have been assigned the **Hex** or **Hex-dominated** element shape option. For more information about assigning element shapes to a region, see *Choosing an element shape*.

What is mapped meshing?

The terms structured meshing and mapped meshing are used interchangeably in the finite element analysis literature. However, Abaqus/CAE makes a subtle distinction between the two terms. Mapped meshing is a subset of structured meshing. Mapped meshing refers only to structured meshing of four-sided, two-dimensional regions—the square mesh pattern in *Figure 1*.

Some models that appear very complex actually contain faces with relatively simple geometry. When you mesh such a model with free or swept meshing, the resulting element quality can be poor on these faces. However, if you allow Abaqus/CAE to use the mapped meshing technique where the geometry is appropriate, it often generates elements of good quality, especially if the region is a long, thin rectangular face.

You cannot apply mapped meshing directly to a region. However, you can apply it indirectly by meshing a region and allowing Abaqus/CAE to apply mapped meshing where appropriate. For example, *Figure 1* shows the effect of free meshing a part and allowing Abaqus/CAE to use mapped meshing where appropriate.

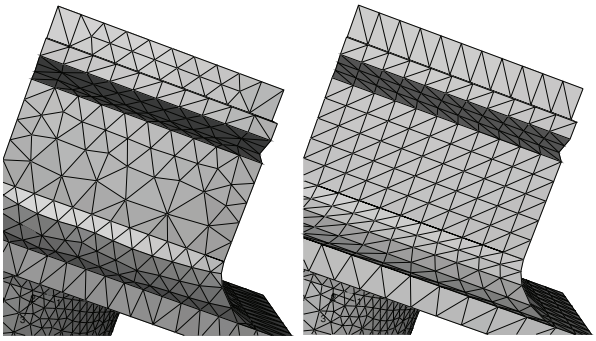

Figure 1: The effect of allowing mapped meshing.

By default, Abaqus/CAE uses mapped meshing where appropriate when you are doing the following:

- Using the advancing front algorithm to sweep mesh a solid region with hexahedral or hexahedral-dominated elements.
- Using the advancing front algorithm to free mesh a shell region with quadrilateral or quadrilateral-dominated elements.
- Free meshing a solid region with tetrahedral elements.
- Free meshing a shell region with triangular elements.

Two-dimensional structured meshing

A two-dimensional region can be meshed using the structured meshing technique if it has the following characteristics:

- The region has no holes, isolated edges, or isolated vertices. *Figure 1* shows regions that cannot be structured meshed.

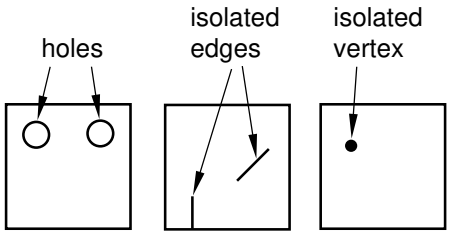

Figure 1: Regions that cannot be structured meshed.

- The region is bounded by three to five logical sides, where each side is a connected set of edges.

In general, structured meshing gives you the most control over the mesh that Abaqus/CAE generates. If you are meshing a four-sided region with all quadrilateral elements, the total number of element edges around the boundary must be even. For three- and five-sided regions, the constraint equations are more complex. Abaqus/CAE respects seed distribution wherever possible when generating a structured mesh. (Seed distribution describes the spacing of the seeds, not necessarily the number of seeds. For example, are the seeds evenly spaced along an edge or more concentrated at one end?) However, meshes must be compatible across regions, and Abaqus/CAE may adjust the nodes of a mesh region that is adjacent to a region that was meshed using the free meshing technique. As a result, the element nodes may not match the seeds exactly.

Figure 2 shows the seeds on the edges of a four-sided region and the effect of different mesh controls.

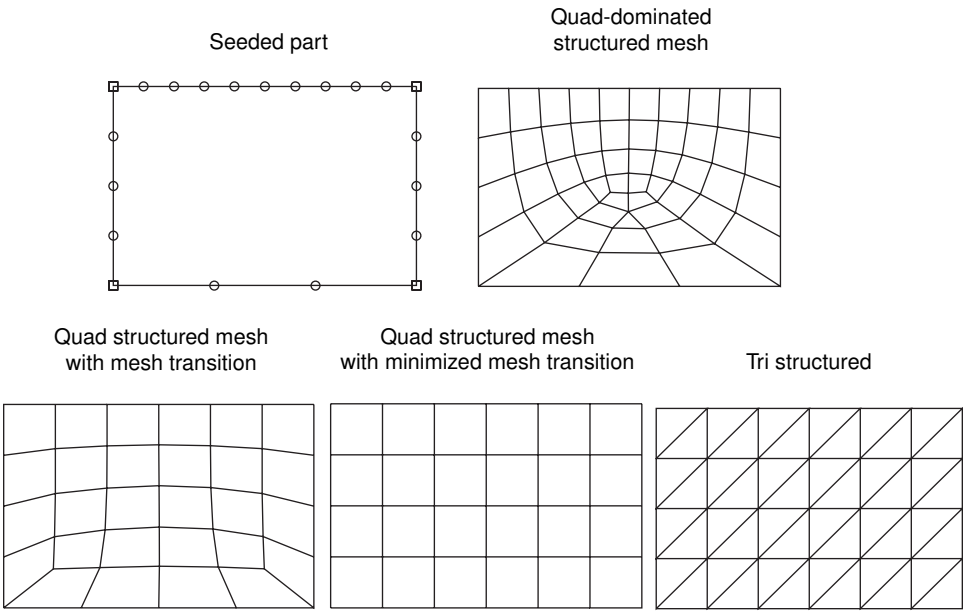

Figure 2: The effect of different mesh controls.

The mesh control effects are as follows:

- In four-sided regions the quadrilateral-dominated structured mesh matches the seeding exactly. There are an odd number of elements around the boundary, and Abaqus/CAE inserts a single triangle into the mesh. (In contrast, when you mesh a three- or a five-sided region with structured quadrilateral-dominated elements, Abaqus/CAE does not insert any triangles. The resulting mesh uses all quadrilateral elements; however, the resulting mesh may not match the mesh seeding exactly.)
- The two quadrilateral structured meshes do not match the seeding. This is even more apparent when you choose to minimize the mesh transition.
- The triangular structured mesh also does not match the seeding. Abaqus/CAE creates the triangular mesh by splitting the diagonals of the quadrilateral structured mesh with minimized mesh transition.

Abaqus/CAE combines edges into a logical side automatically if the edges subtend a shallow angle. For example, each region in *Figure 3* has five edges.

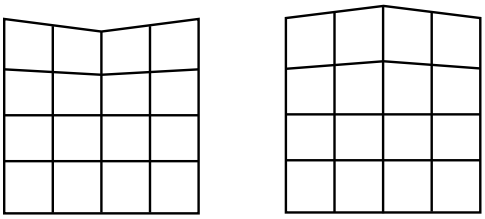

Figure 3: Edges subtending shallow angles.

However, since the top two edges in each region subtend a shallow angle, Abaqus/CAE considers these two edges to be one logical side. Therefore, the mesh pattern for four-sided regions is applied to these regions. If the region contains virtual topology, you can mesh the region using the structured meshing technique only if the region is bounded by four sides. You cannot use structured meshing to mesh three- or five-sided regions that contain virtual topology.

You can use the **Redefine Region Corners** button in the **Mesh Controls** dialog box to combine edges yourself, regardless of the angle they subtend. (To display the **Mesh Controls** dialog box, select **Mesh->Controls** from the main menu bar.) This technique allows you to control which structured mesh pattern is applied to the two-dimensional region. (This technique is not available for three-dimensional regions.) For more information, see *Redefining region corners*.

The region that you plan to mesh with structured quadrilateral elements must be well shaped; otherwise, Abaqus/CAE may create invalid elements as shown in *Figure 4*.

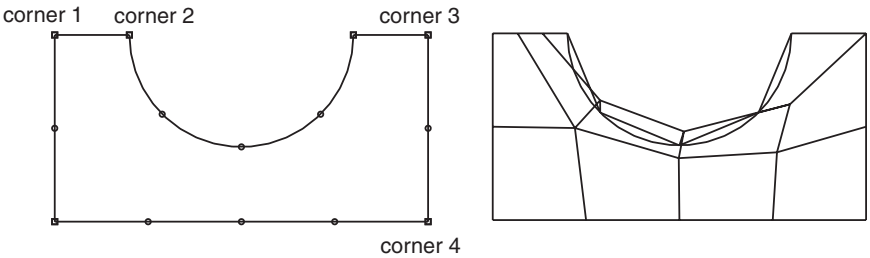

Figure 4: Regions must be well shaped.

If the mesh contains invalid elements, you can use several techniques to correct the mesh:

- Adjust the position of the mesh seeds.
- Redefine the region corners.
- Partition the face into smaller, better shaped regions.

The result of applying each technique is illustrated in *Figure 5*.

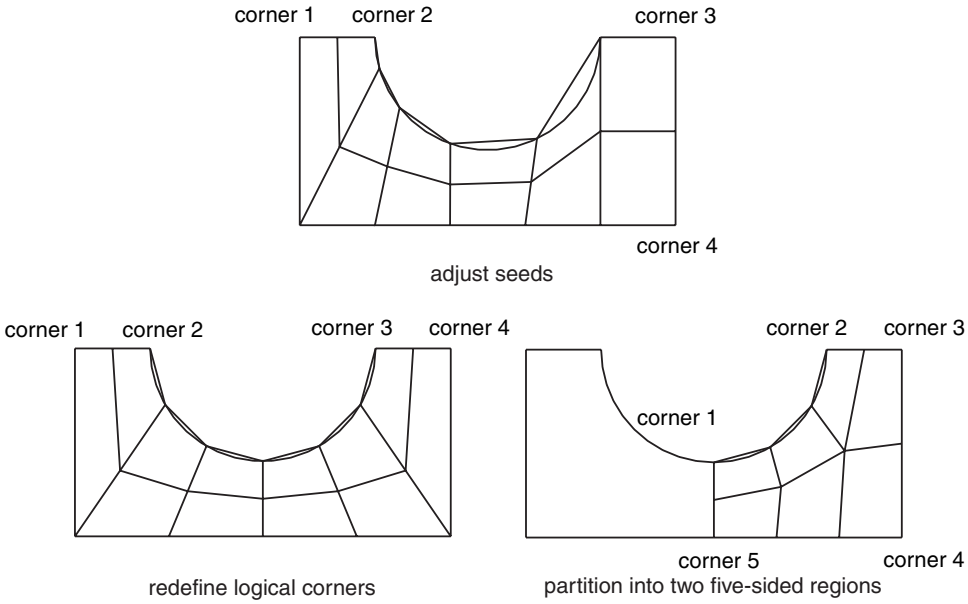

Figure 5: Correcting a mesh that contains invalid elements.

Three-dimensional structured meshing

Figure 1 illustrates examples of simple three-dimensional regions that can be meshed using the structured meshing technique.

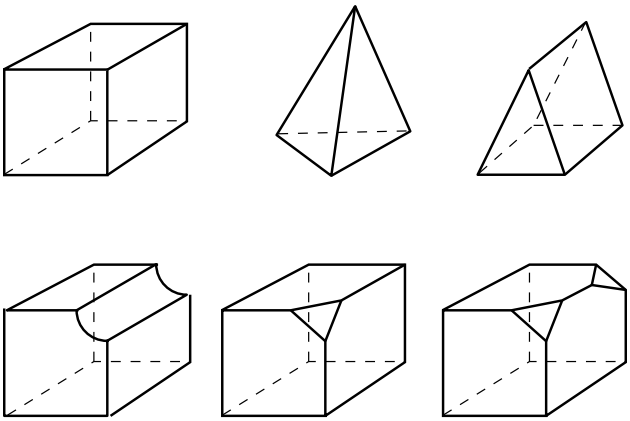

Figure 1: Regions that can be meshed using the structured meshing technique.

Meshing more complex regions with this technique may require manual partitioning. If you do not partition a complex region, your only meshing option may be the free meshing technique with tetrahedral elements. Meshes constructed using the structured meshing technique consist of hexahedral elements, which are preferred over tetrahedral elements.

The characteristics described below are required to mesh a three-dimensional region successfully using the structured meshing technique:

- The region cannot have any holes, isolated faces, isolated edges, or isolated vertices. For example, the regions shown in *Figure 2* cannot be meshed using the structured meshing technique.

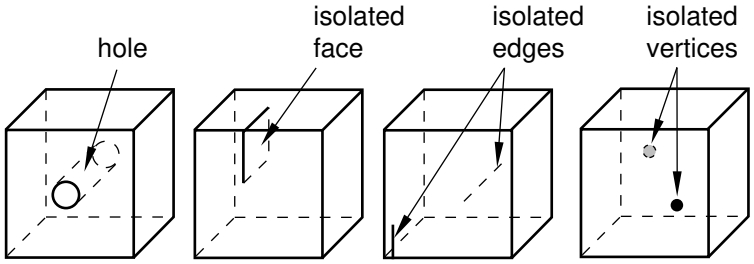

Figure 2: Regions that cannot be meshed using the structured meshing technique.

You can eliminate holes (whether they pass all the way through the part instance or just part way through) by partitioning their circumferences into halves, quarters, etc. For example, the four partitions in *Figure 3* convert the part instance from one region with a hole to four regions without holes.

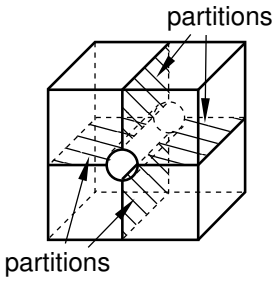

Figure 3: Partitions can make a part structured meshable.

- You should limit arcs to 90° or less to avoid concavities along sides and at edges. For example, the part instance in *Figure 4* has been partitioned so that the single region with 180° arcs becomes two regions with 90° arcs.

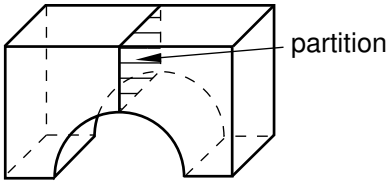

Figure 4: Limit arcs to 90° or less.

- All the faces of the region must have geometries that could be meshed using the two-dimensional structured meshing technique. For example, without partitioning, the semicircles at either end of the part in *Figure 5* have only two sides each. (A face must have at least three sides to be meshed using the structured meshing technique.) If you partition the part into two halves, each semicircle is divided into two faces with three sides each.

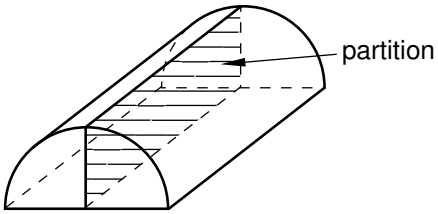

Figure 5: Partitioning creates two faces with three sides.

- Exactly three edges of the region must meet at each vertex. For example, the vertex at the top of an unpartitioned pyramid in *Figure 6* is connected to four edges. However, if you partition the pyramid into two tetrahedral regions, the vertex is connected to only three edges for each individual region.

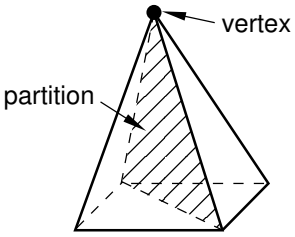

Figure 6: After partitioning the vertex is connected to only three edges for each individual region.

- The region must be bounded by at least four sides (a tetrahedral region). If a region is bounded by fewer than four sides, you can partition the region as necessary to create additional sides.
- If a region contains virtual topology, the region must be bounded by six sides.
- If a region cannot be meshed using the structured meshing technique, you can use virtual topology to combine faces until the region is bounded by six sides. *Figure 7* shows how you can use virtual topology to create a six-sided region that can be meshed using the structured meshing technique.

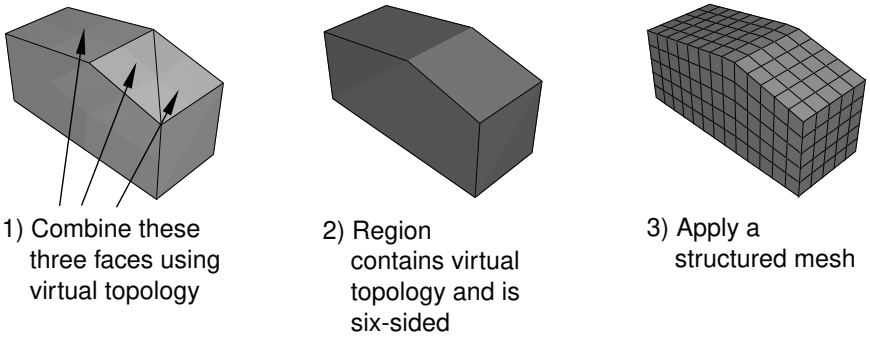

Figure 7: Virtual topology can make a part structured meshable.

- The angles between sides should be as close to 90° as possible; you should partition to eliminate angles greater than 150°.
- Each side of the region must match one of the following definitions:
  - If the region is not a cube, a side must correspond to a single face; that is, the side must not contain multiple faces.
  - If the region is a cube, a side can be a connected set of faces that are on the same geometric surface. However, each face must have four sides. In addition, the pattern of the faces must allow rows and columns of hexahedral elements to be created in a regular grid pattern along that entire side when the cube is meshed. For example, *Figure 8* shows two acceptable face patterns and the resulting regular grid pattern of elements created by meshing the cubes using the structured meshing technique.

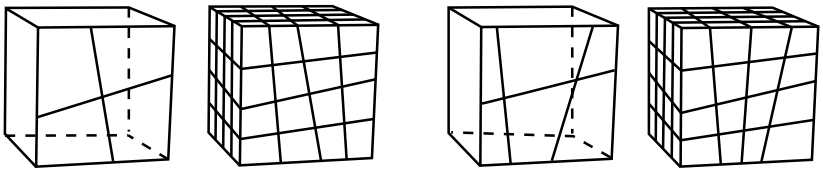

Figure 8: Acceptable face patterns and the resulting meshes.

The sides in *Figure 9* do not have acceptable face patterns:

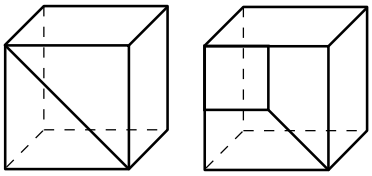

Figure 9: Unacceptable face patterns.

The face pattern shown on the left is unacceptable for structured meshing because each face has only three sides. Each face in the pattern shown on the right has four sides, but the pattern does not allow a regular grid of elements to be created on the partitioned side of the cube, as shown in *Figure 10*.

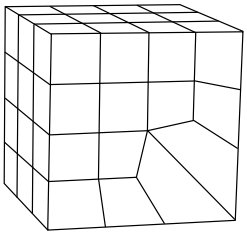

Figure 10: A regular grid of elements cannot be created.

Using structured meshing near concave boundaries

When you mesh a region using any meshing technique, the nodes on the boundary of the mesh are always located on the boundary of the geometric region. However, when Abaqus/CAE creates a mesh using the structured meshing technique, it is possible for nodes in the interior of the mesh to fall outside the region's geometry, which results in a distorted, invalid mesh. This problem typically occurs near concave boundaries.

For example, the region in *Figure 1* has five sides; therefore, when Abaqus/CAE meshes this region using the structured meshing technique, it applies the mesh pattern for a regular pentagon to the region.

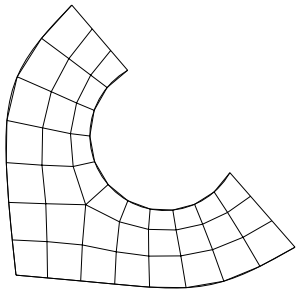

Figure 1: The mesh pattern for a regular pentagon is applied to the region.

However, if you seed the region so that the number of elements is reduced, as shown in *Figure 2*, a distorted mesh results due to the concavity at the highly curved edge. Nodes from the interior of the mesh pattern (indicated by closed circles in *Figure 3*) fall outside the region's geometry, while nodes on the boundary of the mesh (indicated by open circles in *Figure 3*) remain on the boundary of the region's geometry.

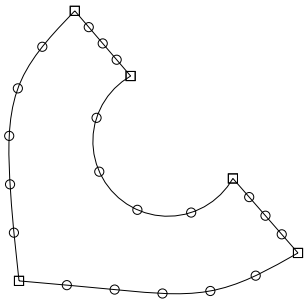

Figure 2: Seeds prescribing a coarser mesh.

When interior nodes fall outside the region's geometry, you can try the following techniques to improve the mesh:

- Change the mesh seeds and remesh. For example, the number of elements along the highly curved edge in *Figure 1* is greater than in *Figure 3*.

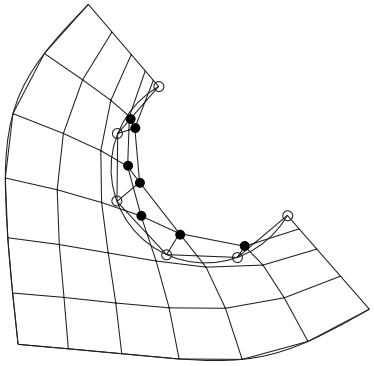

Figure 3: Nodes from the interior of the mesh fall outside the region's geometry.

- Partition the part instance into smaller, more regularly shaped regions. For example, the model was partitioned into three regions in *Figure 4*.

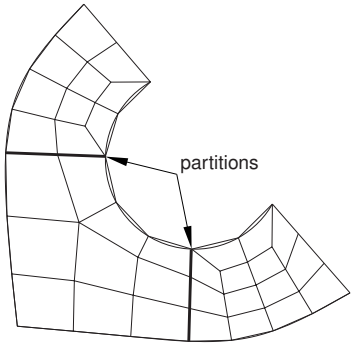

Figure 4: Partition the region.

- Select a different meshing technique. This option is most useful for two-dimensional regions, where you can switch from structured meshing to free meshing and still retain quadrilateral elements in the mesh. (Three-dimensional free meshing is limited to tetrahedral elements. For more information, see *Free meshing*.) *Figure 5* shows the region meshed using the free meshing technique.

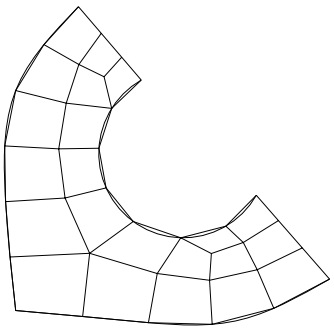

Figure 5: Mesh the region using the free meshing technique.

The mesh in *Figure 5* is not symmetric, which is typical of free meshes.

When can Abaqus/CAE apply mapped meshing?

Abaqus/CAE decides that mapped meshing is appropriate in a four-sided region when:

- it is likely that a regular mesh pattern with reasonable quality can be generated, and
- any minor adjustments to the mesh seeding will not violate the user's intent (as indicated by any existing seed constraints).

When Abaqus/CAE applies mapped meshing, it makes small adjustments to the mesh seeding to ensure that opposite sides of the rectangular region have the same number of seeds. If your model is large and includes many simple regions, it may take slightly longer for Abaqus/CAE to check for rectangular regions and adjust the seeds to produce a mapped mesh than to produce a mesh without mapped meshing. However, for most models the time difference to include mapped meshing is not significant compared to the improvement in mesh quality.

Figure 1 shows a shell part meshed with triangles using the following mesh techniques and algorithms available in Abaqus/CAE:

- Free meshing
- Free meshing using mapped meshing where appropriate
- Structured meshing

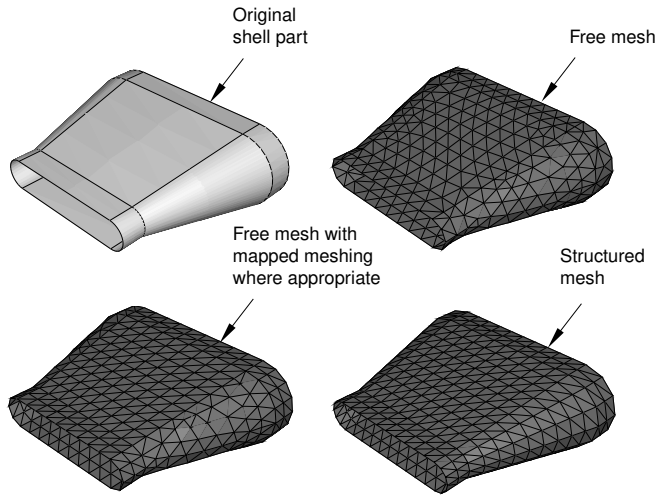

Figure 1: A shell part meshed with triangles in three different ways.

In many cases a free mesh of triangles with mapped meshing where appropriate will be the same as a structured mesh of triangles. The meshes are different in *Figure 1* because Abaqus/CAE honors the original seeding and determines that mapped meshing is not appropriate on the side of the part. In contrast, when Abaqus/CAE creates the structured mesh, it significantly adjusts the seeding to create the structured mesh that was requested by the user.

Swept meshing

This section explains the swept meshing technique and describes the types of regions to which this meshing technique can be applied.

In this section:

- *What is swept meshing?*
- *Swept meshing of surfaces*
- *Swept meshing of three-dimensional solids*
- *Swept meshing of cylindrical solids*
- *Characteristics of the geometry can prevent a part from being swept meshable*

What is swept meshing?

Abaqus/CAE uses swept meshing to mesh complex solid and surface regions. The swept meshing technique involves two phases:

- Abaqus/CAE creates a mesh on one side of the region, known as the source side.
- Abaqus/CAE copies the nodes of that mesh, one element layer at a time, until the final side, known as the target side, is reached. Abaqus/CAE copies the nodes along an edge, and this edge is called the sweep path. The sweep path can be any type of edge—a straight edge, a circular edge, or a spline. If the sweep path is a straight edge or a spline, the resulting mesh is called an extruded swept mesh. If the sweep path is a circular edge, the resulting mesh is called a revolved swept mesh.

For example, *Figure 1* shows an extruded swept mesh. To mesh this model, Abaqus/CAE first creates a two-dimensional mesh on the source side of the model. Next, each of the nodes in the two-dimensional mesh is copied along a straight edge to every layer until the target side is reached.

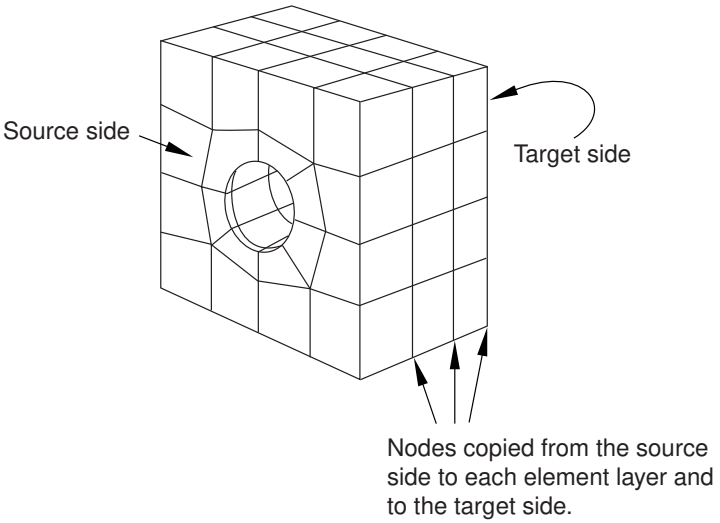

Figure 1: The swept meshing technique for an extruded solid.

To determine if a region is swept meshable, Abaqus/CAE tests if the region can be replicated by sweeping a source side along a sweep path to a target side. In general, Abaqus/CAE selects the most complex side (for example, the side that has an isolated edge or vertex) to be the source side. In some cases you can use the mesh controls to select the sweep path. If some regions of a model are too complex to be swept meshed, Abaqus/CAE asks if you want to remove these regions from your selection before it generates a swept mesh on the remaining regions. You can use the free meshing technique to mesh the complex regions, or you can partition the regions into simplified geometry that can be structured or swept meshed.

When you assign mesh controls to a region, Abaqus/CAE indicates the direction of the sweep path and allows you to control the direction. If the region can be swept in more than one direction, Abaqus/CAE may generate a very different two-dimensional mesh on the faces that it can select as the source side. As a result, the direction of the sweep path can influence the uniformity of the resulting three-dimensional swept mesh, as shown in *Figure 2*.

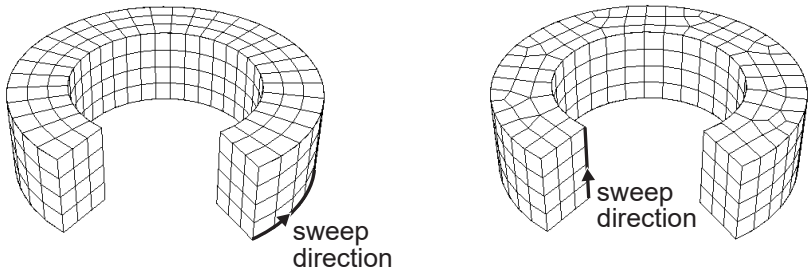

Figure 2: The sweep direction can influence the uniformity of the swept mesh.

In addition, the sweep path controls the default orientation of hexahedral and wedge elements that are used to model gaskets, continuum shells, cylindrical regions using cylindrical elements, and adhesive joints using cohesive elements. For more information, see *Assigning gasket elements to a region*, *Meshing parts with continuum shell elements*, *Swept meshing of cylindrical solids*, and *Creating a model with cohesive elements using geometry and mesh tools*.

Swept meshing of surfaces

Abaqus/CAE can apply the swept meshing technique only to surface regions that can be replicated by sweeping a source side along a sweep path to a target side. The sweep path is always an edge; however, for a surface region the source and target sides are also edges. The surface region can be extruded, revolved, swept, or planar. In addition, an extruded surface region can include twist, and a revolved surface region can include translation. You can apply the swept meshing technique to surface regions using either the **Quad** or **Quad-dominated** element shape options.

If you are creating a revolved swept mesh, Abaqus/CAE meshes the source side and revolves that mesh around the axis of revolution to the source side. The sweep path can be revolved a full 360°. You must use the **Quad-dominated** element shape option when the source side touches the axis of revolution at a point, because a layer of triangular elements is generated at that point. Abaqus/CAE cannot generate a revolved surface mesh when a single surface touches the axis of revolution at two points, unless the revolved surface is a sphere.

For example, the source side touches the axis of revolution at the top of the model shown in *Figure 1* and a layer of triangular elements is generated at that point.

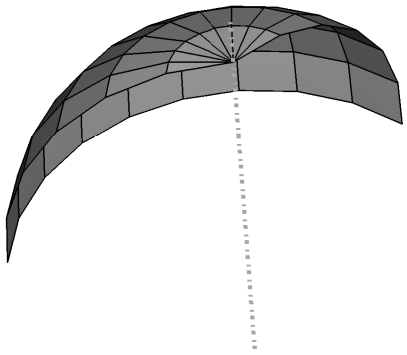

Figure 1: A layer of triangular elements.

(For more information on assigning element shapes to a region, see *Choosing an element shape*.)

Swept meshing of three-dimensional solids

Abaqus/CAE can apply the swept meshing technique to solid regions that can be replicated by sweeping a source side along an edge to the target side. For a three-dimensional solid the sweep path is an edge, but the source and target sides are faces. *Figure 1* illustrates an extruded swept mesh—Abaqus/CAE meshes the source side and extrudes that mesh along an edge to the target side. *Figure 2* illustrates a revolved swept mesh—Abaqus/CAE meshes the source side and revolves that mesh about the axis of the circular edge to the target side.

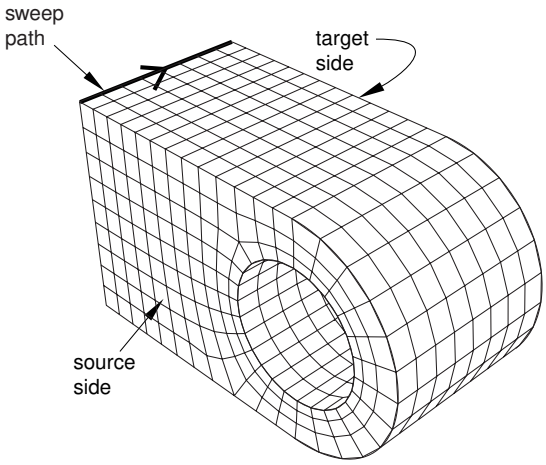

Figure 1: The extruded swept meshing technique sweeps the mesh on the source side along an edge.

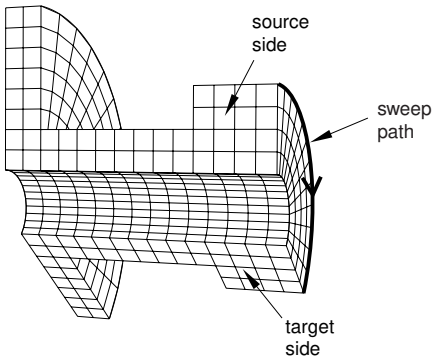

Figure 2: The revolved swept meshing technique sweeps the mesh on the source side along a circular edge.

If a region is swept meshable, Abaqus/CAE can generate the swept mesh on a region that has been assigned the **Hex**, **Hex-dominated**, or **Wedge** element shape option. To generate the preliminary two-dimensional mesh on the source side, Abaqus/CAE uses the free meshing technique with the **Quad**, **Quad-dominated**, or **Tri** element shape option, respectively.

You can choose between the medial axis and advancing front meshing algorithms when you mesh a solid region with hexahedral or hexahedral-dominated elements using the swept meshing technique. (Abaqus/CAE generates hexahedral and hexahedral-dominated meshes by sweeping the quadrilateral and quadrilateral-dominated elements generated by the two algorithms from the source side to the target side.) However, if the region to be meshed contains virtual topology, you can use only the advancing front algorithm to generate the swept mesh. For more information, see *What is the difference between the medial axis algorithm and the advancing front algorithm?*, and *Free meshing with quadrilateral and quadrilateral-dominated elements*.

If you select the advancing front algorithm, Abaqus/CAE will use mapped meshing, if it is appropriate, to improve the mesh for some regions. (Mapped meshing is the same as structured meshing but applies only to four-sided regions.) Abaqus/CAE determines whether it is appropriate to replace the advancing front algorithm with mapped meshing on any of the faces that belong to the source side. For more information, see *What is mapped meshing?*, and *When can Abaqus/CAE apply mapped meshing?*. Abaqus/CAE uses mapped meshing to create quadrilateral and quadrilateral-dominated elements on these appropriate boundary faces and then sweeps the elements from the source side to the target side to create the hexahedral and hexahedral-dominated elements.

A three-dimensional region can be meshed using the swept meshing technique if it has the following characteristics:

- Every side that connects the source side to the target side must have only a single face or be comprised of four-sided combined faces that form a regular grid pattern. *Figure 3* provides two examples of acceptable connecting face patterns.

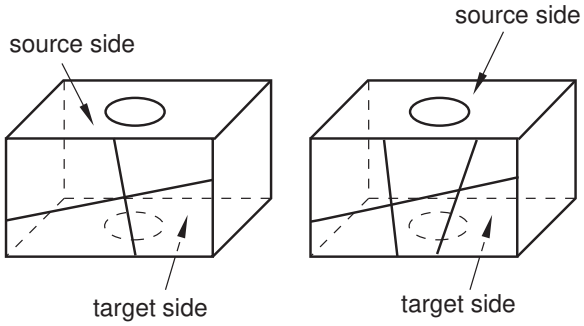

Figure 3: Acceptable connecting face patterns for swept meshing.

The partitioned connecting sides in *Figure 4* do not have acceptable face patterns for swept meshing; the model on the left side has a sweep face with two three-sided faces, while the model on the right side does not have a regular grid pattern.

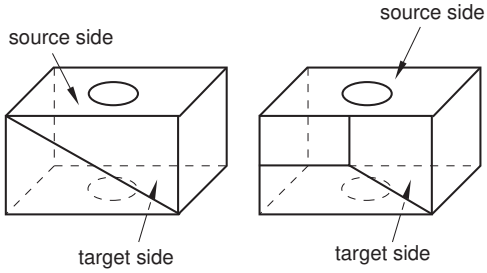

Figure 4: Unacceptable connecting face patterns for swept meshing.

- The target side must contain only a single face without isolated edges or isolated vertices. For example, the region on the left in *Figure 5* can be meshed using the swept meshing technique because all of the isolated edges are on the source side; the region on the right, however, cannot be meshed using this technique because the target side contains two faces.

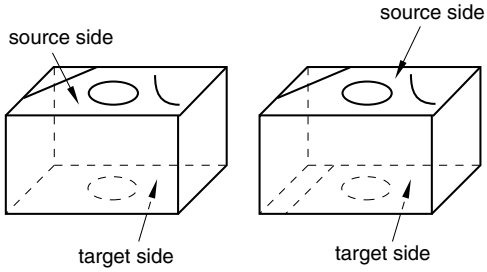

Figure 5: Only the region on the left can be meshed using the swept meshing technique.

Figure 6 illustrates a part that has been swept meshed along a varying cross-section. The part appears to be relatively complex; for example, the source side is nonplanar, and the cross-section of the part varies along the sweep path. However, the rules for generating a swept mesh still apply.

- Every side that connects the source side to the target side contains only a single face.
- Although the source side contains two faces, the target side contains only a single face.

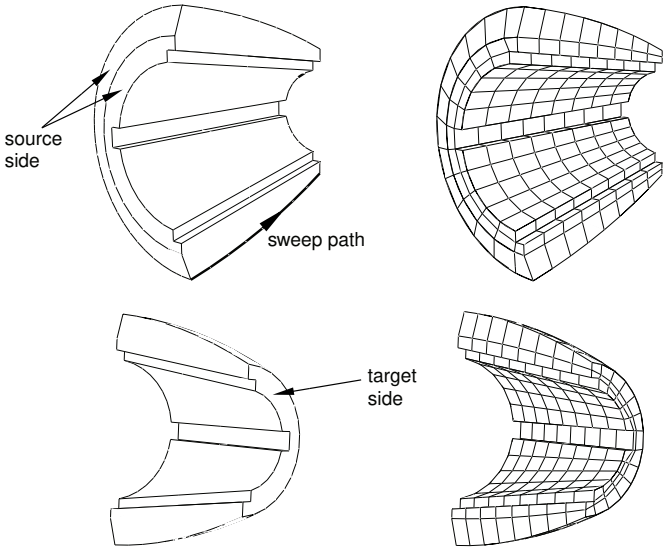

Figure 6: Sweeping the mesh along a varying cross-section.

You may be able to use virtual topology to combine faces on the target side to make a part swept meshable. *Figure 7* illustrates a part that was swept mesh after the five faces on the target side were combined into a single face using virtual topology. However, because the part now contains virtual topology, it can be swept meshed with only the advancing front algorithm.

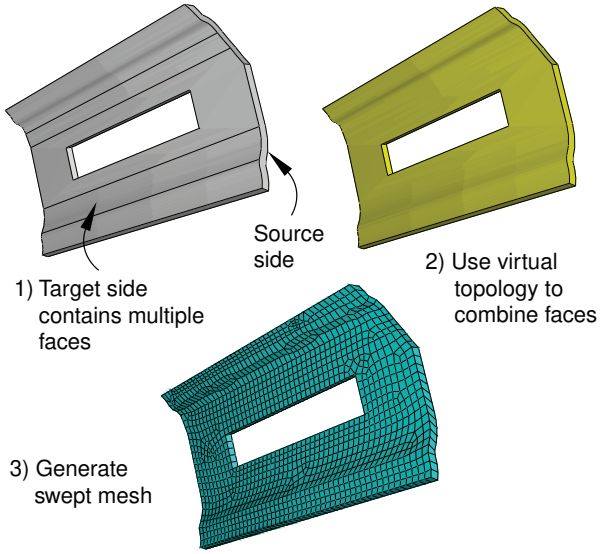

Figure 7: Combining faces makes a part swept meshable.

- For a revolved region, the profile that was revolved to create the region must not touch the axis of revolution at one or more isolated points, as shown in *Figure 8*.

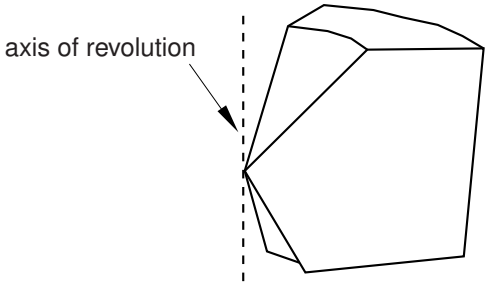

Figure 8: The swept meshing technique cannot mesh a part if an isolated point touches the axis of revolution.

- Similarly, Abaqus/CAE cannot mesh a region with hexahedral or wedge elements if one or more edges lie along the axis of revolution, as shown in *Figure 9*.

Figure 9: Abaqus/CAE cannot mesh a region with hexahedral elements if one or more edges lie along the axis of revolution.

However, Abaqus/CAE can mesh the region with hexahedral-dominated elements by generating layers of wedge elements along the axis, as shown in *Figure 10*.

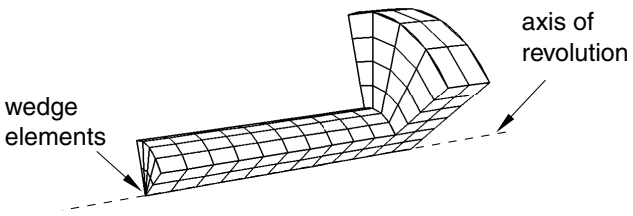

Figure 10: Abaqus/CAE can mesh the region with hexahedral-dominated elements.

As a result, you must select the **Hex-dominated** element shape option before you mesh the region. Alternatively, you can partition the region into simple structural mesh regions and select the **Hex** element shape option to create the mesh using all hexahedral elements. For more information, see *Sweep meshing a solid, revolved region whose profile touches the axis of revolution*.

- A fully revolved region that does not touch the axis of revolution is meshable only if all the edges that are associated with the profile being revolved exist. However, the edges that bound the profile must not create a face. *Figure 11* shows a meshable part instance where all of the edges of the revolved profile exist.

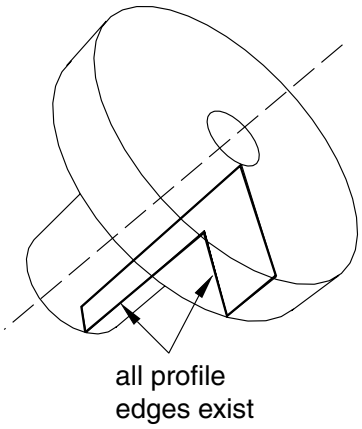

Figure 11: All of the edges of the revolved profile exist; hence, the part instance is meshable.

In this example the user sketched the profile, and Abaqus/CAE revolved the profile to create the part; however, the edges that bound the profile do not form a face. In contrast, *Figure 12* shows a part instance that is not meshable because some of the edges of the revolved profile are missing.

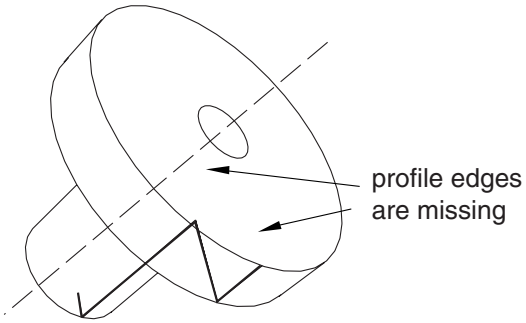

Figure 12: Some of the edges of the revolved profile are missing; hence, the part instance is not meshable.

- A fully revolved region that touches the axis of revolution is meshable only if all of the edges that are associated with the profile being revolved exist except the edges along the axis of revolution. *Figure 13* shows a part instance that is meshable because all of the edges of the revolved profile exist except for the edge along the axis of revolution. If the profile included the edge along the axis of revolution, the part instance would not be meshable.

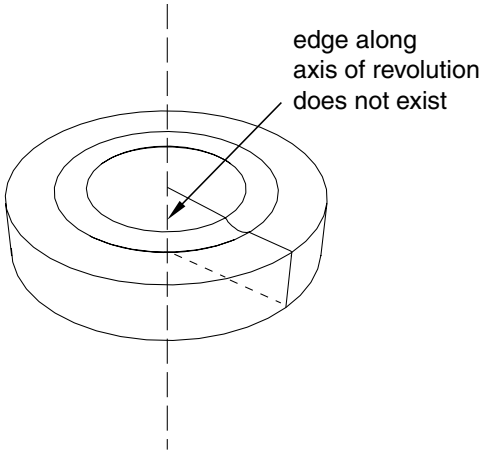

Figure 13: All of the edges of the revolved profile exist, except for the edge along the axis of revolution; hence, the part instance is meshable.

- If a revolved region was created by revolving a sketch that contains a spline, the region is meshable only if the vertices at each end of the spline are not on the axis of revolution.
- If a part was created by sweeping a cross-section along a sweep path that is composed of a closed spline, the resulting part is meshable only if it is split into two or more regions.

Swept meshing of cylindrical solids

You can use swept meshing to create a mesh on cylindrical geometry with many types of solid elements, including elements from the solid cylindrical element library. If you use solid cylindrical elements for a native mesh, Abaqus/CAE uses the sweep path of the selected sweep/revolve region as the circumferential direction for the generated cylindrical elements. You should confirm that the sweep path is set correctly before creating the mesh.

Abaqus considers the following requirements for cylindrical elements when you attempt to mesh solid geometry with cylindrical elements:

- The midside nodes on the circular edges of the cylindrical elements must be placed exactly halfway between the edge nodes.
- All nodes on a cross-section must lie on the same radial plane.
- All the circular edges within an element must span the same angle.
- The centers of the circular arcs within an element must lie on a common axis.
- An element cannot span more than 180°.

These requirements mean that you can create valid cylindrical elements only on revolved parts or parts that you can split into revolved domains. The S-shaped extrusion in *Figure 1* can be meshed with cylindrical elements after partitioning into revolved regions.

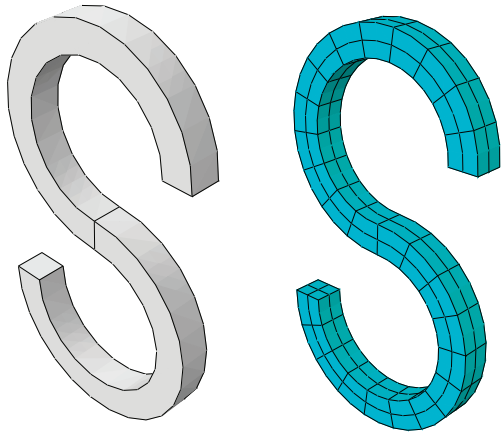

Figure 1: Acceptable geometry for solid cylindrical meshing.

Figure 2 shows three types of geometry—a helical spring, a revolved part with cuts, and a tapered part—that cannot be meshed with solid cylindrical elements because of these meshing requirements.

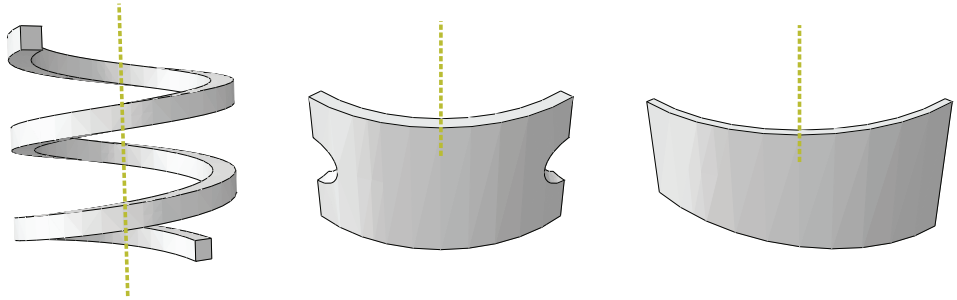

Figure 2: Forms of geometry that cannot be swept meshed with cylindrical elements.

If one of the connecting sides that connect the source face to the target face in a revolved region is separated into multiple faces due to the internal edge or edges that constrain the mesh, the generated elements are likely to be too distorted to be used as cylindrical elements. You must partition the solid region into simpler revolved regions, as shown in the example on the right side of *Figure 3*.

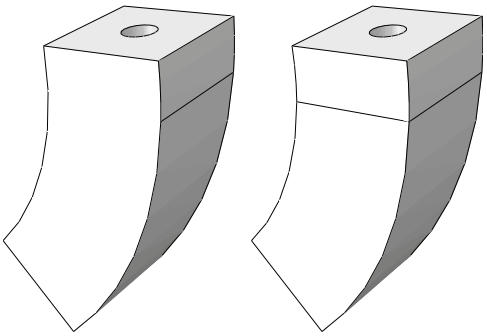

Figure 3: A solid region that is unsuitable for meshing with cylindrical elements (left) and the same region rendered suitable for meshing with cylindrical elements through the use of a partition (right).

When you edit a mesh part by assigning cylindrical elements to it, Abaqus/CAE considers Face 1 and Face 2 of each cylindrical element to be the faces along its radial planes. *Figure 4* indicates the location of these faces for several types of cylindrical elements. You should orient the stack direction for elements in your part before assigning a cylindrical element type to it; for more information, see the descriptions in *Orienting the stack direction*.

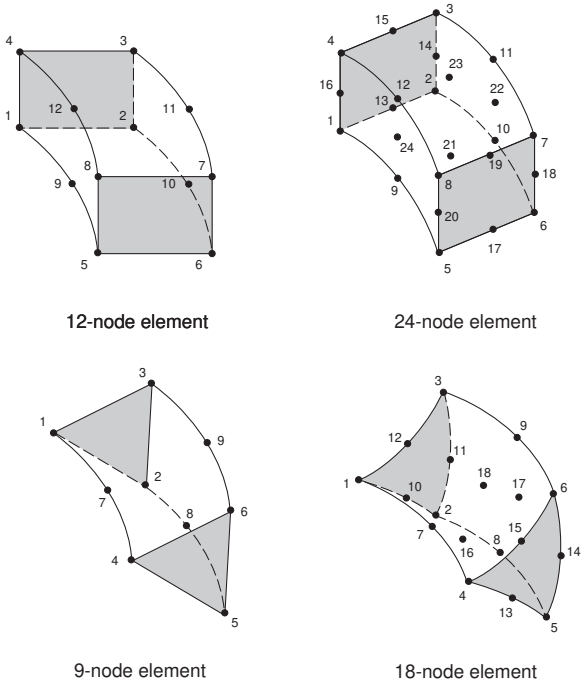

Figure 4: Illustration of node ordering and face numbering for cylindrical elements (with Faces 1 and 2 shaded).

Characteristics of the geometry can prevent a part from being swept meshable

The characteristics of a region described in *Swept meshing of three-dimensional solids* are referred to as "topological characteristics." In some cases, all of the topological characteristics will apply to a region; however, Abaqus/CAE will not allow the region to be swept meshed because some "geometrical characteristics" are not satisfied. The geometric characteristics that Abaqus/CAE looks for when determining if a region is swept meshable are hard to quantify. In general, a three-dimensional region can be meshed using the swept meshing technique if it satisfies the following geometrical characteristics:

- If the source side contains more than one face, the angle between the faces must be relatively flat (close to 180°).
- Each face that connects the source side to the target side (a connecting side) must have four corners. The angle at each of the corners must be close to 90°.
- The angles between the source side and each of the connecting sides should be close to 90°. Similarly, the angles between the target side and each of the connecting sides should be close to 90°.

For example, *Figure 1* shows a part with three faces on the source side. When the angle decreases between the faces that form the source side, the part no longer satisfies the geometric characteristics of a swept meshable region.

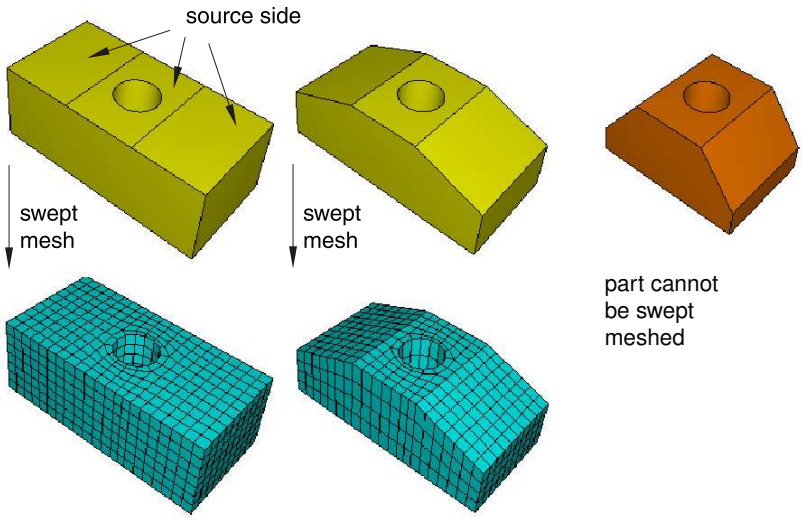

Figure 1: Swept meshing depends on geometrical characteristics.

You may be able to apply virtual topology to satisfy the geometrical characteristics and to make the part swept meshable. For example, *Figure 2* illustrates that the part becomes swept meshable when the three faces on the source side are combined using virtual topology. However, the resulting mesh is of poor quality.

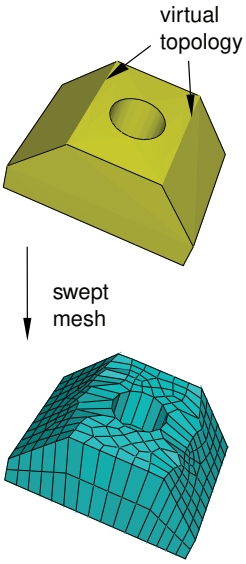

Figure 2: Applying virtual topology can result in poor mesh quality.

In some cases Abaqus/CAE will still allow you to create a swept mesh, even though the geometrical characteristics are not satisfied. The intention is to allow you to create a swept mesh wherever possible. However, the resulting mesh may be of poor quality, or it may be invalid. To ensure that your swept mesh is acceptable, you should use the mesh verify tool to verify its quality. For more information, see *Verifying element quality*.

Free meshing

This section explains how you can use the free meshing technique to mesh two- or three-dimensional models.

In this section:

- *What is free meshing?*
- *Free meshing with quadrilateral and quadrilateral-dominated elements*
- *Free meshing with triangular and tetrahedral elements*
- *What is a tetrahedral boundary mesh?*
- *What can I do with a boundary mesh?*

What is free meshing?

Unlike structured meshing, free meshing uses no preestablished mesh patterns. When you mesh a region using the structured meshing technique, you can predict the pattern of the mesh based on the region topology. In contrast, it is impossible to predict a free mesh pattern before creating the mesh.

Because it is unstructured, free meshing allows more flexibility than structured meshing. The topology of regions that you mesh with the free mesh technique can be very complex.

You can use this technique to mesh a region with the **Tri**, **Quad**, or **Quad-dominated** element shape options for two-dimensional regions or the **Tet** element shape option for three-dimensional regions. For more information on assigning element shapes to a region, see *Choosing an element shape*.

Free meshing with quadrilateral and quadrilateral-dominated elements

Free meshing with quadrilateral elements is the default meshing technique for two-dimensional regions. The free meshing technique with quadrilateral elements can be applied to any planar or curved surface. An example of a mesh generated with this technique is shown in *Figure 1*. Free meshes are usually not symmetric, even if the part or part instance itself is symmetric.

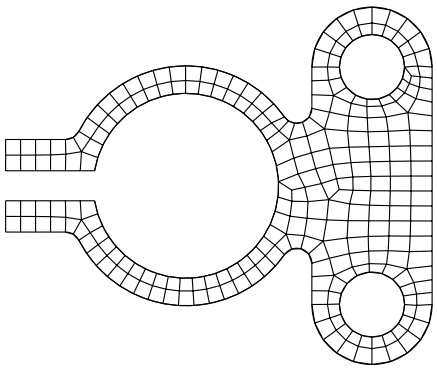

Figure 1: A free mesh generated with quadrilateral elements.

Abaqus/CAE allows you to choose between two meshing algorithms when you create a quadrilateral or quadrilateral-dominated mesh. For more information, see *What is the difference between the medial axis algorithm and the advancing front algorithm?*.

Medial axis

When you free mesh a complex region with quadrilateral elements using the medial axis algorithm, Abaqus/CAE creates internal partitions that divide the region into simple structured mesh regions and then seeds the smaller regions.

If you use the medial axis algorithm to mesh a region and then remesh the region (for example, after modifying the seeds), Abaqus/CAE stores the internal partitions, and the new mesh is generated more quickly. In addition, the internal partitions allow Abaqus/CAE to generate a fine mesh in a similar time to that required to generate a coarse mesh. You cannot use the medial axis algorithm to mesh regions that contain virtual topology, and it does not work well with imprecise parts.

In general, a medial axis-based free mesh with quadrilateral elements does not match the mesh seeds exactly for the following reasons:

- Abaqus/CAE tries to balance the seeds between adjacent regions and the smaller regions created by the internal partitioning.
- Abaqus/CAE tries to minimize element distortions.

However, when you apply fixed seed constraints, Abaqus/CAE matches the number of seeds exactly and attempts to match the seed positions exactly. *Figure 2* illustrates a two-dimensional plate with fixed seeds and movable seeds and the resulting all quadrilateral mesh.

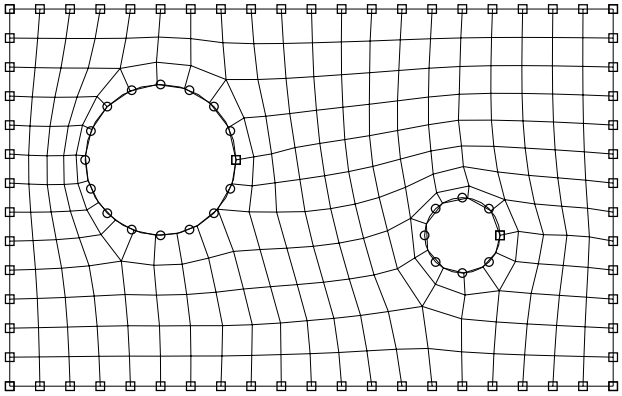

Figure 2: Fixed and movable seeds and the medial axis meshing algorithm.

You should specify fixed seeds on only a few edges, or Abaqus/CAE may not be able to generate a mesh. For example, if you specify fixed seeds around one of the holes in the plate shown in *Figure 2*, the global seeding becomes overconstrained, and Abaqus/CAE cannot generate a mesh.

Using the medial axis algorithm, a free mesh generated with quadrilateral-dominated elements is similar to a free mesh generated with all quadrilateral elements and without transition minimization; however, Abaqus/CAE inserts a few isolated triangles in an effort to match the mesh seeds more closely. Abaqus/CAE can generate a mesh with quadrilateral-dominated elements faster than it can generate a mesh with all quadrilateral elements.

Advancing front

When you free mesh a complex region with quadrilateral elements using the advancing front algorithm, Abaqus/CAE generates quadrilateral elements at the boundary of the region and continues to generate quadrilateral elements as it moves systematically to the interior of the region.

When you choose the advancing front algorithm, Abaqus/CAE matches the seeds exactly (except when you are creating a three-dimensional revolved mesh, and the profile being revolved touches the axis of revolution). A quadrilateral mesh that matches the seeds exactly is shown in *Figure 3*.

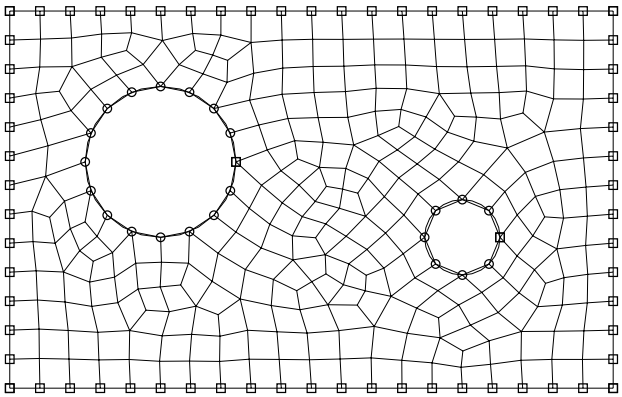

Figure 3: Fixed and movable seeds and the advancing front meshing algorithm.

In general, the mesh transitions generated with the advancing front algorithm are more acceptable than the transitions generated by the medial axis algorithm; however, matching the seeds exactly in narrow regions may compromise the mesh quality. In contrast with the medial axis algorithm, you can use the advancing front algorithm in conjunction with imprecise parts and on regions that contain virtual topology.

If you select the advancing front algorithm, Abaqus/CAE will also use mapped meshing where appropriate. (Mapped meshing is the same as structured meshing but applies only to four-sided regions.) For more information, see *What is mapped meshing?*, and *When can Abaqus/CAE apply mapped meshing?*. When mapped meshing is used, Abaqus/CAE makes minor adjustments to the mesh seeding. If you do not want the seeding to change, you can use mesh controls to prevent the use of mapped meshing. For more information, see *Assigning mesh controls*.

By default, Abaqus/CAE minimizes the mesh transition when it generates a free quadrilateral mesh using the medial axis algorithm. Minimizing the mesh transition results in a better mesh that is generated more quickly; however, the generated nodes deviate further from the mesh seeds. *Figure 4* illustrates the same planar part instance meshed using the medial axis algorithm with and without minimizing the mesh transition and meshed using the advancing front algorithm.

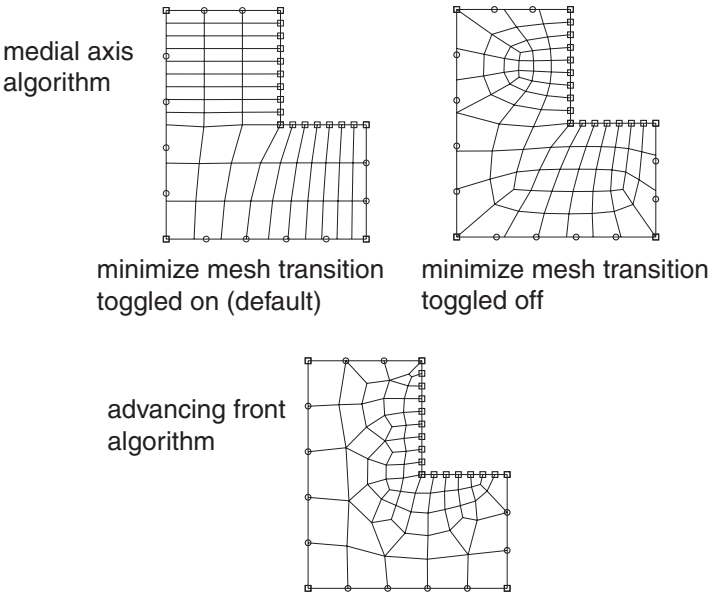

Figure 4: The effect of mesh transition and the meshing algorithm.

Free meshing with triangular and tetrahedral elements

Free meshing with triangular elements can be applied to any planar or curved surface, and the part can be precise or imprecise. For more information, see *What is a valid and precise part?*. A free mesh of triangular elements matches the mesh seeds exactly. This meshing technique can handle large variations in element size, which is useful when you want to refine only part of a mesh. The time taken for Abaqus/CAE to compute a free triangular mesh grows approximately linearly with the number of elements and nodes. *Figure 1* shows an example of a mesh generated using this technique.

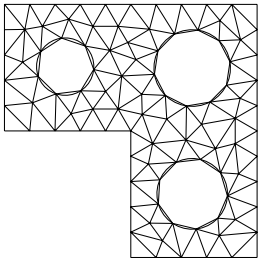

Figure 1: A free mesh generated with triangular elements.

Free meshing with tetrahedral elements can be applied to almost any three-dimensional region; in fact, very complex models can be meshed using this technique without the help of partitioning. Free meshing with tetrahedral elements is similar to free meshing with triangular elements in that the part can be precise or imprecise. In general, Abaqus/CAE matches the mesh seeds exactly although the mesh may be finer around small holes if the mesh seeds are not fully constrained. *Figure 2* shows an example of a free tetrahedral mesh.

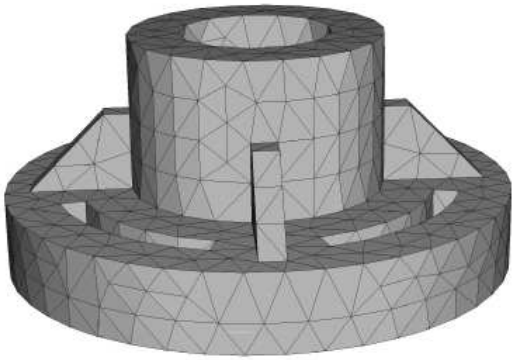

Figure 2: A free mesh generated with tetrahedral elements.

Free meshing of three-dimensional solids using hexahedral elements is not supported.

You should use the Query toolset in the Part module or the Mesh module to check the geometry of the parts or of the assembly before you try to generate a free mesh with tetrahedral elements. You should check the following:

- There are no free edges in the solid.
- There are no short edges, small faces, or small face corner angles.

For more information, see *Using the geometry diagnostic tools*.

When you create a free mesh with tetrahedral elements, you can use the default mesh generation algorithm, or toggle off the default algorithm to use the algorithm that was included with Abaqus/CAE 6.4 and earlier. The default algorithm

is significantly more robust, particularly when meshing complex shapes and thin solids. In addition, the default algorithm allows you to increase the size of the interior elements. If the mesh density is adequate for the model being analyzed and the areas of interest are on the mesh boundary, increasing the size of the interior elements will increase the computational efficiency.

When you are using free meshing to create triangular elements on a surface, Abaqus/CAE will use mapped meshing for some regions if it is appropriate. (Mapped meshing is the same as structured meshing but applies only to four-sided regions.) For more information, see *What is mapped meshing?*, and *When can Abaqus/CAE apply mapped meshing?*. Abaqus/CAE replaces free triangular meshing with mapped triangular meshing only when it is likely that the resulting mesh quality will be improved. If desired, you can use mesh controls to prevent Abaqus/CAE from allowing mapped meshing. For more information, see *Assigning mesh controls*.

Similarly, when you are using free meshing to create tetrahedral elements, you can allow Abaqus/CAE to decide whether mapped meshing is appropriate. After Abaqus/CAE determines that the resulting mesh quality will be improved, it replaces free meshing with mapped meshing on simple boundary faces and converts the resulting triangles into tetrahedral elements.

Figure 3 shows the effect of allowing mapped meshing where appropriate in a free mesh of a solid part using tetrahedral elements. The mesh quality is improved in four-sided regions that can be mapped meshed.

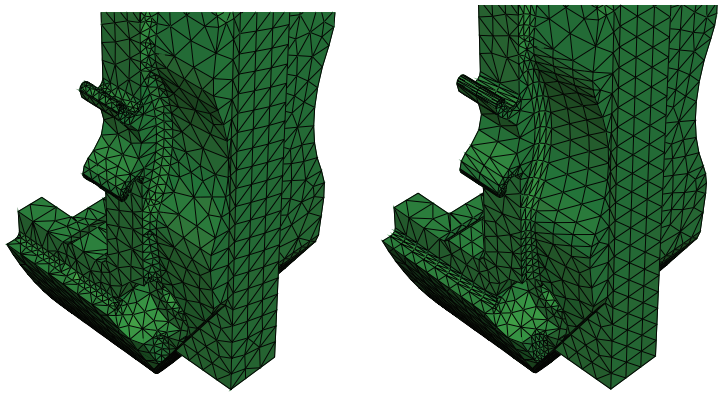

Figure 3: The effect of allowing mapped meshing.

To view the internal tetrahedral elements generated by Abaqus/CAE, you can create a new mesh part from the current mesh and use display groups to remove selected elements. You can also view the internal elements after the analysis is complete by using view cuts in the Visualization module. For more information, see *Using display groups to display subsets of your model* and *Cutting through a model*.

What is a tetrahedral boundary mesh?

When Abaqus/CAE generates a free mesh on a solid with tetrahedral elements, the meshing process consists of two phases:

1. A boundary mesh of triangles is generated on the faces of the solid regions.
2. Abaqus/CAE generates a tetrahedral mesh using the triangles as faces of the tetrahedral elements.

The same process is used to create a quadrilateral boundary mesh and a hexahedral solid mesh for geometric faces of bottom-up mesh regions (for more information, see *Creating the boundary mesh for a bottom-up region*).

If your part is complex, generating a free tetrahedral mesh can be time consuming. Previewing the mesh on the boundary faces can help you identify problems before generating a mesh for the entire part. You can preview the triangles on the boundary faces after the first phase of the meshing process by toggling on **Preview boundary mesh** in the prompt area before you generate the mesh. If the mesh is acceptable, you can continue meshing the interior of the region. If the mesh is not acceptable or if some regions failed to mesh, Abaqus/CAE provides a variety of tools for correcting the problems. For more information, see *What can I do with a boundary mesh?*.

If you decide to preview the triangular boundary mesh for a region, Abaqus/CAE allows you to select faces to mesh even though your final intent is to mesh a solid. When you toggle on **Preview boundary mesh**, Abaqus/CAE automatically changes the selection filter in the prompt area to select **Faces**. For more information, see *Filtering your selection based on the type of object*.

When the **Mesh defaults** color mapping is selected, Abaqus/CAE displays a boundary mesh using white to represent the boundary elements, which is in contrast to the cyan color that Abaqus/CAE uses to represent the final mesh. When you query the tetrahedral boundary mesh, Abaqus/CAE refers to the elements as **Tri boundary elements**. In contrast, when you query the final mesh, Abaqus/CAE refers to the elements as **Linear tetrahedral elements** or **Quadratic tetrahedral elements**. The triangles on the boundary faces have no concept of geometric order.

What can I do with a boundary mesh?

When Abaqus/CAE generates a free mesh on a solid with tetrahedral elements, it first generates a boundary mesh of triangles on the exterior faces of the solid regions, as described in *What is a tetrahedral boundary mesh?*.

When you are creating a free tetrahedral mesh, Abaqus/CAE can create either a free mesh or a mapped mesh on the boundary faces; two mechanisms control the mesh pattern for this triangular surface mesh:

Global mesh control associated with the three-dimensional region

Global controls always exist. They are set when you assign the free tetrahedral meshing technique to the region. You can use them to create a mapped mesh in areas where Abaqus/CAE determines that mapped meshing is appropriate or to create a free mesh on all bounding faces.

Local mesh controls specified on selected faces of the region

To assign local controls, you select one or more faces of the region and specify whether Abaqus/CAE should create a free mesh or a mapped or structured mesh on the selection. If you define local controls, they override the global controls.

If you assign the structured technique to faces of solid regions that will be tetrahedral meshed, these faces are colored green to show the technique assignment for the surface mesh. (For detailed instructions on assigning mesh controls, see *Assigning mesh controls*.)

Note:

The green coloring is applied only while you are assigning mesh controls to the faces. When the procedure ends, the global mesh control colors are displayed.

In addition, Abaqus/CAE highlights any faces on the boundary that failed to mesh. These failures are usually due to mesh seeding that is too coarse or to tiny edges or faces. You can save the highlighted faces in a set, and you can apply finer seeds to only the faces in the set. For more information about seeding faces in a set, see *Can I seed a face or a cell?*. You can use display groups to display only the faces in the set. For more information, see *Plotting display groups*.

You can query a boundary mesh using the Query toolset. In addition, you can check the quality of a boundary mesh using the mesh verify tool. The mesh verify tool allows you to check the quality of all boundary triangles, or you can use the selection filters to check the quality of the boundary triangles of only selected faces.

If tiny edges or faces prevent Abaqus/CAE from generating an acceptable tetrahedral mesh, you can try the following:

- Use the geometry diagnostics tool to find small entities such as short edges, small faces, and faces with small face corner angles that can affect the mesh quality. You can create a set containing these small entities. For more information, see *Using the geometry diagnostic tools*.
- Use the Geometry Edit toolset to remove redundant edges and vertices. You can also remove a face and stitch over the resulting gap. For more information, see *Editing techniques*.
- Use the Virtual Topology toolset to ignore tiny edges or faces. For more information, see *What can I do with the Virtual Topology toolset?*.
- Add partitions to reduce the aspect ratio of long, narrow faces or cells. For more information, see *The Partition toolset*.
- Use the Edit Mesh toolset to modify the preview mesh. You can do the following in the Mesh module:
  - Edit nodes
  - Collapse element edges
  - Swap the diagonal of a pair of adjacent triangular elements

- Split element edges

For more information, see *What can I do with the Edit Mesh toolset?*.

In some cases you will not be able to mesh an imported solid part with tetrahedral elements because of very thin triangular elements in the surface mesh or because some sliver faces cannot be meshed with triangles. *Using a combination of tools to mesh an imported solid part with tetrahedral elements*, describes how you can use the Edit Mesh toolset and other tools in the Mesh module to mesh the part successfully.

Bottom-up meshing

This section explains the bottom-up meshing technique and describes the types of regions to which this meshing technique can be applied. The related topic of mesh associativity is also explained.

In this section:

- *What is bottom-up meshing?*
- *The bottom-up meshing domain*
- *Bottom-up meshing methods*

- *Creating the boundary mesh for a bottom-up region*
- *Improving the quality of boundary meshes for a bottom-up region*
- *Defining connecting sides for a bottom-up swept mesh*
- *Creating a bottom-up mesh*
- *An example including bottom-up meshing techniques*

What is bottom-up meshing?

Bottom-up meshing is a manual, incremental meshing process that allows you to build a hexahedral mesh in any solid region. Structured, swept, and free meshing techniques all work in a top-down manner—they are tied directly to the geometry such that the resulting mesh fills the geometry. Bottom-up meshing relaxes the constraint that ties the mesh to the geometry so that you can build a mesh that ignores some geometric features. You can also use bottom-up meshing techniques to modify a mesh part, in which case there are no geometric features to consider. If you work with geometry, the elements that you create in a bottom-up mesh are always associated with the solid region that you meshed, but the mesh boundaries may not be associated with the geometric boundaries of the region. This allows you to create a mesh using only hexahedral elements where top-down meshing techniques might require extensive partitioning or the use of tetrahedral elements to complete the mesh. However, the relaxed geometry constraints also mean that you must carefully choose the parameters used to create the mesh, since it can vary significantly from the geometry. Once Abaqus has generated a bottom-up mesh, you need to evaluate whether it is suitable for the analysis and, if geometry is present, verify that the mesh is correctly associated with it.

You can apply bottom-up meshing to any solid region, including regions that can be meshed using the top-down techniques, and to meshes that do not have any associated geometry. Since bottom-up meshing is a manual process that can be very time consuming, it is recommended that you use this method only when the top-down methods fail to produce a satisfactory mesh.

Generating the desired mesh may require multiple applications of the bottom-up meshing technique. If multiple applications are required, each bottom-up mesh becomes an incremental building block for the next mesh until you complete the mesh for the region. Each application of the bottom-up meshing technique involves four phases:

1. You select the domain within which Abaqus/CAE will create the mesh. You can choose either a three-dimensional geometry region or orphan elements.
2. You select the method that Abaqus/CAE will use to create the mesh. You can choose from the following methods:
   - Sweep
   - Extrude
   - Revolve
   - Offset (available only for orphan element selections)
3. You select the side, called the source side, that Abaqus/CAE will use to create a two-dimensional mesh to be swept, extruded, or revolved to fill a three-dimensional region.
4. You select the remaining parameters to complete the definition of the bottom-up mesh. For example, if you chose the sweep method, you can choose connecting sides and a target side.

In addition, you may need to edit bottom-up meshes or associate them with geometry before you can use them to continue generating the region mesh. For more information, see *The Edit Mesh toolset*.

Figure 1 shows a part that cannot be meshed with hexahedral elements using top-down techniques.

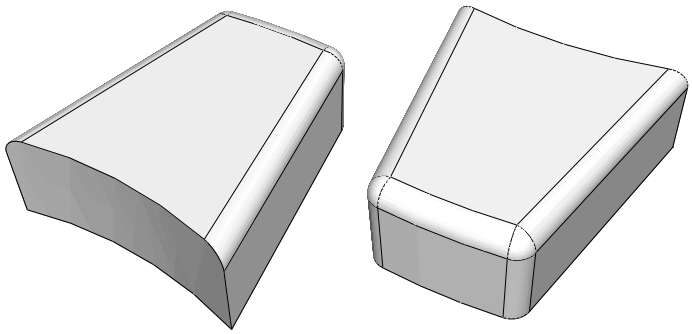

Figure 1: Complex geometry such as fillets can prevent top-down meshing.

The bottom-up sweep method was used to mesh the part in *Figure 2*. The user selected six faces for the source side (magenta), selected the hidden rear face as the target side (white), and used the six remaining sides as connecting sides (yellow), as indicated in the figure. In this example the selected sides are all geometric faces; Abaqus/CAE also allows you to select element faces and two-dimensional elements to define the source side and the connecting sides of a bottom-up mesh.

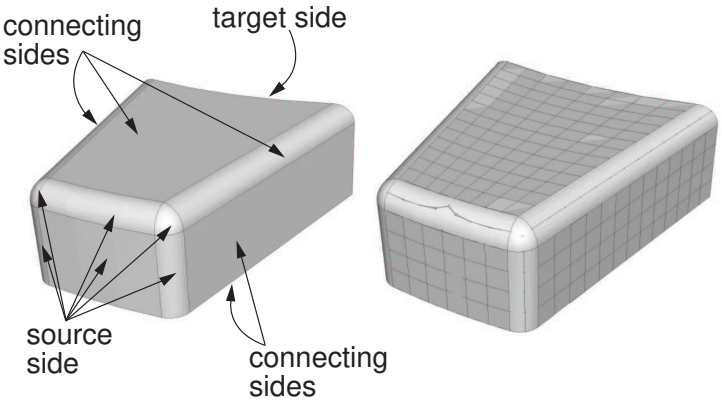

Figure 2: A bottom-up mesh using the sweep method.

You can choose from the sweep, extrude, or revolve methods to mesh a selected geometric region, and you can also choose the offset method if you are working with orphan elements. Depending on the shape of the region and the analysis intent, more than one method may produce acceptable results. The method that you select and the corresponding parameters will determine how well the mesh conforms to the geometry, if applicable. For example, *Figure 3* shows the same part as *Figure 2*; this time the part is meshed with the extrude method. The parameters for the extrude method are a source side, an extrusion vector, and a number of layers. As shown in *Figure 3*, the extruded mesh does not capture the tapered sides and the rounded corners at the back of the model.

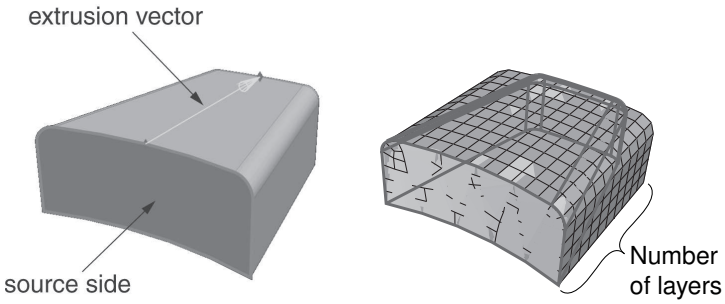

Figure 3: A bottom-up mesh using the extrude method.

If these details are not important, this simplified mesh may be acceptable. Alternatively, you could edit the resulting mesh by modifying or removing the nodes and elements that extend beyond the original geometry. For more information on editing a mesh, see *The Edit Mesh toolset*.

If a resulting bottom-up mesh is not acceptable, you can delete it and try a different bottom-up method for the same region or partition the region and mesh the resulting simpler regions. You can also use the mesh **Undo** and **Redo** functions to undo steps in the bottom-up meshing procedure rather than deleting the entire bottom-up mesh for the region and starting over.

Note:

Undo and redo are not available after some operations, such as deleting a region mesh.

The undo and redo functions are the same as those used for the Edit Mesh toolset (for more information, see *Undoing or redoing a change in the Edit Mesh toolset*).

The bottom-up meshing domain

When you begin creating a bottom-up mesh, the first requirement is to define the domain in which the mesh will be created. The domain determines whether the bottom-up mesh is created as a native mesh or as a collection of orphan nodes and elements. To create a native mesh, you choose a three-dimensional geometric model region that has been assigned the bottom-up meshing technique in the **Mesh Controls** dialog box. (For more information, see *Assigning mesh controls*.) If there are no geometric regions with the bottom-up technique assigned, you must create one or use the orphan element domain.

Selecting a three-dimensional region as the domain also indicates that you intend to fully associate the bottom-up mesh with geometry. The association between mesh and geometry is necessary to transfer loads, boundary conditions, and other information from the geometry to the mesh. Mesh-geometry association is discussed in *Mesh-geometry association*.

Selecting orphan elements as the domain indicates that the bottom-up mesh will not be fully associated with geometry. The created elements may either have no association with geometry, or you may associate the created orphan mesh entities with adjacent geometric faces. Associating the orphan mesh faces with adjacent geometric faces allows Abaqus/CAE to create a compatible mesh when you mesh the geometry.

Bottom-up meshing methods

The control parameters for each bottom-up method are similar to the parameters used internally by Abaqus/CAE to create a comparable top-down swept mesh for a three-dimensional solid. The bottom-up methods and associated parameters are defined as follows:

Sweep

The sweep method creates a three-dimensional mesh by moving a two-dimensional mesh along a sweep path. The sweep method is illustrated in *Figure 2*. You should use the bottom-up sweep meshing method when the region cross-section changes between the starting and ending sides. To use the sweep method, you must first choose a **Source side** that defines the face or faces on which Abaqus/CAE will create a two-dimensional mesh. The source side can be any combination of geometric faces, element faces, and two-dimensional elements. You can define the sweep path by selecting **Connecting sides** that define the sides of the desired sweep region. If you define connecting sides, the mesh conforms closely to the geometry or mesh along the selected sides. Alternatively, for geometry you can select a **Target side** and specify a **Number of layers** and allow Abaqus/CAE to create the sweep path by interpolating between the source and target sides. The **Target side** is a single face that Abaqus/CAE uses to end the mesh. The number of layers refers to the number of element layers that will be placed between the source and the target sides—if you use connecting sides, the two-dimensional meshes of the connecting sides define the number of element layers. Abaqus/CAE sweeps the two-dimensional mesh from the source side into the volume of the solid region to create the mesh.

Extrude

The extrude method is a special case of the sweep method with a linear path defined by a direction and a distance. The extrude method is illustrated in *Figure 3*. You should use the extrude method for regions with a constant cross-section and a linear sweep path. There are three required parameters for a bottom-up extruded mesh. As with the sweep method, you choose the **Source** side that defines the area on which Abaqus/CAE will create a two-dimensional mesh. You then select the starting and ending point of a **Vector** that defines the extrusion direction and can also be used to define the extrusion distance. Finally, you indicate the **Number of layers** to define the number of elements between the source side and the end of the extruded mesh. If you use the vector to define the extrusion distance, the definition is complete. However, you can **Specify** a distance or use **Project to target** and select a target side to define the extrusion distance. The target side can be selected from any geometry, mesh, or datum plane in the viewport; it need not be part of the same part instance as the source. Abaqus/CAE extrudes the two-dimensional mesh from the source side in the direction of the extrusion vector. If you select a target side to define the extrusion distance, Abaqus/CAE ends the extruded mesh at the target side. *Figure 1* shows the source side and target side on the left; the extrusion vector (not shown) extends from the center of the rectangular source side to the center of the cylinder. The resulting extruded mesh is an extension of the source side mesh. It closely matches the target side shape, but no attempt is made to match the node positions of the mesh on the target side.

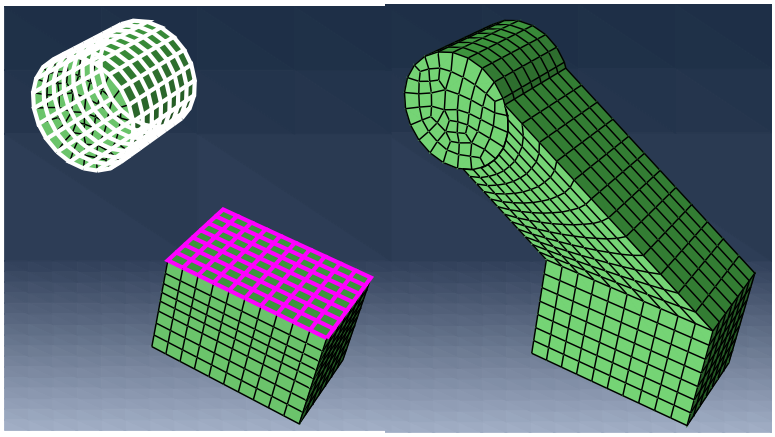

Figure 1: The optional target side (colored white) is used to define the extrusion distance.

The **Bias ratio** parameter defines a change in the element thickness between the source side and the end of an extruded bottom-up mesh in which more than one layer is created. The bias ratio is the ratio of the thickness of the first layer of elements in the extruded mesh to the thickness of the last layer of elements. The default bias ratio of `1.0` has equal thickness elements throughout the extrusion distance.

Revolve

The revolve method is another special case of the sweep method. In this case the sweep path is a circular path defined by an axis and an angle of revolution. The revolve method is illustrated in *Figure 2*. You should use this method for regions with a constant cross-section and a circular sweep path. As with the sweep and extrude methods, you choose the **Source side** that defines the area on which Abaqus/CAE will create a two-dimensional mesh. The source side cannot intersect the axis of revolution, but it may contain edges that coincide with the axis. If so, the elements contacting the axis create a layer of wedge elements in the revolved mesh. The source side should not include any triangular elements along the axis of revolution. You then select the starting and ending point of an **Axis** that defines the axis of revolution. Finally, you indicate the **Angle** and the **Number of layers** to define the number of elements between the source side and the end of the revolved mesh. Abaqus/CAE revolves the two-dimensional mesh from the source side by the specified angle and evenly divides the resulting region into the desired number of element layers. The direction of revolution is clockwise if you look along the axis of revolution from the starting point to the ending point.

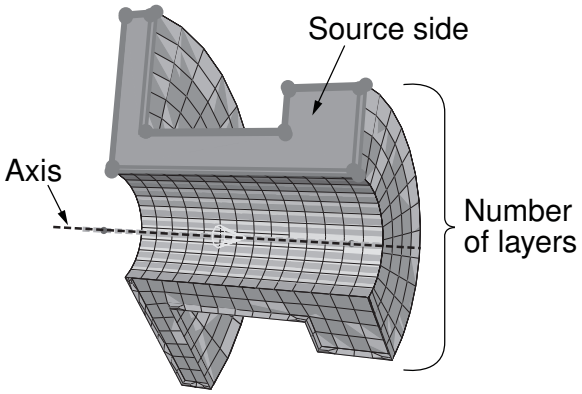

Figure 2: The bottom-up revolve method sweeps the source side mesh by the specified angle about the axis.

Offset

The offset method works the same as **Offset (create solid layers)** in the Edit Mesh toolset; it creates one or more layers of solid elements by offsetting the selected elements. Offset is available only when you are working with orphan elements. To create an offset bottom-up mesh, you enter a total thickness for the offset elements and the desired number of element layers. You can create an element set or extend an existing set, but you cannot create top and bottom surfaces as you can with the Edit Mesh toolset. If you select shell elements as the source, you must indicate in the prompt area the desired offset direction; you can offset shell elements in both directions. If your shell element selection contains sharp corners, toggle on **Constant thickness around corners** to maintain the same total thickness where the elements meet in the corner as in the rest of the selection. Using this option can reduce element distortion and prevent collapsed elements, especially if elements are offset to the inner side of a corner (for more information, see *Reducing element distortion and collapse during mesh offsetting*).

Selecting parameters for a bottom-up mesh

The parameters that you use to create a bottom-up mesh are similar to those that Abaqus/CAE uses to create a comparable top-down swept mesh. In the top-down meshing methods, Abaqus/CAE automatically selects the required geometric sides for the region. Top-down swept meshes—including extruded and revolved meshes—are discussed in *Swept meshing of three-dimensional solids*. The parameters used in the bottom-up mesh methods are described below.

Source side

The **Source side** is a required parameter that defines the face or faces on which Abaqus/CAE will create a two-dimensional mesh that will be swept, extruded, or revolved to create a three-dimensional mesh. The source side may be a combination of geometric faces, element faces, and two-dimensional elements; you can also select saved surfaces instead of selecting from the viewport. For a top-down mesh Abaqus/CAE limits the angularity between multiple faces that it selects as the source side (for more information, see *Characteristics of the geometry can prevent a part from being swept meshable*). There is no limit on the angle between the faces that you can select as the source side of a bottom-up mesh. However, increased angles between the source side faces or between the sourcewill result in decreased quality in the three-dimensional elements.

Connecting sides

Connecting sides define the direction of a swept region. Connecting sides may be a combination of geometric faces, element faces, and two-dimensional elements. Every connecting side must have only a single four-sided geometric face or be comprised of four-sided combined geometric faces, element faces, and two-dimensional elements that form a regular grid pattern.

In a top-down swept mesh Abaqus/CAE creates connecting sides along all edges of the source side. The connecting sides extend completely from the source side to the target side. In a bottom-up swept mesh connecting sides are optional for geometry, but it is recommended that you include as many connecting sides as possible. Connecting sides help to control the mesh as it is swept through the three-dimensional region and enforce *associativity* in the resulting mesh. Including connecting sides reduces the amount of work needed to clean up and associate the bottom-up swept mesh with the geometry. Connecting sides for a bottom-up mesh may extend completely from the source side to the target side or they may cover only part of the distance. They may also be used without a target side, in which case the end of the connecting sides defines the end of the bottom-up swept mesh. For more information, see *Defining connecting sides for a bottom-up swept mesh*.

Target side

The **Target side** defines the end of a swept mesh or an extruded mesh. You cannot select a target side for revolved or offset bottom-up meshes. The target side of a swept mesh must be a single geometric face; the target side for an extruded mesh can be one or more geometric faces, a group of element faces, or a datum plane. The target side is not required for a swept mesh unless you have not included any connecting sides. However, including a target side helps you control the mesh and, if applicable, enforce *associativity* of the mesh to geometry. Abaqus/CAE creates a mesh for the target side by projecting the nodes from the source side if connecting sides are not used or from the last layer of nodes if connecting sides are used. The projected nodes may be positioned outside of the selected geometric target side. The target side is optional for an extruded mesh and is used only to establish the extrusion distance; selection of mesh faces for a target side will not change the extruded mesh to conform to the existing nodes and element faces.

Number of layers

The **Number of layers** parameter defines the number of layers of elements that Abaqus/CAE generates along the sweep, extrude, or revolve direction. If you select the bottom-up sweep method and select connecting sides, the number of element layers is driven by the mesh or seeding of the connecting sides, similar to the top-down

meshing techniques. If you do not select connecting sides for the sweep method or if you choose the extrude or revolve methods, you must specify how many element layers Abaqus/CAE should generate.

Vector

The **Vector** parameter defines the extrusion direction and, optionally, the distance for an extruded mesh. You select an extrusion vector by picking a start point and an end point from the nodes, vertices, datum points, and interesting points in the viewport. Abaqus/CAE extrudes the mesh from the source side by the direction and, if applicable, distance of the vector regardless of where in the viewport you define the vector.

Axis

The **Axis** parameter defines the axis of revolution for a revolved mesh. You can define the axis of revolution by selecting two vertices, nodes, datum points, or interesting points from the viewport.

Angle

The **Angle** parameter defines the angle of revolution for a revolved mesh. You must specify the angle of revolution for the bottom-up revolve technique to indicate where Abaqus/CAE should end the revolved mesh.

Bias ratio

The **Bias ratio** parameter defines a change in the element thickness between the source side and the end of an extruded bottom-up mesh in which more than one layer is created. The bias ratio is the ratio of the thickness of the first layer of elements in the extruded mesh to the thickness of the last layer of elements. A bias ratio less than one creates thinner layers near the source side, a ratio of exactly one has equal thickness layers throughout, and a ratio greater than one creates thicker layers near the source side. Abaqus/CAE evenly distributes the bias through the number of layers in the extrusion.

As you select the parameters to define a bottom-up mesh, consider not only the shape of the current bottom-up mesh but also the desired final mesh shape. Many complex parts will require several bottom-up meshing iterations to generate a complete mesh. For example, you may use connecting sides or element faces of a bottom-up swept mesh as the source side of a bottom-up extruded mesh. If you cannot completely mesh the selected region in the current iteration, consider how you can add another bottom-up mesh or use the Edit Mesh toolset to complete the mesh. For a detailed, step-by-step example of combining top-down and bottom-up techniques to mesh a part, see *An example including bottom-up meshing techniques*.

Creating the boundary mesh for a bottom-up region

When you create a bottom-up mesh for a geometric region, the meshing process consists of two phases:

1. A boundary mesh of quadrilateral elements is generated on the source side—and on the connecting sides of a swept mesh if they are included.
2. Abaqus/CAE generates a hexahedral mesh using the quadrilateral elements as faces of the hexahedral elements.

Creating a boundary mesh allows you to preview the first phase of producing the bottom-up mesh. Viewing the boundary elements can help you identify problems that may prevent generating a bottom-up mesh. The boundary mesh functions for geometric faces of bottom-up mesh regions are identical to the tetrahedral boundary mesh capabilities in Abaqus/CAE except that a bottom-up boundary mesh is composed of quadrilateral elements instead of tetrahedral elements (for more information on tetrahedral boundary meshes, see *What is a tetrahedral boundary mesh?*, and *What can I do with a boundary mesh?*).

To create the boundary mesh for faces of a bottom-up region you must use the top-down region meshing process.

1. From the main menu bar, select **Mesh->Region**.
2. Toggle on **Preview boundary mesh** in the prompt area.

   Abaqus/CAE automatically switches the default selection option from **Regions** to **Faces**.
3. Select the geometric faces of a bottom-up region for which you want to create the boundary mesh.
4. Click **Done** in the prompt area.

   Abaqus/CAE creates a two-dimensional mesh on the selected faces.

When the **Mesh defaults** color mapping is selected, Abaqus/CAE displays a boundary mesh using white to represent the quadrilateral elements, which is in contrast to the cyan color that Abaqus/CAE uses to represent the final solid mesh. When you query the bottom-up boundary mesh, Abaqus/CAE refers to the two-dimensional boundary elements as **Quad boundary elements**. In contrast, when you query the final mesh, Abaqus/CAE refers to the three-dimensional solid elements as **Linear hexahedral elements**.

Improving the quality of boundary meshes for a bottom-up region

The quality of the boundary mesh on the source and connecting sides is a major factor affecting the quality of a swept mesh. Creating the boundary meshes allows you to improve their quality before you use them to create a bottom-up mesh. For example, to use a combination of unassociated geometric and unassociated element faces to create an acceptable source side, you may need to create the boundary mesh and merge the nodes of the two-dimensional mesh. Likewise, you cannot use a combination of geometric and element faces to create a connecting side, but you can create a single boundary mesh and use a combination of its two-dimensional elements and the element faces of an adjacent three-dimensional mesh to create a connecting side.

You can query a boundary mesh using the Query toolset. In addition, you can check the quality of a boundary mesh using the mesh verify tool. The mesh verify tool allows you to check the quality of all the boundary elements, or you can use the selection filters to check the quality of the boundary elements of only selected faces.

To improve the boundary meshes for a bottom-up region, you can try the following:

- Modify the mesh controls for the faces of a bottom-up region. For more information, see *Assigning mesh controls*.
- Use the geometry diagnostics tool to find small entities such as short edges, small faces, and faces with small face corner angles that can affect the mesh quality. You can create a set containing these small entities. For more information, see *Using the geometry diagnostic tools*.
- Use the Geometry Edit toolset to remove redundant edges and vertices. You can also remove a face and stitch over the resulting gap. For more information, see *Editing techniques*.
- Use the Virtual Topology toolset to ignore tiny edges or faces. For more information, see *What can I do with the Virtual Topology toolset?*.
- Add partitions to reduce the aspect ratio of long, narrow faces or cells. For more information, see *The Partition toolset*.
- Use the Edit Mesh toolset to modify the boundary mesh. You can do the following in the Mesh module:
  - Edit nodes
  - Collapse element edges
  - Swap the diagonal of a pair of adjacent triangular elements
  - Split element edges

  For more information, see *What can I do with the Edit Mesh toolset?*.

Defining connecting sides for a bottom-up swept mesh

Defining the connecting sides for a bottom-up swept mesh is a complex task. Connecting sides are required only when creating a swept mesh that uses orphan element faces as the source side. However, even when the connecting sides are not required, using them can save you a significant amount of time after you create the mesh. Connecting sides help control the shape of the swept mesh, and they enforce associativity between the mesh and geometry or force the mesh to match the existing mesh along the connecting sides, depending on whether you are working with geometry or a mesh. In other words, connecting sides force a bottom-up swept mesh to be more similar to a top-down swept mesh. Without connecting sides, you may need to edit the mesh shape, merge nodes, or otherwise modify the mesh to comply with adjacent geometry or meshes, and you will need to manually associate the mesh with the surrounding sides if there are any loads or boundary conditions applied to those sides.

Connecting sides for a bottom-up mesh may be a combination of geometric faces, element faces, and two-dimensional elements. Elements or element faces must be quadrilaterals, and a single connecting side cannot contain both mesh entities and geometric faces. The criteria below and the examples that follow should help you select valid connecting sides or create valid connecting sides from sides that are initially invalid:

- Each geometric face must have four logical sides.
- The corners of each geometric face must be consistent with the mesh sweeping operation.
- Connecting sides must share a common edge with the source side.
- Geometric faces or mesh entities must form a regular grid pattern.

Each geometric face must have four logical sides

In *Figure 1* the top face contains a hole and the front face includes a triangular face. Neither face can be used as a connecting side because of these additional features.

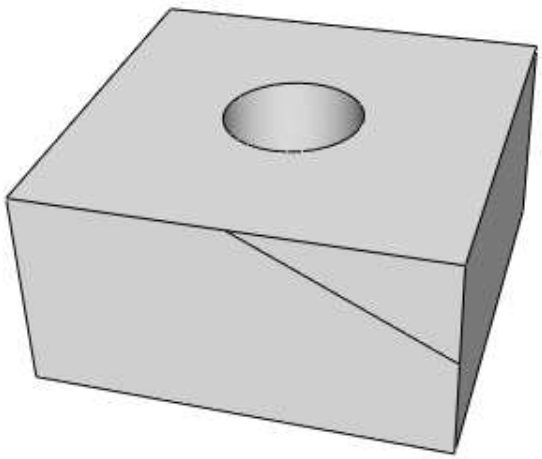

Figure 1: Connecting sides must have four logical sides.

If you select sides such as these, Abaqus/CAE will display an error message indicating that the faces are topologically not four-sided.

In addition to topological tests, Abaqus applies geometric tests to determine whether faces that have four or more edges should be considered four-sided. The geometric tests evaluate the angles at the vertices of the face and determine whether a good quality structured mesh can be generated. You can override the geometric tests by using the mesh controls to assign the structured meshing technique to these faces.

For example, in *Figure 2* the front face is topologically four-sided; however, because the sides meet the top edge along a curve, Abaqus/CAE does not recognize all four of the corners.

Figure 2: Faces with corner radii may require editing for use as connecting sides.

When you finish selecting connecting sides, Abaqus/CAE highlights faces that are not geometrically four-sided and displays an error message. You can use the mesh controls to redefine the region's corners as highlighted in the figure so that the face can be used as a connecting side. For more information on using mesh controls on the faces of bottom-up mesh regions, see *Improving the quality of boundary meshes for a bottom-up region*.

The corners of each geometric face must be consistent with the mesh sweeping operation

The four corners shown on the selected face in *Figure 3* do not match the corners of the adjacent source side (the bottom side of the part). In this case you can finish selecting the connecting sides; but when you attempt to apply the bottom-up swept mesh, Abaqus/CAE indicates that it cannot map the mesh on the connecting sides into a regular grid. If you use mesh controls to remove the corner at the semicircular cut and add a corner at the bottom left corner of the side, you can use the face as a connecting side.

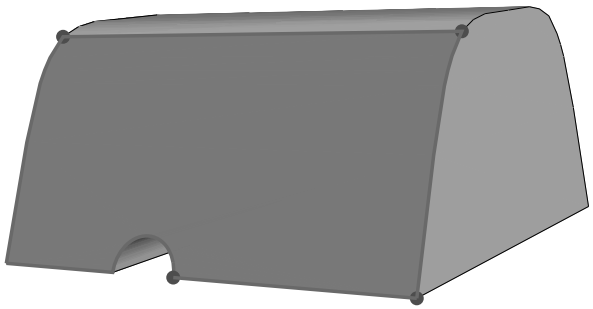

Figure 3: Four-sided faces whose corners do not match the corners of the source side.

Connecting sides must share a common edge with the source side

The common edge shared between the source side and connecting sides cannot extend beyond the edges of the source side. In addition, if you use two-dimensional elements or element faces as the source side and select geometric faces as a connecting side, or vice versa, the element edges must be associated with the geometric edge or Abaqus will not recognize them as sharing a common edge. As an alternative to associating the elements with the geometric edge, you can create a bottom-up boundary mesh on the geometric face and manually merge the nodes of the source side and connecting side meshes (for more information, see *Creating the boundary mesh for a bottom-up region*). If a connecting side does not share a common edge with the source side, Abaqus/CAE indicates that it cannot map the mesh on the connecting sides into a regular grid.

Geometric faces or mesh entities must form a regular grid pattern

The geometric faces or element faces and two-dimensional elements that you select must form a regular grid pattern. *Figure 4* provides two examples of acceptable connecting face patterns.

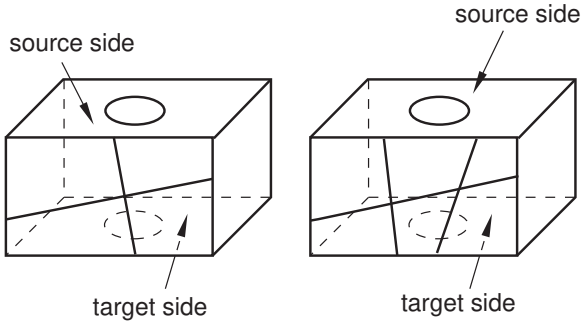

Figure 4: Acceptable connecting face patterns for swept meshing.

The combination of the three four-sided faces in *Figure 5* makes it unacceptable as a connecting side. In this case when you indicate that you are done selecting connecting sides, Abaqus/CAE displays an error message stating that the selected geometric faces do not form a grid pattern.

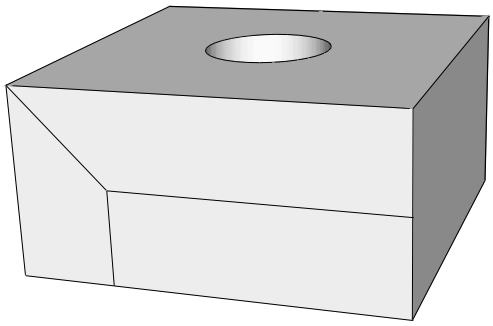

Figure 5: An unacceptable face pattern.

If you are unable to create acceptable connecting sides, you can omit the connecting sides. The resulting mesh may still be acceptable for analysis. However, you should remember to associate the elements along the sides of the region with the geometry, especially if there are loads or other analysis attributes applied to the sides of the mesh. For more information, see *Mesh-geometry association*.

Creating a bottom-up mesh

Bottom-up meshing is a manual process that may be time consuming and require some trial and error to produce an acceptable mesh. Bottom-up meshing is intended for use primarily when you need hexahedral elements for an analysis and you cannot generate them using top-down meshing techniques. You can also use bottom-up meshing in cases where extensive partitioning would be required to create a high-quality top-down mesh on geometry or where you want to extend a mesh part. The following procedure includes the basic steps for creating a bottom-up mesh. To create a bottom-up mesh, you must first have either a mesh region or a solid region with the bottom-up meshing technique assigned (for more information, see *Assigning mesh controls*). You can also create a bottom-up mesh on an assembly containing independent instances of native parts or dependent instances of parts containing any combination of orphan mesh and geometry.

1. From the main menu bar, select **Mesh->Create Bottom-Up Mesh**.

   Tip: You can also click the tool in the Mesh module toolbox. (For more information, see *Using the Mesh module toolbox*.)

   Abaqus/CAE opens the **Create Bottom-Up Mesh** dialog box and displays prompts in the prompt area to guide you through the procedure.

2. Select the **Domain** for which you want to create the bottom-up mesh.

   If there is only one appropriate domain for the current part or assembly, Abaqus/CAE automatically makes the selection. If there are multiple geometry regions, or cells, with the bottom-up technique assigned, click **Select** to select the cell that will be associated with the bottom-up mesh that you are creating. Regions that you can select are colored light tan.

   If you work with orphan elements, there is no association between the elements and any geometric region in the part.

   Note:

   After selecting a geometric region for bottom-up meshing, you can use the **Edit** button to change your selection.

3. Select one of the following meshing methods:

   - **Sweep**
   - **Extrude**
   - **Revolve**
   - **Offset** (available only for element face selections)

   For a description of each method, see *Bottom-up meshing methods*.

4. If you previously selected bottom-up meshing parameters for the current region, you can click **Fetch Last Selections** to reuse your previous selections.

   Abaqus/CAE saves your selections for the domain, source side, connecting sides, target side, extrusion vector, and axis of revolution in the session until they are overwritten by new selections.

   Note:

   If you add a partition to the model, you cannot reuse previously selected geometry; however, as long as you have not modified the mesh, you can reuse mesh selections such as element faces and two-dimensional elements.

5. Click **Select** next to **Source side**; and select the region faces, element faces, or two-dimensional elements where you want the mesh to begin.

   Tip: Use **[Shift] + Click** to select more than one face.

   If you are creating an offset mesh and you selected two-dimensional elements, Abaqus/CAE prompts you to indicate the side of your selection that will be offset. You can choose the **Brown** side, the **Purple** side, or **Both sides**.

   Abaqus/CAE colors your selection magenta.

6. When you have finished selecting the source side, click **Done** in the prompt area.
7. If you chose the **Sweep** method, you must select **Connecting sides** or a **Target side** or both to complete the mesh definition. Complete the following steps to make your selections:
   a. Toggle on **Connecting sides**, and click **Select** to choose one or more sides that connect the source side to the end of the mesh. Connecting geometric sides must be four-sided. You can also select four-sided element faces or two-dimensional elements that form a regular grid pattern. For more information, see *Defining connecting sides for a bottom-up swept mesh*.
   b. If you are working with geometry, you can toggle on **Target side** and click **Select** to choose a single face that Abaqus/CAE uses to end the swept mesh.
8. If you chose the **Extrude** method, you must specify an extrusion vector and choose the extrusion depth.
   a. Click **Select** next to **Vector** to select two points from the viewport or enter coordinates in the prompt area to define the start and end points of the extrusion vector.

      Abaqus/CAE displays a yellow arrow in the viewport to indicate the extrusion vector.
   b. Select a method to define the extrusion depth:

      - Toggle on **Use vector length** to extrude by the length of the vector created in the previous step.
      - Toggle on **Specify** and enter an extrusion depth.
      - Toggle on **Project to target** and click **Select** to specify a target side. The target side must lie along the direction prescribed by the extrusion vector.

        Abaqus/CAE uses the target side to set the extrusion distance. The extruded mesh will closely match the shape of the target side, but it will not conform to a mesh on the target side. (For more information, see *Bottom-up meshing methods*.)

9. If you chose the **Revolve** method, you must specify an axis and an angle of revolution.
   a. Click **Select** next to **Axis** to select two points from the viewport or enter coordinates in the prompt area to define the start and end points of the axis of revolution.

      Abaqus/CAE displays a yellow arrow in the viewport to indicate the axis.
   b. In the **Angle** field, enter the desired angle of revolution, in degrees, for the revolved mesh.
10. If you chose the **Offset** method, you must specify the total thickness, and you can change the way two-dimensional mesh corners are offset.
    a. In the **Total thickness** field, enter the thickness for the offset mesh.
    b. For source sides containing shell elements that form sharp corners, toggle on **Constant thickness around corners** to maintain the same total thickness where the elements meet in the corner as in the rest of the selection. Using the option can reduce element distortion and prevent collapsed elements, especially if elements are offset to the inner side of a corner (for more information, see *Reducing element distortion and collapse during mesh offsetting*).
11. Where applicable, enter the **Number of layers** to define the number of element layers between the source side and the end of the bottom-up mesh.

Note:

The **Number of layers** parameter is required for the **Sweep** method only if you specify a target side with no connecting sides. It is always required for the **Extrude**, **Revolve**, and **Offset** methods.

12. If desired, enter a **Bias ratio** for an extruded bottom-up mesh to skew the thickness of element layers toward or away from the source side. **Bias ratio** is used in conjunction with **Number of layers**.

    The bias ratio is the ratio of the thickness of the element layer at the source side to the thickness of the element layer furthest from the source side.

13. If desired, use the **Options** area to add the new bottom-up elements to element sets:

Extend existing sets

Each new bottom-up element will be added to any mesh sets containing its parent element from the source side.

Create a set for new elements

Create a new element set for the bottom-up elements. You can use the default set name or create a name for the set. If you are working with orphan elements, you can also create a separate set for each layer of elements. If you choose this option, Abaqus/CAE increments the base set name with `-Layer-n`, where *n* is the layer number.

14. The **Undo** field near the bottom of the **Create Bottom-Up Mesh** dialog box allows you to undo and redo bottom-up mesh changes, mesh-geometry associativity changes, and mesh edits. You can access the same functions in the Edit Mesh toolset. For more information, see *Undoing or redoing a change in the Edit Mesh toolset*.
15. Click **Mesh** in the **Create Bottom-Up Mesh** dialog box to generate the bottom-up mesh.
16. Repeat Steps 3 through 15 to create another bottom-up mesh in the same region, or click **Cancel** to end the procedure.

An example including bottom-up meshing techniques

The following is a step-by-step example of meshing a part using a combination of top-down and bottom-up methods.
The procedures and images describe one way that you can create a hexahedral mesh for this part. Before you begin, you should be familiar with top-down meshing, creating partitions, and using the Edit Mesh toolset. You should also have read the sections discussing bottom-up meshing, mesh-geometry associativity, and related techniques:

- *What is bottom-up meshing?*
- *Bottom-up meshing methods*
- *Selecting parameters for a bottom-up mesh*
- *Creating the boundary mesh for a bottom-up region*
- *Improving the quality of boundary meshes for a bottom-up region*
- *Defining connecting sides for a bottom-up swept mesh*

In this section:

- *Partitioning the unmeshable region and meshing the top-down regions*
- *Beginning the bottom-up mesh*
- *Continuing the bottom-up mesh*
- *Completing the mesh for the bottom-up region*
- *Checking the association of the bottom-up mesh with the geometry*
- *Associating the remainder of the bottom-up mesh*

Partitioning the unmeshable region and meshing the top-down regions

The example part (`bottomup_mesh_example_part.sat`) is imported from an ACIS file.

The file is included with the Abaqus installation, and you can use the following utility to obtain a copy:

```
abaqus fetch job=bottomup_mesh_example_part.sat
```

For more information about ACIS files, see *Importing parts from an ACIS-format file*.

Figure 1 shows the original part. There are three solid regions; the regions colored green and yellow can be meshed using the top-down structured and swept meshing techniques, respectively, and the orange region is unmeshable with the automated top-down techniques and hexahedral elements.

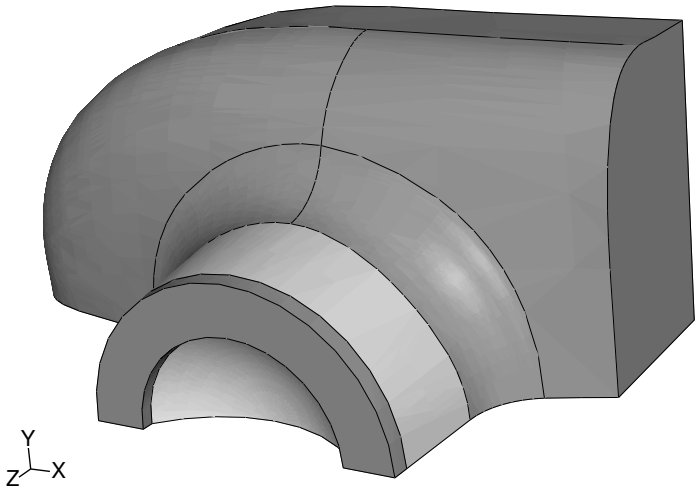

Figure 1: Default mesh color coding on the imported part.

To mesh the part, we will first create three partitions. The first two partitions create another top-down swept meshable region near the outer edge of the unmeshable region. The third partition is a face partition that you will use later as a vector for the bottom-up extrude method. You could apply bottom-up meshing techniques to the entire unmeshable region without partitioning. However, the resulting mesh would contain some poorly formed elements near the outer edge. In practice, you may create several bottom-up meshes before you make a satisfactory mesh for the entire region. Especially for more complex parts, you may want to save copies of a part with different meshing approaches until you decide which approach yields the best mesh.

1. Rotate the part so that you are viewing the bottom of the part, as shown in *Figure 2*.

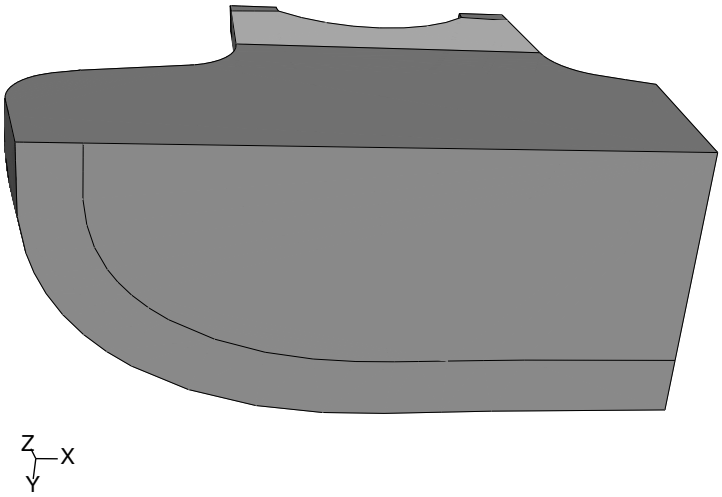

Figure 2: Creating an offset partition on the bottom face.

2. Complete the following steps to partition the face:

   a. From the partition face tools in the module toolbox, select the sketch method tool .
   b. Select the bottom face of the part, and select one of the straight edges to be vertical and on the right.

      Abaqus/CAE opens the Sketcher.

   c. From the Sketcher toolbox, select the offset tool .
   d. Select the curved edge, and click mouse button 2 to accept the selected edge.
   e. Enter `2.5` in the prompt area as the offset distance.

      Abaqus/CAE displays a preview of the offset partition.

   f. Click **OK** if the offset is shown correctly (toward the interior of the part), or click **Flip** if the offset is shown outside the part.
   g. Click mouse button 2 or click **Done** in the prompt area to partition the face.

   Abaqus/CAE returns to the Mesh module and displays the partitioned face as shown in *Figure 2*.

3. Extrude the face partition through the region.

   a. From the partition cell tools in the module toolbox, select the extrude/sweep method tool .
   b. Select the face partition created in Step 1 as the edge to extrude.
   c. Click **Extrude Along Direction** in the prompt area, and pick the edge shown in *Figure 3*.

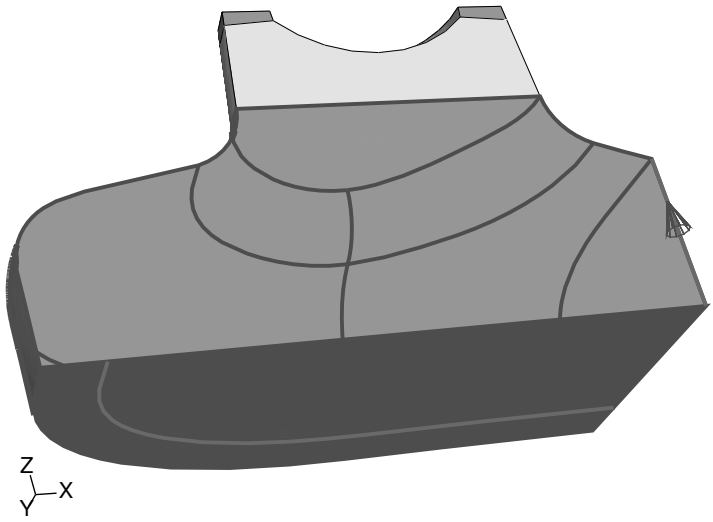

Figure 3: Extruding the face partition through the cell.

d. Click **OK** if the extrusion direction is shown correctly (through the region), or click **Flip** to change the direction.

e. Click **Create Partition** to partition the cell.

Abaqus/CAE displays the outer region of the part in yellow, indicating that it can now be meshed using top-down swept meshing.

4. Partition the front face of the unmeshable region as shown in *Figure 4*.

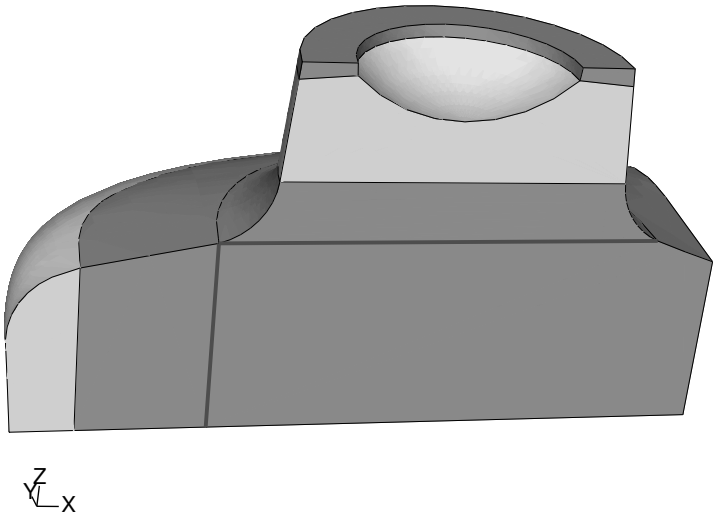

Figure 4: Creating face partitions.

a. From the partition face tools in the module toolbox, select the sketch method tool .

b. Select the front face of the unmeshable region, and select an edge to be vertical and on the right. Abaqus/CAE opens the Sketcher.

c. Use the vertical construction line tool  to create a construction line as shown in *Figure 5*.

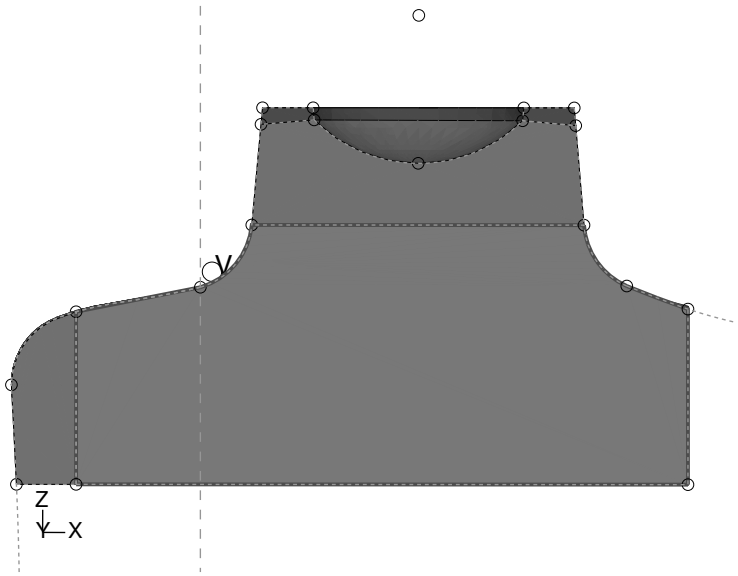

Figure 5: Using a vertical construction line to partition the face.

d. Use the connected lines tool  to create a line connecting the two points where the vertical construction line intersects the face of the part.

e. Create a second line connecting the upper point of the vertical line to the point where the fillet ends on the front face—the line should be nearly horizontal.

f. Click mouse button 2 or click **Done** in the prompt area to partition the face.

There are now three regions in the part that you can mesh using the top-down meshing techniques.

5. Assign global edge seeds to the entire part using an approximate size of `0.9` and the default settings for curvature control.

6. Select **Mesh->Part** from the main menu bar to mesh the top-down regions.

Abaqus/CAE highlights the unmeshable region and displays a warning that you cannot mesh it automatically.

7. Click **OK** to mesh the three top-down regions. *Figure 6* shows the resulting partial mesh.

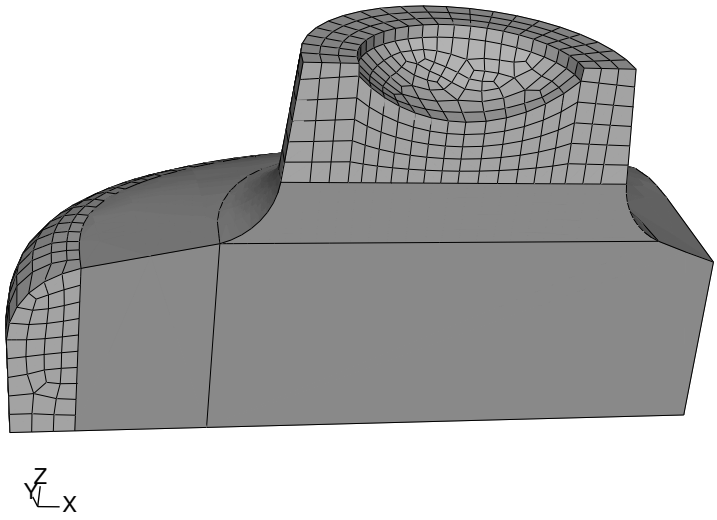

Figure 6: Automatic meshing of the top-down regions.

Beginning the bottom-up mesh

Now that the top-down mesh is complete, you can assign the bottom-up meshing technique and begin creating a hexahedral mesh for the rest of the part.

1. Use the mesh controls tool  to assign the bottom-up meshing technique to the unmeshable region. Abaqus/CAE colors the region light tan.
2. Select **Mesh->Create Bottom-Up Mesh** from the main menu bar.

   Tip: You can also click the  tool in the Mesh module toolbox. (For more information, see *Using the Mesh module toolbox*.)

   Abaqus/CAE displays the **Create Bottom-Up Mesh** dialog box and makes the unmeshed regions translucent. The degree of translucency is determined by the translucency slider, located in the **Color Code** toolbar (for more information, see *Changing the translucency*). In a more complex part, translucency allows you to select internal regions more easily.
3. Select the **Sweep** method, and click **Select** to the right of **Source side**.
4. Select the semi-circular face at the bottom of the protrusion, colored magenta in *Figure 1*, as the source side of the first bottom-up mesh; and click **Done** in the prompt area.

   You must change the default selection options to select the interior face (for more information, see *Using the selection options*).

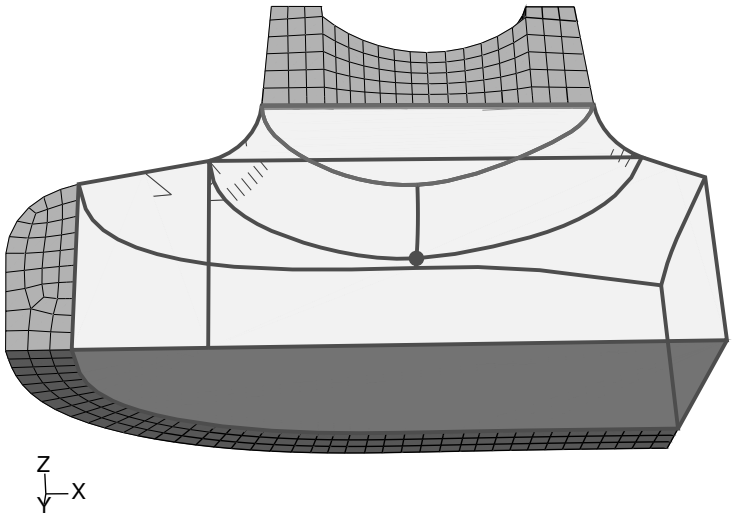

Figure 1: Selecting a geometric face as the source side.

Tip: You can also choose two-dimensional elements or element faces as sides of a bottom-up mesh. In this case an alternative source side selection would be all the element faces on the bottom of the swept mesh.

5. Toggle on **Connecting sides**, and click **Select**. Rotate the part as needed to select the three faces that represent the fillet between the top protrusion and the body of the part and the corresponding flat face on the front of the part, colored yellow in *Figure 2*.

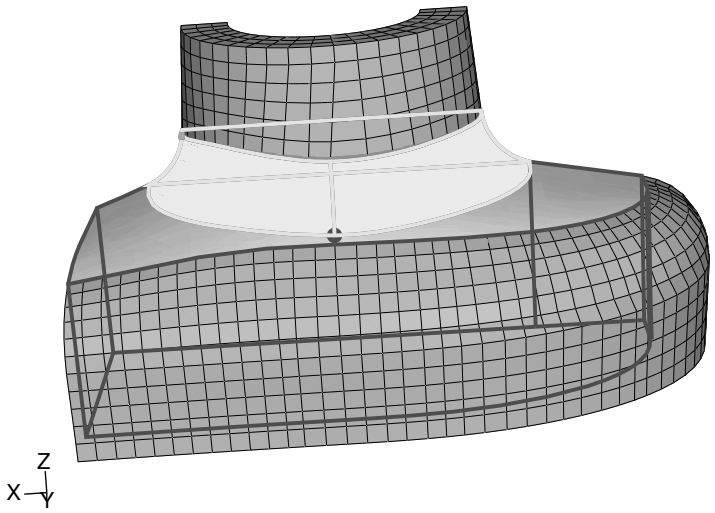

Figure 2: Selecting the connecting sides.

Click **Done** in the prompt area to end selection.

6. Click **Mesh** in the **Create Bottom-Up Mesh** dialog box to create the mesh.

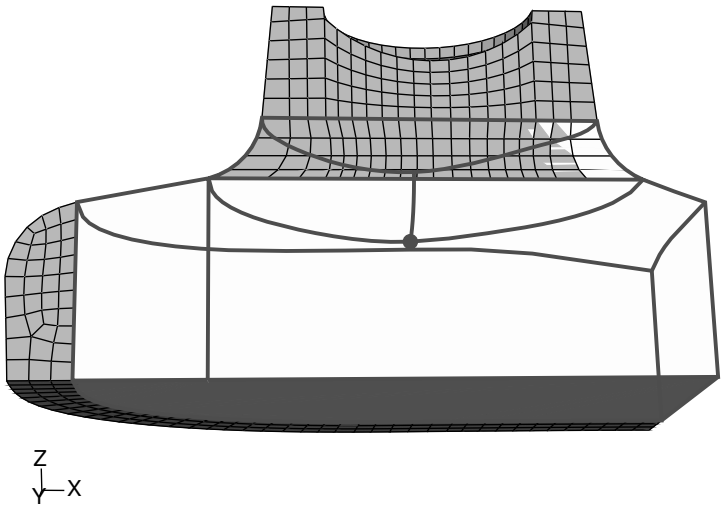

Figure 3: Bottom-up swept mesh of the filleted area.

The mesh extends approximately as far into the region as the selected connecting sides, the bottom-up region remains selected, and the **Create Bottom-Up Mesh** dialog box remains open for the next step.

Continuing the bottom-up mesh

There are at least three methods that you can use to complete the mesh for the part. The simplest method would be to create another swept mesh, using the bottom of the mesh that you just completed and the two faces extending out from the fillet on the top of the remaining unmeshed area as the source side, the three geometric vertical faces and the set of vertical element faces as the connecting sides, and the unmeshed portion of the bottom face as the target side. This method would complete the part mesh in a single bottom-up meshing step, and the elements would be fully associated with the selected faces. You could also use the bottom-up extrude method with the bottom face of the part as the extrude distance. However, for demonstration purposes we will use a longer process that combines use of the bottom-up extrude method, the associativity tool, and the Edit Mesh toolset.

Create a bottom-up extruded mesh

1. Select the **Extrude** method, and click **Select** to the right of **Source side**.
2. Select the element faces at the bottom of the previous bottom-up mesh, as shown in *Figure 1*, as the source side for the second bottom-up mesh.

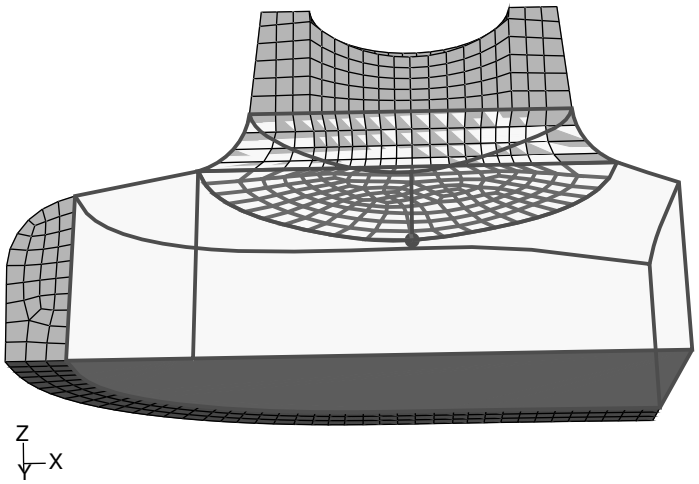

Figure 1: Selecting element faces as the source side.

3. Click **Done** in the prompt area to accept the selected faces.

   The **Create Bottom-Up Mesh** dialog box reappears.
4. Click the **Select** button to choose a vector for the extruded mesh.
5. Select the upper endpoint of the partition as the starting point of the vector, and select the lower endpoint as the end of the vector. *Figure 2* shows the extrusion vector.

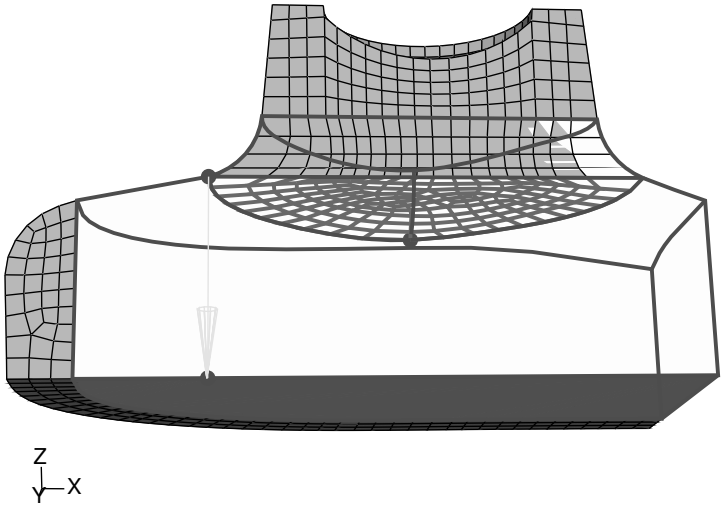

Figure 2: Selecting the vector for the bottom-up extruded mesh.

6. Enter `10` for the **Number of layers**.

   There are 10 elements on the inner face of the top-down swept mesh. Using the same number of elements for the extruded mesh will provide a better match when you create the third, and final, bottom-up mesh.

7. Verify that the extrude depth is set using the default **Use vector length** method, and click **Mesh** in the **Create Bottom-Up Mesh** dialog box to create the mesh.

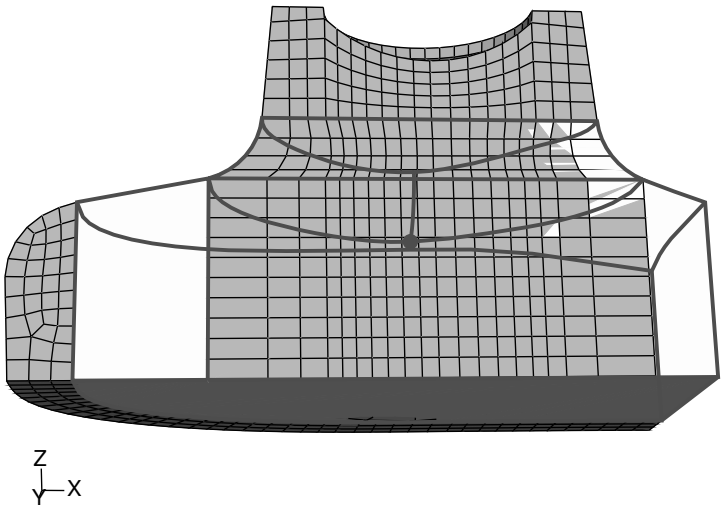

Figure 3: The bottom-up extruded mesh.

Extend the extruded mesh

The extruded bottom-up mesh ends near the bottom face of the region, as dictated by the nonplanar source side and the length of the extrusion vector. You can edit the nodes in the last extruded element layer so that they end exactly on the bottom face of the region.

1. Select the Edit Mesh toolset, located at the bottom of the Mesh module toolbox.
2. Select the **Node** category, and click on **Project** in the **Edit Mesh** dialog box.
3. Use the *angle method* to select all the nodes on the bottom of the bottom-up extruded mesh, as shown in *Figure 4*, and then click **Done** in the prompt area.

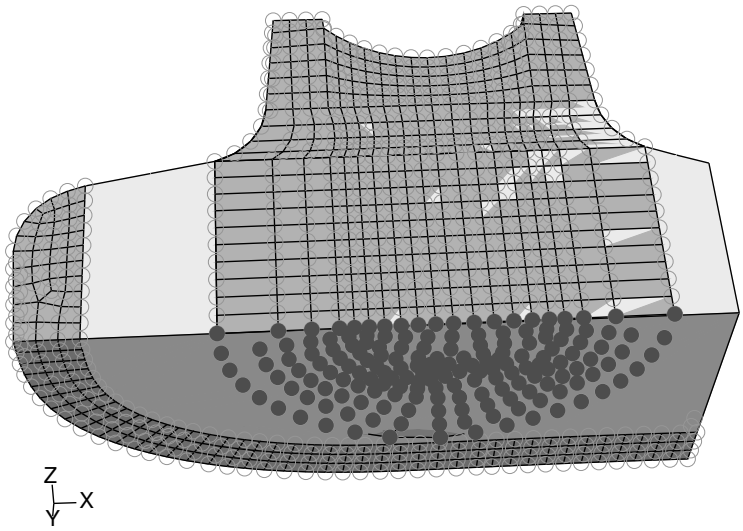

Figure 4: Selecting the nodes to project.

4. Select the bottom face of the bottom-up region, and click **Yes** in the prompt area to project the nodes onto the face.

Completing the mesh for the bottom-up region

We will now create a final swept mesh to complete the mesh for the part.

1. From the main menu bar, select **Mesh->Create Bottom-Up Mesh**.
2. Select the bottom-up region.

   Abaqus/CAE displays the **Create Bottom-Up Mesh** dialog box.
3. Select the **Sweep** method, and click **Select** to the right of **Source side**.
4. Select the two remaining unmeshed faces on the top of the part, as shown in *Figure 1*, and click **Done** in the prompt area.

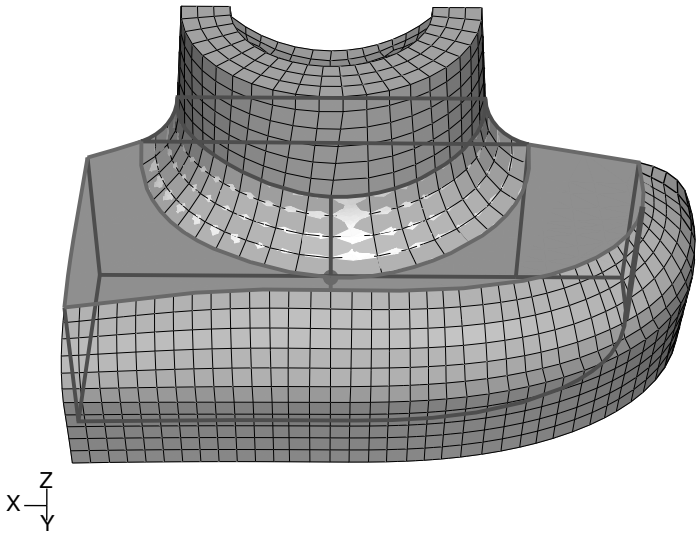

Figure 1: Selecting the source side for the final bottom-up mesh.

5. Toggle on **Connecting sides**, and click **Select**. Rotate the part, and use the angle method to select the interior element faces from the outer swept mesh and the exterior element faces of the extruded mesh as shown in *Figure 2*.

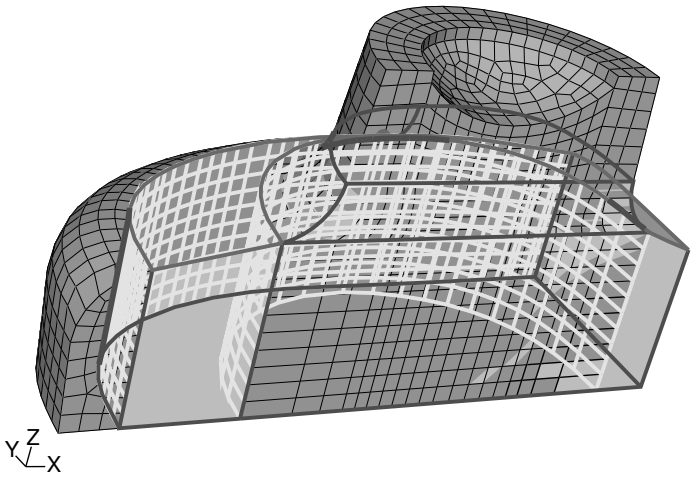

Figure 2: Selecting the element faces as connecting sides.

Click **Done** in the prompt area to end selection.

6. Toggle on **Target side**, and click **Select**.
   Abaqus/CAE prompts you to select a target side for the swept mesh.
7. Select the bottom face of the region.
8. Click **Mesh** in the **Create Bottom-Up Mesh** dialog box to create the mesh.

The part is now completely meshed with hexahedral elements, as shown in *Figure 3*.

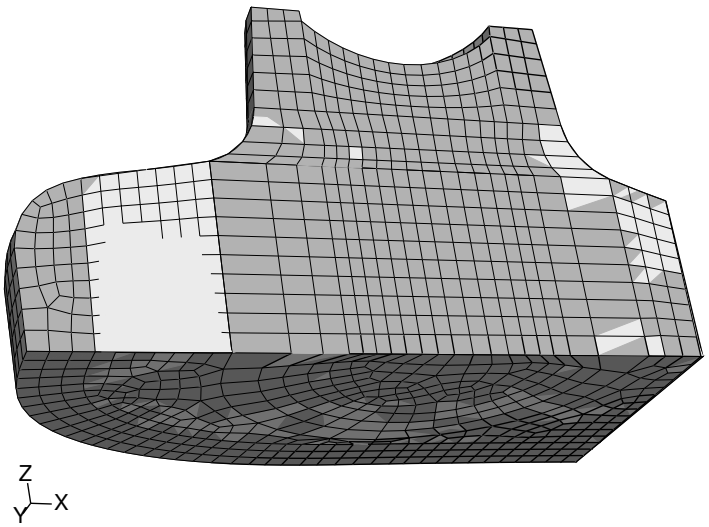

Figure 3: The final meshed part.

Checking the association of the bottom-up mesh with the geometry

Before using the completed bottom-up mesh for an analysis, you should check the association between the region geometry and the bottom-up mesh elements. Loads, boundary conditions, and other attributes in Abaqus are applied to geometry, and they will not transfer correctly to the elements of a bottom-up mesh unless the mesh is correctly associated with the geometry. At minimum, you should check the association for areas of a bottom-up mesh where loads and boundary conditions are applied.

In most cases if you select a geometric feature, such as a face, to define the bottom-up mesh, Abaqus/CAE automatically associates the appropriate elements with that face. However, in cases where the geometry is not used, such as the extruded bottom-up mesh in the center of the example part, the elements are associated only with the region, not the nearby face where a load might be applied. (For more information, see *Mesh-geometry association*.) The following procedure associates the elements on the bottom and front faces of the part with the geometric faces:

1. From the main menu bar, select **Mesh->Associate Mesh with Geometry**.
2. Select the bottom face of the bottom-up region, as shown in *Figure 1*.

   The elements created in the final bottom-up meshing step are colored yellow because they were already associated when the face was used as the target side of the final bottom-up swept mesh. However, the elements in the semi-circular extruded mesh are not associated with the face.

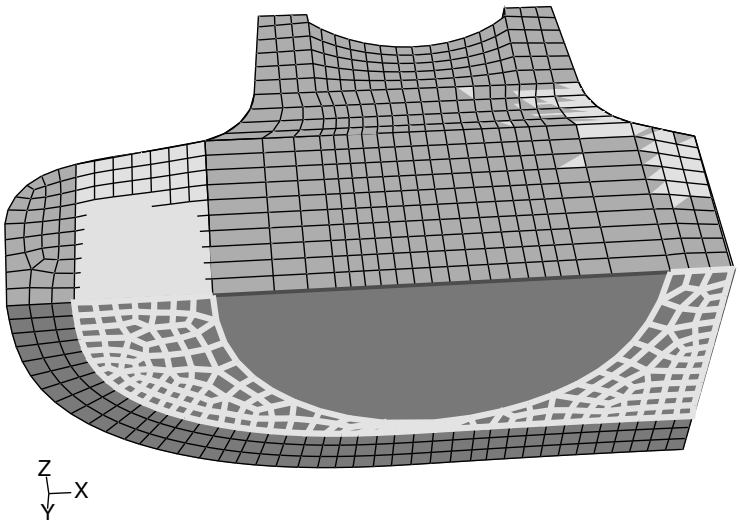

Figure 1: Existing mesh associations on the bottom face.

3. Remove the top-down meshed cell that extends from the bottom-up region to the outer curved face of the part.
   a. Select **Tools->Display Groups->Create**.

      Abaqus/CAE displays the **Create Display Group** dialog box.
   b. Select **Cells** from the item list, and click **Edit Selection**.
   c. From the viewport, pick the top-down swept region that extends along the curved outer edge of the part and click **Done** in the prompt area.
   d. In the **Create Display Group** dialog box, click the **Remove** button.

      Abaqus/CAE removes the selected cell from the viewport.

   For more information, see *Using display groups to display subsets of your model*."

4. Use the angle method to select all the faces on the bottom of the bottom-up region. When you are finished, all of the element faces on the bottom of the bottom-up region should be colored yellow, as shown in *Figure 2*.

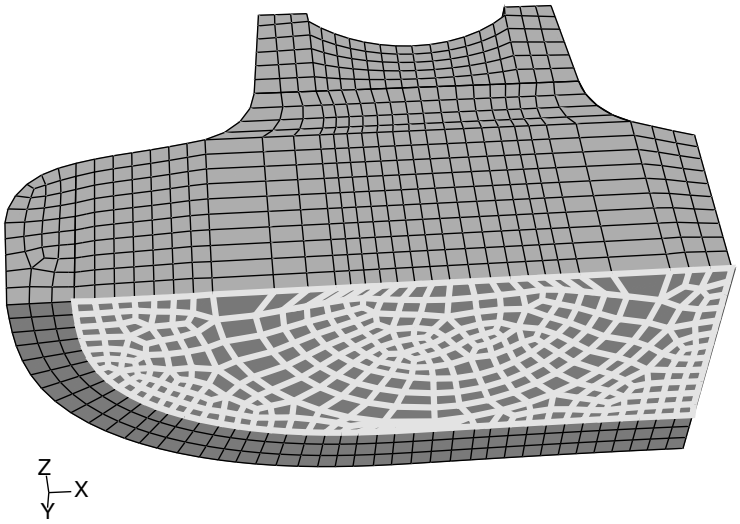

Figure 2: Final mesh associations on the bottom face.

Note:

If you did not remove the outer top-down meshed cell, use of the angle method would have selected the top-down element faces for association as well as the bottom-up faces, leading to an error message when you attempted to associate the faces.

5. Click **Done** in the prompt area to associate the selected elements' faces with the region face.

Associating the remainder of the bottom-up mesh

To fully associate the bottom-up mesh, you should verify and edit the association for the faces on the front side, the right side, and on each of the bounding edges and vertices in the bottom-up region. You associate edges and vertices the same way as you associated the element faces in the previous section, except that you select edges and element edges or vertices and nodes, respectively. Abaqus/CAE attempts to associate nodes with vertices and element edges with geometric edges based on proximity. If all the elements along an edge are associated with the faces bounded by that edge, Abaqus/CAE automatically associates the element edges with the geometric edge.

Once you have a part completely meshed and you have checked the association of the bottom-up mesh, you should save the model. Prior to running an analysis, you should also verify the quality of the mesh. Mesh verification helps ensure that there are no hidden problems, regardless of whether you created the mesh automatically (top-down) or used bottom-up techniques and mesh editing to construct the mesh. For more information on mesh verification, see *Verifying element quality*.

Mesh-geometry association

You can create an association between orphan or bottom-up mesh entities and adjacent geometry. Abaqus/CAE automatically associates top-down meshes with the underlying geometry. Abaqus/CAE can make this association since the mesh conforms exactly to the geometry. In contrast, a bottom-up mesh does not have to conform to geometry and, therefore, Abaqus/CAE may not associate parts of the mesh with the geometry. Similarly, orphan mesh entities are not associated with geometry because they were either created independent of geometry or the geometry from which they were created is not available in the current model.

Creating an association between orphan or bottom-up mesh entities (elements, element faces, element edges, and nodes) and adjacent geometry allows the transfer of loads, interactions, and boundary conditions from the geometry to the mesh. If you fully associate orphan or bottom-up mesh entities with an adjacent geometric face, you can use that face to create a native mesh for the geometry region that is compatible with the orphan or bottom-up mesh with which you started. Full association means that:

- The selected geometric face is associated with element faces that cover the entire face.
- All edges of the geometric face are associated with element edges that span the entire edge.
- All vertices of the face are associated with nodes.

Figure 1 shows an example of the use of mesh-geometry association between a two-dimensional orphan element region and an adjoining geometric region. Associating the geometric edge—the yellow line in the left image—between the two regions with the orphan element edges and nodes results in a compatible hybrid mesh.

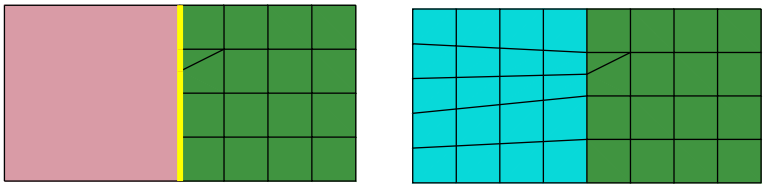

Figure 1: Associating an edge enforces creation of a compatible mesh.

Conversely, if a model has a mesh that you need to preserve—because it includes extensive edits or is ideally suited to an analysis—and you do not want to make an orphan mesh for the entire part, you can delete the association between the mesh and selected entities to create orphan nodes and elements in selected regions. Deleting mesh associativity prevents Abaqus/CAE from deleting the mesh of a region when you edit the geometry. After making your edits, you can reestablish associativity between the geometric faces and the surface entities of the mesh. Nodes along edges are merged with any nodes that currently exist on the geometry.

Note:

If you delete the mesh-geometry associativity for a solid region, the only ways to reestablish a native mesh are to use the **Undo** function in the **Edit Mesh** dialog box or to assign the bottom-up mesh technique to the region and recreate the associativity.

The following rules apply to the association of bottom-up elements when you work with a region of solid geometry:

- Abaqus/CAE always associates bottom-up elements with the selected region.
- When the underlying geometry is used to define the shape of the mesh, Abaqus/CAE associates the mesh with that geometry.
- When portions of the geometry are not used to define the bottom-up mesh, Abaqus/CAE does not associate them, even if the mesh and geometry are in the same location.
- You can edit the mesh-geometry association of any geometry-based bottom-up meshed region.

- Even if you edit a generated mesh so that it matches the geometry, you must still manually associate the mesh with the geometry.

There are three considerations that make mesh-geometry association critical to creating a good analysis model:

1. When you work with geometry, attributes such as loads and boundary conditions are applied to the geometry. Proper mesh-geometry association ensures that these attributes are transferred correctly to the mesh during the analysis.
2. If you select a geometric face as a source or connecting side of a bottom-up mesh, Abaqus reuses the existing mesh entities on that face to create a compatible mesh only if the mesh entities are fully associated with the selected face.
3. Abaqus tries to merge meshes that are associated with the same geometric entities. Unassociated meshes may require you to merge nodes along mesh boundaries using the Edit Mesh toolset.

You should always check that the mesh-geometry associativity is correct when working with bottom-up meshes or editing the associativity of any mesh. Abaqus/CAE will issue an error in the Job module if you submit a job and attributes are applied to geometry with no associated mesh. However, Abaqus/CAE cannot determine whether the association is correct. For example, if a load is applied to a geometric face that should have several hundred elements but only one element is associated with that face, Abaqus/CAE will attempt to analyze the model with the entire load applied at the single associated element. Incorrect association produces incorrect analysis results.

You can use the mesh-geometry association  and delete mesh associativity  tools in the Mesh module toolbox to view and edit or to delete mesh-geometry associations. For detailed instructions, see *Viewing and editing mesh-geometry associativity* and *Deleting mesh-geometry associativity*.

Understanding adaptive remeshing

This section describes how you perform adaptive remeshing in Abaqus/CAE. Adaptive remeshing is described in detail in *Adaptive Remeshing*.

In this section:

- *What are remeshing rules?*
- *Which mesh controls can I use with adaptive remeshing?*
- *Which procedures can I use with adaptive remeshing?*
- *What is the difference between automatic adaptive remeshing and manual adaptive remeshing?*
- *When do I need to use manual adaptive remeshing?*

What are remeshing rules?

Remeshing rules enable Abaqus/CAE to adapt your mesh iteratively to meet error indicator goals that you have specified. You can allow Abaqus/CAE to perform the iterative remeshing and analysis operations, or you can remesh manually and study the effect of your remeshing rule on the mesh and the resulting analysis. Abaqus/CAE remeshes the faces and cells to which you assigned an adaptivity rule and any adjacent faces or cells; the mesh on other regions does not change. For more information, see *About Adaptive Remeshing*.

A remeshing rule describes all aspects of your adaptive meshing specification:

- The region to which the remeshing rule is applied. You can apply a remeshing rule to the entire model or to selected regions.
- A specific step during which Abaqus/CAE will apply the rule. The remeshing rule will be applied only during this step; however, you can apply a different remeshing rule with the same settings to another step in your model.
- The error indicator output variables—the output variables that will be used to calculate the error estimate. For more information, see *Selection of Error Indicators Influencing Adaptive Remeshing*.
- The sizing method—the method that Abaqus/CAE will use to calculate the size of the elements in the mesh. For more information, see *Solution-Based Mesh Sizing*.
- Any constraints on the remeshing calculations.

A remeshing rule works in combination with the edge seeding, element type, and meshing method to determine the mesh at a particular adaptivity iteration. Remeshing rules are stored in the model database and are maintained between sessions. To create a remeshing rule, select **Adaptivity**->**Remeshing Rule**->**Create** from the main menu bar. For more information, see *Creating a remeshing rule*.

You can define multiple remeshing rules over multiple regions of your model. If you apply multiple remeshing rules to the same region of a model, Abaqus/CAE applies a conservative element size specification, and the rule that defines a finer mesh at a particular point takes precedence. If you assign a remeshing rule to a dependent instance, Abaqus/CAE remeshes the original part and each dependent instance of the part inherits the same mesh.

Abaqus/CAE requests error indicator output variables in every job that you create while a remeshing rule is active. The remeshing rule has no effect on the mesh during the first job. However, during the first job Abaqus uses the remeshing rule to calculate the error indicator output variables. In subsequent adaptive remesh iterations the remeshing rule augments your mesh size specification to produce a mesh that attempts to optimize element size and placement to achieve the error indicator goals described in the rule.

Which mesh controls can I use with adaptive remeshing?

Table 1 shows the mesh controls that must be assigned to a region that will use adaptive remeshing.

Table 1: Mesh controls and adaptive remeshing.

Dimensionality	Element Shape	Algorithm	Technique
Two-dimensional	Triangular	n/a	Free
Two-dimensional	Quad-dominated	Advancing front	Free
Three-dimensional	Tetrahedral	n/a	Free

In addition, you must assign the above supported mesh controls to any face or cell that is adjacent to a region that is included in a remeshing rule.

When Abaqus/CAE generates a tetrahedral mesh, it first creates a boundary mesh of triangles on the exterior faces of the solid region and then generates the tetrahedral mesh using the triangles as faces of the exterior tetrahedral elements. When you assign adaptive remeshing to a solid region, Abaqus/CAE applies adaptive remeshing to the boundary mesh of triangles on the exterior faces. For more information, see *Free meshing with triangular and tetrahedral elements*.

If Abaqus/CAE is using the mapped meshing technique in a region you have selected for adaptive remeshing, the mesh resizing algorithm may be slow to converge and require more remeshing iterations to achieve a given target error. To prevent Abaqus/CAE from using mapped meshing, you can toggle off **Use mapped meshing where appropriate** in the **Mesh Controls** dialog box. For more information, see *Setting the mesh algorithm*.

Which procedures can I use with adaptive remeshing?

Adaptive remeshing is available only for Abaqus/Standard. In addition, adaptive remeshing is available only for the following Abaqus/Standard procedures:

- Static (general and linear perturbation)
- Quasi-static
- Heat transfer
- Fully coupled thermal-stress
- Coupled pore fluid diffusion-stress
- Coupled thermal-electrical

What is the difference between automatic adaptive remeshing and manual adaptive remeshing?

If you choose to allow Abaqus/CAE to remesh your model iteratively, the adaptivity process in the Job module controls the adaptive remeshing for you. You need only define the remeshing rule in the Mesh module and apply the rule to the regions in your model that you want to be remeshed.

Conversely, you can manually apply modified remeshing rules and view the impact of your modifications on the generated mesh. When you are satisfied that your remeshing rule is producing the desired mesh, you can use the rule to drive a sequence of iterative remeshing and analysis operations that is controlled by Abaqus/CAE. Select **Adaptivity->Manual Adaptive Remesh** from the main menu bar to apply the adaptive remesh rules manually. For more information, see *Manually resizing and remeshing*.

When you apply manual adaptive remeshing, you must enter the name of the output database file that was generated by a previous analysis of your model. This output database contains the error indicator output variables that Abaqus/CAE uses to calculate the mesh sizing functions. The error indicator output variables stored in the output database limit the changes that you can make to a remeshing rule. For example, if your original rule specified energy density in a certain region, you will not be able to switch the rule to use error in equivalent plastic strain without first rerunning the analysis. You can modify the sizing method and the element size constraints in the remeshing rule and still use the output database from a previous analysis. However, the output database cannot be used if you modify the step, the region, or the error indicator output variables.

When do I need to use manual adaptive remeshing?

You can use manual adaptive remeshing to do the following:

- To learn about the impact of various size function and error indicator output variables on the mesh generated by Abaqus/CAE.
- If your analysis is expected to take a long time, you can close the Abaqus/CAE session and make the license tokens available for another user or for a new session. However, to continue the adaptive process, you must read the output database generated by the analysis and manually remesh the model.
- If the analysis ended prematurely (for example, because of insufficient memory), you can use manual remeshing to continue the adaptivity process.

Advanced meshing techniques

This section contains information about how to accomplish advanced meshing tasks that are not straightforward.

In this section:

- *Meshing multiple three-dimensional solid regions*
- *Meshing multiple two- and three-dimensional shell regions*
- *Compatible meshes between part instances*
- *Parametric modeling*
- *Meshing complex solids with hexahedral elements*

Meshing multiple three-dimensional solid regions

Abaqus/CAE assigns a default meshing technique to each region depending on its geometry and topology. However, sometimes the default meshing techniques applied to adjacent regions of a three-dimensional part or part instance are not compatible, and Abaqus/CAE cannot generate a compatible mesh.

For example, Abaqus/CAE cannot generate a compatible mesh over the entire part instance in *Figure 1* using the default meshing techniques because the nodes from the structured mesh on the left cannot be merged with the nodes of the swept mesh on the right. (The cube on the right side of the part instance is a swept region because it is joined to the cylinder, which is also a swept region.)

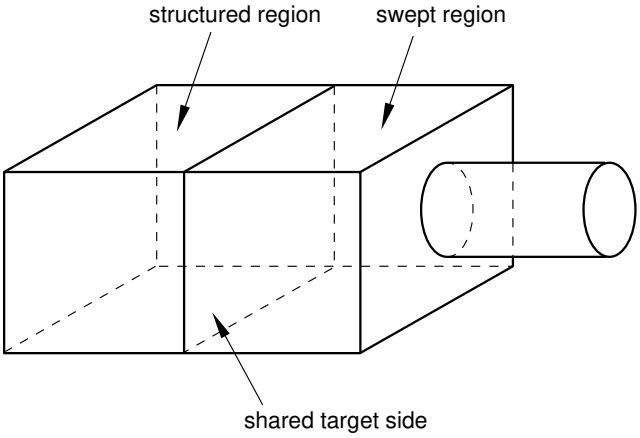

Figure 1: A compatible mesh is impossible using these default meshing techniques.

The mismatch that would occur between the nodes of the structured region and the nodes of the swept region is obvious if you mesh the two regions separately, as shown in *Figure 2*.

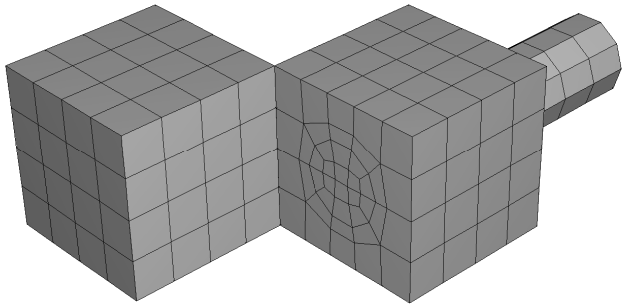

Figure 2: The structured region and the swept region meshed separately.

If you initiate the meshing procedure and Abaqus/CAE cannot generate a compatible mesh using the default meshing techniques, Abaqus/CAE attempts to replace the default meshing techniques with new meshing techniques. These new techniques are determined not only by the region's geometry and topology but also by the characteristics of neighboring regions in the part or part instance. Abaqus/CAE evaluates the interfaces between regions and tries to minimize the number of incompatible interfaces.

For example, the default meshing technique for the cube on the left side of the part instance in *Figure 1* is structured, and the resulting incompatible mesh is shown in *Figure 2*. However, this cube can also be meshed using the swept meshing technique. Therefore, Abaqus/CAE changes the meshing technique assigned to this region from structured

to swept, and a compatible mesh is generated over the whole part instance. (The element shapes assigned to a region remain unchanged when Abaqus/CAE changes the meshing technique assigned to the region.)

When you initiate the meshing procedure for a three-dimensional part or part instance, Abaqus/CAE determines if a compatible mesh can be generated using the default techniques assigned to each region. If a compatible mesh is possible, meshing proceeds. If a compatible mesh cannot be generated using the default techniques, Abaqus/CAE checks to see if it can replace the default meshing techniques with different techniques that will allow a compatible mesh to be generated.

- If different techniques will allow a compatible mesh, Abaqus/CAE highlights the incompatible interfaces and prompts you to select one of the following options:
  - Cancel the meshing procedure.
  - Allow Abaqus/CAE to replace the default techniques as necessary and generate a compatible mesh.
  - Allow Abaqus/CAE to use the default meshing techniques and automatically generate tie constraints across the incompatible interfaces. Abaqus/CAE automatically chooses one side of the interface as the secondary surface and the other as the main surface for the automatically generated tie constraint but creates common (merged) nodes on the perimeter of the incompatible interface. The nodes on the secondary surface are constrained to have the same value of displacement, temperature, pore pressure, or electrical potential as the point on the main surface to which they are tied. Abaqus/CAE generally selects the surface with the finer mesh to be the secondary surface. The computation for the depth of the secondary node adjustment zone for the tie constraint is based on the bounding dimensions of the interfacing regions. (For more information on tie constraints, see *Mesh Tie Constraints*.)
- If different techniques will still not allow a compatible mesh, Abaqus/CAE highlights the incompatible interfaces and prompts you to select one of the following options:
  - Cancel the meshing procedure.
  - Automatically generate tied surface interactions across the incompatible interfaces, as described above.

If a compatible mesh cannot be generated, you can try one of the following approaches:

- Partition as necessary to generate a compatible mesh.
- Use the free meshing technique to mesh the entire part or part instance.

In general, the following restrictions apply to generating a compatible mesh on a three-dimensional solid part or part instance:

- A swept region cannot share its target side with a structured region. However, it can share a source side or a connecting side with a structured region, as shown in *Figure 3*.

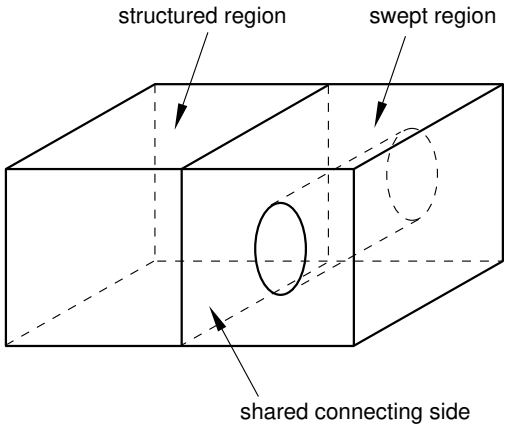

Figure 3: The connecting side of the swept region is shared with the structured region.

- In some situations Abaqus/CAE cannot mesh a part or part instance that contains multiple regions that have all been assigned the swept meshing technique. For example, Abaqus/CAE cannot sweep a mesh along the part instance shown in *Figure 4* because a compatible mesh cannot be generated on the shared target face.

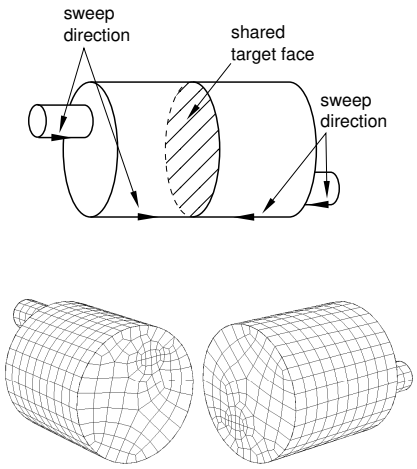

Figure 4: A compatible swept mesh cannot be generated along this part instance.

However, *Figure 5* shows how you can use partitions to produce a mesh that incorporates four swept regions.

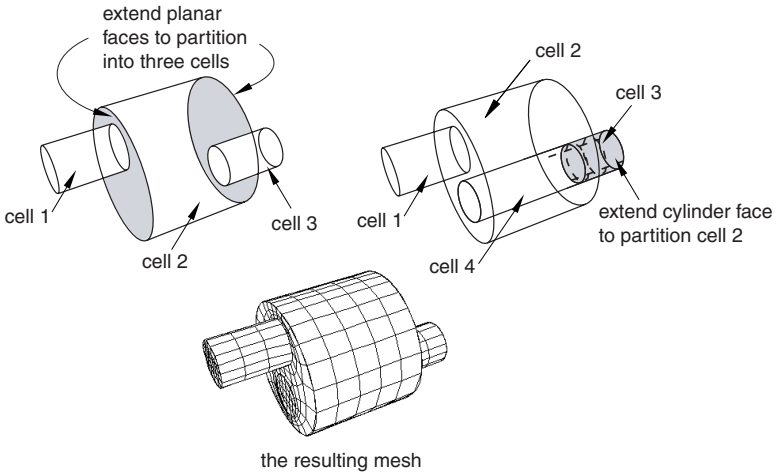

Figure 5: Using partitions to generate a compatible swept mesh.

Different regions of the same part or part instance can be meshed with hexahedral and tetrahedral elements as shown in *Figure 6*.

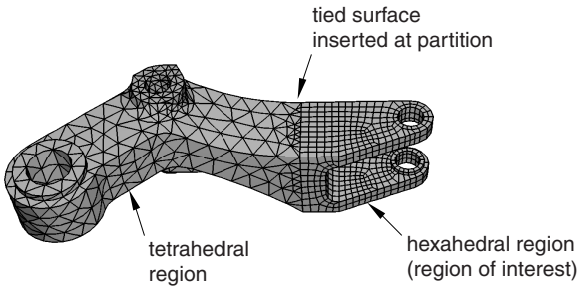

Figure 6: Different regions of the same part or part instance can be meshed with hexahedral and tetrahedral elements.

You can use the hexahedral elements where accuracy is important, such as adjacent to contact surfaces or in areas of special interest that require a fine mesh. You can use tetrahedral elements in other regions, and Abaqus/CAE creates tied surfaces where the regions connect. When you mesh one region, Abaqus/CAE does not adjust an existing mesh on adjacent regions.

Meshing multiple two- and three-dimensional shell regions

Meshing multiple three-dimensional solid regions, describes how the default meshing techniques applied to adjacent regions of a three-dimensional solid part or part instance may not allow you to generate a mesh that is compatible across the regions. In contrast, adjacent regions of a two- or three-dimensional shell part or part instance are always compatible.

Figure 1 illustrates a three-dimensional shell part instance with adjacent regions that Abaqus/CAE can mesh using the free, swept, and structured meshing techniques.

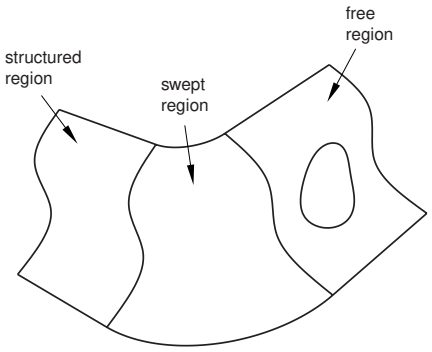

Figure 1: Adjacent regions of a three-dimensional shell part instance.

Figure 2 illustrates the resulting mesh.

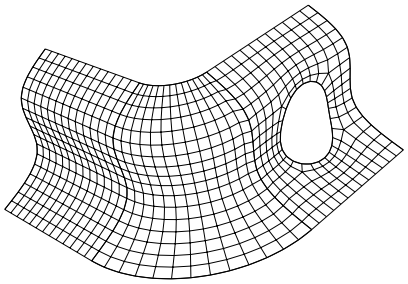

Figure 2: The resulting mesh.

Compatible meshes between part instances

You cannot prescribe meshes that are compatible between part instances. If you require mesh compatibility between two or more instances, you can do one of the following:

- Create a single part that contains all the bodies so that multiple instances are not necessary.
- Assemble instances of the parts in the Assembly module and use the **Merge/Cut** tool to merge the instances into a single instance. If you need to maintain the concept of separate part instances, you can create a partition at the common interface of the merged instances.

  Similarly, you can create a single part instance from multiple instances containing orphan elements and nodes, using the **Merge/Cut** tool to merge duplicate nodes. For more information, see *Performing Boolean operations on part instances*.
- If you must use separate parts, you can use tied contact to avoid the issue of mesh compatibility. Keep in mind that this is not true compatibility, and the accuracy of the solution may suffer. For more information on tied contact, see *Understanding interactions*.

Parametric modeling

A useful feature of the Mesh module is the ability to regenerate partitions and mesh attributes—such as element type assignments, seeds, and mesh controls—after a part has been modified. (You must always recreate the mesh itself after modifying a model.)

For example, the model shown in *Figure 1* has been partitioned into four regions and then seeded to specify an approximate element size of 3.

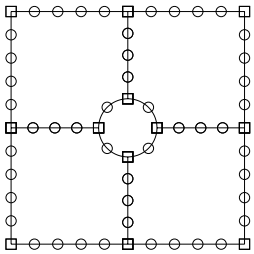

Figure 1: Seeded model with small hole.

You can return to the Part module and modify the hole at the center of the model so that it is slightly larger. When you return to the Mesh module, the partitions and the seeds are regenerated, as shown in *Figure 2*.

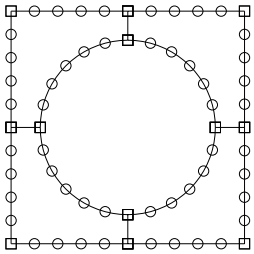

Figure 2: Seeds are regenerated after the part is modified.

In addition, settings in the **Mesh Controls** and **Element Type** dialog boxes (such as element shape, element type, and meshing technique) are also regenerated. (You can display these two dialog boxes by selecting **Mesh->Controls** and **Mesh->Element Type** from the main menu bar.)

Note:

If you drastically modify the part, the seeds and partitions may fail to regenerate. In these cases you must create new seeds and partitions after reentering the Mesh module.

Meshing complex solids with hexahedral elements

You can use the Part module to create complex solid revolved parts that include a translation along the axis of revolution, and you can also create solid extruded parts that include a twist about a selected center point. Free meshing allows you to mesh these parts with tetrahedral elements, as described in *Free meshing with triangular and tetrahedral elements*. In addition, you can use hexahedral elements to mesh an extruded part that is twisted, as shown in *Figure 1*.

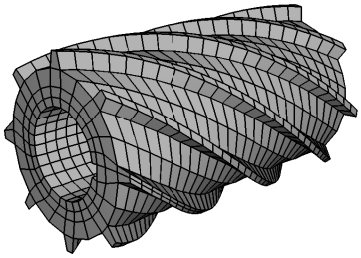

Figure 1: A hexahedral swept mesh on an extruded part with twist.

However, if you want to use hexahedral elements to mesh a revolved part that is translated, you will probably have to introduce partitions to make the part swept meshable, as described in the following paragraphs.

For the Mesh module to create a three-dimensional swept mesh of hexahedral elements, every side that connects the source side to the target side must contain only a single face (see *Figure 4* in *Swept meshing of three-dimensional solids*). However, when you create a part that is revolved more than 180° and then translated along the axis of revolution, Abaqus/CAE inserts rings along the length of the solid. These rings exist only on the surface of the part, and they do not create faces that cut through the part. As a result, the side that connects the source side and the target side now contains more than one face, and the part is not swept meshable with hexahedral elements unless you introduce partitions.

For example, *Figure 2* shows a part that represents a coil spring. The figure also shows the rings that Abaqus/CAE inserted when the part was created. These rings divide the connecting face between the source side and the target side; as a result, you cannot mesh an instance of the coil spring with a swept mesh of hexahedral elements until you partition the part.

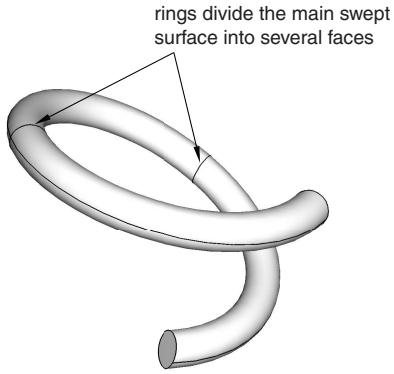

Figure 2: Rings divide the coil into several segments.

The partitioning operation introduces partitions through the solid coil using N-sided patches to define the new faces. You select the rings to define the N-sided patches, as shown in *Figure 3*.

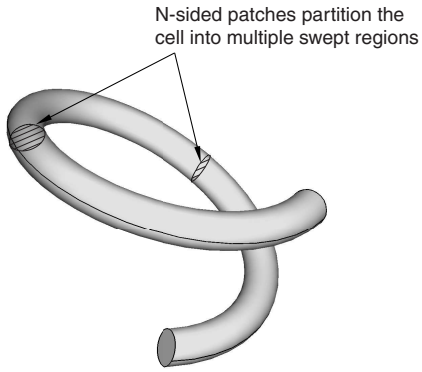

Figure 3: N-sided patches partition the cell.

You can now seed the part instance and generate a swept mesh using hexahedral elements, as shown in *Figure 4*.

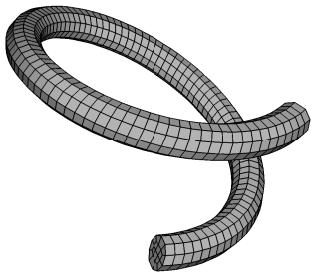

Figure 4: The model is swept meshed with hexahedral elements.

Using the Mesh module toolbox

You can access all the Mesh module tools through either the main menu bar or the toolbox. *Figure 1* shows the hidden icons for all the tools in the Mesh module toolbox.

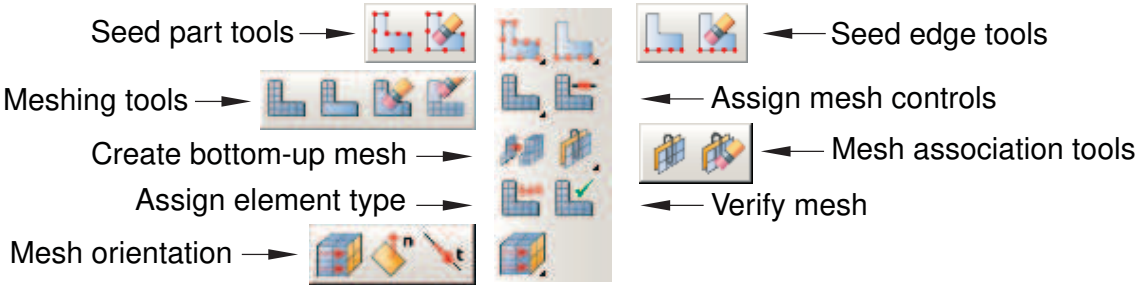

Figure 1: The Mesh module toolbox.

For information on using each of the Mesh module tools, refer to the following sections:

- *Bottom-up meshing*
- *Mesh-geometry association*
- *Seeding a model*
- *Creating and deleting meshes*
- *Controlling mesh characteristics*
- *Obtaining mesh information and statistics*

Seeding a model

This section explains how to use the seeding tools to apply seeds throughout a part instance.

In this section:

- *Defining seed density for an entire part or part instance*
- *Seeding an edge by prescribing the number of elements*
- *Seeding an edge by prescribing element size*
- *Prescribing biased seeding along an edge*
- *Applying constraints to edge seeds*
- *Seeding previously meshed parts, part instances, or regions*
- *Deleting part or instance seeds*
- *Deleting edge seeds*
- *Relaxing constraints using the error dialog box*

Defining seed density for an entire part or part instance

You can select **Seed->Part** or **Seed->Instance** from the main menu to define the approximate element size for all edges of a part or part instance that do not already have magenta-colored edge seeds. Seeds defined in this way are called part seeds or instance seeds and are colored white. (For more information, see *Controlling the seed density*.) You should apply seeds to all edges. If a uniform seed distribution is sufficient, the recommended approach is to seed the entire part or part instance.

1. From the main menu bar, select **Seed->Part** or **Seed->Instance**.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also seed a part or part instance using the  tool, located with the seed tools in the Mesh module toolbox. (For more information, see *Using the Mesh module toolbox*.)

2. If you are seeding a part instance and your assembly contains more than one part instance, select the part instance to seed and click mouse button 2.

   Note:

   Edge seeds always override part and instance seeds; therefore, if you have already individually seeded all the edges of the part or part instance, the instance seeds are unused and do not appear. If necessary, use the seed deletion tool, described in *Deleting edge seeds*, to remove any unwanted edge seeds; if you have assigned part or instance seeds, these seeds automatically appear on the edges where you delete edge seeds.

3. In the **Global Seeds** dialog box that appears, enter an approximate element size.
4. By default, Abaqus/CAE applies curvature control to the seeding of your part or part instance such that small holes or regions of high curvature are properly approximated in the mesh. Curvature control allows Abaqus/CAE to calculate the seed distribution based on the curvature of the edge along with the target element size. To control the effect of curvature on seeding, enter a value for the **Maximum deviation factor**. The deviation factor is a measure of how much the element edges deviate from the original geometry. To help you visualize the influence of the deviation factor, Abaqus/CAE displays the number of elements it would create around a circle corresponding to the setting that you enter.
5. If desired, change the **Minimum size control**. Specifying a minimum size control helps prevent Abaqus/CAE from creating unnecessarily fine meshes in areas of high curvature if these areas are not important to the analysis intent. Choose one of the following options:

   - Specify the minimum as a fraction of the global element size. Abaqus/CAE uses this method with a value of `0.1` (10%) as the default minimum size.
   - Enter an absolute minimum element size. The size must be greater than `0.0` and less than the approximate global element size.

6. Click **Apply** to view the seeding that Abaqus/CAE will use, and adjust the values that you entered in the **Global Seeds** dialog box if necessary.
7. Click **OK** to commit the element size and to close the dialog box.

   White seeds appear on all edges of the part or part instance except those already assigned magenta edge seeds.

8. To exit the part or instance seeding procedure, press **[Enter]** or click mouse button 2.

Additional information

- *Seeding a model*

- *Selecting objects within the viewport*

Seeding an edge by prescribing the number of elements

You can define the element size along selected edges by entering the number of elements to create. Abaqus/CAE allows you to select edges, faces, or cells to seed. However, seeds are positioned only along edges—the edges that you select or the edges of faces and cells that you select.

All the edge seeding tools generate edge seeds, which are displayed in magenta. Edge seeds override any part or instance seeds you have specified. You should apply seeds to all edges.

1. From the main menu bar, select **Seed->Edges**.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also seed an edge by prescribing the number of elements using the tool, located with the seed tools in the Mesh module toolbox. (For more information, see *Using the Mesh module toolbox*.)

2. Select the edges, faces, or cells you want to seed.

   By default, Abaqus/CAE allows you to select only edges to seed. To select faces or cells to seed, use the **Selection** toolbar to change the type of object that you can select to **Face**, **Cells**, or **All**. For more information, see *Filtering your selection based on the type of object*.

3. When you have finished selecting edges, faces, or cells, click **Done** in the prompt area. For more information on selecting objects, see *Selecting objects within the viewport*."

4. From the **Local Seeds** dialog box that appears, choose **By number**.

   Note:

   If you selected edges that you previously seeded using a combination of seeding methods, Abaqus/CAE provides an **As Is** option that allows you to retain the seeding method on the selected edges.

5. Enter the number of elements that Abaqus should generate along each edge.
6. Choose a bias control of **None**.
7. If desired, change the default seed constraints on the **Constraints** tabbed page. See *Applying constraints to edge seeds*, for further information on setting seed constraints.
8. If desired, toggle on **Create set with name** to create a set containing the edges, faces, and cells you selected and enter the name of the set. If you subsequently want to change the seeding, you can select the set in Step 2 without having to reselect the edges, faces, and cells.
9. Click **Apply** to view the seeding that Abaqus/CAE will use.

   Magenta seeds appear on the selected edges.

10. If necessary, adjust the values that you entered in the **Local Seeds** dialog box.
11. Click **OK** to commit the element seeding and to close the dialog box.

Additional information

- *Seeding a model*
- *Understanding seeding*
- *Using the Mesh module toolbox*
- *Selecting objects within the viewport*

Seeding an edge by prescribing element size

You can define the element size along selected edges by entering the approximate element size. You can also define curvature control parameters that Abaqus/CAE uses to adjust the element size in regions of high curvature. Abaqus/CAE allows you to select edges, faces, or cells to seed. However, seeds are positioned only along edges—the edges that you select or the edges of faces and cells that you select.

All the edge seeding tools generate edge seeds, which are displayed in magenta. Edge seeds override any *part or instance seeds* you have specified. You should apply seeds to all edges.

1. From the main menu bar, select **Seed->Edges**.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also seed an edge by element size using the tool, located with the seed tools in the Mesh module toolbox. (For more information, see *Using the Mesh module toolbox*.)

2. Select the edges, faces, or cells you want to seed.

   By default, Abaqus/CAE allows you to select only edges to seed. To select faces or cells to seed, use the **Selection** toolbar to change the type of object that you can select to **Face**, **Cells**, or **All**. For more information, see *Filtering your selection based on the type of object*.

3. When you have finished selecting edges, faces, or cells, click **Done** in the prompt area. For more information on selecting objects, see *Selecting objects within the viewport*."

4. From the **Local Seeds** dialog box that appears, choose **By size**.

   Note:

   If you selected edges that you previously seeded using a combination of seeding methods, Abaqus/CAE provides an **As Is** option that allows you to retain the seeding method on the selected edges.

5. Enter the approximate element size to be used along the selected edges.

6. Choose a bias control of **None**.

7. By default, Abaqus/CAE applies curvature control to the seeding of your part or part instance to allow for small holes or regions of high curvature that you wish to model. Curvature control allows Abaqus/CAE to calculate the seed distribution based on the curvature of the edge along with the target element size. To control the effect of curvature on seeding, do the following:

   a. Enter a value for the deviation factor. The deviation factor is a measure of how much the element edges deviate from the original geometry. To help you visualize the influence of the deviation factor, Abaqus/CAE displays the number of elements it would create around a circle corresponding to the setting that you enter.

   b. If desired, specify a minimum size factor as a fraction of the global element size. Specifying a minimum size factor prevents Abaqus/CAE from creating very fine meshes in areas of high curvature that you have no interest in modeling.

8. If desired, change the default seed constraints by clicking the **Constraints** button in the prompt area and responding to the dialog box that appears. See *Applying constraints to edge seeds*, for further information on setting seed constraints.

9. If desired, toggle on **Create set with name** to create a set containing the edges, faces, and cells you selected and enter the name of the set. If you subsequently want to change the seeding, you can select the set in Step 2 without having to reselect the edges, faces, and cells.

10. Click **Apply** to view the seeding that Abaqus/CAE will use.
    Magenta seeds appear on the selected edges.
11. If necessary, adjust the values that you entered in the **Local Seeds** dialog box.
12. Click **OK** to commit the element seeding and to close the dialog box.

Additional information

- *Seeding a model*
- *Understanding seeding*
- *Using the Mesh module toolbox*
- *Selecting objects within the viewport*

Prescribing biased seeding along an edge

You can define a nonuniform distribution of elements along selected edges by defining the size of the coarsest and finest element along the edges or the number of elements and the ratio of the two sizes.
You can define a single bias that changes the mesh density from one end of the edge to the other. Alternatively, you can define a double bias that changes the mesh density from the center of the edge to each end of the edge.

For example, *Figure 1* shows a combination of edges with single- and double-bias seeding.

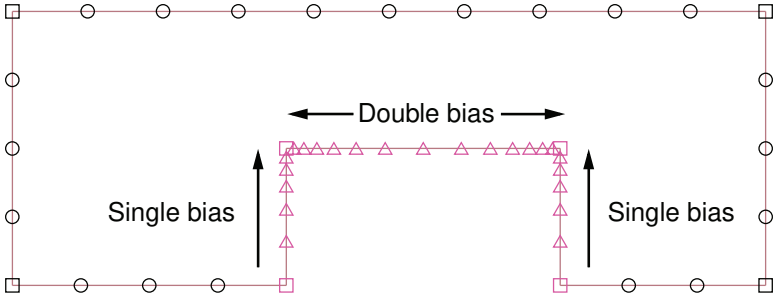

Figure 1: Single- and double-bias seeding.

All the edge seeding tools generate edge seeds, which are displayed in magenta. Edge seeds override any part or instance seeds you have specified. You should apply seeds to all edges.

1. From the main menu bar, select **Seed->Edges**.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also click the tool, located with the seed tools in the Mesh module toolbox. (For more information, see *Using the Mesh module toolbox*.)

2. Choose the approach for picking from the viewport:

   - For single-bias seeding, toggle on **Use single-bias picking** and select the edges you want to seed. You can select only edges for single-bias seeding, and you must select each edge near the end where you expect the mesh to be denser.
   - For double-bias seeding, toggle off **Use single-bias picking** and select the edges, faces, or cells you want to seed. The location of your selection does not influence the seeding.

     By default, Abaqus/CAE allows you to select only edges to seed. To select faces or cells to seed, use the **Selection** toolbar to change the type of object that you can select to **Face**, **Cells**, or **All**. For more information, see *Filtering your selection based on the type of object*.

3. When you have finished selecting edges, faces, or cells, click **Done** in the prompt area.
4. From the **Local Seeds** dialog box that appears, choose the bias control (**Single** or **Double**).

   Note:

   If you selected edges that you previously seeded using a combination of bias seeding methods, Abaqus/CAE provides an **As Is** option that allows you to retain the bias seeding method on the selected edges.

   If you selected single-bias seeding, Abaqus/CAE displays arrows on each selected edge indicating the direction in which the element density will increase. If you selected double-bias seeding, Abaqus/CAE

displays arrows at the center of each edge indicating the directions in which the element density will increase.

5. Choose the sizing method (**By size** or **By number**).
   a. If you selected **By size**, enter the minimum and maximum size of the elements—the approximate size of the elements at each end of the biased seeding. You cannot apply curvature control to biased seeding.
   b. If you selected **By number**, enter the number of elements and the bias ratio. The bias ratio is the approximate ratio of the size of the largest and smallest element on the edge and must be greater than one.
   c. If desired, click **Select** to reverse the direction of the seeding bias. (When you select an edge to which biased seeding will be applied, the element density increases toward the end of the edge that is closest to the location of your pick.)

      Abaqus/CAE reverses the direction of the arrow on each selected edge.

Note:

If you selected edges that you previously seeded using a combination of element size or number parameters, Abaqus/CAE provides an **As Is** option that allows you to retain the size parameters on the selected edges.

6. If desired, change the default seed constraints by clicking the **Constraints** button in the prompt area and responding to the dialog box that appears. See *Applying constraints to edge seeds*, for further information on setting seed constraints.
7. If desired, toggle on **Create set with name** to create a set containing the edges, faces, and cells you selected and enter the name of the set. If you subsequently want to change the seeding, you can select the set in Step 2 without having to reselect the edges, faces, and cells.
8. Click **Apply** to view the seeding that Abaqus/CAE will use.

   Magenta seeds appear on the selected edges.
9. If necessary, adjust the values that you entered in the **Local Seeds** dialog box.
10. Click **OK** to commit the element seeding and to close the dialog box.

Additional information

- *Selecting objects within the viewport*

Applying constraints to edge seeds

You can apply constraints to seeds at the same time you define them by using the **Constraints** tabbed page of the **Local Seeds** dialog box that appears during the edge seeding procedures.

Warning: Use care when constraining mesh seeds; overconstraint can make automatic mesh generation impossible if you are trying to generate a mesh that contains quadrilateral- or hexahedral-shaped elements.

1. From the main menu bar, select **Seed->Edges**. Then select the edges that you want to seed, and click mouse button 2. For more information on performing these tasks, see the following sections:
   - *Seeding an edge by prescribing the number of elements*
   - *Seeding an edge by prescribing element size*
   - *Prescribing biased seeding along an edge*

   Note:

   If you selected edges that you previously seeded using a combination of constraints, Abaqus/CAE provides an **As Is** option that allows you to retain the constraints on the selected edges.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.
2. Click the **Constraints** tabbed page of the **Local Seeds** dialog box.
3. Choose the desired constraint. The choices are:

Allow the number of elements to increase or decrease

This option leaves the seeds totally unconstrained. Therefore, the number of elements that Abaqus/CAE creates along an edge can be greater or smaller than the number of elements dictated by the seeds; however, the mesh generator tries to adhere to the requested seed pattern as much as possible. This option provides the greatest flexibility to the automatic mesh generator and, therefore, gives the greatest chance of success when generating the mesh.

Allow the number of elements to increase only

This option (default) partially constrains the seeds so that the number of elements along an edge can only be greater than or remain the same as that dictated by the seeds. Unconstrained seeds that are located near partially constrained seeds tend to behave as though they are partially constrained.

Do not allow the number of elements to change

This option fully constrains the seeds so that the exact number of elements that you have specified with your seeds is maintained.

Use this option with care, since adjustment of the number of elements along the boundary of a region is usually required to generate a mesh; preventing such adjustments can make mesh generation impossible.

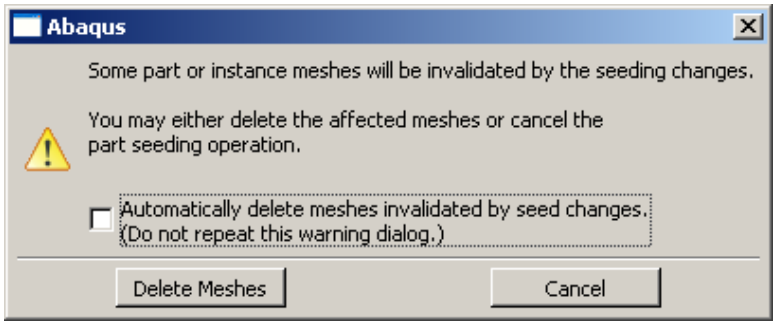
Note:

The constraint options described above allow you to control only the number of elements along an edge, not the positions of the nodes along the edge. Abaqus/CAE creates meshes that adhere to the seeds as closely as possible.

4. Click **OK**.

   The mesh seeds change shape to indicate the constraint you have chosen:

   - Circle: unconstrained seed.
   - Triangle: partially constrained seed. The triangle points upward, indicating that the number of elements along the edge can only increase.
   - Square: fully constrained seed.



Additional information

- *Seeding a model*
- *Understanding seeding*
- *Selecting objects within the viewport*

Seeding previously meshed parts, part instances, or regions

To reseed a part, a part instance, or a region that has already been meshed, you must first delete the mesh in one of the following ways:

- Before seeding, use the mesh deletion tools, described in *Deleting a mesh*, to delete the mesh from the part, part instance, or region of interest.
- Do not delete the mesh yourself; instead, attempt to seed the part, part instance, or region of interest. As soon as you select the parts or edges to seed, Abaqus/CAE displays a window similar to the following:

You can delete the mesh by clicking **Delete Meshes**, or you can keep your mesh and exit the seeding procedure by pressing **Cancel**.

You can avoid this warning message for the remainder of the current session by toggling on **Automatically delete meshes invalidated by seed changes**. The next time you attempt to seed a part, part instance, or region that already contains a mesh, the mesh will be deleted immediately without any warning being displayed.

Additional information

- *Seeding a model*
- *Understanding seeding*
- *Selecting objects within the viewport*

Deleting part or instance seeds

Delete part or instance seeds by selecting **Seed->Delete Part Seeds** or **Seed->Delete Instance Seeds** from the main menu bar.

1. From the main menu bar, select **Seed->Delete Part Seeds** or **Seed->Delete Instance Seeds**.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also delete seeds using the  tool, located with the seed tools in the Mesh module toolbox. (For more information, see *Using the Mesh module toolbox*.)

2. Do one of the following:

   - If you are deleting part seeds, click **Yes** in the prompt area to confirm the deletion.
   - If your assembly contains only one part instance, click **Yes** in the prompt area to confirm the deletion.
   - If your assembly contains more than one part instance, select the instances whose seeds you want to delete and click mouse button 2 to commit your selection.

   Abaqus/CAE deletes the seeds.

Additional information

- *Seeding a model*
- *Understanding seeding*
- *Using the Mesh module toolbox*
- *Selecting objects within the viewport*

Deleting edge seeds

Delete edge seeds by selecting **Seed->Delete Edge Seeds** from the main menu bar and then selecting the edges, faces, or cells from which to delete edge seeds.

1. From the main menu bar, select **Seed->Delete Edge Seeds**.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

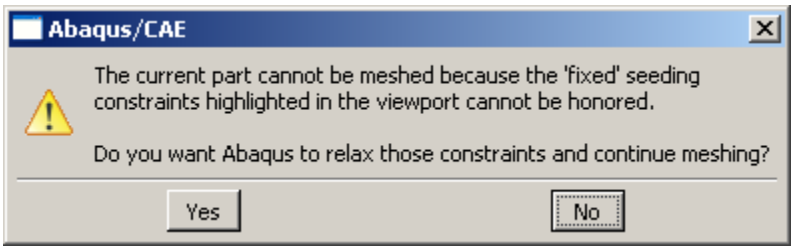
   Tip: You can also delete seeds using the  tool, located with the seed tools in the Mesh module toolbox. (For more information, see *Using the Mesh module toolbox*.)

2. Select the edges whose edge seeds you want to delete.

   By default, Abaqus/CAE allows you to select from all items to delete edge seeds. To limit object selection to only edges, faces, or cells, use the **Selection** toolbar to change the type of object that you can select to **Edges**, **Faces**, or **Cells**. For more information, see *Filtering your selection based on the type of object*.

3. When you have finished selecting edges, faces, or cells, press mouse button 2 to commit your selections. For more information on selecting objects, see *Selecting objects within the viewport*."

   The seeds disappear from all edges of the selected objects.



Additional information

- *Seeding a model*

- *Using the Mesh module toolbox*
- *Selecting objects within the viewport*

Relaxing constraints using the error dialog box

Sometimes mesh generation fails if seeds are overconstrained. Several options are available to handle the overconstraints.

When Abaqus/CAE is unable to create a mesh because of overconstrained seeds, the following dialog box appears:

In addition, the overconstrained seeds are highlighted in the viewport. You can choose one of the following options:

- Click **Yes** to relax the seed constraints and to continue meshing the region.
- Click **No** to save the seed constraints and to cancel the meshing procedure.

Additional information

• *Applying constraints to edge seeds*

Creating and deleting meshes

This section explains how to use the mesh tools to create and delete meshes throughout a part instance or region.

In this section:

- *Creating a mesh*
- *Deleting a mesh*

Creating a mesh

You can create meshes throughout entire parts or part instances or just within selected regions.
To create a mesh, select either **Mesh->Part**, **Mesh->Instance**, or **Mesh->Region** from the main menu bar.

1. From the **Object** field in the context bar, select the part to mesh or select the assembly.
2. From the main menu bar, select **Mesh->Part**, **Mesh->Instance**, or **Mesh->Region**.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also mesh parts, part instances, or regions using the  and  tools, located with the mesh tools in the Mesh module toolbox. (For more information, see *Using the Mesh module toolbox*.)

3. If you are meshing the assembly, you must select the instances or regions to mesh. Click mouse button 2 to indicate that you have finished selecting. (For more information on selecting objects, see *Selecting objects within the viewport*.)

   Select only those part instances or regions that are colored green, pink, or yellow, indicating they are meshable. To make orange regions meshable, you must either subdivide them using the partitioning tools, assign the bottom-up meshing technique, or assign tetrahedral-shaped elements to them. Regions that you have already assigned the bottom-up meshing technique are colored light tan; you must either mesh them using the bottom-up technique or assign another meshing technique. (For more information on creating bottom-up meshes, see *Bottom-up meshing*.) Parts colored white cannot be meshed, because they are associated with independent instances.

   Note:

   Part instances are colored according to their meshability only when the **Mesh defaults** color mapping is selected. Apply this color mapping if the colors in your viewport do not match those described in this step.

4. Do one of the following:

   - From the prompt area, click **Yes** to generate the mesh on those regions that are meshable.
   - If the assembly includes a solid region that will be meshed with tetrahedral elements, Abaqus/CAE asks if you want to preview the triangular mesh on the exterior faces of the region.

     1. To preview the mesh, toggle on **Preview boundary mesh** from the prompt area and click **Yes** to create the boundary mesh.

        Abaqus/CAE generates the triangular boundary mesh on the mesh on those regions that are meshable.

     2. If some regions fail to mesh or if the boundary mesh is not acceptable, Abaqus/CAE provides a variety of tools that will help you generate a mesh in all regions and create an acceptable mesh. For more information, see *What can I do with a boundary mesh?*.

     3. If the boundary mesh is acceptable, click **Yes** from the prompt area to continue meshing the interior of the parts, instances, or regions.

Abaqus/CAE generates the mesh on those regions that are meshable.

Deleting a mesh

You can delete Abaqus native meshes throughout entire parts, part instances, or just within selected regions. To delete a mesh, select either **Mesh->Delete Part Native Mesh**, **Mesh->Delete Instance Native Mesh**, or **Mesh->Delete Region Native Mesh** from the main menu bar.

Note: Deleting a mesh does not cause the underlying seeds to be deleted, so you can modify the seeding pattern and regenerate the mesh.

1. From the main menu bar, select either **Mesh->Delete Part Native Mesh**, **Mesh->Delete Instance Native Mesh**, or **Mesh->Delete Region Native Mesh**.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also delete meshes using the  or  tools, located with the mesh tools in the Mesh module toolbox. (For more information, see *Using the Mesh module toolbox*.)

2. Do one of the following:

   - If you are deleting a part mesh, click **Yes** from the prompt area to confirm that you want to delete the mesh.
   - If you are deleting region meshes from a part or an assembly, select the regions from which to delete the mesh. Click mouse button 2 to indicate that you have finished selecting. (For more information on selecting objects, see *Selecting objects within the viewport*.)
   - If you are deleting instance meshes from the assembly, select the instances from which to delete the mesh. Click mouse button 2 to indicate that you have finished selecting. (For more information on selecting objects, see *Selecting objects within the viewport*.)

   Abaqus/CAE deletes the mesh.

Additional information

- *Understanding seeding*

Controlling mesh characteristics

This section explains how you control the overall characteristics of your mesh.

In this section:

- *Assigning mesh controls*
- *Choosing an element shape*
- *Selecting a meshing technique*
- *Redefining region corners*
- *Setting the mesh algorithm*
- *Specifying the sweep path*
- *Sweep meshing a solid, revolved region whose profile touches the axis of revolution*
- *Applying a mesh stack orientation*
- *Changing mesh controls for previously meshed regions*
- *Associating Abaqus elements with mesh regions*
- *Changing the labels of all nodes and elements*
- *Adding layers of wedge elements to tetrahedral mesh boundaries*

Assigning mesh controls

The **Mesh Controls** dialog box allows you to specify the shape of the elements in a mesh as well as the meshing technique that Abaqus/CAE uses to create the mesh. In some cases, you can also select transition options and redefine region corners.

1. From the main menu bar, select **Mesh->Controls**.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also click the  tool, located in the Mesh module toolbox.

2. If your part or assembly contains more than one region, select the regions whose mesh controls you want to view or modify and then press mouse button 2. All the selected regions must have the same dimensionality.

   Note:

   To view or modify the mesh controls for faces of a region to which the free meshing technique and tetrahedral element shape are assigned or for faces of a bottom-up region, you must change the entity selection type in the prompt area to **faces of solid regions**.

   The **Mesh Controls** dialog box appears.

3. Select the mesh controls of your choice. For information on specific mesh controls, see the following:

   - *Choosing an element shape*
   - *Selecting a meshing technique*
   - *Redefining region corners*
   - *Setting the mesh algorithm*
   - *Adding layers of wedge elements to tetrahedral mesh boundaries*

4. If desired, click **Defaults** to change the settings in the **Mesh Controls** dialog box back to the default values.
5. Click **OK** to save your settings and to close the **Mesh Controls** dialog box.

Additional information

- *Assigning Abaqus element types*
- *Using the Mesh module toolbox*
- *Selecting objects within the viewport*

Choosing an element shape

You can control the shape of the elements in your mesh by selecting **Mesh->Controls** from the main menu bar. The **Element Shape** options are located at the top of the **Mesh Controls** dialog box that appears.

1. From the main menu bar, select **Mesh->Controls**.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

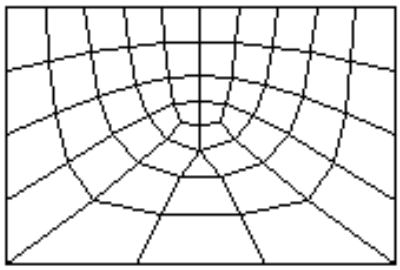
   Tip: You can set the element shape using the tool, located in the Mesh module toolbox.

2. If your part or assembly contains more than one region, select those regions whose element shapes you want to view or modify and then press mouse button 2. All the selected regions must have the same dimensionality.

   The **Mesh Controls** dialog box appears.

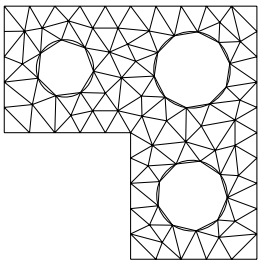
3. From the list of **Element Shape** options, select the element shape of your choice.

   If you selected a two-dimensional region, you can choose from the following element shape options:



Quad

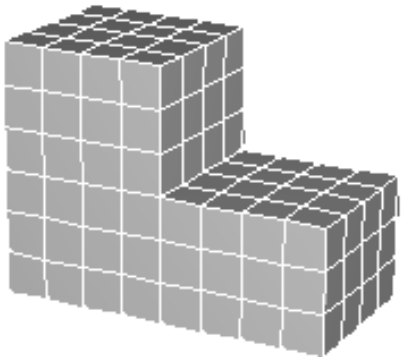
Use exclusively quadrilateral elements. The following figure shows an example of a mesh that was constructed using this setting:



Quad-dominated

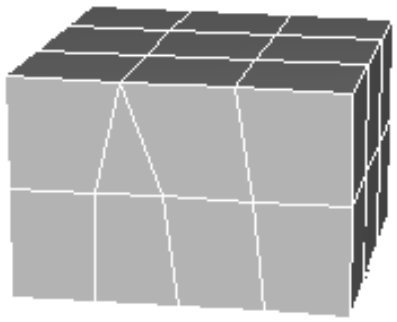
Use primarily quadrilateral elements, but allow triangles in transition regions. This setting is the default. The following figure shows an example of a mesh that was constructed using this setting:

Tri



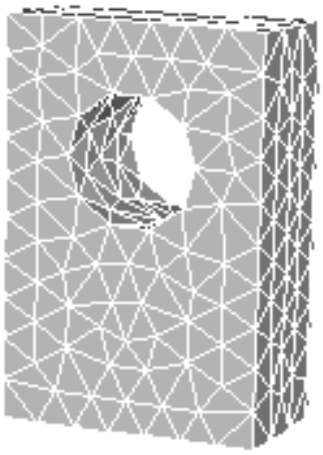
Use exclusively triangular elements. This setting is the only one available when you apply mesh controls to faces of solid regions since the triangular face mesh will be used to generate a tetrahedral solid mesh. The following figure shows an example of a mesh that was constructed using this setting:

If you selected a three-dimensional region, you can choose from the following element shape options:



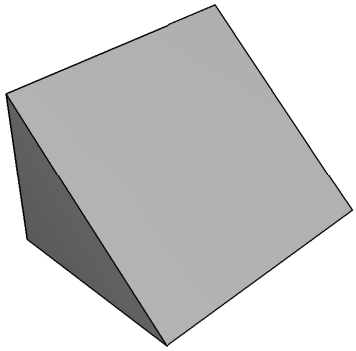
Hex

Use exclusively hexahedral elements. This setting is the default. The following figure shows an example of a mesh that was constructed using this setting:



Hex-dominated

Use primarily hexahedral elements, but allow some triangular prisms (wedges) in transition regions. The following figure shows an example of a mesh that was constructed using this setting:



Tet

Use exclusively tetrahedral elements. The following figure shows an example of a mesh that was constructed using this setting:

Wedge

Use exclusively wedge elements. The following figure shows an example of a single-element mesh that was constructed using this setting:

4. Click **OK**.

   The next time you generate a mesh on the selected regions, your selections will be honored.

   If the selected regions are already meshed, you will be prompted to delete the mesh or to cancel the mesh control procedure.

Additional information

- *Controlling mesh characteristics*
- *Understanding mesh generation*
- *Using the Mesh module toolbox*
- *Selecting objects within the viewport*

Selecting a meshing technique

Abaqus/CAE assigns a default top-down meshing technique to each meshable region of your model based on the geometry of the region and the current element shape selection for that region. Abaqus/CAE uses the mesh technique assigned to a region to generate a mesh for the region. You can use the **Mesh Controls** dialog box to select an alternate meshing technique.

1. From the main menu bar, select **Mesh->Controls**.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also set the meshing technique using the  tool, located in the Mesh module toolbox.

2. Select **faces of solid regions** to assign mesh controls to boundary faces of solid regions that will be tetrahedral meshed or bottom-up meshed.
3. If your part or assembly contains more than one region, select those regions whose meshing technique you want to view or modify and press mouse button 2. The selected regions must all have the same dimensionality.

   The **Mesh Controls** dialog box appears.
4. From the list of **Technique** options, select the meshing technique of your choice. (Some techniques are available only if they are valid for the selected region.)

   - Abaqus/CAE selects **As is** if, in the previous step, you selected multiple regions that have different meshing techniques already assigned to them.
   - Select ***Free*** to create a free mesh.
   - Select ***Structured*** to create a structured mesh.
   - Select ***Sweep*** to create a swept mesh.
   - Select ***Bottom-up*** to create a bottom-up mesh.
   - Abaqus/CAE selects **Multiple** if a change in element shape assignment results in multiple techniques being assigned automatically to the selected regions. For example, suppose the free meshing technique is applied to all the regions of a solid part instance. If you change the element shape assignment of these regions from **Tet** to **Hex** or **Hex-dominated**, Abaqus/CAE automatically changes the meshing technique assigned to each region from the free meshing technique to whatever technique is appropriate for each region; for example, structured meshing for some regions and swept meshing for others.

     Note:

     The bottom-up meshing technique must be manually assigned to or removed from a region. When you modify the geometry of a region to which the bottom-up meshing technique is assigned, the resulting region or regions will also be assigned the bottom-up meshing technique. You can click **Defaults** in the **Mesh Controls** dialog box to assign a top-down technique to a bottom-up region.

   For detailed information on each meshing technique, see *Understanding mesh generation*.

   While assigning mesh controls to faces of a region, Abaqus/CAE color codes the faces according to the mesh technique that will be used on the faces. The face colors may not be the same as the color for the region. For example, the faces of a bottom-up region will appear pink by default since they are free meshed. If you assign the structured mesh technique to some faces, they will be colored green.

The solid region color for a bottom-up region is light tan, and the color for a solid region that will be tetrahedral meshed is pink.

5. Click **OK** to close the dialog box and to save your mesh technique selection.

   The next time you generate a mesh on the selected part instance or region, your selections will be honored.

   If the selected region already contains a mesh, you will be prompted to delete the mesh or to cancel the mesh control procedure.

Additional information

- *Controlling mesh characteristics*
- *Understanding mesh generation*
- *Using the Mesh module toolbox*
- *Selecting objects within the viewport*

Redefining region corners

Structured meshing patterns exist for regions with particular topologies. For example, Abaqus/CAE applies a particular structured pattern to quadrilateral regions and another pattern to pentagonal regions. In some cases, however, you can change the structured pattern assigned to a surface region by redefining the region's corners. You can redefine region corners only for surface regions to which the structured meshing technique has been assigned.

If you click **Redefine Region Corners** in the **Mesh Controls** dialog box, you can select which corners of the region you want Abaqus/CAE to consider when creating the mesh. If you leave a corner unselected, Abaqus/CAE internally "combines" the edges on either side of the unselected corner into a single logical edge (though the actual topology of the region remains unchanged). For example, if you leave one corner of a pentagonal region unselected, Abaqus/CAE considers that region to have only four edges instead of five. As a result, the structured meshing pattern for quadrilateral regions will be applied to the region rather than the pattern for pentagonal regions. For more information, see *Two-dimensional structured meshing*.

A surface region can be meshed using the structured meshing technique only if the region is bounded by three to five logical sides. However, if the region contains virtual topology, Abaqus/CAE can apply structured meshing only if the region has four corners. As a result, to redefine the corners of a region with virtual topology, the region must be bounded by more than four corners, and you must select four of the existing corners.

1. From the main menu bar, select **Mesh->Controls**.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also click the  tool, located in the Mesh module toolbox. (For more information, see *Using the Mesh module toolbox*.)

2. If your part or assembly contains more than one region, select those regions whose corners you want to redefine and then press mouse button 2. The regions that you select should have three or more vertices.

   The **Mesh Controls** dialog box appears.

3. Select **Structured** as the meshing technique if it is not already selected.

   The **Redefine Region Corners** button appears on the right side of the **Mesh Controls** dialog box.

4. Click **Redefine Region Corners**.

   If you selected multiple regions, this procedure considers each of the selected regions in turn. (Abaqus/CAE skips selected regions that a structured pattern cannot be applied to or that contain three or fewer vertices.) The region currently being considered becomes highlighted in magenta. The currently selected corners for the region are highlighted in yellow.

5. In the prompt area, select an option for determining region corners.

   - If you click **Accept Highlighted**, Abaqus/CAE accepts the currently highlighted corners. If multiple regions are selected, options are presented for the next region. If only one region is selected, the procedure is complete, and the **Mesh Controls** dialog box reappears.
   - If you click **Select New**, the currently selected vertices turn red. You must go on to the next step.
   - If you click **Revert to Defaults**, the default corners of the region are highlighted. You are prompted to select either **Accept Highlighted** or **Select New**, described above.

6. If you clicked **Select New** in the previous step, select the vertices of the region that you want as region corners. You can select between three and five vertices.

   - **[Shift] + Click** to select a vertex without unselecting all the other vertices.

- **[Ctrl] + Click** to unselect an individual vertex without unselecting all the other vertices.
- When you have finished selecting vertices, click mouse button 2.

Selected vertices are red, and unselected vertices are yellow.

If multiple regions are selected, the procedure starts over with the next region. If only one region is selected, the procedure is complete and the **Mesh Controls** dialog box reappears.

Additional information

- *Controlling mesh characteristics*
- *Using the Mesh module toolbox*
- *Selecting objects within the viewport*

Setting the mesh algorithm

The mesh algorithm options that are available depend on the element shape and the meshing technique that you have selected. If the mesh algorithm option is applicable to the type of mesh you are creating, an **Algorithm** field appears on the right side of the **Mesh Controls** dialog box.

Abaqus/CAE provides the following mesh algorithm options:

Choose the mesh algorithm

Choose either **Medial axis** or **Advancing front**. It is difficult to predict which algorithm will produce a better mesh for a particular region; you may have to experiment with the two algorithm settings. For more information, see *What is the difference between the medial axis algorithm and the advancing front algorithm?*.

Minimize the mesh transition

You can control whether Abaqus/CAE will try to minimize the mesh transition when it moves from a coarse mesh to a fine mesh. In most cases, toggling on **Minimize the mesh transition** will reduce mesh distortion. However, if you toggle off **Minimize the mesh transition**, the mesh may move closer to the specified mesh seeds. For more information, see *What is a mesh transition?*.

Use mapped meshing where appropriate

Some models that appear very complex actually contain faces with relatively simple geometry. By default, Abaqus/CAE uses the mapped meshing technique where appropriate to generate elements on simple faces. You can toggle off **Use mapped meshing where appropriate** to prevent Abaqus/CAE from using mapped meshing. However, if you mesh a model with simple faces and do not allow mapped meshing, the resulting element quality can be poor on the simple faces. For more information, see *What is mapped meshing?*, and *When can Abaqus/CAE apply mapped meshing?*.

Insert boundary layer

When you are creating a free mesh of tetrahedral elements, you can add a boundary layer of wedge elements along the faces of region boundaries. The boundary layer is composed of a series of wedge elements stacked normal to the solid wall of the region with the thinnest elements against the wall. Boundary layers create a mesh with a high density at the wall and decreasing density as it progresses toward the tetrahedral mesh in the interior of the region. For detailed instructions on creating a boundary layer, see *Adding layers of wedge elements to tetrahedral mesh boundaries*.

Use the default algorithm

When you are creating a free mesh of tetrahedral elements, you can choose the default mesh generation algorithm or the algorithm that was included with Abaqus/CAE 6.4 and earlier. In most cases the default algorithm is more robust, particularly when meshing complex shapes and thin solids. For more information, see *Free meshing with triangular and tetrahedral elements*.

Increase the size of the interior elements

If you choose the default mesh generation algorithm to create a free mesh of tetrahedral elements, you can toggle on **Non-standard interior element growth** and use either the slider control or the text field to specify a growth rate for interior elements. The growth rate must be between `1.0` (no or minimal growth) and `2.0` (maximum growth).

If the mesh density is adequate for the model being analyzed and the areas of interest are on the mesh boundary, increasing the size of the interior elements will increase the computational efficiency. To view the internal elements generated by Abaqus/CAE, you can use a view cut or use display groups to remove exterior elements from the view.

1. From the main menu bar, select **Mesh->Controls**.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also click the  tool, located in the Mesh module toolbox. (For more information, see *Using the Mesh module toolbox*.)

2. If your part or assembly contains more than one region, select the regions of interest and click mouse button 2.

   The **Mesh Controls** dialog box appears. If the mesh algorithm option is applicable to the selected element shape and meshing technique, an **Algorithm** field appears on the right side of the **Mesh Controls** dialog box.

3. Select the desired algorithm options, and click **OK** to save your data and to close the dialog box.

Additional information

- *Free meshing*
- *Controlling mesh characteristics*
- *Using the Mesh module toolbox*
- *Selecting objects within the viewport*

Specifying the sweep path

If you apply the swept meshing technique to a particular region, a **Redefine sweep path** button appears in the **Mesh Controls** dialog box for that region. If the region has more than one valid sweep path, you can click **Redefine sweep path** to select the path of your choice. (For more information on sweep paths, see *Swept meshing*.)

This option is of particular interest if you are assigning mesh controls to a gasket, continuum shell, cylindrical, or cohesive region. Unless you assign another orientation (for more information, see *Applying a mesh stack orientation*), the directional properties of these region types are dependent on the sweep path. When you mesh a gasket region, the axis of each gasket element will be coincident with the sweep path direction. (For more information, see *Gaskets*," and *About Gasket Elements*.) When you mesh a continuum shell or cohesive region, the sweep path is aligned with the stack direction. (For more information, see *Meshing parts with continuum shell elements*, and *Creating a model with cohesive elements using geometry and mesh tools*.) When you mesh a cylindrical region with cylindrical elements, the sweep path of the selected sweep/revolve region is aligned along the circumferential direction of the cylindrical geometry. (For more information, see *Swept meshing of cylindrical solids*.)

1. From the main menu bar, select **Mesh->Controls**.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also click the  tool, located in the Mesh module toolbox. (For more information, see *Using the Mesh module toolbox*.)

2. If your part or assembly contains more than one region, select the sweep-meshable regions of interest and then press mouse button 2.

   The **Mesh Controls** dialog box appears.

3. In the **Mesh Controls** dialog box, select **Sweep** as the meshing technique if it is not already selected.

   If more than one valid sweep path exists for the regions that you selected, a **Redefine Sweep Path** button appears toward the bottom of the dialog box.

4. Click **Redefine Sweep Path**.

   If you selected multiple regions, this procedure considers each of the selected regions in turn. The region currently being considered becomes highlighted in magenta, and the default sweep path is highlighted in red with an arrow indicating the sweep direction.

5. Specify the sweep path and direction of your choice by selecting the appropriate option in the prompt area:

   - Click **Accept Highlighted** to accept the sweep path highlighted in the viewport.
   - Click **Flip** to change the direction of the currently selected sweep path. Then click **Yes** to indicate that the new sweep path direction is correct.
   - Click **Select New** (if applicable) to select a different edge as the sweep path. Then perform the following steps:

     1. Select an edge in the sweep path. You can indicate the desired sweep direction by clicking the mouse button toward the end of the edge that you want to coincide with the end of the sweep path.

        The new sweep path is highlighted in red with an arrow indicating the sweep direction.

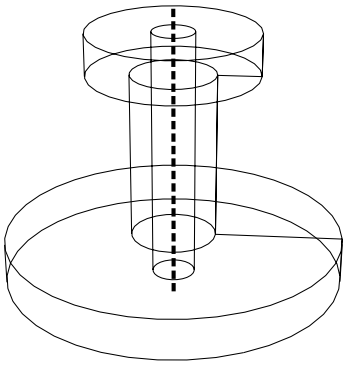
     2. Click **Yes** in the prompt area if the path and direction are correct, or click **Flip** if you want to change the direction of the sweep path. Then click **Yes** to indicate that the new sweep path direction is correct.

If multiple regions are selected with more than one valid sweep path, the procedure starts over with the next region. If only one region is selected, the procedure is complete and the **Mesh Controls** dialog box reappears.

Sweep meshing a solid, revolved region whose profile touches the axis of revolution

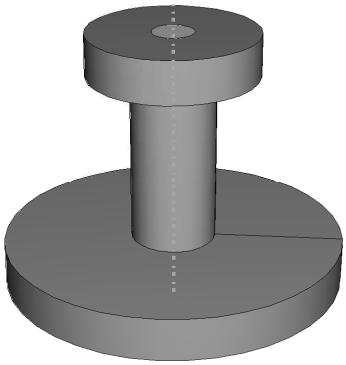
You can use the partitioning technique to make a part swept meshable.

In most cases, unless you create strategically placed partitions, you cannot sweep mesh a revolved solid region with all hexahedral elements if the profile that was revolved to create the region touches the axis of revolution. For example, the cylindrical part in the following figure cannot be swept meshed.



The partitioning technique to make the part swept meshable involves dividing the part or part instance into the following two regions:

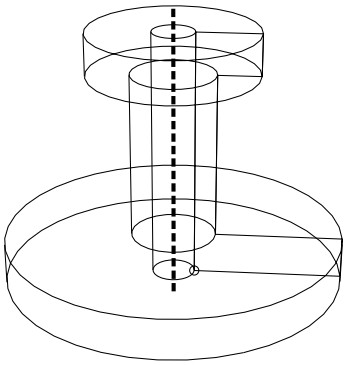
- A cylindrical core region that can be meshed using the extruded swept meshing technique.
- An outer region that can be meshed using the revolved swept meshing technique.



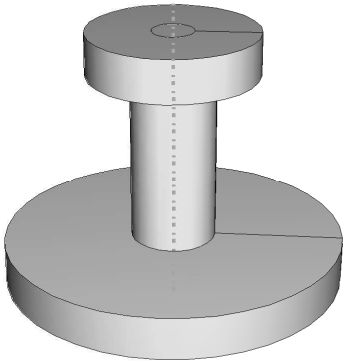
(For detailed information on sweep meshing solid regions, see *Swept meshing of three-dimensional solids*.)

Tip: The following instructions refer to color cues that appear only when the **Mesh defaults** color mapping is selected. Apply this color mapping to your viewport before attempting to partition a solid, revolved region for sweep meshing.

1. Use the Partition toolset to create a cylindrical core at the center of the region. (For detailed information on partitions, see *The Partition toolset*.) The partitions creating the cylindrical core are outlined in red in the figure below.



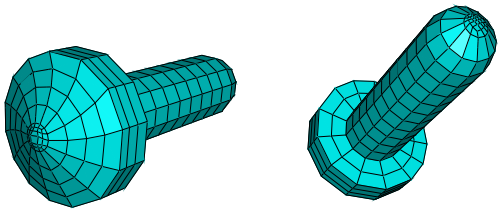
The cylindrical core is meshable using the extruded swept meshing technique and therefore becomes yellow. The outer region remains orange because it is still unmeshable.



In the next step you will create additional partitions that allow Abaqus/CAE to recognize the outer region as a revolved solid whose profile does not touch the axis of revolution.

2. Use the Partition toolset to create whatever partitions are necessary to outline a revolution profile for the outer region. The profile will serve as the source side of the revolved mesh and will be swept along the circular edge defined by the cylindrical core to create the solid mesh.

   For example, partitions are used to outline the profile (shown in red) of the outer region in the figure below.



Once the profile has been defined, both the cylindrical inner region and the outer region are colored yellow and are ready for sweep meshing.

The resulting mesh is shown below.

You can apply a similar technique to mesh revolved regions even though the source side and the target side are not planar, as shown below.

Applying a mesh stack orientation

The mesh stack orientation is important when meshing parts with continuum shell, cohesive, cylindrical, or gasket elements because these elements have a distinctive directional behavior. If you use sweep meshing, the default stack orientation follows the direction of the sweep path, and you may be able to change the stack orientation by picking a different sweep path. However, you must assign a sweep direction to each cell in a part separately—a time-consuming process—and the available sweep directions may not include your desired stack direction.

The stack orientation tool allows you to assign a stack orientation to all cells or to selected cells within a solid part or part instance, as long as the cells do not have tetrahedral elements assigned. You can use the tool to apply a stack orientation quickly to a group of cells in a single operation. You assign the stack orientation based on a selected face; the stack is oriented such that the selected face is the top of the stack. Abaqus/CAE applies the orientation regardless of the mesh technique used for the cells; so the sweep direction, if one exists, does not matter.

The stack orientation tool was used to assign an orientation through the thickness of the part in *Figure 1*, as shown by the red arrow; the top faces of the elements are colored brown. The complex profile of the swept solid part did not allow the desired stack orientation using the sweep path—the two available sweep directions are indicated by the black arrow in the figure.

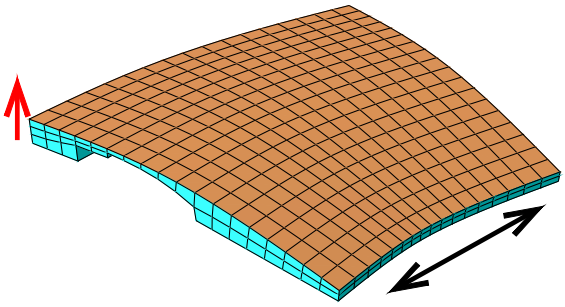


Figure 1: The stack orientation need not follow the sweep direction.

Application of a new stack orientation may vary depending on the cells selected. *Figure 2* illustrates a case where the stack direction changes as more cells are meshed. The upper left face was used for the reference orientation, so the mesh orientations for the two disconnected cells in the center image match this orientation. However, when the center cell is meshed, the orientation of the elements in the lower right cell is updated to align with the other two cells, as shown in the image on the right.

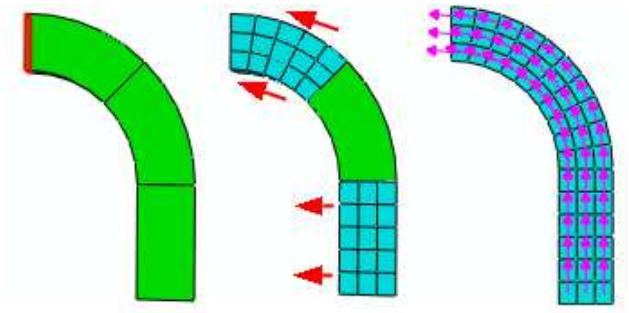

Figure 2: Stack orientation may change if you add cells to a mesh.

1. From the main menu bar, select **Mesh->Orientation->Stack**.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

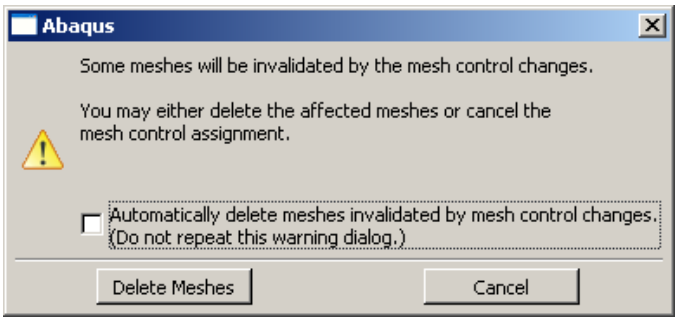
Tip: You can also set a mesh stack direction using the  tool, located in the Mesh module toolbox (for more information, see *Using the Mesh module toolbox*.), and the **Assign stack direction** button, located in the **Mesh Controls** dialog box.

2. If your part contains multiple cells, select the cells for which you want to assign a stack direction.
3. Select a top face to define the reference orientation.

   Abaqus/CAE prompts you to confirm your selections before assigning the orientation.
4. Click **Yes** to accept the selected face and corresponding orientation, or click **No** to return to Step 3.

   When you accept the reference face, Abaqus/CAE applies the stack direction to the selected cells.

   If any of the selected cells contains cylindrical elements, Abaqus/CAE displays a warning message indicating that the cylindrical elements must be deleted to apply a new stack direction. Click **Yes** to delete the cylindrical mesh or **No** to cancel the stack direction procedure.



Additional information

- *Controlling mesh characteristics*

Changing mesh controls for previously meshed regions

If you change any of the mesh controls assigned to a previously meshed region, that region's mesh may become invalid.

In these cases, the following warning dialog appears when you click **OK** in the **Mesh Controls** dialog box.

You can delete the mesh by clicking **Delete Meshes**, or you can keep your mesh and cancel the new settings in the **Mesh Controls** dialog box by clicking **Cancel**.

You can also avoid this warning message for the remainder of the current session by toggling on **Automatically delete meshes invalidated by mesh control changes**. The next time you attempt to change the controls assigned to a region that already contains a mesh, the mesh will be deleted immediately without the appearance of the warning dialog box.

Additional information

• *Controlling mesh characteristics*

Associating Abaqus elements with mesh regions

To associate particular Abaqus elements with mesh regions or with orphan elements, select **Mesh->Element Type** from the main menu bar.
Then select those regions whose element type you want to assign, and make the assignment using the **Element Type** dialog box that appears.

You can use the dialog box to specify Abaqus element settings for all the element shapes that could conceivably appear in the regions you select, even if the regions currently contain only a few different element shapes. For example, even though a selected region may contain only quadrilateral elements, you can associate an element type with other shapes, too, such as triangles.

For information on populating the **Element Type** dialog box with preferred element types, see *Preferred element types list*.

The element type setting behaves like a feature. For example, if you assign element types to a region and then later partition that region into several more regions, the new regions will inherit the element type settings of the original parent region.

1. From the main menu bar, select **Mesh->Element Type**.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also choose element types using the 

   tool, located in the Mesh module toolbox. (For more information, see *Using the Mesh module toolbox*.)

2. If your assembly or part contains both orphan elements and geometric regions, choose **geometry** in the prompt area to assign an element type to the geometry.

   Orphan elements in an assembly belong to dependent part instances; you cannot assign an element type to a dependent part instance. To assign an element type to orphan elements, you must select the mesh part from the parts list in the **Object** field of the context bar and assign the element type to the desired elements of the part.

3. If you are selecting from multiple geometric regions or if you are selecting elements from a part imported from an output database, use the following selection techniques:

Geometry

Use the mouse to select the desired regions in the viewport, and then click mouse button 2 when your selection is complete.

You can select only regions from parts of the same type; for example, you cannot select both a rigid surface and a deformable body. Likewise, the regions that you choose must have the same dimensionality.

Orphan mesh

Use the mouse to select the desired orphan elements, and then click mouse button 2 when your selection is complete.

Alternatively, you can click **Sets** on the right side of the prompt area. A dialog box appears with a list of all of the elements sets associated with the meshed part. Select the element set of your choice and then click **Continue**. For information on creating sets, see *The Set and Surface toolsets*.

All elements that you select, regardless of the selection method, must be of the same order. In addition, the elements must belong to parts of the same type.

The **Element Type** dialog box appears.

4. In the upper left corner of the dialog box, select the **Element Library** option of your choice.

   Select **Standard** to choose from the list of Abaqus/Standard elements, or select **Explicit** to choose from the list of Abaqus/Explicit elements.

5. Select the **Geometric Order** of your choice: **Linear** (first order) or **Quadratic** (second order).
6. From the **Family** list on the right side of the dialog box, select an appropriate element family for the type of analysis you will perform on the model. For example, if you plan to do a heat transfer analysis, select the **Heat Transfer** family.

   The name of the default element for the element library, geometric order, and family that you specified appears in the lower half of the dialog box.

   Note:

   You can set the element type corresponding to only a single family. For example, you cannot set the element type for linear triangles in both the plane strain and heat transfer families; you must select either heat transfer or plane strain. If, after setting element types for one family, you switch to another family, the settings for the first family are lost.

7. Choose the Abaqus element type of your choice for each element shape.
   a. Click the tab corresponding to the element shape of interest.
   b. Select the element characteristics of your choice. For more information on the element control options, see *Section Controls*.

      The name of the Abaqus element that meets all your criteria appears at the bottom of the tabbed page with a brief description.

8. Click **OK** to commit your element type assignments, or click **Defaults** and then **OK** to return all element settings to their default values.

   The element types are changed according to your specifications.

9. To set element types for additional regions, repeat this procedure starting from Step 2.

Additional information

- *How do mesh elements correspond to Abaqus elements?*
- *What kinds of elements must be generated outside the Mesh module?*
- *Element type assignment*
- *Importing parts*
- *Using the prompt area during procedures*
- *Using the Mesh module toolbox*
- *Selecting objects within the viewport*

Changing the labels of all nodes and elements

Select **Mesh->Global Numbering Control** from the main menu to change the node and element labels of a native region or of selected native part instances in the assembly. Enter the start labels, and Abaqus/CAE changes the nodes and elements labels while preserving the original order and incrementation. You can change the labels before or after Abaqus/CAE generates the mesh. (For information on renumbering orphan nodes, see *Renumbering nodes* and *Renumbering elements*.)

1. Enter the Mesh module.
2. From the main menu, select **Mesh->Global Numbering Control**.
3. If you are working with the assembly, select the native geometry part instances to modify.

   You can select independent or dependent part instances to modify. However, any operations applied to dependent part instances are performed at the part level and, therefore, apply to all instances of the part, even if not all instances were selected.

   Abaqus/CAE displays the **Global Numbering Control** dialog box and the start label for the nodes and elements. If you selected a single part instance, the values displayed are the current start label for the nodes and elements of the selected part instance. If you selected multiple part instances that have the same start labels for their nodes and elements, those values are displayed; otherwise, no values are displayed.
4. From the **Global Numbering Control** dialog box, enter the start labels for the nodes and elements. Abaqus/CAE Applies the same start labels to each of the part instances you selected.
5. Click **OK** to renumber the nodes and elements.

   If the mesh exists, Abaqus/CAE renumbers the nodes and elements and preserves the original order and incrementation. If the mesh has not been created, the new start labels are applied when Abaqus/CAE meshes the part or part instances.

Additional information

- *Renumbering nodes*
- *Renumbering elements*

Adding layers of wedge elements to tetrahedral mesh boundaries

If you apply the free meshing technique and tetrahedral element shape to a region, an **Insert boundary layer** toggle and **Assign Controls** button are available in the **Mesh Controls** dialog box.

If you add a boundary layer to multiple meshing cells, Abaqus/CAE temporarily fixes the seeding on any internal faces between the cells to simplify creation of the boundary layer across these faces.

1. From the main menu bar, select **Mesh->Controls**. (For detailed instructions, see *Assigning mesh controls*.)

   Note:

   You must select a free tetrahedral mesh to include a boundary layer of wedge elements.

2. Toggle on **Insert boundary layer** near the bottom of the **Mesh Controls** dialog box, and click **Assign Controls**.

   Abaqus/CAE displays the **Boundary Layer** dialog box.

3. Enter the **Wall element height**.

   The wall element height sets the height or thickness of the first layer of wedge elements against the boundary walls.

4. Enter the **Growth factor**.

   Starting from the wall elements and moving inward, the height of each successive layer is determined by multiplying the height of the previous layer by the growth factor. The growth factor must be between `1.0` and `2.0`, inclusive, where `1.0` results in no growth and `2.0` doubles the thickness of each new layer.

5. Enter the number of wedge element layers in the boundary layer.

   Abaqus/CAE displays the total **Boundary layer thickness** based on your entries in Step 3 through Step 5.

6. If desired, toggle on **Inactive faces**, and click **Edit** to select faces that you do not want to include in the boundary layer.

   The inactive faces are expected to be approximately planar and perpendicular to local flow directions or along a plane of symmetry.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

7. If desired, toggle on **Create set**, and enter a set name to save a set containing all the boundary layer elements.
8. Click **OK** to close the **Boundary Layer** dialog box.

   The boundary layer will be created when you mesh the regions.

   If mesh generation fails due to problems in the boundary layers, Abaqus/CAE displays a preview of the boundary layer mesh along with a warning dialog box. Before closing the warning dialog and deleting the mesh preview, look for problems such as self-intersecting layers near sharp corners; the possible failure modes are similar to those described for offset meshes in *Reducing element distortion*

and collapse during mesh offsetting. Make the necessary corrections to the boundary layer controls and try to mesh the regions again.

Additional information

• *Controlling mesh characteristics*

Obtaining mesh information and statistics

This section explains how you use the verification tool in the Mesh module to verify graphically the quality of the elements used in a mesh. This section also describes how you use the Query toolset in the Mesh module to obtain listings of mesh, element, and node statistics.

In this section:

- *Verifying element quality*
- *Obtaining mesh information*

Verifying element quality

You can verify the quality of the mesh in selected regions as well as the quality of selected elements,

To verify the quality of a mesh, select **Mesh->Verify** from the main menu bar. The mesh verify tool allows you to do the following:

- Select a part, or select one or more part instances or regions; and highlight elements that do not meet specified criteria, such as aspect ratio. You can also obtain mesh statistics for each selected part, part instance, or region, such as the total number of elements, the number of highlighted elements, and the average and worst values of the selection criterion.
- Select a part, or select one or more part instances or regions; and highlight elements that do not pass the mesh quality tests that are included with the input file processor in Abaqus/Standard and Abaqus/Explicit.
- Save sets containing the elements highlighted by the verification tests. For native meshes, you can save sets of cells, faces, or edges related to the highlighted elements.

You can also obtain quality information for individual elements. For more information, see *Verifying your mesh*.

Additional information

• *Verifying your mesh*
• *Obtaining mesh information*

Verify selected elements

1. To verify the quality of selected elements, select **Mesh->Verify** from the main menu bar.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

   Tip: You can also verify selected elements using the  tool, located in the Mesh module toolbox. (For more information, see *Using the Mesh module toolbox*.)

2. From the **Select the regions to verify by** field in the prompt area, select **Element**.
3. Select the element that you want to verify. Abaqus/CAE displays the following in the message area:
   - The name of the part or part instance
   - The element index
   - The element shape
   - The shape factor for triangle and tetrahedra elements
   - The minimum and maximum face corner angles
   - The aspect ratio
   - The geometric deviation factor
   - The stable time increment
   - The maximum allowable frequency for acoustic elements
   - The shortest edge and longest edge
   - Whether the element passes the checks found in the input file processor in Abaqus/Standard and Abaqus/Explicit
4. Continue selecting elements, as desired.

5. When you have finished selecting elements, either
   - Click mouse button 2 in the viewport, or
   - Select any other tool from the toolbox, or
   - Click the cancel button  in the prompt area, or
   - Click the verify mesh tool in the Mesh module toolbox.

Verify a part, a part instance, or a region

1. From the **Object** field in the context bar, select a part or select the assembly.
2. From the main menu bar, select **Mesh->Verify** from the main menu bar.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

    **Tip:** You can also verify a mesh using the  tool, located in the Mesh module toolbox. (For more information, see *Using the Mesh module toolbox*.)

3. From the text field in the prompt area, select the type of region to verify:
   - Select **Part** or **Part Instances** and select the part or part instances whose mesh you want to verify, and press mouse button 2.
   - **Geometric Regions**. Select the cells, faces, or edges whose mesh you want to verify, and press mouse button 2.

   Abaqus/CAE displays the **Verify Mesh** dialog box.
4. From the top of the **Verify Mesh** dialog box, click the tab corresponding to the desired verification checks. The following verification types are available:
   - **Shape metrics**
   - **Size metrics**
   - **Analysis checks**

   You can specify verification checks on multiple tabbed pages. Abaqus/CAE refers to the verification checks specified on all three tabbed pages when you click **Highlight**.
5. To save a set containing results of the selected verification checks, toggle on **Create set** near the bottom of the **Verify Mesh** dialog and either accept the default set name or enter a new name for the set.

   If there are any results displayed, Abaqus/CAE creates the set when you click **Highlight**, as described in the following steps.
6. If you want to specify verification checks on the **Shape metrics** tabbed page, do the following:
   a. From the **Shape factor** options, specify the shape factor criterion for triangular elements and tetrahedral elements in your selection. If your selection includes both triangular elements and tetrahedral elements, the **Shape factor** options provide separate controls for each type; if your selection includes only triangular elements or only tetrahedral elements, a single control is provided.
   b. If your selection includes triangular elements, you can specify the small face corner angle and the large face corner angle for triangular elements from the **Tri-Face Corner Angle** options.
   c. If your selection includes tetrahedral elements, you can specify the small face corner angle and the large face corner angle for tetrahedral elements from the **Quad-Face Corner Angle** options.
   d. Specify a value for the **Aspect ratio**.

For a detailed description of the selection criteria, see *Verifying your mesh*.

7. If you want to specify verification checks on the **Size metrics** tabbed page, specify failure criteria for any of the following:

   - **Geometric deviation factor**
   - **Shortest edge**
   - **Longest edge**
   - **Stable time increment**
   - **Maximum allowable frequency for acoustic elements**

   Stable time increment is available only for elements in the Abaqus/Explicit element library. **Maximum allowable frequency for acoustic elements** is available only for acoustic elements in the Abaqus/Standard element library.

   For a detailed description of the selection criteria, see *Verifying your mesh*.

8. If you want to specify analysis checks, click the **Analysis checks** tab, and toggle **Errors** and **Warnings** to select which elements will be highlighted.
9. Click **Highlight**.

   Abaqus/CAE highlights elements that fail the element checks specified in the **Shape Metrics** or **Size Metrics** tabbed pages as warnings. In addition, any elements that generated errors or warnings using the checks found in the input file processor in Abaqus/Standard and Abaqus/Explicit are highlighted in the appropriate colors. If you selected **Create set** in Step 5, Abaqus/CAE saves a set containing the highlighted results. In addition, Abaqus/CAE displays information in the message area, such as the name of the part instance, the total number of elements, the number of highlighted elements, and the average and worst value of the selection criterion.

   Regardless of your selection of **Errors** and **Warnings** in the **Analysis checks** tabbed page, Abaqus/CAE also displays in the message area the total number of elements tested and the number of errors and warnings. In most cases, it will be obvious from the element shape why the input file processor issued an error or a warning. If necessary, you can submit a datacheck analysis from the Job module and review the messages that Abaqus writes to the data file. Abaqus/CAE does not support analysis checks for beam, gasket, or cohesive elements.

10. From the buttons along the bottom of the **Verify Mesh** dialog box, do the following:

    - Click **Reselect** to select different part instances or regions.
    - Click **Defaults** to restore the default element failure criteria on all of the tabs.
    - Click **Dismiss** to close the **Verify Mesh** dialog box.

Your changes to the mesh verification criteria are saved for use in future Abaqus/CAE sessions.

Obtaining mesh information

To obtain information on the mesh, select **Tools->Query** from the main menu bar. You can request information on the following:

- The total number of nodes and elements in a selected part, part instance, or region along with the number of elements of each element shape.
- The type and connectivity of a selected element.
- The positive and negative sides of shell and membrane faces.
- The direction of beam and truss tangents.
- The mesh stack orientation.
- Whether any edges of boundary faces have incompatible interfaces, cracks, or gaps and whether any edges intersect other faces.
- Whether there are free or non-manifold exterior element edges.
- Whether there are unmeshed regions.

1. From the **Object** field in the context bar, select a part or select the assembly.
2. From the main menu bar, select **Tools->Query**.

    **Tip:** You can also select the  tool in the Query toolset.

   Abaqus/CAE displays the **Query** dialog box.
3. From the **Query** dialog box, select one of the following queries:

Shell element normals

Abaqus/CAE displays the part or the assembly using the shaded render style. The side of the shell where the surface normal coincides with the shell normal (top face) is shaded brown; the opposite side (bottom face) is shaded purple.

Beam element tangents

Abaqus/CAE displays cyan arrows indicating the direction of the beam tangents.

Mesh stack orientation

For hexahedral and wedge elements, Abaqus/CAE colors the top face brown and the bottom face purple. Similarly, arrows indicate the orientation of quadrilateral elements. In addition, Abaqus/CAE highlights any element faces and edges that have inconsistent orientation.

Mesh

For an assembly, part or part instance, geometric region, or element, Abaqus/CAE displays the following:

- The total number of nodes and elements in the selected area
- The number of elements for each element shape

By default, Abaqus/CAE displays mesh information in the message area, but you can display this information in a tabular format in the **Mesh Statistics** dialog box by toggling on **Display detailed report** in the prompt area. The **Mesh Statistics** dialog box also enables you to display mesh information by part instance or by element type.

Element

Select an element. Abaqus/CAE displays the following in the message area:

- The element label
- The element topology
- The element type that Abaqus/CAE will use for the analysis
- Nodal connectivity

Mesh gaps/intersections

Select a part instance. Abaqus/CAE highlights any edges of boundary faces of the model in the current viewport with the following:

- Incompatible interfaces
- Cracks or gaps
- Intersections with other faces

In addition, if intersecting elements are found, Abaqus/CAE displays a dialog box that allows you to save a set containing elements that share the highlighted edges. If the model geometry is available, you can save a set containing the cells, faces, or edges related to the highlighted element edges.

Free/Non-manifold edges

If the current viewport contains an assembly with more than one part instance, select one or more solid or shell instances for the query. Abaqus/CAE highlights two types of exterior element edges:

- Free element edges are exterior edges that belong to a single exterior element face.
- Non-manifold element edges are exterior edges shared by more than two adjacent exterior element faces.

If Abaqus/CAE finds free or non-manifold element edges, it displays the combined total number of these edges in the message area. Abaqus/CAE also displays a dialog box from which you can save an element set containing all the elements with the highlighted edges. If there are no free or non-manifold edges, the message area indicates that all exterior element edges are shared by exactly two exterior element faces. *Figure 1* shows an extruded shell part with the free and non-manifold edges highlighted in red. The element edges along outer boundaries of the three planar faces are free edges. The element edges at the intersection of the three faces are non-manifold edges—each shared by three exterior element faces.

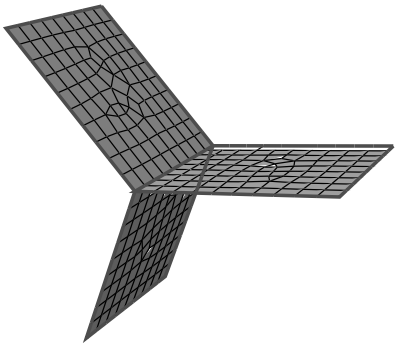


Figure 1: Free element edges make up the exterior edges, and non-manifold edges form the center where the three planar shells are joined.

Shell parts should contain free edges and non-manifold edges where appropriate for the part design. Solid parts should not contain any free or non-manifold edges.

Unmeshed regions

Abaqus/CAE displays a warning dialog and highlights any regions of the model that are not meshed. Toggle on **Save regions in a set** and select a set name to save a set containing the unmeshed regions.

If there are no unmeshed regions, Abaqus/CAE displays a message in the message area indicating that all regions are fully meshed. The query does not consider regions that do not require a mesh, such as display bodies and analytical rigid surfaces.

Unassociated geometry

Abaqus/CAE displays the **Query Unassociated Geometry** dialog box, which enables you to highlight the cells, faces, edges, or vertices in your part or model that are not associated with a mesh. Toggle on **Create set** and select a set name to save a set containing the geometry that is not associated with a mesh.

If all the geometry you select is associated with a mesh, Abaqus/CAE displays a dialog box indicating that all selected geometry is associated with a mesh. The query does not consider regions that do not require a mesh, such as display bodies and analytical rigid surfaces.

4. When you are finished obtaining mesh information, close the **Query** dialog box.

Additional information

- *Controlling mesh characteristics*
- *Verifying element quality*

Creating a mesh part

Select **Mesh->Create Mesh Part** from the main menu bar to create a mesh part with no geometric features from the current meshed part or assembly. You can also create a mesh part from selected part instances that you have meshed. If you have meshed only some regions of the assembly or the selected part instances, Abaqus/CAE creates a mesh part from only those meshed regions; unmeshed regions are not included in the mesh part.

A mesh part contains no feature information and is defined by a collection of nodes, elements, surfaces, and sets. Sets, surfaces, and section assignments are copied from the source parts or part instances when you create a mesh part, so loads and interactions applied to the original parts are also applied to the mesh part. You can add geometric features to a mesh part, and you can use the mesh editing tools to modify its nodes and elements. For more information, see *What can I do with the Edit Mesh toolset?*.

1. From the **Object** field in the context bar, select a meshed part or select the assembly.
2. From the main menu bar, select **Mesh->Create Mesh Part**.
3. If the assembly contains more than one part instance, you must select the part instances that you want to include in the mesh part. In the prompt area, click **Done** to indicate that you have finished selecting part instances.
4. In the prompt area, enter the name of the new part. If you selected part instances from the assembly, you can toggle on **Replace part instances** to replace the assembly instances with an instance of the new mesh part.

   Abaqus/CAE creates the mesh part.

Controlling adaptive remeshing

This section describes how you can define an adaptive remeshing rule and how you can adaptively remesh your model manually.

In this section:

- *Creating a remeshing rule*
- *Selecting the step and error indicator output variables for the remeshing rule*
- *Choosing the remeshing rule sizing method*
- *Choosing remeshing rule constraints*
- *The Remeshing Rules Manager*
- *Manually resizing and remeshing*

Creating a remeshing rule

Remeshing rules enable Abaqus/CAE to adapt your mesh iteratively to meet error indicator targets and sizing criteria that you have specified. For more information, see *What are remeshing rules?*.

1. From the main menu bar, select **Adaptivity->Remeshing Rule->Create**.

   Tip: You can also create a remeshing rule using the tool, located with the mesh tools in the Mesh module toolbox. (For more information, see *Using the Mesh module toolbox*.)

2. Select the regions to which Abaqus/CAE will apply the remeshing rule, or click **Done** to select the entire model. If you assign a remeshing rule to a dependent instance, Abaqus/CAE remeshes the original part and each dependent instance of the part inherits the same mesh. The modeling space of the region must be homogeneous. For example, Abaqus/CAE does not allow you to select a region that contains both solids and shells.

   If necessary, you should use the Partition toolset to isolate regions that will generate stress singularities and to exclude those regions from the remeshing rule. For more information, see *Singularities*.

3. The **Create Remeshing Rule** dialog box appears.
4. If desired, use the **Name** text field to change the name of the new rule.
5. If desired, use the **Description** text field to enter a description of the remeshing rule. You can use the description to help you keep track of the scope and the purpose of your remeshing rules. The **Remeshing Rules Manager** displays the name and the description of a remeshing rule.
6. Click the **Step and Indicator** tab to select the following:

   - The step to which the remeshing rule will be applied.
   - The error indicator output variables that Abaqus/CAE will write to the output database, and the frequency at which they will be written.

   For more information, see *Selecting the step and error indicator output variables for the remeshing rule*.

7. Click the **Sizing Method** tab to select the following:

   - The method that Abaqus/CAE will use to calculate the size of the elements during the remeshing process.
   - Whether to use automatic reduction of error indicator targets for the adaptive remeshing process or whether to specify the error indicator targets.

   For more information, see *Choosing the remeshing rule sizing method*.

8. Click the **Constraints** tab to select constraints on the element size during the remeshing process. For more information, see *Choosing remeshing rule constraints*.
9. Click **OK** to create the remeshing rule and to close the **Create Remeshing Rule** dialog box.

Additional information

- *Understanding adaptivity processes*
- *Understanding adaptive remeshing*
- *Manually resizing and remeshing*
- *About Adaptive Remeshing*

Selecting the step and error indicator output variables for the remeshing rule

When you create a remeshing rule, you must select the step to which the rule will be applied. You must also select the error indicator output variables that Abaqus/CAE will write to the output database during the analysis and the frequency at which they are written. The error indicator output variables are the basis of the adaptive remeshing process. They provide information to Abaqus/CAE that describes where a mesh needs refinement to approach or achieve the desired error indicator goals. In addition, Abaqus/CAE uses the error indicator output variables to determine where the mesh can be coarsened without introducing unacceptable errors. *Selection of Error Indicators Influencing Adaptive Remeshing*.

You can use the adaptivity plotter plug-in to review the history of selected error indicators and the element count during an adaptivity analysis. For more information, see *Displaying the history of the adaptive remeshing error indicator*.

1. From the **Create Remeshing Rule** dialog box, click the **Step and Indicator** tab.
2. Click the arrow to the right of the **Step** field, and select the step of your choice from the list that appears. The remeshing rule will be applied only during this step; however, you can apply a different remeshing rule with the same settings to another step in your model. Adaptive remeshing is available only for procedures that use Abaqus/Standard. In addition, Abaqus/CAE cannot apply adaptive remeshing in frequency extraction and steady-state dynamic procedures. For more information, see *Which procedures can I use with adaptive remeshing?*.
3. Choose the frequency at which the error indicator output variables will be written to the output database. You can choose to write the variables after each increment or after the end of the last increment of the step. Abaqus/CAE remeshes the model based on the value of the error indicators in the last increment of the step. However, if your analysis fails to converge and you saved the error indicator output variables after every increment, you can use the most recent values to remesh your model manually and to continue. For more information, see *Manually resizing and remeshing*.
4. From the list of **Error Indicator Variables**, select one or more variables that will be written to the output database. For each variable that you select, Abaqus/CAE also writes an accompanying base solution variable to the output database.

Additional information

- *Selection of Error Indicators Influencing Adaptive Remeshing*
- *Understanding adaptivity processes*
- *Understanding adaptive remeshing*
- *Creating a remeshing rule*
- *About Adaptive Remeshing*
- *Displaying the history of the adaptive remeshing error indicator*

Choosing the remeshing rule sizing method

You can allow Abaqus/CAE to choose a default sizing method based on the error indicator output variable, or you can specify a sizing method that will be used for all error indicators in the remeshing rule. If you specify the sizing method, you can also specify the adaptivity goal. For more information, see *Solution-Based Mesh Sizing*.

1. From the **Create Remeshing Rule** dialog box, click the **Sizing Method** tab.
2. Click the arrow to the right of the **Method** field, and select one of the following mesh size algorithms:
   - Choose **Default method and parameters** to allow Abaqus/CAE to choose the default calculation method for each error indicator output variable. By default, all of the error indicators except for element energy (ENDENERI) and heat flux (HFLERI) use the **Minimum/maximum control** mesh sizing algorithm. ENDENERI and HFLERI use the **Uniform error distribution** algorithm. The default error target is **Automatic target reduction** with a moderate mesh bias.
   - Choose the **Uniform error distribution** mesh sizing algorithm to force Abaqus/CAE to apply a sizing method that attempts to meet the specified error target in every element in the model. In most cases this approach leads to a globally converging mesh.
   - Choose the **Minimum/maximum control** mesh sizing algorithm to control the mesh density at the location of the minimum and maximum values of the base solution.

   For more information, see *Solution-Based Mesh Sizing*.
3. If you selected **Uniform error distribution**, specify the approach that Abaqus/CAE will use to determine the error indicator target:
   - Choose **Automatic target reduction** to allow Abaqus/CAE to generate successive mesh refinements that attempt to reduce the solution error by a fixed amount from the prior job in the adaptivity process. You select the maximum number of mesh iterations while creating an adaptivity process in the Job module. If you select **Automatic target reduction**, Abaqus/CAE will consider the rule to be satisfied when the error indicator reaches 1%. The criterion of 1% is intended only to provide protection against excessively expensive analysis jobs. In most cases Abaqus/CAE will complete all of the remesh iterations that you specified when you created the adaptivity process in the Job module.
   - Choose **Fixed target**, and enter the percentage error target. Abaqus/CAE uses this value to apply a sizing method that attempts to meet the error target in every element in the model. Such an approach ensures a globally converging mesh. Abaqus/CAE will consider the rule to be satisfied when the error indicator reaches the error indicator target.
4. If you selected **Minimum/maximum control**, do the following from the **Error Indicator Targets** region:
   a. Specify the approach that Abaqus/CAE will use to determine the error target:
      - Choose **Automatic target reduction** to generate successive mesh refinements that attempt to reduce the solution error by a fixed amount from the prior analysis. You select the maximum number of mesh iterations in the Job module. If you select **Automatic target reduction**, Abaqus/CAE will consider the rule to be satisfied when the error indicator reaches 1%. The criterion of 1% is intended only to provide protection against excessively expensive analysis jobs. In most cases Abaqus/CAE will complete all of the remesh iterations that you specified when you created the adaptivity process in the Job module.
      - Choose **Fixed targets**, and enter the percentage error indicator targets at the location of the maximum and minimum value of the base solution. Abaqus/CAE uses these values to apply a heterogeneous sizing method that attempts to meet both targets at their respective locations. Abaqus/CAE will consider the rule to be satisfied when the error indicator corresponding to

the maximum value of the base solution is reached. In addition, both error targets help Abaqus/CAE ensure that mesh refinement is focused on areas of interest. Conversely, they also help Abaqus/CAE ensure that disproportionate refinement is not applied to areas where the values of the base solution results are low.

b. Specify the **Mesh Bias**. The mesh bias further tunes the distribution of sizing between the locations of the maximum and minimum base solutions. When you choose **Strong**, the sizing method acts more aggressively and focuses more elements near locations of high base solution intensity. When you choose **Weak**, the sizing method acts less aggressively and generates fewer elements near locations of high base solution intensity. *Figure 1* illustrates the effect of the bias factor.

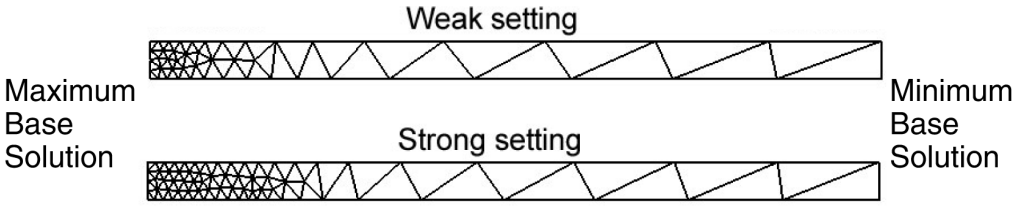

Figure 1: The impact of the bias factor on element size distribution.

Additional information

- *Solution-Based Mesh Sizing*
- *Understanding adaptivity processes*
- *Understanding adaptive remeshing*
- *Creating a remeshing rule*
- *About Adaptive Remeshing*

Choosing remeshing rule constraints

You can define constraints on the element size that Abaqus/CAE will apply during the adaptive remeshing process. You can also specify rate limits that control the introduction of larger and smaller elements and modulate how aggressively Abaqus/CAE applies the sizing method.

The minimum and maximum element sizes that you specify limit the size used in the mesh sizing function, which Abaqus/CAE uses to guide the internal meshing algorithm. The sizes that you specify are not absolute constraints on the element size—the element sizes in the generated mesh only approximate the sizing function. Therefore, some element edges may be larger or smaller than the maximum and minimum element sizes that you specified.

The maximum number of elements that you specify limits the number of elements generated by the mesh sizing function. The mesh sizing function adjusts the target error and the element sizes such that the number of elements generated in a remeshing region does not exceed the specified value. The number of elements in the generated mesh (as with the element sizes) only approximates the sizing function. Therefore, the number of elements generated may be greater than the maximum number of elements that you specified.

1. From the **Create Remeshing Rule** dialog box, click the **Constraints** tab.
2. Specify the minimum and maximum **Element Size**.
   - Specify a **Minimum** value to impose a lower bound on the size of the elements calculated by the remesh algorithm. You can choose either the minimum element size computed by Abaqus/CAE, or you can enter the minimum element size.
   - Specify a **Maximum** value to impose an upper bound on the size of the elements calculated by the remesh algorithm. You can choose either the maximum element size computed by Abaqus/CAE, or you can enter the maximum element size.
3. If desired, specify the **Approximate maximum number of elements** to impose an upper bound on the total number of elements calculated by the remesh algorithm.
4. Specify the **Rate Limits**.
   - The **Refinement** rate limit modulates the aggressivity of the sizing method and controls the introduction of smaller elements. Choose one of the following:
     - **Use default** to specify a refinement limit midway between **High** and **Low**.
     - **Specify** and drag the **Refinement** slider to specify the rate limit. Specifying **Low** indicates minimal reduction in the element size; specifying **High** indicates a maximum reduction of the original element size.

       The refinement factor has a significant effect on the convergence of the adaptive meshing procedure and may help you achieve faster and more efficient mesh convergence.
     - **Do not refine** to prevent reduction in the element size.
   - The **Coarsening** rate limit modulates the aggressivity of the sizing method and controls the introduction of larger elements. Choose one of the following:
     - **Use default** to use the default limit.
     - **Specify** and drag the **Coarsening** slider to specify the rate limit. Specifying **Low** indicates minimal growth in the element size; specifying **High** indicates a maximum growth of the element size.

- **Do not coarsen** to prevent growth in the element size.

- *About Adaptive Remeshing*

The Remeshing Rules Manager

The **Remeshing Rules Manager**, which is similar to other managers in Abaqus/CAE, allows you to do the following:

- Create a remeshing rule. For more information, see *Creating a remeshing rule*.
- Edit the selected remeshing rule.
- Copy, rename, suppress, resume, or delete the selected remeshing rule.

You can display the **Remeshing Rules Manager** by selecting **Adaptivity**->**Remeshing Rule**->**Manager** from the main menu bar.

The two columns in the **Remeshing Rules Manager** display the following:

Name

The **Name** column displays the name of the remeshing rule. Click **Rename** to rename the selected remeshing rule.

Description

The **Description** column displays the description of the remeshing rule. You can use the description to help you keep track of the scope and the purpose of your remeshing rules.

Manually resizing and remeshing

To learn about the impact of a remeshing rule on the mesh generated by Abaqus/CAE, you can manually apply a rule and view its impact on the resulting mesh. However, before you can remesh your model, you must run an analysis and create an output database that contains error indicator output variables. You can then change the sizing methods and constraints and view the impact of the modified rule on the generated mesh. When you are confident that a remeshing rule is capturing your intent, you can use the same rule to control several iterations that are driven by automatic remeshing. You can also use manual remeshing to continue an adaptivity process that ended prematurely.

For more information, see *What is the difference between automatic adaptive remeshing and manual adaptive remeshing?*, and *When do I need to use manual adaptive remeshing?*.

1. From the main menu bar, select **Adaptivity->Manual Adaptive Remesh**.

   Abaqus/CAE displays the **Manual Adaptive Remesh** dialog box.

   Tip: You can also manually resize and remesh using the tool, located with the mesh tools in the Mesh module toolbox. (For more information, see *Using the Mesh module toolbox*.)

2. In the **ODB** field, enter the name of the output database that contains the error indicator output variables. Abaqus/CAE uses the error indicators to drive the remeshing algorithm.

   Abaqus/CAE displays the following information about each of the remeshing rules in the output database:

   - The name of the rule.
   - A description of the error indicator output variable that was used by the rule.
   - The percentage target error. This is the value you specified when you created the remeshing rule. If you selected fixed targets, Abaqus/CAE displays the maximum and/or minimum base solution targets. Abaqus/CAE displays a dash if you selected **Default methods and parameters** or **Auto** if you selected **Automatic target reduction**.
   - The sizing method used by the rule.

3. If desired, click **Display Error**.

   Abaqus/CAE displays the percentage **Error Indicator Result** and the **Element Count** for each error indicator output variable. The element count is the number of elements in the region to which the remeshing rule is applied.

4. Click **Manual Adaptive Remesh**.

   Abaqus/CAE remeshes the model. All of the active (not suppressed) remeshing rules contribute to the remeshing of the model. If you applied more than one remeshing rule to the same region, the rule that results in the finest mesh takes precedence.

5. If desired, you can select **Adaptivity->Remeshing Rule->Edit->*rule name*** from the main menu and modify the parameters that define the rule. You can then return to the **Manual Adaptive Remesh** dialog box and view the effect of the modified rule on the error estimate and the resulting mesh.

   Note:

   When you edit a remeshing rule, you can modify parameters such as the remeshing rule sizing method and constraints on the element size and view the effect of your changes on the resulting mesh. However, if you change the step or the error indicator output variables, you must run the analysis again.

6. You can modify the remeshing rules and remesh your model manually until you are satisfied with the resulting mesh. You can then use the same rules to drive a sequence of iterative remeshing operations that are controlled by Abaqus/CAE. For more information, see *Creating, editing, and manipulating adaptivity processes*.

The Optimization module

You use the Optimization module to create an optimization task that can be used to optimize the topology or shape of your model given a set of objectives and a set of restrictions. For example, an optimization can attempt to remove material from selected regions to satisfy a maximum weight objective while maintaining a minimum stiffness.

In this section:

- *Understanding the role of the Optimization module*
- *Entering and exiting the Optimization module*
- *Understanding optimization*
- *Using the Optimization module toolbox*
- *Viewing and troubleshooting an optimization*
- *Creating and configuring an optimization task*
- *Configuring design responses*
- *Creating objective functions*
- *Creating constraints*
- *Configuring geometric restrictions*
- *Creating local stop conditions*

Understanding the role of the Optimization module

You can use the Optimization module to perform the following tasks:

Create optimization tasks

An optimization task contains the definition of your optimization. You run an optimization in the Job module using an optimization process. An optimization process refers to an optimization task.

Create design responses

A design response is a single scalar value that is extracted from an optimization. A design response can be extracted directly from the output database, such as the volume of the model. Alternatively, the Optimization module can extract data from the output database and calculate the design response, such as the total strain energy of the model, a measure of its flexibility.

Create objective functions

An objective function defines the objective of the optimization and refers to the value of a design response or a combination of design responses. For example, the objective function of the optimization can be to minimize the total strain energy in the model (maximize its stiffness).

Create constraints

Constraints define the changes that the Optimization module can apply to the topology or the shape of the model during the optimization. For example, the volume of the optimized model can be constrained to be 50% of the original volume. If a constraint cannot be satisfied, the optimization is not feasible. A constraint also refers to the value of a design response, but it cannot refer to a combination of design responses.

Create geometric restrictions

A geometric restriction places restrictions on the changes that the Optimization module can make to the topology of the model. Geometrical restrictions include frozen regions from which material cannot be removed and manufacturing constraints, such as restrictions on cavities and undercuts, that would prevent the optimized model from being removed from a mold.

Create stop conditions

A stop condition is an indicator that the optimization has converged to a solution. For example, an optimization can be considered complete after a specified number of iterations or when the change in an optimization function between iterations is less than a specified value.

Entering and exiting the Optimization module

You can enter the Optimization module at any time during an Abaqus/CAE session by clicking **Optimization** in the **Module** list located in the context bar. The **Task**, **Design Response**, **Objective Function**, **Constraint**, **Geometric Restriction**, **Stop Condition**, and **Tools** menus appear on the main menu bar. If the current viewport contains something other than the assembly, the contents of the viewport disappear when you start the Step module.

To exit the Optimization module, select any other module from the **Module** list. You need not save your optimization definition before exiting the module; it will be saved automatically when you save the model database by selecting **File**->**Save** or **File**->**Save As** from the main menu bar.

Understanding optimization

An optimization is an iterative process that modifies the structure of your model while it searches for an optimized solution given a set of objectives and constraints that must be satisfied. This section briefly describes the components of an optimization that you can create with the Optimization module.
For more detailed information, see *About Structural Optimization*.

In this section:

- *About tasks*
- *About design responses*
- *About objective functions*
- *About constraints*
- *About geometric restrictions*
- *About stop conditions*
- *About optimization processes*

About tasks

An optimization task contains the components that define your optimization, such as the design responses, objectives, constraints, and geometric restrictions. To run an optimization, you execute an optimization process. An optimization process refers to an optimization task.

For more information, see *Creating an optimization task*.

About design responses

The inputs to your optimization are called the design responses. Design responses can be read from the Abaqus output database file; for example, stiffness, stresses, eigenfrequencies, and displacements. Alternatively, the Optimization module can extract the design responses from the position of nodes or the layout of elements in your model; for example, its weight, center of mass, or inertia.

A design response is associated with a region of your model; however, it consists of a single scalar value, such as the maximum stress in a region or the total volume of the model. In addition, a design response can be associated with a particular step or load case. For more information, see *Configuring design responses*, and *Design Responses*.

About objective functions

The objective functions define the objective of your optimization. The objective function is extracted from a design response, such as the lowest eigenfrequencies or the minimum stress. The objective function can be formulated from multiple design responses. If you specify that the objective functions minimize or maximize the design responses, the Optimization module calculates the objective function by adding each of the values determined from the design responses. In addition, you can specify a weighting factor (the default weighting factor is 1.0). For the most common optimization formulations you do not need to change the default value of the weighting factor. However, in some cases you may have to change the weighting factor to balance the effect of an objective function that is dominating the optimization. You should be aware that changing the weighting factor can have a significant impact on the final design. In addition, a design response that is dominant at the start of the optimization may have less effect as the Optimization module modifies your model. For more information, see *Creating objective functions*, and *Objectives and Constraints*.

About constraints

Constraints are also extracted from the design responses. Constraints restrict the value of a design response; for example, you can specify that the volume must be reduced by 45% or the absolute displacement in a region must not exceed 1 mm. You can also apply manufacturing and geometric constraints that are independent of the optimization; for example, a structure must be able to be cast or stamped or the diameter of a bearing surface cannot be changed.

When you execute an optimization process, Abaqus generates history output from the constraints you defined in the Optimization module. For volume design responses the history output is always reported as a fraction of the initial value. For all other design responses the history output is reported as an absolute value.

Satisfying the constraints has priority over the minimization or maximization of the objective function. The optimization algorithms start to maximize or minimize the objectives only after the constraints are satisfied.

You can specify only a volume constraint for a condition-based topology or shape optimization, and the volume constraint must be either equal to a fixed value or a fraction of the value before the optimization starts. If the requested volume differs greatly from the initial volume, the Optimization module may need several design cycles to satisfy the volume constraint. A general topology optimization provides more flexibility; and you can select any of the design responses as a constraint, except for the design response that calculates the eigenfrequencies with the Kreisselmeier-Steinhauser formula. The constraint in a general topology optimization can be less than, greater than, or equal to a fixed value or a fraction of the value before the optimization starts. For more information, see *Creating constraints*, and *Objectives and Constraints*.

About geometric restrictions

Geometric restrictions are manufacturing and geometric constraints that are independent of the optimization; for example, a structure must be able to be cast or stamped or the diameter of a bearing surface cannot be changed. For more information, see *Configuring geometric restrictions*, and *Objectives and Constraints*.

About stop conditions

A global stop condition defines the maximum number of iterations an optimization should perform. A local stop condition specifies that the optimization should end when a local minimum (or maximum) has been reached. For more information, see *Creating local stop conditions*, and *Objectives and Constraints*.

About optimization processes

You create optimization processes in the Job module. An optimization process reads an optimization task that you defined in the Optimization module and iteratively searches for an optimized solution based on the objective functions and constraints that you defined in the optimization task. For more information, see *What is an optimization process?*. You can use a view cut in the Visualization module to view the results of an optimization process. For more information, see *Cutting through a model*.

Using the Optimization module toolbox

You can access all the Optimization module tools through either the main menu bar or through the Optimization module toolbox. *Figure 1* shows the icons for all the Optimization module tools in the toolbox.

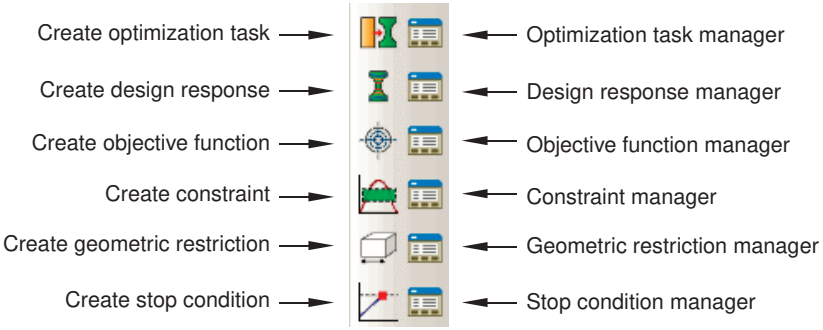

Figure 1: The Optimization module tools.

To see a tooltip containing a brief definition of an Optimization module tool, hold the mouse over the tool for a moment. For information on using toolboxes and selecting hidden icons, see *Using toolboxes and toolbars that contain hidden icons*.

Viewing and troubleshooting an optimization

You can use the field and history output generated by Abaqus to view the results generated by your optimization process. You can also use the output to diagnose any problems with the optimization; for example, to determine if the optimization is converging on an objective or to study the rate of convergence. You view the results by clicking **Results** in the **Optimization Process Manager**.

When you submit an optimization process for analysis, Abaqus creates an output database (`.odb`) file for each design cycle of the optimization. The output database files are stored in the *jobname*`\SAVE.odb` directory. You must combine the separate output database files into a single output database file before you can view the optimization in the Visualization module. The behavior of the Visualization module depends on whether the output database file was created from a topology optimization, a shape optimization, a sizing optimization, or a bead optimization.

Topology optimization

When you view the results of a topology optimization, Abaqus/CAE automatically displays a view cut superimposed on the current view that represents the optimized design surface. The isosurface variable of the view cut is the normalized material property that the Optimization module uses to "add" or "remove" elements from the analysis. By default, Abaqus/CAE displays the view cut with the normalized material property set to 0.3. You can use the view cut manager to modify the value of the isosurface variable and to view the resulting boundary of the isosurface. Boundary conditions are not displayed while an optimization view cut is active. For more information, see *Managing view cuts*.

Shape optimization

When you view the results of a shape optimization, Abaqus/CAE displays the model in its optimized shape using the new position of the surface nodes.

Sizing optimization

When you view the results of a sizing optimization, Abaqus/CAE displays the shell model and the optimized shell thickness, which varies as the optimization progresses. (When you view the results of a nonoptimized analysis of a shell model, the shell thickness is read from the model data and does not change during the analysis.)

Bead optimization

When you view the results of a bead optimization, Abaqus/CAE displays the shell model in its optimized shape using the new position of the surface nodes.

After you combine the separate output database files into a single output database file, each design cycle in the optimization process appears as a frame in the output database, and you can open the **Step/Frame** dialog box to display the results from each design cycle. You can view the results of an optimization process while it is still in progress. As the optimization process moves toward completion, the lists of completed steps and frames are updated every time you close and reopen the **Step/Frame** dialog box. For more information, see *Selecting a specific results step and frame*, and *Stepping through frames*.

You can perform a time history animation of a deformed or contour plot and view the progress of the optimization as Abaqus attempts to satisfy the objective functions while respecting the constraints. For a topology optimization you can view the progressive removal of elements from the analysis and the resulting effect on the mechanical behavior of the model, such as the change in deformation or stress. Turning on translucency allows you to see the progression of the optimization through interior elements; for example, the removal of interior elements to create voids. For more information, see *Changing the translucency*. For a shape optimization you can view the incremental change in the position of the surface nodes as the optimization progresses; and, similar to a topology optimization, you can view the resulting effect on the mechanical behavior of the model.

In addition, the optimization process writes data files (`optimization_report.csv` and `optimization_status_all.csv`) to the *jobname* directory that you can use to track the design variables. For example, you can create an *X–Y* plot showing how the objective functions and constraints change after each design cycle. The resulting plot indicates how the Optimization module tries to meet the specified objective functions while satisfying the constraints. You can use an *X–Y* plot of the objective functions and constraints as a diagnostic tool to view the progression of the optimization after each design cycle and to determine if the optimization is converging on a solution, as shown in *Figure 1*.

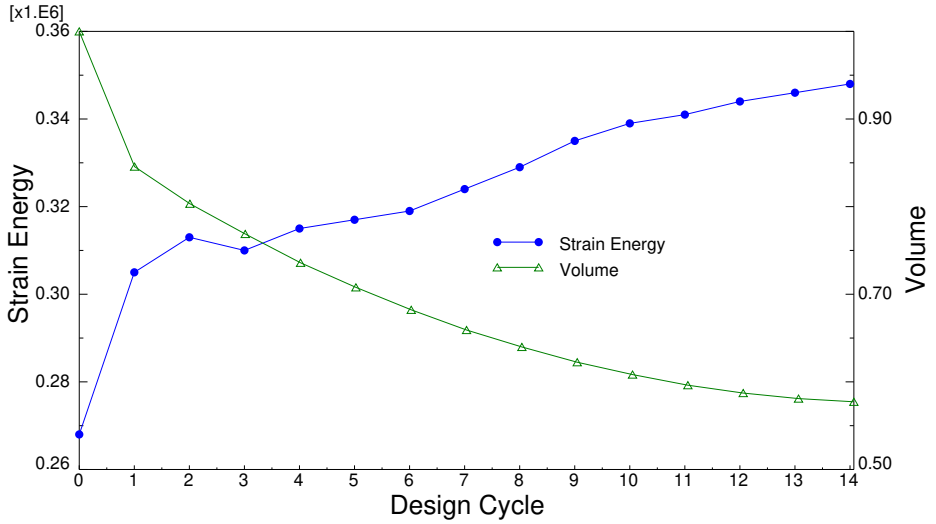

Figure 1: The design objective and constraint during an optimization.

You can also view an *X–Y* plot showing how the objective function and constraints change after each design cycle by monitoring the progress of an optimization process from the optimization process manager. See *Monitoring your optimization process*, for more information.

Additional information

- *Understanding X–Y plotting*

Creating and configuring an optimization task

You can create and configure an optimization task. An optimization task contains the definition of your optimization.

In this section:

- *Creating an optimization task*
- *Configuring a topology optimization task*
- *Configuring a shape optimization task*
- *Configuring a sizing optimization task*
- *Configuring a bead optimization task*

Creating an optimization task

You can create a topology optimization task. An optimization task contains the definition of your optimization, such as the design responses, objectives, constraints, and geometric restrictions. To run an optimization, you create an optimization process in the Job module. An optimization process refers to an optimization task.

1. From the main menu bar, select **Task->Create**.

   The **Create Optimization Task** dialog box appears.

   Tip: You can initiate the **Create** procedure in two other ways:

   - Click **Create** in the **Optimization Task Manager**. (You can display the **Optimization Task Manager** by selecting **Task->Manager** from the main menu bar.)
   - Click the  tool in the Optimization module toolbox.

2. From the **Create Optimization Task** dialog box that appears, enter the name of the task.
3. Select the optimization **Type** (**Topology optimization**, **Shape optimization**, **Sizing optimization**, or **Bead optimization**), and click **Continue**. For more information, see *About Structural Optimization*.
4. From the viewport, select the region that will be optimized or click **Done** to optimize the entire model.

   By default, Abaqus/CAE allows you to select all of the model. To select faces or cells, use the **Selection** toolbar to change the type of object that you can select to **Face** or **Cells**. For more information, see *Filtering your selection based on the type of object*.

   The **Edit Optimization Task** dialog box appears.

   If you would rather select from a list of existing sets, do the following:

   a. Click **Sets** on the right side of the prompt area.

      Abaqus/CAE displays the **Region Selection** dialog box containing a list of available sets.

   b. Select the set of interest, and click **Continue**.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click the button—**Select in Viewport** or **Sets**—on the right side of the prompt area.

5. When you have finished selecting the optimization region, click **Done** in the prompt area. For more information on selecting objects, see *Selecting objects within the viewport*."
6. Configure the optimization task, as described in *Configuring a topology optimization task*, *Configuring a shape optimization task*, *Configuring a sizing optimization task*, and *Configuring a bead optimization task*.

Additional information

- *Configuring a topology optimization task*
- *Configuring a shape optimization task*
- *Configuring a sizing optimization task*
- *Configuring a bead optimization task*

Configuring a topology optimization task

The Optimization module provides a variety of settings that allow you to configure a topology optimization task. The configuration settings depend on whether you are configuring an optimization task for a general topology optimization or a condition-based topology optimization.

In this section:

- *Configuring a general topology optimization task*
- *Configuring a condition-based topology optimization task*

Configuring a general topology optimization task

A general topology optimization is a flexible, sensitivity-based optimization that allows you to apply a range of constraints and objective functions to your model. You use the optimization task editor to customize various aspects of a general topology optimization.
To locate the editor, select **Task->Edit->*optimization task name*** from the main menu bar. To specify a general topology optimization, select the **Advanced** tab and choose **General optimization (sensitivity-based)**.

In this section:

- *Configuring basic settings*
- *Configuring the density settings*
- *Configuring the perturbation settings*
- *Configuring convergence options*
- *Configuring advanced options*

Configuring basic settings

You can configure a general topology optimization.

1. In the optimization task editor, click the **Basic** tab.
2. Choose whether to freeze load or boundary condition regions.

   It is recommended that you freeze regions to which prescribed conditions are applied because you do not want these regions to be removed during the optimization. Freezing these regions stabilizes the optimization and often leads to a significantly lower number of iterations.

Configuring the density settings

You can configure a general topology optimization.

1. In the optimization task editor, click the **Density** tab.
2. Select the **Density update strategy**.

   This setting controls the rate at which the Optimization module updates the relative material density of design elements during the optimization. In most cases you should accept the default setting (**Normal**). However, if the design responses are very sensitive and you have problems fulfilling the constraints, you may need a more conservative rate that requires more optimization iterations.
3. Do either of the following to specify the relative density of each element during the initial optimization iteration:

   - Select **Optimization product default** to allow the Optimization module to determine the initial density. If the material volume is selected as a constraint, the Optimization module calculates the initial density such that the volume constraint is fulfilled exactly. If the material volume is selected as an objective function, each element has an initial relative density of 50%.
   - Select **Specify** and enter a value ($0.0 < \textit{initial density} \quad 1.0$). You should use this option only if volume is selected as an objective function and not as a constraint and if you know, prior to the optimization, that setting the initial density to a larger or smaller value will fulfill other constraints; for example, displacement constraints. You can use a value greater that 0.5 in conjunction with volume constraints to stabilize nonlinear or contact problems and to improve the convergence behavior.
4. Enter the **Minimum density**, the **Maximum density**, and the **Maximum change per design cycle**.

   The minimum density must be greater than 0.0, and the maximum density must be less than or equal to 1.0. Changing the density bounds is not recommended, in particular the upper bound. You may need to increase the lower bound if the default value leads to a nearly singular stiffness matrix.

   Numerical experiments indicate that a value of 0.25 (default) is acceptable for the maximum change in density. A lower limit in the change of density, such as 0.1, is recommended for complicated design responses and optimization formulations. However, a lower limit often leads to a higher number of optimization iterations.

Configuring the perturbation settings

You can configure a general topology optimization.

1. In the optimization task editor, click the **Perturbation** tab.
2. Enter the number of eigenmodes to track. The default value is five, which means that the Optimization module tracks the five lowest eigenfrequencies.

   In some cases many local low frequency eigenmodes appear during the optimization iterations, which leads to a high number of modes to track and degrades performance. You can avoid tracking a high number of modes by choosing the lower bound of the eigenfrequencies to be 25% of the eigenfrequency of interest in the first optimization iteration.

   Mode tracking is not required if your design response will use the Kreisselmeier-Steinhauser formulation to evaluate the eigenfrequencies. Your Abaqus model must include an output request for at least the number of eigenfrequencies you are tracking.
3. Select the region over which the Optimization module should track the eigenmodes.

   By default, the Optimization module tracks the eigenmodes of all the nodes in the model, which can degrade performance if you have a large model. You can improve the performance by tracking the eigenmodes over only a selected region; for example, over selected surfaces of your model or over points where lumped or rigid masses are attached.

Configuring convergence options

You can configure a general topology optimization.

1. In the optimization task editor, click the **Convergence** tab.
2. Specify the **Convergence Criteria**. The following options allow you to specify the convergence criteria for a general topology optimization:

Specifying when to start checking for convergence

You can specify the iteration during which the Optimization module will begin to check the two convergence criteria. The optimization will always continue at least until this value has been reached. The default value is 4.

Specifying which convergence criterion to check

You can specify whether the optimization should end when either of the convergence criterion has been fulfilled or both of the criteria have been fulfilled. The default value is that both criteria must be fulfilled.

Convergence based on the change in optimization function

You can specify that the optimization will end based on the change in the objective function from one iteration to the next. The default value is 0.001.

Convergence based on the change in element densities

Element density is the design variable for a topology optimization. You can specify that the optimization will end based on the average change in the element density from one iteration to the next. The default value is 0.005.

Configuring advanced options

You can configure a general topology optimization.

1. In the optimization task editor, click the **Advanced** tab.
2. Select the **General optimization** algorithm.
3. Choose whether to **Delete soft elements in region**.

   During the topology optimization process, the Optimization module distributes a given mass within the design area while it tries to satisfy the constraints and optimize the objective. At the end of the optimization, the structure contains hard (filled) and soft (void) elements. The soft elements have a negligible influence on the stiffness of the structure; but they are still relevant for the number of degrees of freedom of the structure and, hence, influence the speed of the optimization process. The **Delete soft elements** option allows you to select a region from which soft elements that have only soft neighboring elements will be removed. The deleted elements are reactivated if needed; for example, if the force flow changes during the optimization.

   Choosing to delete soft elements can help Abaqus converge on a solution because those elements would otherwise degenerate or collapse and is recommended when you are optimizing a nonlinear model. In addition, selecting a **Conservative** density update strategy and a small change in density per design cycle will improve the accuracy of the results. See *Configuring the density settings*, for more information.
4. If you chose to delete soft elements, you can prevent isolated soft elements from being removed by choosing to delete only soft elements that have neighboring soft elements. You can define a neighboring element as being within the radius specified by the **Average edge length** (default) or specified by a value that you enter. If the element edge length varies considerably within the mesh, the radius calculated from the average edge length can be misleading.
5. If you chose to delete soft elements, you can select the method that the Optimization module will use to delete elements:

Favor continuity (Standard)

Choose **Favor continuity (Standard)** and enter a **Relative material density threshold** to check for continuity before deleting soft elements. If the optimized model contains an “island” of hard elements that are separated from the rest of the model by soft elements, the Optimization module does not remove the soft elements. In addition, the Optimization module retains soft elements that are preventing hard elements from moving with respect to each other; for example, hard elements that share a common edge but not a common face. An element is considered “soft” if its relative material density is less than the threshold value, and the Optimization module removes it from the analysis.

Favor continuity (Aggressive)

Choose **Favor continuity (Aggressive)** and enter a **Relative material density threshold** to remove soft elements regardless of continuity. An element is considered “soft” if its relative material density is less than the threshold value, and the Optimization module removes it from the analysis.

Maximum shear strain

Choose **Maximum shear strain** and enter a **Maximum shear strain threshold**. The Optimization module removes elements from the analysis that have a shear strain larger than the threshold.

Minimum principal strain

Choose **Minimum principal strain** and enter a **Minimum principal strain threshold**. The Optimization module removes elements that have a principal strain lower than the threshold.

Maximum elastoplastic strain

Choose **Maximum elastoplastic strain** and enter a **Maximum elastoplastic strain threshold**. The Optimization module removes elements that have an elastoplastic strain larger than the threshold.

Volume compression

Choose **Volume compression** and enter a **Relative volume compression**. The Optimization module removes elements that are compressing and have a relative volume that is lower than the threshold. The relative volume V_{rel} is defined as $\frac{V_{deform}-V_{org}}{V_{org}}$, where V_{deform} is the deformed element volume and V_{org} is the original element volume.

You should choose **Volume compression** if your model uses shell or membrane elements or if your model is experiencing large deformations.

Note:

The soft delete method that you select is dependent on the material behavior and the element type, and you might have to experiment to determine the best method and its threshold value. The file, `TOSCA.OUT`, contains information about the elements that are being removed and will help you determine the best soft delete method and threshold value. The **Favor continuity** methods provide a default **Relative material density threshold** of 0.05. In contrast, the strain and volume methods do not provide a default threshold because the appropriate value depends on your model; for example, on the properties of the materials.

6. Choose the **Material interpolation technique** and the **Penalty factor**.

   Optimization generates hard elements with a density close to one or void elements with a density close to zero. Topology optimization introduces elements with a density between one and zero, and the material interpolation technique calculates the relationship between density and stiffness for these intermediate elements. The **SIMP** (solid isotropic material with penalization) interpolation scheme defines an exponential relationship between the density and the stiffness of an element and is suitable for static problems. The penalty factor should be greater than `1`, and numerical experiments indicate that the default value of 3 produces good results. The **RAMP** (rational approximation of material properties) interpolation scheme is suitable for dynamic problems. The penalty factor should be greater than 0, and numerical experiments indicate that the default value of 3 produces good results. The **MIMP** material interpolation is a combination of the SIMP for the constitutive material interpolation and a new material interpolation for the physical density.

   By default, the Optimization module selects the **SIMP** interpolation scheme for static problems and the interpolation scheme is switched to **PEDE** automatically by TOSCA if at least one dynamic load case appears in your model.

7. You can choose **Use Abaqus sensitivities when possible** to use Abaqus to compute the design responses and their sensitivities whenever possible. This workflow modification improves the optimization process performance.

8. Select **Use Group Operator when possible** to use large groups of more than 5000 elements or nodes in the design response definition in an efficient way. This workflow modification uses a new algorithm based on Abaqus sensitivities.

Configuring a condition-based topology optimization task

A condition-based topology optimization uses a strain energy objective function and a volume constraint. You use the optimization task editor to customize various aspects of the condition-based topology optimization. To locate the editor, select **Task->Edit->*optimization task name*** from the main menu bar. To specify a condition-based topology optimization, select the **Advanced** tab and choose **Condition-based optimization**.

In this section:

- *Configuring basic settings*
- *Configuring advanced options*

Configuring basic settings

You can configure a condition-based topology optimization.

1. In the optimization task editor, click the **Basic** tab.
2. Choose whether to freeze load or boundary condition regions.

   It is recommended that you freeze regions to which prescribed conditions are applied because you do not want these regions to be removed during the optimization. Freezing these regions stabilizes the optimization and often leads to a significantly lower number of iterations.

Configuring advanced options

You can configure a condition-based topology optimization.

1. In the optimization task editor, click the **Advanced** tab.
2. Select the **Condition-based optimization** algorithm.
3. Select the rate at which the Optimization module will modify the element properties during a topology optimization. You can select the rate (**Very small**, **Small**, **Moderate**, **Medium**, or **Large**) and allow the Optimization module to calculate the number of design cycles required to meet this rate.

   Alternatively, you can select **Dynamic** and enter the maximum number of design cycles. The minimum number of design cycles is 10, and the default value is 15. A reduction in the number of design cycles can lead to undesired effects in the optimization. Although the resulting structures have the same stiffness (the sum of the strain energy is almost equal for the different results), changing the optimization speed can cause a different truss configuration in the solution.
4. Select the volume deleted after the first cycle. You can enter a percentage or an absolute value.

   By default, the Optimization module removes 5% of the optimization region volume in the first iteration. In some cases increasing this starting value will accelerate the optimization without influencing the solution, especially for models where relatively low stresses are present in large areas. Conversely, the Optimization module may remove too many elements in the first iteration if the starting value is too high, leading to a failure in the optimization or a coarse structure.

Configuring a shape optimization task

Shape optimization determines the displacement of each surface node in an effort to homogenize the stress on the surface and satisfy the objective function and any constraints.
You can use the optimization task editor to customize various aspects of the shape optimization and to incorporate durability analysis into the optimization. You can specify a condition-based shape optimization (default) or a general (sensitivity-based) shape optimization.

To locate the editor, select **Task**->**Edit**->***optimization task name*** from the main menu bar. The default settings for shape tasks provide reasonable results across a variety of optimization models; and, in most cases, you do not need to modify the default settings.

In this section:

- *Configuring basic settings*
- *Configuring mesh smoothing quality*
- *Configuring advanced options*
- *Configuring durability options*

Configuring basic settings

During a shape optimization the Optimization module modifies the surface of your model. If the Optimization module modifies only the surface nodes without adjusting the inner nodes, the layer of surface elements will become distorted. Therefore, the results of the Abaqus analysis will no longer be reliable, and the quality of the optimization will suffer. To maintain the quality of the surface elements, the Optimization module applies mesh smoothing to selected regions, which adjusts the position of the inner nodes in relation to the surface nodes. For more information, see *Applying Mesh Smoothing to a Shape Optimization*.

The Optimization module can apply mesh smoothing only to triangular, quadrilateral, and tetrahedral elements. Other element types are ignored during the mesh smoothing.

Note:

It is important to have a good quality finite element mesh before you start the shape optimization, especially in areas where you expect the shape to change.

1. In the optimization task editor, click the **Basic** tab.
2. Choose whether to freeze boundary condition regions.

   Regions to which you have applied a displacement boundary condition in the Load module have the same displacement boundary condition during the optimization. The coordinate system that governs the displacement boundary condition in the Load module is used to govern the boundary condition in the optimization.
3. By default, the Optimization module freezes boundary conditions for the whole model. If desired, click  and select the region in which the boundary conditions should be frozen.
4. Select the region to which the mesh smoothing will be applied:

   - Select **Specify smoothing region** (default), and click  to select the region. You can apply mesh smoothing to cells or faces.
   - Select **Specify first layer**, and click  to select the faces representing the first layer of elements to smooth. Enter the number of element layers to smooth.
   - Select **Smooth six layers using the task region** to smooth six layers of elements of the design region.

   It is recommended that you accept the default selection and manually select the region to which mesh smoothing will be applied.
5. Select the number of layers of nodes adjacent to the design region that should be allowed to move during the mesh smoothing operation:

   - Select **Fix all** (default) to prevent free surface nodes from moving.
   - Select **Fix none** to allow all the free surface nodes to move.
   - Select **Specify** and enter the number of adjacent layers of free surface nodes that should be allowed to move.

Configuring mesh smoothing quality

Mesh smoothing attempts to improve the quality of the mesh despite the mesh distortion that results from the displacement of the design nodes during the shape optimization. You can specify the relative quality of the smoothed mesh, and you can specify the range of angles (quadrilateral and triangular elements) or the range of aspect ratios (tetrahedral elements) that define an element that is considered good quality. Elements that are considered poor are given a quality rating. The poorer an element is rated, the greater the consideration it will be given in improving the element quality.

1. In the optimization task editor for a shape optimization, click the **Mesh Smoothing Quality** tab.
2. Do either of the following:
   - Toggle on **Target mesh quality**, and select a setting (**Low**, **Medium**, or **High**).

     In most cases you should accept the default setting of **Low**. You should select a higher convergence level only after you have determined the mesh quality is not satisfactory. Even though it is computationally expensive, you may want to select a higher convergence level if your mesh contains a large number of tetrahedral elements; otherwise, the mesh quality may not be acceptable.

     If you are unable to obtain a satisfactory mesh quality, even with a convergence level of **High**, you should consider reducing the amount of displacement during the shape optimization by reducing the **Growth scale factor** and the **Shrink scale factor**, as described in *Configuring advanced options*.
   - Toggle off **Target mesh quality** to deactivate the algorithm that calculates the element quality.
3. Toggle on **Report poor quality elements** to generate a list of elements that fall outside the ranges defined in the element quality table.
4. Toggle on **Report solver quality criteria violation** to report elements that Abaqus considers to be of poor quality.
5. If you toggled on **Report solver quality criteria violation**, you can choose to stop the optimization process if Abaqus encounters elements of poor quality. It is possible that the Optimization module will generate a poor quality mesh that will not allow the Abaqus analysis to complete successfully, especially as the number of design cycles increases. If Abaqus stops the analysis prematurely, no results are available to the Optimization module, and the optimization ends prematurely. If you allow the Optimization module to stop the optimization because the Abaqus element quality criteria is violated, it will be easier for you to troubleshoot the optimization and determine why it failed.
6. If you chose to allow the Optimization module to adjust mesh quality, you can use the table to specify the range of angles (quadrilateral and triangular elements) or the range of aspect ratios (tetrahedral elements) that define an element that is considered good quality. You can also enter the maximum skew angle for quadrilateral and tetrahedral elements and the maximum taper for quadrilateral elements. In most cases, you should not modify the default values. Modifying the range of angles or aspect ratios has a minimal effect on the quality of the mesh. You should try to match the acceptable mesh quality in the Optimization module with the acceptable mesh quality in Abaqus. It is preferable to have your optimization process end because of degrading mesh quality rather than allowing Abaqus to end the optimization process or generate meaningless results.
7. Choose the strategy or algorithm that the mesh smoothing operation will use. By default, the Optimization module uses the **Constrained Laplacian** mesh smoothing algorithm. If you have a relatively small model (less than 1000 nodes in the mesh smooth area), you can select the **Local gradient** mesh smoothing algorithm.
8. If you selected a strategy of **Constrained Laplacian**, do the following:
   a. Select the **Convergence level**, a measure of the amount of time the Optimization module should spend trying to improve the quality of the mesh. In most cases you should accept the default value of **Low**, which results in the Optimization module applying a few iterations with large increments. Selecting **Medium** or **High** will result in more iterations with smaller increments; however, the

computational time will increase significantly. You should use the **Mesh Smoothing Quality** tabbed page to adjust the target mesh quality before you modify the convergence level.

b. Select the **Frequency of evaluating geometric restrictions**, which determines how often the Optimization module applies any geometric restrictions while the mesh smoothing algorithm is executing. In most cases you should accept the default value of **Low**. Selecting **Medium** or **High** will result in the Optimization module applying the geometric restrictions more often, and the computation time will increase significantly.

9. If you selected a strategy of **Local gradient**, enter the **Feature recognition angle**, which is the angle that the Optimization module uses during the mesh smoothing operation to recognize features by detecting edges and corners. The default value is 30°, which provides good results in most cases.

Configuring advanced options

You can configure a shape optimization task.

1. In the optimization task editor, click the **Advanced** tab.
2. Choose the shape optimization algorithm.
   - Select **General optimization (sensitivity-based)** to use a sensitivity-based shape optimization that allows you to apply a range of constraints and objective functions to your model.
   - Select **Condition-based optimization** (default) to use a condition-based shape optimization that uses a strain energy objective function and volume constraint.
3. Enter values specifying the **Growth scale factor** and the **Shrink scale factor**. The growth scale factor is applied to the displacement of nodes that are growing (increasing the volume of the model) as a result of the shape optimization. The shrink scale factor is applied to the displacements of nodes that are shrinking (decreasing the volume of the model) as a result of the shape optimization.

   It is recommended that you perform an optimization with default scale factors of 1.0 and examine the results before you attempt an optimization with modified scale factors. A value greater than 1.0 increases the incremental displacement of nodes and accelerates the optimization. Conversely, a value less than 1.0 decreases the incremental displacement of nodes and slows down the optimization.

   You should consider increasing the scale factors if the first few iterations of the optimization produce little change in the position of the surface nodes; for example, if you have a dense mesh with small element edge lengths. Conversely, if the scale factor is too large, mesh quality will suffer, individual elements might collapse, and the optimization might not be able to converge on the optimal solution.

   You should consider decreasing the scale factors if the original model is close to being optimal. Decreasing the scale factor and slowing down the optimization is also beneficial when the optimization includes many geometric restrictions and when the beginning mesh quality is poor.

   To optimize regions that are in contact, you might want to enter a negative value to reverse the direction of the optimization. As a result, areas of high stress will shrink and areas of low stress will grow.
4. Choose whether to update the optimization shape vectors after every optimization cycle (default) or only after the first cycle.

   The Optimization module determines an optimization displacement vector for every node in the design area. The vector lies along the normal to the outer surface at the node and indicates the direction of displacement during the optimization. If you choose to update the optimization shape vectors after every optimization cycle, the Optimization module adjusts the vectors to account for changing conditions, such as changes in the shape of the structure, the mesh quality, and design variable restrictions. If you choose to update the optimization shape vectors only after the first optimization cycle, the vectors remain fixed in subsequent cycles.

   In most cases, the default value of updating the optimization shape vectors after every optimization cycle provides better results because the mesh smoothing algorithm is less restricted, resulting in an improved mesh quality.
5. Choose whether the step size should be determined by the minimum displacement of the nodes in the design area during the optimization or the average displacement.

   The Optimization module examines your mesh and limits the amount of displacement of the nodes in the design area during each optimization cycle. This limit prevents the large displacement of one node from causing the collapse of a neighboring element. In addition, the condition-based optimization algorithm provides control of the displacement of the nodes in the design area after every design cycle—the step size. The step size depends on the limit that the Optimization module has applied to the nodes. For example, if the Optimization module decreases the allowed displacement, the condition-based optimization algorithm decreases the increment size.

This option allows you to choose which displacement is used by the condition-based optimization algorithm to determine the step size. You can choose the average value of the allowed displacement of the nodes in the design area during the optimization or the minimum value (default). Selecting the average value results in a larger step size and a faster calculation of the optimum solution. However, selecting the average value can result in limited displacement of nodes for which only small displacements are allowed causing undesirable corners in the design area.

6. Choose the method that the Optimization module will use to interpolate the midside nodes.

   If you select **Linearly by position** (default), the optimization linearly interpolates the position of the midside node from the optimized position of the connected corner nodes. If you select **By optimization displacement of corner nodes**, the optimization interpolates the position of the midside node from the optimization displacement of the connected corner nodes.

   If the nodes are in their original position, the midside node sits on the line between the corner nodes and there is no difference between the two interpolation methods. However, to prevent element bending, you must select **By optimization displacement of corner nodes**.

7. If desired, toggle on **Edge length for movement vector** and enter a value.

   The Optimization module modifies the displacement of nodes in areas of high curvature to prevent the mesh from collapsing because of a large volume change. In effect, sharp corners are smoothed out. The default value of the minimum element edge length that triggers smoothing is 5.0. A larger value results in a larger radius for the smoothed region.

8. The Optimization module can use a filter to smooth out local stress peaks. You can define the filter function by toggling on **Max. influence radius for equivalent stress** and entering the following:

   - A value for the maximum distance between nodes that are influenced by the filter.
   - A value that determines how much the local surface curvature will be used to adjust the maximum distance between nodes that are influenced by the filter. The default value is 0.2; a smaller value increases the effect of the surface curvature.
   - A weighting value that controls the effect of the filter depending on the distance from the node.

9. Volume is the only constraint you can apply to a shape optimization, and you can specify that the volume be reduced to a specified value or to a fraction of the initial value. The **Equality constraint tolerance** specifies the minimum difference between the specified volume constraint and the calculated volume that results in the Optimization module assuming the solution has converged. The Optimization module compares the absolute value of the difference with the tolerance value you enter. The default value is 0.001.
10. If you selected **General optimization (sensitivity-based)**, you can select **Use Abaqus sensitivities when possible** to use Abaqus to compute the design responses and their sensitivities whenever possible. This workflow modification improves the optimization process performance.
11. If you selected **General optimization (sensitivity-based)**, you can choose **Use Group Operator when possible** to use large groups of more than 5000 elements or nodes in the design response definition in an efficient way. This workflow modification uses a new algorithm based on Abaqus sensitivities.

Configuring durability options

Typically, you use shape optimization to modify the surface geometry of a component to minimize stress concentrations. In most cases reducing the stress levels leads to a significant increase in durability. However, it is possible that the regions of peak stress identified by a static analysis differ from the regions of maximum damage identified from a durability (or damage) analysis and using shape optimization alone to modify the surface geometry might decrease the durability. To avoid this situation, you can incorporate a durability solver in the optimization loop to ensure that you are both reducing stress levels and increasing durability.

To include durability in your optimization, you must enable durability analysis in the optimization task editor and configure the selected durability solver. In addition, you must create a damage design response that will be used as an objective. The objective must attempt to minimize the maximum damage in the critical areas.

1. In the optimization task editor, click the **Durability** tab.
2. Select **Optimize based on durability analysis**.
3. From the **Durability solver** options, select one of the following:

fe-safe	Uses the **fe-safe** durability solver.
FEMFAT	Uses the **FEMFAT** durability solver.
Custom	Allows you to use a Tosca Structure optimization neutral file generated by a durability analysis (ONF 600 or ONF 601). Contact your SIMULIA support office for more information about the format of this file.

4. Select the durability input files that will be read by the durability solver. The durability input files must be located in the working directory.
5. Enter the name of any additional files in the working directory that will be read by the durability solver. If a file is stored outside the working directory, you must provide the path to the file along with the name of the file.

Configuring a sizing optimization task

A sizing optimization is a flexible, sensitivity-based optimization that allows you to apply a range of constraints and objective functions to your model. You use the optimization task editor to customize various aspects of a sizing optimization.
To locate the editor, select **Task**->**Edit**->***optimization task name*** from the main menu bar.

In this section:

- *Configuring basic settings*
- *Configuring the thickness settings*
- *Configuring the perturbation settings*
- *Configuring convergence options*
- *Configuring advanced options*

Configuring basic settings

You can configure a sizing optimization task.

1. In the optimization task editor, click the **Basic** tab.
2. Choose whether to freeze load or boundary condition regions.

   It is recommended that you freeze regions to which prescribed conditions are applied because you do not want these regions to be removed during the optimization. Freezing these regions stabilizes the optimization and often leads to a significantly lower number of iterations.

Configuring the thickness settings

You can configure a sizing optimization task.

1. In the optimization task editor, click the **Thickness** tab.
2. Select the **Thickness update strategy**.

   This setting controls the rate at which the Optimization module updates the shell thickness of design elements during the optimization using the method of moving asymptotes. In most cases you should accept the default setting (**Normal**). However, if the design responses are very sensitive and you have problems fulfilling the constraints, you may need a more conservative rate that requires more optimization iterations. Selecting an aggressive rate may lead to unstable optimization or prevent the optimization from converging on a solution.
3. Enter the **Maximum change per design cycle**.

   This setting controls the limit on the change in shell element thickness during each design cycle.

Configuring the perturbation settings

You can configure a sizing optimization task.

1. In the optimization task editor, click the **Perturbation** tab.
2. Enter the number of eigenmodes to track. The default value is five, which means that the Optimization module tracks the five lowest eigenfrequencies.

   In some cases many local low frequency eigenmodes appear during the optimization iterations, which leads to a high number of modes to track and degrades performance. You can avoid tracking a high number of modes by choosing the lower bound of the eigenfrequencies to be 25% of the eigenfrequency of interest in the first optimization iteration.

   Mode tracking is not required if your design response will use the Kreisselmeier-Steinhauser formulation to evaluate the eigenfrequencies. Your Abaqus model must include an output request for at least the number of eigenfrequencies you are tracking.
3. Select the region over which the Optimization module should track the eigenmodes.

Configuring convergence options

You can configure a sizing optimization task.

1. In the optimization task editor, click the **Convergence** tab.
2. Specify the **Convergence Criteria**. The following options allow you to specify the convergence criteria for a sizing optimization:

Specifying when to start checking for convergence

You can specify the iteration during which the Optimization module will begin to check the two convergence criteria. The optimization will always continue at least until this value has been reached. The default value is 4.

Specifying which convergence criterion to check

You can specify whether the optimization should end when either of the convergence criterion has been fulfilled or both of the criteria have been fulfilled. The default value is that both criteria must be fulfilled.

Convergence based on the change in optimization function

You can specify that the optimization will end based on the change in the objective function from one iteration to the next. The default value is 0.001.

Convergence based on the change in element thickness

Element thickness is the design variable for a sizing optimization. You can specify that the optimization will end based on the average change in the element thickness from one iteration to the next. The default value is 0.005.

Configuring advanced options

You can configure a sizing optimization task.

1. In the optimization task editor, click the **Advanced** tab.
2. Select **Use Abaqus sensitivities when possible** to use Abaqus to compute the design responses and their sensitivities whenever possible. This workflow modification improves the optimization process performance.
3. You can choose **Use Group Operator when possible** to use large groups of more than 5000 elements or nodes in the design response definition in an efficient way. This workflow modification uses a new algorithm based on Abaqus sensitivities.

Configuring a bead optimization task

The Optimization module provides a variety of settings that allow you to configure a bead optimization task. The configuration settings depend on whether you are configuring an optimization task for a condition-based bead optimization (default) or for a general bead optimization.

In this section:

- *Configuring a condition-based bead optimization task*
- *Configuring a general bead optimization task*

Configuring a condition-based bead optimization task

A condition-based bead optimization is based upon a special bending hypothesis and uses special filters to generate beads along the bending trajectories. You use the optimization task editor to customize various aspects of a condition-based bead optimization.
To locate the editor, select **Task->Edit->*optimization task name*** from the main menu bar. To specify a condition-based bead optimization, select the **Advanced** tab and choose **Condition-based optimization**.

In this section:

- *Configuring basic settings*
- *Configuring advanced options*

Configuring basic settings

You can configure a condition-based bead optimization task.

1. In the optimization task editor, click the **Basic** tab.
2. Choose whether to respect boundary conditions that have been applied to the model.

   It is recommended that you freeze regions to which boundary conditions are applied because you do not want these regions to be moved during the optimization. Freezing these regions stabilizes the optimization and often leads to a significantly lower number of iterations.
3. By default, the Optimization module freezes boundary conditions for the whole model. If desired, click  and select the region in which the boundary conditions should be frozen.

Configuring advanced options

You can configure a condition-based bead optimization task.

1. In the optimization task editor, click the **Advanced** tab.
2. Toggle on **Growth direction opposite to shell normal** to reverse the direction of the nodal displacement that forms the bead.
3. By default, the direction in which the nodes are moved to form the bead is determined from the stress state of the model at the start of the optimization—the first cycle. Alternatively, you can specify that the optimization determines the direction in which the nodes are moved after every design cycle.
4. By default, an internally computed value will be used for the bead width. Alternatively, you can specify the absolute value of the width of the bead.
5. Specify the number of iterations the bead optimization will perform. The number of iterations modifies the step size of the optimization. The default value is 2.
6. Specify the following **Penalty Conditions**:

Minimum stress ratio

Enter the value of the minimum von Mises stress ratio to prevent Abaqus/CAE from optimizing regions with very low stresses. Abaqus/CAE does not apply bead optimization in the regions where the von Mises stress is less than the value computed from the specified ratio multiplied by the highest von Mises stress in the design area ($0.0 < \textit{Minimum stress ratio} < 1.0$). The default value is 0.001.

Maximum membrane stress ratio

Enter the value of the maximum membrane stress ratio to prevent Abaqus/CAE from optimizing regions in a predominately membrane, or inplane, stress state (the introduction of a bead in a region under a predominately membrane stress state may make the structure softer).

Abaqus/CAE does not apply bead optimization in regions where the membrane stress is greater than the constant value computed from the maximum bending stress in the original model divided by the specified ratio ($0.0 < \textit{Maximum membrane stress ratio}$). The default value is 1.0.

7. Specify the following **Mesh Smoothing Parameters**:

Curve smooth

Enter the relative value of the radius defining a region of high curvature.

The introduction of a bead during the optimization can squeeze nodes together and result in small elements. For even higher degrees of curvature and large bead heights, the nodes can begin to overlap causing the analysis to fail. To prevent the collapse of the mesh, Abaqus/CAE can modify how it moves nodes while creating a bead in a region of high curvature. High curvature is defined as the radius calculated by multiplying the **Curve smooth** value and the average element edge length in the design area. High values of **Curve smooth** and, hence, a large radius encompassing many elements, can be computationaly expensive. The default value is five times the average element length.

Node smooth

By default, the value for **Node smooth** is $0.25 \times \textit{bead width}$. Alternatively, you can specify the absolute minimum in-plane distance between neighboring nodes during the creation of a bead. Values between 0.0 and $0.5 \times \textit{bead width}$ are allowed.

Node smoothing is applied to prevent sudden changes in displacement of neighboring nodes, especially near the boundary between the design area and the rest of the model or where active design variable constraints are restraining the displacement of nodes.

Configuring a general bead optimization task

A general bead optimization is a flexible, sensitivity-based optimization that allows you to apply a range of constraints and objective functions to your model. The sensitivity-based algorithm does not implement a bead filter; therefore, the optimization may not generate a distinct bead pattern. You use the optimization task editor to customize various aspects of a bead optimization.
To locate the editor, select **Task**->**Edit**->***optimization task name*** from the main menu bar. To specify a general bead optimization, select the **Advanced** tab and choose **General optimization (sensitivity-based)**.

In this section:

- *Configuring basic settings*
- *Configuring the nodal move settings*
- *Configuring the perturbation settings*
- *Configuring advanced options*

Configuring basic settings

You can configure a general bead optimization task.

1. In the optimization task editor, click the **Basic** tab.
2. Choose whether to respect boundary conditions that have been applied to the model.

   It is recommended that you freeze regions to which boundary conditions are applied because you do not want these regions to be moved during the optimization. Freezing these regions stabilizes the optimization and often leads to a significantly lower number of iterations.
3. By default, the Optimization module freezes boundary conditions for the whole model. If desired, click  and select the region in which the boundary conditions should be frozen.

Configuring the nodal move settings

You can configure a general bead optimization task.

1. In the optimization task editor, click the **Nodal Move** tab.
2. Select the **Nodal update strategy**.

   This setting controls the rate at which the Optimization module updates the shell thickness of design elements during the optimization using the method of moving asymptotes. In most cases you should accept the default setting (**Conservative**). However, if the design responses are very sensitive and you have problems fulfilling the constraints, you may need a more aggressive rate that requires more optimization iterations. Selecting an aggressive rate may lead to unstable optimization or prevent the optimization from converging on a solution.
3. Enter the **Nodal move limit**.

   This setting limits the nodal displacement per iteration relative to the maximum displacement prescribed ($0.0 < \textit{Nodal move limit} < 1.0$). The default value is 0.1. If you encounter a difficult optimization problem that is slow to converge, you can reduce the size of each optimization iteration by reducing the **Nodal move limit**.

   Note:

   You prescribe the maximum displacement of a node by specifying the height of the stiffening bead when you create a bead optimization constraint.

Configuring the perturbation settings

You can configure a general bead optimization task.

1. In the optimization task editor, click the **Perturbation** tab.
2. Enter the number of eigenmodes to track. The default value is five, which means that the Optimization module tracks the five lowest eigenfrequencies.

   In some cases many local low frequency eigenmodes appear during the optimization iterations, which leads to a high number of modes to track and degrades performance. You can avoid tracking a high number of modes by choosing the lower bound of the eigenfrequencies to be 25% of the eigenfrequency of interest in the first optimization iteration.

   Mode tracking is not required if your design response will use the Kreisselmeier-Steinhauser formulation to evaluate the eigenfrequencies. Your Abaqus model must include an output request for at least the number of eigenfrequencies you are tracking.
3. Select the region over which the Optimization module should track the eigenmodes. Selecting a region other than the whole model may result in increased performance.

Configuring advanced options

You can configure a general bead optimization task.

1. In the optimization task editor, click the **Advanced** tab.
2. Specify the **Filter Radius** of the Sigmund filter, which smoothes the resulting optimization solution. Changing this value might help you to avoid known problems from fluctuations in sensitivity values. The following options allow you to specify the filter radius for a general bead optimization:

   ### Relative to average edge length

   Enter the relative filter radius. Abaqus/CAE computes the filter radius as the value specified multiplied by the average element length in the design area (the region that will be optimized). The default value is four. A value of zero turns off the filter; the resulting bead optimization might generate an unsmooth result that is numerically optimal but not a realistic physical solution.

   ### Absolute value

   Enter the absolute value of the radius.

3. For the sensitivity calculation, choose whether the optimization should consider only the nodes in the region that will be optimized (default) or all the nodes in the model.
4. Enter the **Bead perturbation**. Abaqus/CAE uses this value to compute a semianalytical sensitivity analysis using a finite difference on the element matrices. The finite difference is computed as the perturbation value specified multiplied by the average element edge length. The default value is 0.0001, which is suitable for most bead optimization problems.
5. Select **Use Abaqus sensitivities when possible** to use Abaqus to compute the design responses and their sensitivities whenever possible. This workflow modification improves the optimization process performance.
6. You can choose **Use Group Operator when possible** to use large groups of more than 5000 elements or nodes in the design response definition in an efficient way. This workflow modification uses a new algorithm based on Abaqus sensitivities.

Configuring design responses

This section describes the design response editor and the options that appear in the design response editor.

In this section:

- *Creating and editing a design response*
- *Selecting the data source of a design response*
- *Combining design responses*

Creating and editing a design response

You use the design response editor to create and configure your design responses. You associate a design response with a region of your model; however, the design response consists of a single scalar value, such as the maximum stress in the region or the total volume of the model. In addition, you can associate a design response with a particular step or a load case within a step. Design responses are used by objective functions and constraints. The design responses that are available depend on the type of optimization task you created; for more information, see *Design Responses*.

A design response can cover multiple models. You can incorporate multiple models into your optimization when linear perturbations about a base state are no longer sufficient as load cases. For example, you can simulate nonlinear load cases (which are not supported by Abaqus/CAE) by creating multiple copies of your nonlinear model and by creating a step in each model during which different loads and boundary conditions are applied. Each model must have the same mesh and the same section assignments, and the models must be open in your Abaqus/CAE session.

1. From the main menu bar, select **Design Response->Create**.

   The **Create Design Response** dialog box appears.

   Tip: You can initiate the **Create** procedure in two other ways:

   - Click **Create** in the **Design Response Manager**. (You can display the **Design Response Manager** by selecting **Design Response->Manager** from the main menu bar.)
   - Click the tool in the Optimization module toolbox.

2. From the prompt area, select the region to which the design response will be applied:

   - Select **Whole Model** (default) to apply the design response to the entire model.
   - Select **Body (elements)**, and select the region to which the design response will be applied. During the optimization, the design response will be applied to the elements in the selected region.
   - Select **Point (nodes)**, and select the region to which the design response will be applied. During the optimization, the design response will be applied to the nodes in the selected region.

   By default, Abaqus/CAE allows you to select all regions of the model. Use the **Selection** toolbar to change the type of object that you can select to **Vertices**, **Edges**, **Faces**, or **Cells**. For more information, see *Filtering your selection based on the type of object*.

   If you would rather select from a list of existing sets, do the following:

   a. Click **Sets** on the right side of the prompt area.

      Abaqus/CAE displays the **Region Selection** dialog box containing a list of available sets.

   b. Select the set of interest, and click **Continue**.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click the button—**Select in Viewport** or **Sets**—on the right side of the prompt area.

3. When you have finished selecting the design response region, click **Done** in the prompt area. For more information on selecting objects, see *Selecting objects within the viewport*."

   The **Edit Design Response** dialog box appears.

4. By default, the Optimization module assumes a design response, such as a displacement along an axis, is defined in the global coordinate system. To change the coordinate system in which the design response is defined, click  for the **CSYS** option and do one of the following:

   - Select an existing datum coordinate system in the viewport.
   - Select an existing datum coordinate system by name.
     1. From the prompt area, click **Datum CSYS List** to display a list of datum coordinate systems.
     2. Select a name from the list, and click **OK**.
   - Click **Use Global CSYS** from the prompt area to revert to the global coordinate system.

   Alternatively, click  to define a new datum coordinate system.
5. From the **Edit Design Response** dialog box, select the **Variable** tabbed page.
6. Select the variable and, if applicable, its component.

   Note:

   By default, the Optimization module displays all of the variables that are available for the selected optimization task. To avoid creating a design response that cannot be used as expected, you can display only the variables that are available for an objective function or only the variables that are available for a constraint.
7. If you are creating an internal force or internal moment design response, you must select the nodal subset region. This region contains the nodes that form a cross section of the elements in the region in which the internal force or moment will be maximized or minimized.
8. Select the **Steps** tabbed page, and specify the model and step or load case of interest. In addition, if you are performing an eigenfrequency optimization, you must select the modes of interest from the **Steps** tabbed page. For more information, see *Selecting the data source of a design response*.
9. Select the operator that will be applied on the selected variable across the design area.

   - **Sum of values**: The sum of the values across the design area. For some variables (such as volume, weight, moment of inertia, and gravity) **Sum of values** is the only operator, and it is selected by default.
   - **Minimum value**: The minimum value across the design area.
   - **Maximum value**: The maximum value across the design area. For some variables (such as stress, contact stress, and strain) **Maximum value** is the only operator, and it is selected by default.
10. If applicable, select the operator that will be applied on the selected variable across steps and load cases.

    - **Sum of values**: The sum of the values across the selected steps or load cases.
    - **Minimum value**: The minimum value across the selected steps or load cases.
    - **Maximum value**: The maximum value across the selected steps or load cases.
11. Click **OK** to save your data and to exit the editor.

Additional information

• *Selecting the data source of a design response*

- *Combining design responses*

Selecting the data source of a design response

By default, the Optimization module uses the data from the last load case, if any, and the last step of your Abaqus model to define the design response. Alternatively, if your model contains multiple steps or load conditions, you can select which steps or load conditions will be used to define the design response. Finally, if you have multiple models open in your session, you can select which models and which steps or load conditions within each model will be used to define the design response.

In addition, if the design response is calculating an eigenfrequency, you can choose which mode or range of modes to examine.

1. From the **Create Design Response** dialog box, select the **Steps** tabbed page.
2. Do either of the following:
   - Select **Use last step and last load case** to define the design response using data from the last step or last load case.
   - Select **Specify** to select the step or load condition that will be used to define the design response.
3. If you selected **Specify**, do the following to select the models, steps or load cases (within a step) that will be used to define the design response.
   - Select  to add a step from the current model to the list of steps.
   - Select  to add all of the valid steps from the current model to the list of steps.
   - Select  to add all of the valid steps from all of the open models in your session to the list of steps. (Abaqus/CAE displays an asterisk next to the name of the current model.)
   - Select  to delete a step from the list of steps.
4. If desired, click on a cell in the table, and select an alternate model, step, or load case from the menu that appears.
5. If the design response will calculate an eigenfrequency, you can select a mode or a range of modes from which the eigenfrequency will be calculated.
6. If the design region is a shell, you can select the location in the shell section from which the Optimization module will calculate the shell stresses. You can choose from the following:
   - The value of the shell stress at the top, middle, or bottom layer of the shell. (The middle layer experiences no bending and behaves as a membrane.)
   - The maximum value of the shell stress from the top, middle, or bottom layer of the shell.
   - The minimum value of the shell stress from the top, middle, or bottom layer of the shell.
7. Select how the Optimization module will extract the design response from the selected region. You can choose from the following:
   - The maximum value from the selected region.
   - The minimum value from the selected region.
   - The sum of the values from the selected region.
8. Select how the Optimization module will extract the design response from the steps and load cases. You can choose from the following:

- The maximum value from all the selected steps and load cases.
- The minimum value from all of the selected steps and load cases.
- The sum of the values from all of the selected steps and load cases.

9. Click **OK** to save your data and to exit the editor.

Additional information

• *Creating and editing a design response*
• *Combining design responses*

Combining design responses

The simplest approach for combining design responses is to create an objective function with a weighted sum of design responses. Alternatively, you can combine design responses using the design response editor.
You should be careful how you combine design responses to avoid creating a meaningless optimization task. In addition, you should understand how condition-based and general optimization combine terms and how they differ.

In this section:

- *Combining design responses for a condition-based topology or shape optimization*
- *Combining design responses for a general topology optimization*
- *Filtering a design response for a shape optimization*
- *Applying a cutoff filter to a design response for a shape optimization*
- *Normalizing a design response for a shape optimization*

Combining design responses for a condition-based topology or shape optimization

For both condition-based topology and shape optimization the following methods are available for combining up to four design responses (R_1, R_2, R_3, and R_4):

Add	$R_1 + R_2 + R_3 + R_4$
Multiply	$R_1 \times R_2 \times R_3 \times R_4$
Minimum	$Min\,(R_1, R_2, R_3, R_4)$
Maximum	$Max\,(R_1, R_2, R_3, R_4)$

For both condition-based topology and shape optimization the following methods are available for combining two design responses (R_1 and R_2):

Subtract	$R_1 - R_2$
Divide	$\frac{R_1}{R_2}$

For both condition-based topology and shape optimization the following methods are available for operating on a single design response:

Absolute value	$abs\,(R_1)$
Sine	$Sin\,(R_1)$
Cosine	$Cos\,(R_1)$
Tangent	$Tan\,(R_1)$
Common logarithm	$Log\,(R_1)$
Natural logarithm	$Ln\,(R_1)$
Square root	$\sqrt{R_1}$
Exponential	$exp\,(R_1)$
Nth Root	$\sqrt[n]{R_1}$
Nth Power	${R_1}^n$
Integer	$Int\,(R_1)$
Nearest integer number	$Nint\,(R_1)$
Sign	$Sign\,(R_1)$
Δ_{ij}, the difference between two iterations	$R_1 i - R_1 j$

Additional information

- *Creating and editing a design response*
- *Selecting the data source of a design response*

Combining design responses for a general topology optimization

For a general topology optimization you can create a design response calculated as the difference or the absolute difference between two design responses of the same type or a weighted combination of several (up to 10) displacement design responses.

A typical example uses the absolute difference in the displacement between two design responses to constrain the displacement of two vertices relative to each other. The following table shows which design responses can be combined:

Design responses	Absolute difference	Weighted sum	Subtract
Displacements and rotation	√	√	√
Absolute displacements and rotations			
Reaction forces	√	√	√
Absolute reaction forces			
Internal forces	√	√	√
Absolute internal forces			
Modal eigenfrequencies	√		√

Although a design response is a single scalar value, you can use the appropriate weighting to combine design responses that are defined in different directions or in different coordinate systems.

Additional information

- *Creating and editing a design response*
- *Selecting the data source of a design response*

Filtering a design response for a shape optimization

You can apply a filter to a design response that will smooth out local peaks for a shape optimization. The filter is defined as

$$\Phi_j = \frac{\sum_{i-1}^{N} \Phi_i B_{ij}}{\sum_{i-1}^{N} B_{ij}},$$

$$B_{ij} = (r_j - d_{ji})^p,$$

$$r_j = r_{\max} e^{-0.5(k_{\max} \int \sigma)},$$

$$k_{\max} = \max(|n_j \times n_k|),$$

where $\Phi_j$is the filter function for node *j*. The main filter function, B_{ij}, decreases with the distance, *d*, between nodes *i* and *j*. The maximum radius of influence, r_{max}, defines the maximum distance from node *j* for the nodes *i* to influence the filter value. The local curvature, κ_{max}, is approximated by the vector product of the node normal, n_j, and the neighboring nodes, n_k. The curvature dependency, r_j, defines a weight function that reduces the radius at higher local curvature.

You can specify the following:

- The maximum radius of influence, r_{max}.
- The exponent, *p*, which defines the weight function that controls the influence of the distance between nodes *i* and *j*. The default value is 1.0.
- The surface bending radius reduction, σ. The default value of σ is 0.2. A larger value of σ decreases the influence of the surface curvature.

Additional information

• *Creating and editing a design response*
• *Selecting the data source of a design response*

Applying a cutoff filter to a design response for a shape optimization

You can apply a filter that cuts off local peaks of the design response for a shape optimization. You can specify the following:

- The lower bound of the design response. All values less than this lower bound are assumed to be zero.
- The upper bound of the design response. All values greater than this upper bound are assumed to be the value of the upper bound.

Additional information

- *Creating and editing a design response*
- *Selecting the data source of a design response*

Normalizing a design response for a shape optimization

You can normalize the vectors used as terms for the algorithm that calculates a shape optimization. You may want to normalize design responses before you combine them using a weighted combination; for example, if different loads are applied to different regions. If desired, you can apply either of the following nomalizations:

- A normalization based on the maximum value in each design cycle (in effect, a normalization of 1.0 for each cycle).
- A normalization based on the initial value of the design response (the maximum value during the first design cycle).

Additional information

- *Creating and editing a design response*
- *Selecting the data source of a design response*

Creating objective functions

An objective function defines the objective of your optimization. To configure an objective function, you select a design response or a combination of design responses and specify the target; for example, to minimize the total strain energy in the model.

1. From the main menu bar, select **Objective Function->Create**.

   The **Create Objective Function** dialog box appears.

   Tip: You can initiate the **Create** procedure in two other ways:

   - Click **Create** in the **Objective Function Manager**. (You can display the **Objective Function Manager** by selecting **Objective Function->Manager** from the main menu bar.)
   - Click the tool in the Optimization module toolbox.

2. From the **Create Objective Function** dialog box that appears, enter the name of the objective function.

   The **Edit Objective Function** dialog box appears.

3. Select the **Target** of the objective function. You can select one of the following:

   - **Minimize design response values**: create an optimized model that tries to minimize the sum of the weighted differences between the design response and the reference value.
   - **Maximize design response values**: create an optimized model that tries to maximize the sum of the weighted differences between the design response and the reference value.
   - **Minimize the maximum design response values**: find the maximum weighted difference between the design response and the reference value and create an optimized model that minimizes that maximum difference.

4. From the menu in the **Name** column, select the design response that will be used to define this objective function.

   The objective function editor displays the type of the design response along with its default weight and reference value.

5. To create an objective function that is a weighted sum of multiple design responses, choose from the following:

   - Select to add a design response to the list of design responses.
   - Select to add all of the valid design responses to the list of design responses.
   - Select to delete a design response from the list of design responses.
   - Select to create a new design response and add it to the list of design responses.

6. If desired, click on the weight or reference value of an objective function and enter a new value.
7. Click **OK** to save your data and to exit the editor.

Creating constraints

A constraint constrains the Optimization module from making changes to the topology of the model during the optimization. If a constraint cannot be satisfied, the optimization is not feasible. To configure a constraint, you select a design response or a combination of design responses and specify the value of the constraint; for example, the volume of the optimized model can be constrained to be 50% of the original volume.

When you execute an optimization process, Abaqus generates history output from the constraints you defined in the Optimization module. For volume design responses the history output is always reported as a fraction of the initial value. For all other design responses the history output is reported as an absolute value.

1. From the main menu bar, select **Constraint->Create**.

   The **Create Constraint** dialog box appears.

   Tip: You can initiate the **Create** procedure in two other ways:

   - Click **Create** in the **Constraint Manager**. (You can display the **Constraint Manager** by selecting **Constraint->Manager** from the main menu bar.)
   - Click the  tool in the Optimization module toolbox.

2. From the **Create Constraint** dialog box that appears, enter the name of the constraint.

   The **Edit Constraint** dialog box appears.

3. From the menu, select the design response that will be used to define this constraint. Alternatively, you can select  to create a new design response and add it to the list of design responses.

   The constraint editor displays the type of the design response, which is the variable you are constraining. If you are performing a condition-based optimization, you must select a volume constraint.

4. Define the constraint. The editor provides different options, depending on the type of optimization task you selected.

   - If you are defining a constraint for a condition-based topology or shape optimization, the volume constraint can be either of the following:
     - Equal to a fixed value.
     - Equal to a fraction of the value before the optimization starts.
   - If you are defining a constraint for a general topology optimization, the constraint can be one of the following:
     - Less than, greater than, or equal to a fixed value.
     - Less than, greater than, or equal to a fraction of the value before the optimization starts.

     Note:

     During a condition-based topology or shape optimization, the volume is reduced incrementally until the volume constraint is satisfied during the last step. In contrast, a general topology optimization satisfies the volume constraint in the first design cycle. As a consequence, a general topology optimization starts with a much weaker structure, and the element density is scaled to satisfy the remaining constraints and objectives.

5. Click **OK** to save your data and to exit the editor.

Additional information

Configuring geometric restrictions

This section describes the geometric restriction editor and the options that appear in the geometric restriction editor.

In this section:

- *Creating and editing geometric restrictions*
- *Creating a geometric restriction in a topology or sizing optimization*
- *Creating a geometric restriction in a shape optimization*
- *Creating a geometric restriction in a bead optimization*

Creating and editing geometric restrictions

You can create geometric restrictions that place boundaries on the changes that the Optimization module can make to the topology of the model.

Geometrical restrictions include frozen regions from which material cannot be removed and manufacturing constraints, such as restrictions on undercuts that would prevent the optimized model from being removed from a mold.

1. From the main menu bar, select **Geometric Restriction->Create**.

   The **Create Geometric Restriction** dialog box appears.

   Tip: You can initiate the **Create** procedure in two other ways:

   - Click **Create** in the **Geometric Restriction Manager**. (You can display the **Geometric Restriction Manager** by selecting **Geometric Restriction->Manager** from the main menu bar.)
   - Click the  tool in the Optimization module toolbox.

2. From the **Create Geometric Restriction** dialog box that appears, enter the name of the geometric restriction.
3. Select the type of geometric restriction to apply, and click **Continue**.
4. From the viewport, select the region to which the geometric restriction will be applied, or click **Done** to apply the geometric restriction to the entire model.

   By default, Abaqus/CAE allows you to select all of the model. To select faces or cells, use the **Selection** toolbar to change the type of object that you can select to **Face** or **Cells**. For more information, see *Filtering your selection based on the type of object*.

   If you would rather select from a list of existing sets, do the following:

   a. Click **Sets** on the right side of the prompt area.

      Abaqus/CAE displays the **Region Selection** dialog box containing a list of available sets.

   b. Select the set of interest, and click **Continue**.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

5. When you have finished selecting the geometric restriction region, click **Done** in the prompt area. For more information on selecting objects, see *Selecting objects within the viewport*.

   The **Edit Geometric Restriction** dialog box appears. The content of the dialog box depends on the type of geometric restriction you are creating.

6. Click **OK** to save your data and to exit the editor.

Additional information

- *Creating a geometric restriction in a topology or sizing optimization*

Creating a geometric restriction in a topology or sizing optimization

This section describes how to create a geometric restriction in a topology or sizing optimization.

In this section:

- *Creating a frozen area restriction*
- *Creating a member size restriction*
- *Creating a cyclic symmetry restriction*
- *Creating a planar symmetry restriction*
- *Creating a rotational symmetry restriction*
- *Creating a point symmetry restriction*
- *Creating a minimum width restriction*
- *Creating a thickness control restriction*
- *Creating a clustering restriction*
- *Creating a demold restriction*
- *Creating an overhang control restriction*
- *Creating a milling control restriction*
- *Creating a rib design restriction*

Creating a frozen area restriction

You can select regions of your model that will not be modified during a topology or sizing optimization. The regions continue to contribute to variables such as the weight and the inertia of the model. You can freeze regions that are contacting other parts, such as regions that are used to support the model and regions that form bearing surfaces. It is recommended that you freeze regions to which prescribed conditions are applied. You can freeze these regions using a geometric restriction; or you can request that the Optimization module freeze them automatically when you create a topology optimization task, as described in *Creating an optimization task*. Freezing these regions stabilizes the optimization and often leads to a significantly lower number of iterations.

1. From the main menu bar, select **Geometric Restriction->Create**. The **Create Geometric Restriction** dialog box appears.

   Tip: You can initiate the **Create** procedure in two other ways:

   - Click **Create** in the **Geometric Restriction Manager**. (You can display the **Geometric Restriction Manager** by selecting **Geometric Restriction->Manager** from the main menu bar.)
   - Click the tool in the Optimization module toolbox.

2. From the **Create Geometric Restriction** dialog box that appears, enter the name of the geometric restriction.
3. Select **Frozen area** or **Frozen area (Sizing)** from the list of geometric restrictions, and click **Continue**.
4. From the viewport, select the regions that will be frozen.

   By default, Abaqus/CAE allows you to select all of the model. To select faces or cells, use the **Selection** toolbar to change the type of object that you can select to **Face** or **Cells**. For more information, see *Filtering your selection based on the type of object*.

   If you would rather select from a list of existing sets, do the following:

   a. Click **Sets** on the right side of the prompt area.

      Abaqus/CAE displays the **Region Selection** dialog box containing a list of available sets.

   b. Select the set of interest, and click **Continue**.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

5. When you have finished selecting the region to freeze, click **Done** in the prompt area. For more information on selecting objects, see *Selecting objects within the viewport*."

   The **Edit Geometric Restriction** dialog box appears.

6. Click **OK** to freeze the selected regions and to exit the editor.

Additional information

- *Creating a geometric restriction in a topology or sizing optimization*
- *Creating a geometric restriction in a shape optimization*

Creating a member size restriction

For a topology optimization you can specify the minimum or maximum size of selected regions of your model; for example, the minimum size of a region in which the optimization creates trusses.
You can also specify the minimum distance between trusses. Specifying a maximum member size forces the optimization to split thick regions into several smaller regions and prevents it from creating large contiguous regions that might be difficult to cast. Specifying a minimum member size avoids thin trusses that may be difficult to manufacture. The minimum member size must be greater than twice the average element size to prevent the results from being dependent on the mesh size.

In most cases you can specify the same value for both the minimum and maximum member size, and the Optimization module creates trusses that are approximately equal to the specified value. To prevent the structure from collapsing, the Optimization module tries to avoid creating thin trusses in regions where prescribed conditions are applied.

Specifying the minimum or maximum member size is very computationally expensive and should be used only where necessary. You should perform an optimization without member size restrictions to identify any regions where the restrictions should be applied.

Note: You can combine a member size constraint and a demold constraint only for a general topology optimization.

1. From the main menu bar, select **Geometric Restriction->Create**.

   The **Create Geometric Restriction** dialog box appears.

   Tip: You can start the **Create** procedure in two other ways:

   - Click **Create** in the **Geometric Restriction Manager**. (You can display the **Geometric Restriction Manager** by selecting **Geometric Restriction->Manager** from the main menu bar.)
   - Click the  tool in the Optimization module toolbox.

2. From the **Create Geometric Restriction** dialog box that appears, enter the name of the geometric restriction.
3. Select **Member size (Topology)** from the list of geometric restrictions, and click **Continue**.
4. From the viewport, select the region to which the member size restriction will be applied or click **Done** to apply the member size restriction to the entire model.

   By default, Abaqus/CAE allows you to select all of the model. To select faces or cells, use the **Selection** toolbar to change the type of object that you can select to **Face** or **Cells**. For more information, see *Filtering your selection based on the type of object*.

   To select from a list of existing sets, do the following:

   a. Click **Sets** on the right side of the prompt area.

      Abaqus/CAE displays the **Region Selection** dialog box containing a list of available sets.

   b. Select the set of interest, and click **Continue**.

   Note: The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

5. When you have finished selecting the geometric restriction region, click **Done** in the prompt area. For more information on selecting objects, see *Selecting objects within the viewport*."

   The **Edit Geometric Restriction** dialog box appears.

6. Do one of the following:
   - Select **Minimum thickness**, and enter the minimum member thickness.
   - Select **Maximum thickness**, and enter the maximum member thickness.
   - Select **Envelope**, and enter the following:
     - The **Minimum** member thickness.
     - The **Maximum** member thickness.
     - The **Minimum gap** between members.
7. Select a **Method** algorithm: **Filter** or **Local Volume** when the restriction type is **Maximum thickness** or **Envelope**.
8. Click **OK** to create the frozen area geometric restriction and to exit the editor.

Additional information

- *Creating a geometric restriction in a topology or sizing optimization*
- *Creating a geometric restriction in a shape optimization*

Creating a cyclic symmetry restriction

You can specify a cyclic symmetry geometric restriction for a topology or sizing optimization.

A cyclic symmetry geometric restriction replicates a selected region over a specified distance, as shown in *Figure 1*.

Figure 1: Cyclic symmetry from a topology optimization.

The selected region is replicated along an axis of a coordinate system. You can use the global coordinate system, or you can create a datum coordinate system (see *Methods for creating a datum coordinate system*, for more information). You can choose to remove frozen regions from the symmetry restriction.

1. From the main menu bar, select **Geometric Restriction->Create**.

   The **Create Geometric Restriction** dialog box appears.

   Tip: You can initiate the **Create** procedure in two other ways:

   - Click **Create** in the **Geometric Restriction Manager**. (You can display the **Geometric Restriction Manager** by selecting **Geometric Restriction->Manager** from the main menu bar.)
   - Click the tool in the Optimization module toolbox.

2. From the **Create Geometric Restriction** dialog box that appears, enter the name of the geometric restriction.
3. Select **Cyclic symmetry** or **Cyclic symmetry (Sizing)** from the list of geometric restrictions, and click **Continue**.
4. From the viewport, select the region that will be replicated by the cyclic symmetry or click **Done** to apply the cyclic symmetry restriction to the entire model.

   By default, Abaqus/CAE allows you to select all of the model. To select faces or cells, use the **Selection** toolbar to change the type of object that you can select to **Face** or **Cells**. For more information, see *Filtering your selection based on the type of object*.

   If you would rather select from a list of existing sets, do the following:

   a. Click **Sets** on the right side of the prompt area.

      Abaqus/CAE displays the **Region Selection** dialog box containing a list of available sets.

   b. Select the set of interest, and click **Continue**.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

5. When you have finished selecting the geometric restriction region, click **Done** in the prompt area. For more information on selecting objects, see *Selecting objects within the viewport*."

   The **Edit Geometric Restriction** dialog box appears.

6. Select the coordinate system, and select the axis along which the region will be replicated.
7. Enter the distance that the selected region will be translated along the axis.
8. If desired, toggle on **Ignore frozen area** to remove any frozen regions from the region that will be translated.
9. Click **OK** to create the cyclic symmetry geometric restriction and to exit the editor.

Additional information

- *Creating a geometric restriction in a topology or sizing optimization*
- *Creating a geometric restriction in a shape optimization*

Creating a planar symmetry restriction

You can specify a planar symmetry geometric restriction for a topology or sizing optimization.

A planar symmetry geometric restriction forces the optimized model to be symmetric about a specified plane, as shown in *Figure 1*:

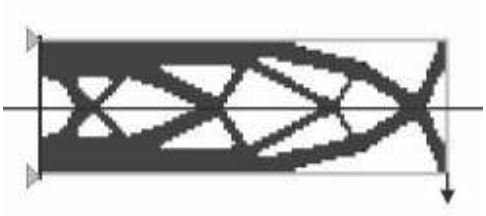

Figure 1: Planar symmetry from a topology optimization.

You specify the plane of symmetry by selecting the axis of a coordinate system that is the normal to the plane of symmetry. You can use the global coordinate system, or you can create a datum coordinate system (see *Methods for creating a datum coordinate system*, for more information). You can choose to remove frozen regions from the symmetry restriction.

1. From the main menu bar, select **Geometric Restriction->Create**.

   The **Create Geometric Restriction** dialog box appears.

   Tip: You can initiate the **Create** procedure in two other ways:

   - Click **Create** in the **Geometric Restriction Manager**. (You can display the **Geometric Restriction Manager** by selecting **Geometric Restriction->Manager** from the main menu bar.)
   - Click the tool in the Optimization module toolbox.

2. From the **Create Geometric Restriction** dialog box that appears, enter the name of the geometric restriction.
3. Select **Planar symmetry** or **Planar symmetry (Sizing)** from the list of geometric restrictions, and click **Continue**.
4. From the viewport, select the region in which the planar symmetry will be enforced or click **Done** to apply the planar symmetry restriction to the entire model.

   By default, Abaqus/CAE allows you to select all of the model. To select faces or cells, use the **Selection** toolbar to change the type of object that you can select to **Face** or **Cells**. For more information, see *Filtering your selection based on the type of object*.

   If you would rather select from a list of existing sets, do the following:

   a. Click **Sets** on the right side of the prompt area.

      Abaqus/CAE displays the **Region Selection** dialog box containing a list of available sets.

   b. Select the set of interest, and click **Continue**.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

5. When you have finished selecting the geometric restriction region, click **Done** in the prompt area. For more information on selecting objects, see *Selecting objects within the viewport*."

   The **Edit Geometric Restriction** dialog box appears.

6. Select the coordinate system, and select the axis of the coordinate system that represents the normal to the plane of symmetry.
7. If desired, toggle on **Ignore frozen area** to remove any frozen regions from the symmetry restriction.
8. Click **OK** to create the planar symmetry geometric restriction and to exit the editor.

Additional information

- *Creating a geometric restriction in a topology or sizing optimization*
- *Creating a geometric restriction in a shape optimization*

Creating a rotational symmetry restriction

You can specify a rotational symmetry geometric restriction for a topology or sizing optimization.

A rotational symmetry geometric restriction forces the optimized model to be symmetric about a specified axis, as shown in *Figure 1*:

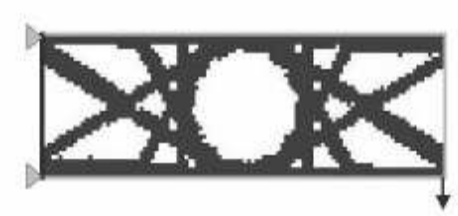

Figure 1: Rotational symmetry from a topology optimization.

You specify the axis of symmetry by selecting the axis of a coordinate system. You can use the global coordinate system, or you can create a datum coordinate system (see *Methods for creating a datum coordinate system*, for more information). In addition, you must enter an angle that specifies the size of the repeating segment. You can choose to remove frozen regions from the symmetry restriction.

1. From the main menu bar, select **Geometric Restriction->Create**.

   The **Create Geometric Restriction** dialog box appears.

   Tip: You can initiate the **Create** procedure in two other ways:

   - Click **Create** in the **Geometric Restriction Manager**. (You can display the **Geometric Restriction Manager** by selecting **Geometric Restriction->Manager** from the main menu bar.)
   - Click the tool in the Optimization module toolbox.

2. From the **Create Geometric Restriction** dialog box that appears, enter the name of the geometric restriction.
3. Select **Rotational symmetry** or **Rotational symmetry (Sizing)** from the list of geometric restrictions, and click **Continue**.
4. From the viewport, select the region in which the rotational symmetry will be enforced or click **Done** to apply the rotational symmetry restriction to the entire model.

   By default, Abaqus/CAE allows you to select all of the model. To select faces or cells, use the **Selection** toolbar to change the type of object that you can select to **Face** or **Cells**. For more information, see *Filtering your selection based on the type of object*.

   If you would rather select from a list of existing sets, do the following:

   a. Click **Sets** on the right side of the prompt area.

      Abaqus/CAE displays the **Region Selection** dialog box containing a list of available sets.

   b. Select the set of interest, and click **Continue**.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

5. When you have finished selecting the geometric restriction region, click **Done** in the prompt area. For more information on selecting objects, see *Selecting objects within the viewport*."

   The **Edit Geometric Restriction** dialog box appears.
6. Select the coordinate system, and select the axis of the coordinate system that represents the axis of symmetry.
7. Enter the **Repeating segment size**, which is the angle (in degrees) specifying the size of the repeating segment. The value must be greater than or equal to 2°.
8. If desired, toggle on **Ignore frozen area** to remove any frozen regions from the symmetry restriction.
9. Click **OK** to create the rotational symmetry geometric restriction and to exit the editor.

Additional information

- *Creating a geometric restriction in a topology or sizing optimization*
- *Creating a geometric restriction in a shape optimization*

Creating a point symmetry restriction

You can specify a point symmetry geometric restriction for a topology or sizing optimization.

A point symmetry geometric restriction forces the optimized model to be symmetric about a specified point, as shown in *Figure 1*.

Figure 1: Point symmetry from a topology optimization.

You specify the point of symmetry by selecting a coordinate system (the point of symmetry is assumed to be the origin of the coordinate system). You can use the global coordinate system, or you can create a datum coordinate system (see *Methods for creating a datum coordinate system*, for more information). You can choose to remove frozen regions from the symmetry restriction.

1. From the main menu bar, select **Geometric Restriction->Create**.

   The **Create Geometric Restriction** dialog box appears.

   Tip: You can initiate the **Create** procedure in two other ways:

   - Click **Create** in the **Geometric Restriction Manager**. (You can display the **Geometric Restriction Manager** by selecting **Geometric Restriction->Manager** from the main menu bar.)
   - Click the tool in the Optimization module toolbox.

2. From the **Create Geometric Restriction** dialog box that appears, enter the name of the geometric restriction.
3. Select **Point symmetry** or **Point symmetry (Sizing)** from the list of geometric restrictions, and click **Continue**.
4. From the viewport, select the region in which the point symmetry will be enforced or click **Done** to apply the point symmetry restriction to the entire model.

   By default, Abaqus/CAE allows you to select all of the model. To select faces or cells, use the **Selection** toolbar to change the type of object that you can select to **Face** or **Cells**. For more information, see *Filtering your selection based on the type of object*.

   If you would rather select from a list of existing sets, do the following:

   a. Click **Sets** on the right side of the prompt area.

      Abaqus/CAE displays the **Region Selection** dialog box containing a list of available sets.

   b. Select the set of interest, and click **Continue**.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

5. When you have finished selecting the geometric restriction region, click **Done** in the prompt area. For more information on selecting objects, see *Selecting objects within the viewport*."

   The **Edit Geometric Restriction** dialog box appears.

6. Select the coordinate system. The point of symmetry is assumed to be the origin of the selected coordinate system.
7. If desired, toggle on **Ignore frozen area** to remove any frozen regions from the symmetry restriction.
8. Click **OK** to create the point symmetry geometric restriction and to exit the editor.

Additional information

- *Creating a geometric restriction in a shape optimization*

Creating a minimum width restriction

A sizing optimization determines the optimal element thickness when modeling a sheet metal structure with shell elements. Specifying the minimum width of a region containing elements of the same thickness prevents narrow slivers of elements with equal thickness from appearing in the solution after a sizing optimization. Specifying a minimum width will also prevent oscillations in the shell thickness or a "checkerboard" pattern of element thicknesses. The minimum width must be larger than the average length of the element edges.

1. From the main menu bar, select **Geometric Restriction->Create**.

   The **Create Geometric Restriction** dialog box appears.

   Tip: You can initiate the **Create** procedure in two other ways:

   - Click **Create** in the **Geometric Restriction Manager**. (You can display the **Geometric Restriction Manager** by selecting **Geometric Restriction->Manager** from the main menu bar.)
   - Click the  tool in the Optimization module toolbox.

2. From the **Create Geometric Restriction** dialog box that appears, enter the name of the geometric restriction.
3. Select **Member size (Sizing)** from the list of geometric restrictions and click **Continue**.
4. From the viewport, select the region to which the minimum width restriction will be applied or click **Done** to apply the minimum width restriction to the entire model.

   By default, Abaqus/CAE allows you to select all of the model. To select faces or cells, use the **Selection** toolbar to change the type of object that you can select to **Face** or **Cells**. For more information, see *Filtering your selection based on the type of object*.

   If you would rather select from a list of existing sets, do the following:

   a. Click **Sets** on the right side of the prompt area.

      Abaqus/CAE displays the **Region Selection** dialog box containing a list of available sets.

   b. Select the set of interest, and click **Continue**.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

5. When you have finished selecting the geometric restriction region, click **Done** in the prompt area. For more information on selecting objects, see *Selecting objects within the viewport*."

   The **Edit Geometric Restriction** dialog box appears.

6. Select **Minimum width** and enter the minimum width.
7. Click **OK** to create the minimum width geometric restriction and to exit the editor.

Additional information

- *Creating a geometric restriction in a shape optimization*

Creating a thickness control restriction

You can specify upper and lower bounds on the thickness of shell elements when you are configuring a sizing optimization. The value can be an absolute thickness or a fraction of the initial thickness.

1. From the main menu bar, select **Geometric Restriction->Create**.

   The **Create Geometric Restriction** dialog box appears.

   Tip: You can initiate the **Create** procedure in two other ways:

   - Click **Create** in the **Geometric Restriction Manager**. (You can display the **Geometric Restriction Manager** by selecting **Geometric Restriction->Manager** from the main menu bar.)
   - Click the  tool in the Optimization module toolbox.

2. From the **Create Geometric Restriction** dialog box that appears, enter the name of the geometric restriction.
3. Select **Thickness control (Sizing)** from the list of geometric restrictions, and click **Continue**.
4. From the viewport, select the region to which the thickness control restriction will be applied or click **Done** to apply the thickness control restriction to the entire model.

   By default, Abaqus/CAE allows you to select all of the model. To select faces or cells, use the **Selection** toolbar to change the type of object that you can select to **Face** or **Cells**. For more information, see *Filtering your selection based on the type of object*.

   If you would rather select from a list of existing sets, do the following:

   a. Click **Sets** on the right side of the prompt area.

      Abaqus/CAE displays the **Region Selection** dialog box containing a list of available sets.

   b. Select the set of interest, and click **Continue**.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

5. When you have finished selecting the geometric restriction region, click **Done** in the prompt area. For more information on selecting objects, see *Selecting objects within the viewport*."

   The **Edit Geometric Restriction** dialog box appears.

6. Do one of the following:

   - Select **Thickness by value** to enter the absolute value of the shell element thickness.
   - Select **Thickness by fraction** to enter a fraction of the shell element thickness relative to the initial value.

7. Select **Minimum** and enter the minimum thickness.
8. Select **Maximum** and enter the maximum thickness.
9. Click **OK** to create the thickness control geometric restriction and to exit the editor.

Additional information

- *Creating a geometric restriction in a topology or sizing optimization*

- *Creating a geometric restriction in a shape optimization*

Creating a clustering restriction

You can specify that selected regions contain clusters of shell elements of equal thickness after a sizing optimization or clusters of elements of equal pseudodensities after a topology optimization.

You can use clustering to

- generate strengthening ribs or rings in the sheet metal structure you are optimizing,
- define borders between regions of equal thickness, or
- obtain an extrudable profile in the solid structures.

Clustered regions can be reproduced in manufacturing using sheets of constant thickness; for example, a vehicle “body in white” formed by welding and stamping individual sheet metal structures. To allow for maximum design flexibility, you should first optimize your structure without specifying clustering and use the initial design to decide which regions to cluster in your final optimization.

1. From the main menu bar, select **Geometric Restriction->Create**.

   The **Create Geometric Restriction** dialog box appears.

   Tip: You can initiate the **Create** procedure in two other ways:

   - Click **Create** in the **Geometric Restriction Manager**. (You can display the **Geometric Restriction Manager** by selecting **Geometric Restriction->Manager** from the main menu bar.)
   - Click the  tool in the Optimization module toolbox.

2. From the **Create Geometric Restriction** dialog box that appears, enter the name of the geometric restriction.
3. Select **Cluster areas (Sizing)** or **Cluster areas (Topology)** from the list of geometric restrictions, and click **Continue**.

   The **Edit Geometric Restriction** dialog box appears.
4. From the list of **Eligible Sets**, select the sets specifying regions that will contain clusters of elements of equal thickness or of equal pseudo densities after the optimization.

   Note:

   If the desired set does not exist, click  to create it.
5. Click the arrow to move the selected sets to the list of **Selected Sets**.
6. Click **OK** to create the thickness clustering geometric restriction and to exit the editor.

Additional information

- *Creating a geometric restriction in a topology or sizing optimization*
- *Creating a geometric restriction in a shape optimization*

Creating a demold restriction

You can specify a demold geometric restriction for a topology optimization. A demold geometric restriction forces the optimized model to satisfy specified manufacturing requirements; for example, it can prevent undercuts and hollow regions in a part that must be extracted from a mold.

1. From the main menu bar, select **Geometric Restriction->Create**.

   The **Create Geometric Restriction** dialog box appears.

   Tip: You can initiate the **Create** procedure in two other ways:

   - Click **Create** in the **Geometric Restriction Manager**. (You can display the **Geometric Restriction Manager** by selecting **Geometric Restriction->Manager** from the main menu bar.)
   - Click the  tool in the Optimization module toolbox.

2. From the **Create Geometric Restriction** dialog box that appears, enter the name of the geometric restriction.
3. Select **Demold** from the list of geometric restrictions, and click **Continue**.
4. From the viewport, select the region in which the demold restriction will be enforced or click **Done** to apply the demold symmetry restriction to the entire model.

   By default, Abaqus/CAE allows you to select all of the model. To select faces or cells, use the **Selection** toolbar to change the type of object that you can select to **Face** or **Cells**. For more information, see *Filtering your selection based on the type of object*.

   If you would rather select from a list of existing sets, do the following:

   a. Click **Sets** on the right side of the prompt area.

      Abaqus/CAE displays the **Region Selection** dialog box containing a list of available sets.

   b. Select the set of interest, and click **Continue**.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

5. When you have finished selecting the geometric restriction region, click **Done** in the prompt area. For more information on selecting objects, see *Selecting objects within the viewport*."

   The **Edit Geometric Restriction** dialog box appears.

6. By default, the region in which the Optimization module checks for collisions is the same as the region in which it enforces the demold restriction. If desired, select  from the top of the **Edit Geometric Restriction** dialog box, and select the collision check region. To avoid cavities, the collision check region should include the demold region and any cells that are adjacent to the demold region.
7. Choose one of the following demold techniques:

   - Choose **Demolding with a central plane** and select how the Optimization module will determine the central plane:
     - Choose **Determine automatically**. The Optimization module determines the optimal location of the central plane such that the optimization adds or removes material only in the pull direction

or in the opposite direction. Toggle on **Prevent hole formation** to prevent the optimization from removing material from the central plane.

- Choose **Specify**, and click  to select a point on the central plane. The Optimization module creates a structure that can be released from a mold in both pull directions away from the central plane.

- Choose **Forging (deform only in the pull direction)**. The central plane, the plane at which two halves of a mold meet, is assumed to lie at the back of the model and perpendicular to the pull direction. The optimization adds or removes material only in the pull direction.
- Choose **Stamping**. If the Optimization module decides to remove an element from the structure, it also removes all the elements behind or in front of the element (relative to the vector indicating the pull direction).
- Choose **Demolding at the region surface** to force the optimization to add or remove material only from the surface of the constrained region.

8. Click , and select two points specifying the vector along the pull direction.
9. Enter the **Draft angle**. The draft angle is a small angle relative to the pull direction that will be introduced to the optimized model to ensure the part can be removed from its mold. Normally the value is between 0° and 10°.
10. Click **OK** to create the demold geometric restriction and to exit the editor.

Additional information

- *Creating a geometric restriction in a topology or sizing optimization*
- *Creating a geometric restriction in a shape optimization*

Creating an overhang control restriction

You can specify a geometric restriction for overhang control in a topology optimization.

An overhang control geometric restriction forces the optimized model to satisfy specified additive manufacturing requirements. The restriction can prevent overhanging features in a model that exceed a critical angle. In general, an overhanging feature with an angle greater than 45° is difficult to print and usually requires the addition of support structures.

The base plane defines the printing bed. Only parts of the model situated above the base plane need support. By default, the overhang restriction tries to remove all overhanging features so that support structures are not required. Depending on the geometry, this can lead to unreasonable results. You can specify that there is no base plane, in which case boundary features are always printable. Alternatively, you can specify the base plane with a user-defined point in space on the plane perpendicular to the print direction. The point should be above overhanging features that are mandatory and under overhanging features that should be removed.

1. From the main menu bar, select **Geometric Restriction->Create**.

   The **Create Geometric Restriction** dialog box appears.

   Tip: You can initiate the **Create** procedure in two other ways:

   - Click **Create** in the **Geometric Restriction Manager**. (You can display the **Geometric Restriction Manager** by selecting **Geometric Restriction->Manager** from the main menu bar.)
   - Click the tool in the Optimization module toolbox.

2. Enter the name of the geometric restriction.
3. Select **Overhang control (Topology)** from the list of geometric restrictions, and click **Continue**.
4. From the viewport, select the region in which the overhang control restriction is enforced, or click **Done** to apply the overhang control restriction to the entire model.

   By default, Abaqus/CAE allows you to select all of the model. To select faces or cells, use the **Selection** toolbar to change the type of object that you can select to **Face** or **Cells**. For more information, see *Filtering your selection based on the type of object*.

   If you would rather select from a list of existing sets, do the following:

   a. Click **Sets** on the right side of the prompt area.

      Abaqus/CAE displays the **Region Selection** dialog box containing a list of available sets.

   b. Select the set of interest, and click **Continue**.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

5. When you have finished selecting the geometric restriction region, click **Done** in the prompt area. For more information on selecting objects, see *Selecting objects within the viewport*.

   The **Edit Geometric Restriction** dialog box appears.

6. By default, the region in which the Optimization module checks for critical overhanging features is the same as the region in which it enforces the overhang control restriction. If desired, select from the top of the **Edit Geometric Restriction** dialog box, and select the check region.
7. Select the base plane to define the printing bed.

- Select **Determine automatically** to allow the Optimization module to determine the optimal location of the base plane such that all overhanging features are removed.
- Select **Specify**, and click  to select a point on the plane perpendicular to the print direction.
- Select **None** to indicate that all boundary features should be printed.

8. By default, the Optimization module assumes the print direction is defined in the global coordinate system. To change the coordinate system, click  for the **CSYS** option and do one of the following:
   - Select an existing datum coordinate system in the viewport.
   - Select an existing datum coordinate system by name.
     1. From the prompt area, click **Datum CSYS List** to display a list of datum coordinate systems.
     2. Select a name from the list, and click **OK**.
   - Click **Use Global CSYS** from the prompt area to revert to the global coordinate system.

   Alternatively, click  to define a new datum coordinate system.
9. Click , and select two points specifying the vector along the print direction.
10. Enter the **Overhang angle**. The overhang angle is an angle relative to the print direction that is introduced to the optimized model to ensure the part does not contain unacceptable features. The default value is 45°.
11. Enter the **Radius**. The radius defines the size of the cones that are used in the internal check for the overhang criteria. The default value in 1.5 times the average element length.
12. Click **OK** to create the overhang control geometric restriction and to exit the editor.

Creating a milling control restriction

You can specify a milling control geometric restriction for a topology optimization.
A milling geometric restriction forces the optimized model to satisfy specified manufacturing requirements; for example, it can arrange undercuts and hollow regions in a part to facilitate material removal by milling.

1. From the main menu bar, select **Geometric Restriction->Create**.

   The **Create Geometric Restriction** dialog box appears.

   Tip: You can initiate the **Create** procedure in two other ways:

   - Click **Create** in the **Geometric Restriction Manager**. (You can display the **Geometric Restriction Manager** by selecting **Geometric Restriction->Manager** from the main menu bar.)
   - Click the  tool in the Optimization module toolbox.

2. From the **Create Geometric Restriction** dialog box that appears, enter the name of the geometric restriction.
3. Select **Milling control** from the list of geometric restrictions, and click **Continue**.
4. From the viewport, select the region in which the milling restriction will be enforced or click **Done** to apply the milling symmetry restriction to the entire model.

   By default, Abaqus/CAE allows you to select all of the model. To select faces or cells, use the **Selection** toolbar to change the type of object that you can select to **Face** or **Cells**. For more information, see *Filtering your selection based on the type of object*.

   If you would rather select from a list of existing sets, do the following:

   a. Click **Sets** on the right side of the prompt area.

      Abaqus/CAE displays the **Region Selection** dialog box containing a list of available sets.

   b. Select the set of interest, and click **Continue**.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

5. When you have finished selecting the geometric restriction region, click **Done** in the prompt area. For more information on selecting objects, see *Selecting objects within the viewport*."

   The **Edit Geometric Restriction** dialog box appears.

6. By default, the region in which the Optimization module checks for milling is the same as the region in which it enforces the milling restriction. If desired, select  from the top of the **Edit Geometric Restriction** dialog box, and select the milling check region.
7. By default, the Optimization module assumes the milling directions are defined in the global coordinate system. To change the coordinate system, click  for the **CSYS** option and do one of the following:

   - Select an existing datum coordinate system in the viewport.
   - Select an existing datum coordinate system by name.

     1. From the prompt area, click **Datum CSYS List** to display a list of datum coordinate systems.
     2. Select a name from the list, and click **OK**.

- Click **Use Global CSYS** from the prompt area to revert to the global coordinate system.

Alternatively, click  to define a new datum coordinate system.

8. Click , and select two points specifying the vector along the milling direction. It specifies the direction in which the model is supposed to be milled. Repeat the step to specify multiple directions in case of multiaxis milling.
9. Enter the **Radius**. The radius value is used internally for the collision check during the removal of the elements.
10. Click **OK** to create the milling geometric restriction and to exit the editor.

Additional information

- *Creating a geometric restriction in a topology or sizing optimization*
- *Creating a geometric restriction in a shape optimization*

Creating a rib design restriction

You can specify a rib design geometric restriction for a topology optimization.

The rib pattern restriction forces the optimizer to prevent material accumulation and to generate substructures in the form of ribs.

1. From the main menu bar, select **Geometric Restriction->Create**.

   The **Create Geometric Restriction** dialog box appears.

   Tip: You can initiate the **Create** procedure in two other ways:

   - Click **Create** in the **Geometric Restriction Manager**. (You can display the **Geometric Restriction Manager** by selecting **Geometric Restriction->Manager** from the main menu bar.)
   - Click the tool in the Optimization module toolbox.

2. From the **Create Geometric Restriction** dialog box that appears, enter the name of the geometric restriction.
3. Select **Rib design** from the list of geometric restrictions, and click **Continue**.
4. From the viewport, select the region in which the rib design restriction will be enforced or click **Done** to apply the rib design restriction to the entire model.

   By default, Abaqus/CAE allows you to select all of the model. To select faces or cells, use the **Selection** toolbar to change the type of object that you can select to **Face** or **Cells**. For more information, see *Filtering your selection based on the type of object*.

5. **Optional:** If you would rather select from a list of existing sets, do the following:
   a. Click **Sets** on the right side of the prompt area.

      Abaqus/CAE displays the **Region Selection** dialog box containing a list of available sets.

   b. Select the set of interest, and click **Continue**.

   Note: The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

6. When you have finished selecting the geometric restriction region, click **Done** in the prompt area. For more information on selecting objects, see *Selecting objects within the viewport*."

   The **Edit Geometric Restriction** dialog box appears.

7. **Optional:** By default, the region in which the Optimization module checks for rib design is the same as the region in which it enforces the rib design restriction. If desired, select from the top of the **Edit Geometric Restriction** dialog box, and select the rib design check region.
8. **Optional:** By default, the Optimization module assumes the rib direction is defined in the global coordinate system. To change the coordinate system, click for the **CSYS** option and do one of the following:

   - Select an existing datum coordinate system in the viewport.
   - Select an existing datum coordinate system by name:

     1. From the prompt area, click **Datum CSYS List** to display a list of datum coordinate systems.

2. Select a name from the list, and click **OK**.

- Click **Use Global CSYS** from the prompt area to revert to the global coordinate system.

Alternatively, click  to define a new datum coordinate system.

9. Click , and select two points specifying the out-of-plane growth direction of the ribs.
10. Enter the **Rib thickness**.

    The rib thickness is the averaged thickness of the ribs.
11. Enter the **Rib distance**.

    The rib distance is the averaged distance between the rib centers. The distance must be larger than twice the average element edge length.
12. Click **OK** to create the rib design geometric restriction and to exit the editor.

Creating a geometric restriction in a shape optimization

This section describes how to create a geometric restriction in a shape optimization.

In this section:

- *Creating a member size restriction*
- *Creating a planar symmetry restriction*
- *Creating a rotational symmetry restriction*
- *Creating a point symmetry restriction*
- *Creating a stamp control restriction*
- *Creating a turn control restriction*
- *Creating a demold control restriction*
- *Creating a drill control restriction*
- *Creating a penetration check restriction*
- *Creating a fixed region restriction*
- *Creating a growth restriction*
- *Creating a design direction restriction*
- *Creating a slide region control restriction*

Creating a member size restriction

You can specify the minimum or maximum size of selected regions of your model; for example, the minimum thickness of a rib that is modified during the shape optimization. The value that you enter can be thought of as a radius. During the optimization the Optimization module restrains the thickness of a member to be twice the value that you entered (the diameter). If you enter a value for the minimum thickness, the Optimization module adjusts surface nodes such that the minimum diameter must be achieved along a normal to the surface of the model. If the structure is smaller than the specified value in certain regions, the shape optimization permits only growth until the member size in the regions areas satisfies the restriction. Conversely, if you enter a value for the maximum thickness, the Optimization module adjusts surface nodes such that a maximum diameter must be achieved along a normal to the surface of the model. If the structure is larger than the specified value in certain regions, the shape optimization permits only shrinkage until the member size in the regions areas satisfies the restriction.

1. From the main menu bar, select **Geometric Restriction->Create**.

   The **Create Geometric Restriction** dialog box appears.

   Tip: You can initiate the **Create**. procedure in two other ways:

   - Click **Create** in the **Geometric Restriction Manager**. (You can display the **Geometric Restriction Manager** by selecting **Geometric Restriction->Manager** from the main menu bar.)
   - Click the  tool in the Optimization module toolbox.

2. From the **Create Geometric Restriction** dialog box that appears, enter the name of the geometric restriction.
3. Select **Member size (Shape)** from the list of geometric restrictions, and click **Continue**.
4. From the viewport, select the region to which the member size restriction will be applied or click **Done** to apply the member size restriction to the entire model.

   By default, Abaqus/CAE allows you to select all of the model. To select faces or cells, use the **Selection** toolbar to change the type of object that you can select to **Face** or **Cells**. For more information, see *Filtering your selection based on the type of object*.

   If you would rather select from a list of existing sets, do the following:

   a. Click **Sets** on the right side of the prompt area.

      Abaqus/CAE displays the **Region Selection** dialog box containing a list of available sets.

   b. Select the set of interest, and click **Continue**.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

5. When you have finished selecting the geometric restriction region, click **Done** in the prompt area. For more information on selecting objects, see *Selecting objects within the viewport*."

   The **Edit Geometric Restriction** dialog box appears.

6. Do either of the following:

   - Select **Minimum thickness**, and enter the minimum radius of a member.
   - Select **Maximum thickness**, and enter the maximum radius of a member.

7. If desired, toggle on **Ignore in first design cycle** (default). When the optimization starts, it assumes the selected regions already include members larger than the minimum thickness. If the regions include smaller members, the Optimization module issues a warning and tries to continue. If you toggle off **Ignore in first design cycle**, and the regions include smaller members, the Optimization module issues an error message and stops execution.
8. If desired, toggle on **Check node group**, and select the node group region.
9. Click **OK** to create the member size geometric restriction and to exit the editor.

Additional information

- *Creating a geometric restriction in a topology or sizing optimization*
- *Creating a geometric restriction in a shape optimization*

Creating a planar symmetry restriction

You can specify a planar symmetry geometric restriction for a shape optimization. A planar symmetry geometric restriction forces selected faces of the optimized model to be symmetric about a specified plane. You specify the plane of symmetry by selecting the axis of a coordinate system that is the normal to the plane of symmetry. The origin of the coordinate system is a point on the plane of symmetry. You can use the global coordinate system, or you can create a datum coordinate system (see *Methods for creating a datum coordinate system*, for more information).

The mesh must be approximately symmetric across the plane of symmetry before the optimization starts somast that the Optimization module can identify pairs of nodes on either side of the plane of symmetry—the main node and the secondary node. By default, the main node is the node that the optimization moves out the most (the most growth) or moves in the least (the least shrinkage). The optimization displaces the main node, and the symmetry condition applies an equal displacement to the secondary node so that it remains symmetrical to the main node. Alternatively, if you are trying to optimize surfaces that are in contact, you can force the Optimization module to select the main node as the node to which the optimization is applying the least growth or the most amount of shrinkage.

1. From the main menu bar, select **Geometric Restriction->Create**.

   The **Create Geometric Restriction** dialog box appears.

   Tip: You can initiate the **Create** procedure in two other ways:

   - Click **Create** in the **Geometric Restriction Manager**. (You can display the **Geometric Restriction Manager** by selecting **Geometric Restriction->Manager** from the main menu bar.)
   - Click the  tool in the Optimization module toolbox.

2. From the **Create Geometric Restriction** dialog box that appears, enter the name of the geometric restriction.
3. Select **Planar symmetry** from the list of geometric restrictions, and click **Continue**.
4. From the viewport, select the faces in which the planar symmetry will be enforced. For more information, see *Using the face curvature method to select multiple faces*.

   If you would rather select from a list of existing sets, do the following:

   a. Click **Sets** on the right side of the prompt area.

      Abaqus/CAE displays the **Region Selection** dialog box containing a list of available sets.

   b. Select the set of interest, and click **Continue**.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

5. When you have finished selecting faces, click **Done** in the prompt area.

   The **Edit Geometric Restriction** dialog box appears.

6. Select the coordinate system, and select the axis of the coordinate system that represents the normal to the plane of symmetry.
7. Select the method that the optimization will use to determine the main point. In most cases you should select **Determine from most growth and least shrinkage**. You should select **Determine from least growth and most shrinkage** only if you are trying to optimize faces that are involved in contact.
8. Enter the tolerance that will be used to determine symmetric points in the *X*-, *Y*-, and *Z*-axes.

The Optimization module uses the tolerance to identify the pairs of symmetric nodes across the symmetry plane.

9. If desired, toggle on **Ignore in first design cycle** (default). When the optimization starts, it assumes the faces are already symmetric about the plane. If the faces are not symmetric, the Optimization module issues a warning and tries to continue. If you toggle off **Ignore in first design cycle**, and the faces are not symmetric, the Optimization module issues an error message and stops execution.
10. If desired, toggle on **Allow nonsymmetric mesh** (default) to use the planar symmetry geometric restriction for nonsymmetric meshes as well. Toggle off **Allow nonsymmetric mesh** to use the planar symmetry geometric restriction with symmetric meshes only.
11. Click **OK** to create the planar symmetry geometric restriction and to exit the editor.

Creating a rotational symmetry restriction

You can specify a rotational symmetry geometric restriction for a shape optimization. A rotational symmetry geometric restriction forces selected faces of the optimized model to be symmetric about a specified axis. You choose the axis of symmetry by specifying the starting and ending coordinates of a vector representing the axis. You can use the global coordinate system, or you can create a datum coordinate system (see *Methods for creating a datum coordinate system*, for more information).

The mesh must be approximately symmetric around the axis of symmetry before the optimization starts so that the Optimization module can identify the group of nodes that sit on a selected face in a plane normal to the axis of symmetry. By default, the main node is the node in the group that the optimization moves out the most (the most growth) or moves in the least (the least shrinkage). The optimization displaces the main node, and the symmetry condition applies an equal displacement to the rest of the nodes in the group (the secondary nodes) so that they remain symmetrical about the axis. If you are trying to optimize surfaces that are in contact, you can force the Optimization module to select the main node as the node to which the optimization is applying the least growth or the most amount of shrinkage. Alternatively, you can select a single point that will be used as the main node by all other nodes. The optimization determines how much the main node is displaced, and all other nodes are moved the same amount so that they remain symmetric about the selected axis.

1. From the main menu bar, select **Geometric Restriction->Create**.

   The **Create Geometric Restriction** dialog box appears.

   Tip: You can initiate the **Create** procedure in two other ways:

   - Click **Create** in the **Geometric Restriction Manager**. (You can display the **Geometric Restriction Manager** by selecting **Geometric Restriction->Manager** from the main menu bar.)
   - Click the  tool in the Optimization module toolbox.

2. From the **Create Geometric Restriction** dialog box that appears, enter the name of the geometric restriction.
3. Select **Rotational symmetry (Shape)** from the list of geometric restrictions, and click **Continue**.
4. From the viewport, select the faces in which the rotational symmetry will be enforced. For more information, see *Using the face curvature method to select multiple faces*.

   If you would rather select from a list of existing sets, do the following:

   a. Click **Sets** on the right side of the prompt area.

      Abaqus/CAE displays the **Region Selection** dialog box containing a list of available sets.

   b. Select the set of interest, and click **Continue**.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

5. When you have finished selecting faces, click **Done** in the prompt area.

   The **Edit Geometric Restriction** dialog box appears.

6. Enter the coordinates of the starting point and the ending point of a vector representing the axis of symmetry.
7. Toggle on **Create a repeating pattern**, and enter the angle over which the pattern created by the optimization will be repeated. The value must be between 0° and 360°. A value of 0° implies the

secondary nodes are symmetric about the axis of symmetry, but the optimization does not create a repeating pattern.

8. If desired, toggle on **Allow nonsymmetric mesh** (default) to use the rotational symmetry geometric restriction for nonsymmetric meshes as well. Toggle off **Allow nonsymmetric mesh** to use the rotational symmetry geometric restriction with symmetric meshes only. When you allow nonsymmetric meshes, you can pick the **Start point** of the repeating pattern.
9. Select the method that the optimization will use to determine the main point. In most cases you should select **Determine from most growth and least shrinkage**. You should select **Determine from least growth and most shrinkage** only if you are trying to optimize faces that are involved in contact.

   Alternatively, you can select **Region** and select a vertex that will be used to represent the main node.
10. Enter the tolerance that will be used to determine symmetric points in the *X*-, *Y*-, and *Z*-axes.

    The Optimization module uses the tolerance to identify the nodes on the surface that lie on a plane normal to the axis of symmetry and are equidistant from the axis of symmetry.
11. If desired, toggle on **Ignore in first design cycle** (default). When the optimization starts, it assumes the faces are already symmetric about the axis. If the faces are not symmetric, the Optimization module issues a warning and tries to continue. If you toggle off **Ignore in first design cycle** and the faces are not symmetric, the Optimization module issues an error message and stops execution.
12. Click **OK** to create the rotational symmetry geometric restriction and to exit the editor.

Additional information

- *Creating a geometric restriction in a shape optimization*

Creating a point symmetry restriction

You can specify a point symmetry geometric restriction for a shape optimization. A rotational symmetry geometric restriction forces selected faces of the optimized model to be symmetric about a specified point of symmetry. You specify the point of symmetry by selecting a coordinate system (the point of symmetry is assumed to be the origin of the coordinate system). You can use the global coordinate system, or you can create a datum coordinate system (see *Methods for creating a datum coordinate system*, for more information).

The mesh must be approximately symmetric about the point before the optimization starts so that the Optimization module can identify pairs of nodes on either side of the point of symmetry—the main node and the secondary node. By default, the main node is the node that the optimization moves out the most (the most growth) or moves in the least (the least shrinkage). The optimization displaces the main node, and the symmetry condition applies an equal displacement to the secondary node so that it remains symmetrical to the main node. Alternatively, if you are trying to optimize surfaces that are in contact, you can force the Optimization module to select the main node as the node to which the optimization is applying the least growth or the most amount of shrinkage.

1. From the main menu bar, select **Geometric Restriction->Create**.

   The **Create Geometric Restriction** dialog box appears.

   Tip: You can initiate the **Create** procedure in two other ways:

   - Click **Create** in the **Geometric Restriction Manager**. (You can display the **Geometric Restriction Manager** by selecting **Geometric Restriction->Manager** from the main menu bar.)
   - Click the  tool in the Optimization module toolbox.

2. From the **Create Geometric Restriction** dialog box that appears, enter the name of the geometric restriction.
3. Select **Point symmetry (Shape)** from the list of geometric restrictions, and click **Continue**.
4. From the viewport, select the faces in which the point symmetry will be enforced. For more information, see *Using the face curvature method to select multiple faces*.

   If you would rather select from a list of existing sets, do the following:

   a. Click **Sets** on the right side of the prompt area.

      Abaqus/CAE displays the **Region Selection** dialog box containing a list of available sets.

   b. Select the set of interest, and click **Continue**.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

5. When you have finished selecting faces, click **Done** in the prompt area.

   The **Edit Geometric Restriction** dialog box appears.

6. Select the coordinate system. The point of symmetry is assumed to be the origin of the selected coordinate system.
7. Select the method that the optimization will use to determine the main point. In most cases you should select **Determine from most growth and least shrinkage**. You should select **Determine from least growth and most shrinkage** only if you are trying to optimize faces that are involved in contact.
8. Enter the tolerance in the *X*-, *Y*-, and *Z*-planes that will be used to determine symmetric points .

The Optimization module uses the tolerance to identify the nodes that are symmetric to the point of symmetry.

9. If desired, toggle on **Ignore in first design cycle** (default). When the optimization starts, it assumes the faces are already symmetric about the point. If the faces are not symmetric, the Optimization module issues a warning and tries to continue. If you toggle off **Ignore in first design cycle** and the faces are not symmetric, the Optimization module issues an error message and stops execution.
10. Click **OK** to create the point symmetry geometric restriction and to exit the editor.

Creating a stamp control restriction

You can specify a stamp control geometric restriction for a shape optimization. A stamp control geometric restriction results in an optimized model that can be manufactured by a tool and die stamping operation along a specified direction. You choose the direction by specifying the starting and ending coordinates of a vector representing the direction. You can use the global coordinate system, or you can create a datum coordinate system (see *Methods for creating a datum coordinate system*, for more information).

The mesh should define a stampable model before the optimization starts; otherwise, the mesh may become distorted when the optimization creates a stampable model in the first iteration. The main node can lie anywhere in the region that you select to be governed by the stamp restriction. By default, the main node is the node in the region that the optimization moves out the most (the most growth) or moves in the least (the least shrinkage). The optimization displaces the main node, and the stamp condition applies an equal displacement to the rest of the nodes in the region (the secondary nodes) so that the model remains stampable. If you are trying to optimize surfaces that are in contact, you can force the Optimization module to select the main node as the node to which the optimization is applying the least growth or the most amount of shrinkage. Alternatively, you can select a single point that will be used as the main node by all other nodes. The optimization determines how much the main node is displaced, and all other nodes are moved the same amount so that the model remains stampable.

1. From the main menu bar, select **Geometric Restriction->Create**.

   The **Create Geometric Restriction** dialog box appears.

   Tip: You can initiate the **Create** procedure in two other ways:

   - Click **Create** in the **Geometric Restriction Manager**. (You can display the **Geometric Restriction Manager** by selecting **Geometric Restriction->Manager** from the main menu bar.)
   - Click the  tool in the Optimization module toolbox.

2. From the **Create Geometric Restriction** dialog box that appears, enter the name of the geometric restriction.
3. Select **Stamp control** from the list of geometric restrictions, and click **Continue**.
4. From the viewport, select the faces to which the stamp control will be applied. For more information, see *Using the face curvature method to select multiple faces*.

   If you would rather select from a list of existing face sets, do the following:

   a. Click **Sets** on the right side of the prompt area.

      Abaqus/CAE displays the **Region Selection** dialog box containing a list of available sets.

   b. Select the set of interest, and click **Continue**.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

5. When you have finished selecting faces, click **Done** in the prompt area.

   The **Edit Geometric Restriction** dialog box appears.

6. Enter the coordinates of the starting point and the ending point of a vector representing the direction along which the stamping tool moves.
7. Enter the draw angle, which represents the angle of the tool that is creating the stamped model. The value must be between 0° and 45°.

8. Enter a positive value for the amount of undercut that can be tolerated in the stamping region.
9. Select the method that the optimization will use to determine the main point. In most cases you should select **Determine from most growth and least shrinkage**. You should select **Determine from least growth and most shrinkage** only if you are trying to optimize faces that are involved in contact.

   Alternatively, you can select **Region** and select a vertex that will be used to represent the main node.
10. Enter the tolerance in the *X*-, *Y*-, and *Z*-axes.

    The Optimization module uses the tolerance to identify the nodes on the surface that lie on a plane normal to the axis of symmetry and are equidistant from the axis of symmetry.
11. If desired, toggle on **Ignore in first design cycle** (default). When the optimization starts, it assumes the model is stampable. If the model is not stampable, the Optimization module issues a warning and tries to continue. If you toggle off **Ignore in first design cycle** and the model is not stampable, the Optimization module issues an error message and stops execution.
12. Click **OK** to create the stamp control geometric restriction and to exit the editor.

Creating a turn control restriction

You can specify a turn control geometric restriction for a shape optimization. A turn control geometric restriction results in an optimized model that can be manufactured by a tool on a lathe cutting into the model along a specified direction. You choose the direction by specifying the starting and ending coordinates of a vector representing the direction. You can use the global coordinate system, or you can create a datum coordinate system (see *Methods for creating a datum coordinate system*, for more information).

The mesh should define a turnable model before the optimization starts; otherwise, the mesh may become distorted when the optimization creates a turnable model in the first iteration. The main node can lie anywhere in the region that you select to be governed by the turn restriction. By default, the main node is the node in the region that the optimization moves out the most (the most growth) or moves in the least (the least shrinkage). The optimization displaces the main node, and the stamp condition applies an equal displacement to the rest of the nodes in the region (the secondary nodes) so that the model remains turnable. If you are trying to optimize surfaces that are in contact, you can force the Optimization module to select the main node as the node to which the optimization is applying the least growth or the most amount of shrinkage. Alternatively, you can select a single point that will be used as the main node by all other nodes. The optimization determines how much the main node is displaced, and all other nodes are moved the same amount so that the model remains turnable.

1. From the main menu bar, select **Geometric Restriction->Create**.

   The **Create Geometric Restriction** dialog box appears.

   Tip: You can initiate the **Create** procedure in two other ways:

   - Click **Create** in the **Geometric Restriction Manager**. (You can display the **Geometric Restriction Manager** by selecting **Geometric Restriction->Manager** from the main menu bar.)
   - Click the tool in the Optimization module toolbox.

2. From the **Create Geometric Restriction** dialog box that appears, enter the name of the geometric restriction.
3. Select **Turn control** from the list of geometric restrictions, and click **Continue**.
4. From the viewport, select the faces to which the turn control will be applied. For more information, see *Using the face curvature method to select multiple faces*.

   If you would rather select from a list of existing face sets, do the following:

   a. Click **Sets** on the right side of the prompt area.

      Abaqus/CAE displays the **Region Selection** dialog box containing a list of available sets.

   b. Select the set of interest, and click **Continue**.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

5. When you have finished selecting faces, click **Done** in the prompt area.

   The **Edit Geometric Restriction** dialog box appears.

6. Enter the coordinates of the starting point and the ending point of a vector representing the direction along which the cutting tool moves.

7. Select the method that the optimization will use to determine the main point. In most cases you should select **Determine from most growth and least shrinkage**. You should select **Determine from least growth and most shrinkage** only if you are trying to optimize faces that are involved in contact.
8. Enter the tolerance in the *X*-, *Y*-, and *Z*-axes.

   The Optimization module uses the tolerance to identify the nodes on the surface that lie on a plane normal to the axis of symmetry and are equidistant from the axis of symmetry.
9. If desired, toggle on **Ignore in first design cycle** (default). When the optimization starts, it assumes the model is turnable. If the model is not turnable, the Optimization module issues a warning and tries to continue. If you toggle off **Ignore in first design cycle** and the model is not turnable, the Optimization module issues an error message and stops execution.
10. Click **OK** to create the turn control geometric restriction and to exit the editor.

Additional information

- *Creating a geometric restriction in a topology or sizing optimization*
- *Creating a geometric restriction in a shape optimization*

Creating a demold control restriction

You can specify a demold geometric restriction for a shape optimization. A demold geometric restriction forces the optimized model to satisfy specified manufacturing requirements; for example, it can prevent undercuts and hollow regions in a part that must be extracted from a mold. You choose the demolding direction by specifying the starting and ending coordinates of a vector representing the axis. You can use the global coordinate system, or you can create a datum coordinate system (see *Methods for creating a datum coordinate system*, for more information).

The mesh should define a demoldable model before the optimization starts; otherwise, the mesh may become distorted when the optimization creates a demoldable model in the first iteration. The main node can lie anywhere in the region that you select to be governed by the demold control restriction. By default, the main node is the node in the region that the optimization moves out the most (the most growth) or moves in the least (the least shrinkage). The optimization displaces the main node, and the stamp condition applies an equal displacement to the rest of the nodes in the region (the secondary nodes) so that the model remains demoldable. If you are trying to optimize surfaces that are in contact, you can force the Optimization module to select the main node as the node to which the optimization is applying the least growth or the most amount of shrinkage. Alternatively, you can select a single point that will be used as the main node by all other nodes. The optimization determines how much the main node is displaced, and all other nodes are moved the same amount so that the model remains demoldable.

1. From the main menu bar, select **Geometric Restriction->Create**

   The **Create Geometric Restriction** dialog box appears.

   Tip: You can initiate the **Create** procedure in two other ways:

   - Click **Create** in the **Geometric Restriction Manager**. (You can display the **Geometric Restriction Manager** by selecting **Geometric Restriction->Manager** from the main menu bar.)
   - Click the  tool in the Optimization module toolbox.

2. From the **Create Geometric Restriction** dialog box that appears, enter the name of the geometric restriction.
3. Select **Demold control** from the list of geometric restrictions, and click **Continue**.
4. From the viewport, select the faces to which the demold control will be applied. For more information, see *Using the face curvature method to select multiple faces*.

   If you would rather select from a list of existing face sets, do the following:

   a. Click **Sets** on the right side of the prompt area.

      Abaqus/CAE displays the **Region Selection** dialog box containing a list of available sets.

   b. Select the set of interest, and click **Continue**.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

5. When you have finished selecting faces, click **Done** in the prompt area.

   The **Edit Geometric Restriction** dialog box appears.

6. By default, the region in which the Optimization module checks for collisions is the same as the region in which it enforces the demold restriction. If desired, select  from the top of the **Edit Geometric Restriction** dialog box, and select the collision check region.

Faces inside the collision check region cannot be penetrated by faces outside the region. If a node attempts to penetrate an element in the collision check region during the shape optimization, the Optimization module scales back the displacement of the node. The collision check region must include the faces to which the demold control will be applied.

7. Enter the coordinates of the starting point and the ending point of a vector representing the direction along which a mold is withdrawn from the demold region.
8. Enter the draw angle, which represents the angle of a mold that is being withdrawn from the demold region. The value must be between 0° and 45°.
9. Enter a positive value for the amount of undercut that can be tolerated in the demold control region.
10. Select the method that the optimization will use to determine the main point. In most cases you should select **Determine from most growth and least shrinkage**. You should select **Determine from least growth and most shrinkage** only if you are trying to optimize faces that are involved in contact.
11. Enter the tolerance in the *X*-, *Y*-, and *Z*-axes.

    The Optimization module uses the tolerance to identify the nodes on the surface that lie on a plane normal to the axis of symmetry and are equidistant from the axis of symmetry.
12. If desired, toggle on **Ignore in first design cycle** (default). When the optimization starts, it assumes a mold could be withdrawn from the demold region. If the mold could not be withdrawn, the Optimization module issues a warning and tries to continue. If you toggle off **Ignore in first design cycle**, and the mold could not be withdrawn, the Optimization module issues an error message and stops execution.
13. Click **OK** to create the demold geometric restriction and to exit the editor.

- *Creating a geometric restriction in a topology or sizing optimization*
- *Creating a geometric restriction in a shape optimization*

Creating a drill control restriction

You can specify a drill control geometric restriction for a shape optimization. A drill control geometric restriction results in an optimized model that can be manufactured by a tool drilling into the model along a specified direction. The hole created by the tool is symmetric about the axis of the tool. In addition, the tool can be withdrawn from the hole. You choose the axis of the tool (and the drilling direction) by specifying the starting and ending coordinates of a vector representing the axis. You can use the global coordinate system, or you can create a datum coordinate system (see *Methods for creating a datum coordinate system*, for more information).

The mesh should define a drillable model before the optimization starts; otherwise, the mesh may become distorted when the optimization creates a drillable model in the first iteration. The main node can lie anywhere in the region that you select to be governed by the drill control restriction. By default, the main node is the node in the region that the optimization moves out the most (the most growth) or moves in the least (the least shrinkage). The optimization displaces the main node, and the stamp condition applies an equal displacement to the rest of the nodes in the region (the secondary nodes) so that the model remains drillable. If you are trying to optimize surfaces that are in contact, you can force the Optimization module to select the main node as the node to which the optimization is applying the least growth or the most amount of shrinkage. Alternatively, you can select a single point that will be used as the main node by all other nodes. The optimization determines how much the main node is displaced, and all other nodes are moved the same amount so that the model remains drillable.

1. From the main menu bar, select **Geometric Restriction->Create**.

   The **Create Geometric Restriction** dialog box appears.

   Tip: You can initiate the **Create** procedure in two other ways:

   - Click **Create** in the **Geometric Restriction Manager**. (You can display the **Geometric Restriction Manager** by selecting **Geometric Restriction->Manager** from the main menu bar.)
   - Click the tool in the Optimization module toolbox.

2. From the **Create Geometric Restriction** dialog box that appears, enter the name of the geometric restriction.
3. Select **Stamp control** from the list of geometric restrictions, and click **Continue**.
4. From the viewport, select the faces to which the drill control will be applied. For more information, see *Using the face curvature method to select multiple faces*.

   If you would rather select from a list of existing face sets, do the following:

   a. Click **Sets** on the right side of the prompt area.

      Abaqus/CAE displays the **Region Selection** dialog box containing a list of available sets.

   b. Select the set of interest, and click **Continue**.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

5. When you have finished selecting faces, click **Done** in the prompt area.

   The **Edit Geometric Restriction** dialog box appears.

6. Enter the coordinates of the starting point and the ending point of a vector representing the direction along which the drilling tool moves.

7. Enter the draw angle, which represents the angle of the tool that is drilling the hole. The value must be between 0° and 45°.
8. Enter a positive value for the amount of undercut that can be tolerated in the drill control region.
9. Select the method that the optimization will use to determine the main point. In most cases you should select **Determine from most growth and least shrinkage**. You should select **Determine from least growth and most shrinkage** only if you are trying to optimize faces that are involved in contact.

   Alternatively, you can select **Region** and select a vertex that will be used to represent the main node.
10. Enter the tolerance in the *X*-, *Y*-, and *Z*-axes.

    The Optimization module uses the tolerance to identify the nodes on the surface that lie on a plane normal to the axis of symmetry and are equidistant from the axis of symmetry.
11. If desired, toggle on **Ignore in first design cycle** (default). When the optimization starts, it assumes the model is drillable. If the model is not drillable, the Optimization module issues a warning and tries to continue. If you toggle off **Ignore in first design cycle** and the model is not drillable, the Optimization module issues an error message and stops execution.
12. Click **OK** to create the drill control geometric restriction and to exit the editor.

Creating a penetration check restriction

A penetration check geometric restriction in a shape optimization results in an optimized model with faces that cannot penetrate selected regions.

1. From the main menu bar, select **Geometric Restriction->Create**.

   The **Create Geometric Restriction** dialog box appears.

   Tip: You can initiate the **Create** procedure in two other ways:

   - Click **Create** in the **Geometric Restriction Manager**. (You can display the **Geometric Restriction Manager** by selecting **Geometric Restriction->Manager** from the main menu bar.)
   - Click the tool in the Optimization module toolbox.

2. From the **Create Geometric Restriction** dialog box that appears, enter the name of the geometric restriction.
3. Select **Penetration check (Shape)** from the list of geometric restrictions, and click **Continue**.
4. From the viewport, select the faces to which the penetration check will be applied. For more information, see *Using the face curvature method to select multiple faces*.

   If you would rather select from a list of existing face sets, do the following:

   a. Click **Sets** on the right side of the prompt area.

      Abaqus/CAE displays the **Region Selection** dialog box containing a list of available sets.

   b. Select the set of interest, and click **Continue**.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

5. When you have finished selecting faces, click **Done** in the prompt area.

   The **Edit Geometric Restriction** dialog box appears.

6. Select the regions that cannot be penetrated by faces of the optimized model.
7. If desired, toggle on **Ignore in first design cycle** (default). When the optimization starts, it assumes the model is not already penetrating the selected regions. If the model is penetrating the selected region, the Optimization module issues a warning and tries to continue. If you toggle off **Ignore in first design cycle** and the model is penetrating the selected region, the Optimization module issues an error message and stops execution.
8. Click **OK** to create the penetration check geometric restriction and to exit the editor.

Additional information

- *Creating a geometric restriction in a topology or sizing optimization*
- *Creating a geometric restriction in a shape optimization*

Creating a fixed region restriction

You can specify a fixed region restriction for a shape optimization. A fixed region is restrained in selected degrees of freedom (**1-**, **2-**, or **3-direction**. The degrees of freedom are defined relative to a selected coordinate system.

1. From the main menu bar, select **Geometric Restriction->Create**.

   The **Create Geometric Restriction** dialog box appears.

   Tip: You can initiate the **Create** procedure in two other ways:

   - Click **Create** in the **Geometric Restriction Manager**. (You can display the **Geometric Restriction Manager** by selecting **Geometric Restriction->Manager** from the main menu bar.)
   - Click the  tool in the Optimization module toolbox.

2. From the **Create Geometric Restriction** dialog box that appears, enter the name of the geometric restriction.
3. Select **Fixed region** from the list of geometric restrictions, and click **Continue**.
4. From the viewport, select the faces to which the fixation will be applied. For more information, see *Using the face curvature method to select multiple faces*.

   If you would rather select from a list of existing face sets, do the following:

   a. Click **Sets** on the right side of the prompt area.

      Abaqus/CAE displays the **Region Selection** dialog box containing a list of available sets.

   b. Select the set of interest, and click **Continue**.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

5. When you have finished selecting faces, click **Done** in the prompt area.

   The **Edit Geometric Restriction** dialog box appears.

6. Select the coordinate system that defines the degrees of freedom. You can select the global coordinate system, or you can create a datum coordinate system (see *Methods for creating a datum coordinate system*, for more information).
7. Toggle on the degrees of freedom that you want to restrain.
8. If desired, toggle on **Ignore in first design cycle** (default). When the optimization starts, it assumes the region is already restrained in the selected degrees of freedom. If the region has displacement in the selected degrees of freedom, the Optimization module issues a warning and tries to continue. If you toggle off **Ignore in first design cycle** and the region has displacement in the selected degrees of freedom, the Optimization module issues an error message and stops execution.
9. Click **OK** to create the fixed region geometric restriction and to exit the editor.

Additional information

- *Creating a geometric restriction in a topology or sizing optimization*
- *Creating a geometric restriction in a shape optimization*

Creating a growth restriction

You can specify a growth restriction for a shape optimization. A growth restriction limits how much a face can grow (surface nodes are moved out) or shrink (surface nodes are moving in) relative to the initial design. For example, if you are optimizing a model that will be cast, you can use a growth restriction to control the maximum and minimum wall thickness in a region.

1. From the main menu bar, select **Geometric Restriction->Create**.

   The **Create Geometric Restriction** dialog box appears.

   Tip: You can initiate the **Create** procedure in two other ways:

   - Click **Create** in the **Geometric Restriction Manager**. (You can display the **Geometric Restriction Manager** by selecting **Geometric Restriction->Manager** from the main menu bar.)
   - Click the tool in the Optimization module toolbox.

2. From the **Create Geometric Restriction** dialog box that appears, enter the name of the geometric restriction.
3. Select **Growth** from the list of geometric restrictions, and click **Continue**.
4. From the viewport, select the faces to which the growth restrictions will be applied. For more information, see *Using the face curvature method to select multiple faces*.

   If you would rather select from a list of existing face sets, do the following:

   a. Click **Sets** on the right side of the prompt area.

      Abaqus/CAE displays the **Region Selection** dialog box containing a list of available sets.

   b. Select the set of interest, and click **Continue**.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

5. When you have finished selecting faces, click **Done** in the prompt area.

   The **Edit Geometric Restriction** dialog box appears.

6. Toggle on **Maximum in shrink direction**, and enter a positive value specifying the maximum inward displacement of a surface node.
7. Toggle on **Maximum in growth direction**, and enter a positive value specifying the maximum outward displacement of a surface node.
8. If desired, toggle on **Ignore in first design cycle** (default). When the optimization starts, it assumes the growth of the face is already limited. If the growth of the face exceeds the specified value, the Optimization module issues a warning and tries to continue. If you toggle off **Ignore in first design cycle** and the growth of the face exceeds the specified value, the Optimization module issues an error message and stops execution.
9. Click **OK** to create the growth geometric restriction and to exit the editor.

Additional information

- *Creating a geometric restriction in a topology or sizing optimization*
- *Creating a geometric restriction in a shape optimization*

Creating a design direction restriction

You can specify a design direction restriction for a shape optimization. You can use a design direction restriction to keep selected nodes of your model on a planar or circular surface during the optimization. The optimization displaces the main node, and the design direction restriction applies an equal displacement (either magnitude or direction or both) to the rest of the nodes in the region (the client nodes). In addition, you can specify the axes of a coordinate system (rectangular, cylindrical, or spherical) that are applied.

The mesh should define nodes that can be moved along the design direction before the optimization starts; otherwise, the mesh may become distorted when the optimization moves nodes in the first iteration. The main node can lie anywhere in the region that you select to be governed by the design direction restriction. By default, the main node is the node in the region that the optimization moves out the most (the most growth) or moves in the least (the least shrinkage). If you are trying to optimize surfaces that are in contact, you can force the Optimization module to select the main node as the node to which the optimization is applying the least growth or the most amount of shrinkage. Alternatively, you can select a single point that will be used as the main node by all other nodes.

1. From the main menu bar, select **Geometric Restriction->Create**.

   The **Create Geometric Restriction** dialog box appears.

   Tip: You can initiate the **Create** procedure in two other ways:

   - Click **Create** in the **Geometric Restriction Manager**. (You can display the **Geometric Restriction Manager** by selecting **Geometric Restriction->Manager** from the main menu bar.)
   - Click the  tool in the Optimization module toolbox.

2. From the **Create Geometric Restriction** dialog box that appears, enter the name of the geometric restriction.
3. Select **Design Direction** from the list of geometric restrictions, and click **Continue**.
4. From the viewport, select the faces to which the design direction restriction will be applied. For more information, see *Using the face curvature method to select multiple faces*.

   If you would rather select from a list of existing face sets, do the following:

   a. Click **Sets** on the right side of the prompt area.

      Abaqus/CAE displays the **Region Selection** dialog box containing a list of available sets.

   b. Select the set of interest, and click **Continue**.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

5. When you have finished selecting faces, click **Done** in the prompt area.

   The **Edit Geometric Restriction** dialog box appears.

6. Choose whether a client node should follow the main node by moving in the same direction or with the same magnitude or both.
7. If you chose to move a client node in both the same direction and with the same magnitude as the main node, toggle on the axes along which the movement will be applied.

8. Select the method that the optimization will use to determine the main node. In most cases you should select **Determine from most growth and least shrinkage**. You should select **Determine from least growth and most shrinkage** only if you are trying to optimize faces that are involved in contact.

   Alternatively, you can select **Region** and select a vertex that will be used to represent the main node.

9. If desired, toggle on **Ignore in first design cycle** (default). When the optimization starts, it assumes the nodes can be moved along the specified design direction. If the nodes cannot be moved along the design direction, the Optimization module issues a warning and tries to continue. If you toggle off **Ignore in first design cycle** and the nodes cannot be moved along the design direction, the Optimization module issues an error message and stops execution.
10. Click **OK** to create the design direction geometric restriction and to exit the editor.

Additional information

- *Creating a geometric restriction in a topology or sizing optimization*
- *Creating a geometric restriction in a shape optimization*

Creating a slide region control restriction

You can specify a slide region control, or contact, geometric restriction for a shape optimization. A slide region control geometric restriction results in an optimized model with a face that contacts a specified surface and follows the contours of the surface. You can select the specified surface from the model. Alternatively, the specified surface can be a surface of revolution generated by a rotating a selected face about a selected axis. You choose the axis of rotation by specifying the starting and ending coordinates of a vector representing the axis. You can use the global coordinate system, or you can create a datum coordinate system (see *Methods for creating a datum coordinate system*, for more information).

If you select the face from the model, the definition of the surface slide control restriction is complete. If you select a face that will be used to form a surface of revolution, the Optimization module selects the main node from the nodes on the face. By default, the main node is the node on the face that the optimization moves out the most (the most growth) or moves in the least (the least shrinkage). The optimization displaces the main node, and the surface slide restriction forces an equal displacement to the rest of the nodes on the face (the secondary nodes) so that the contact conditions are satisfied.

1. From the main menu bar, select **Geometric Restriction->Create**.

   The **Create Geometric Restriction** dialog box appears.

   Tip: You can initiate the **Create** procedure in two other ways:

   - Click **Create** in the **Geometric Restriction Manager**. (You can display the **Geometric Restriction Manager** by selecting **Geometric Restriction->Manager** from the main menu bar.)
   - Click the  tool in the Optimization module toolbox.

2. From the **Create Geometric Restriction** dialog box that appears, enter the name of the geometric restriction.
3. Select **Slide region control** from the list of geometric restrictions, and click **Continue**.
4. From the viewport, select the faces to which the surface slide control will be applied. For more information, see *Using the face curvature method to select multiple faces*.

   If you would rather select from a list of existing face sets, do the following:

   a. Click **Sets** on the right side of the prompt area.

      Abaqus/CAE displays the **Region Selection** dialog box containing a list of available sets.

   b. Select the set of interest, and click **Continue**.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

5. When you have finished selecting faces, click **Done** in the prompt area.

   The **Edit Geometric Restriction** dialog box appears.

6. Select the approach that you will use to define the contact surface.
7. If you selected the **Free-form** approach, select the contact surface.
8. If you selected the **Conserve a turnable surface** approach, do the following:

   a. Select the **Master Node Criteria**.

   b. Select the starting point and the ending point of a vector representing the axis of rotation.

c. Select the coordinate system that defines the vector. You can select the global coordinate system, or you can create a datum coordinate system (see *Methods for creating a datum coordinate system*, for more information).

d. Enter the tolerance in the *X*-, *Y*-, and *Z*-axes.

The Optimization module uses the tolerance to identify the nodes on the contact surface.

9. If desired, toggle on **Ignore in first design cycle** (default). When the optimization starts, it assumes the surfaces are in contact. If the surfaces are not in contact, the Optimization module issues a warning and tries to continue. If you toggle off **Ignore in first design cycle** and the surfaces are not in contact, the Optimization module issues an error message and stops execution.

10. Click **OK** to create the slide region control geometric restriction and to exit the editor.

Creating a geometric restriction in a bead optimization

This section describes how to create a geometric restriction in a bead optimization.

In this section:

- *Creating a filter restriction*
- *Creating a fixed region restriction*
- *Creating a growth restriction*
- *Creating a penetration check restriction*
- *Creating a planar symmetry restriction*
- *Creating a point symmetry restriction*
- *Creating a rotational symmetry restriction*

Creating a filter restriction

You can specify a filter restriction for a bead optimization.

A filter restriction creates a more consistent workflow between bead and other optimization types. In addition, it usually leads to better optimization convergence behavior.

1. From the main menu bar, select **Geometric Restriction->Create**.

   The **Create Geometric Restriction** dialog box appears.

   Tip: You can initiate the **Create** procedure in two other ways:

   - Click **Create** in the **Geometric Restriction Manager**. (You can display the **Geometric Restriction Manager** by selecting **Geometric Restriction->Manager** from the main menu bar.)
   - Click the  tool in the Optimization module toolbox.

2. From the **Create Geometric Restriction** dialog box that appears, enter the name of the geometric restriction.
3. Select **Filter (Bead)** from the list of geometric restrictions, and click **Continue**.
4. From the viewport, select the faces to which the fixation will be applied.

   For more information, see *Using the face curvature method to select multiple faces*.

   To select from a list of existing face sets, do the following:

   a. Click **Sets** on the right side of the prompt area.

      Abaqus/CAE displays the **Region Selection** dialog box containing a list of available sets.

   b. Select the set of interest, and click **Continue**.

   Note: The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

5. When you have finished selecting faces, click **Done** in the prompt area.

   The **Edit Geometric Restriction** dialog box appears.

6. **Optional:** By default, the region in which the Optimization module checks for the filter restriction is the same as the region in which it enforces the filter restriction. If desired, select  from the top of the **Edit Geometric Restriction** dialog box, and select the filter region check region.
7. Enter the **filter radius** in terms of value and whether absolute or relative units are used.

   If this value is omitted, double the average edge length of the model is used.

8. **Optional:** Select **Relative radius** to input the relative radius value.

   By default, this check box is off.

9. Click **OK** to create the filter geometric restriction and to exit the editor.

Additional information

- *Creating a geometric restriction in a bead optimization*

Creating a fixed region restriction

You can specify a fixed region restriction for a bead optimization. A fixed region is restrained in selected degrees of freedom (**1-**, **2-**, or **3-direction**. The degrees of freedom are defined relative to a selected coordinate system.

1. From the main menu bar, select **Geometric Restriction->Create**.

   The **Create Geometric Restriction** dialog box appears.

   Tip: You can initiate the **Create** procedure in two other ways:

   - Click **Create** in the **Geometric Restriction Manager**. (You can display the **Geometric Restriction Manager** by selecting **Geometric Restriction->Manager** from the main menu bar.)
   - Click the  tool in the Optimization module toolbox.

2. From the **Create Geometric Restriction** dialog box that appears, enter the name of the geometric restriction.
3. Select **Fixed Region (Bead)** from the list of geometric restrictions, and click **Continue**.
4. From the viewport, select the faces to which the fixation will be applied. For more information, see *Using the face curvature method to select multiple faces*.

   If you would rather select from a list of existing face sets, do the following:

   a. Click **Sets** on the right side of the prompt area.

      Abaqus/CAE displays the **Region Selection** dialog box containing a list of available sets.

   b. Select the set of interest, and click **Continue**.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

5. When you have finished selecting faces, click **Done** in the prompt area.

   The **Edit Geometric Restriction** dialog box appears.

6. Select the coordinate system that defines the degrees of freedom. You can select the global coordinate system, or you can create a datum coordinate system (see *Methods for creating a datum coordinate system*, for more information).
7. Toggle on the degrees of freedom that you want to restrain.
8. Click **OK** to create the fixed region geometric restriction and to exit the editor.

Additional information

- *Creating a geometric restriction in a bead optimization*

Creating a growth restriction

You can specify a growth restriction for a bead optimization. A growth restriction limits how much a face can grow (shell nodes at the location of the beads are moving out) relative to the initial design during the creation of the bead.

For a general bead optimization, you must limit the bead height by creating a growth geometric restriction that limits the displacement in the growth direction. The growth geometric restriction is required because it is the only restriction on the displacement of the nodes.

1. From the main menu bar, select **Geometric Restriction->Create**.

   The **Create Geometric Restriction** dialog box appears.

   Tip: You can initiate the **Create** procedure in two other ways:

   - Click **Create** in the **Geometric Restriction Manager**. (You can display the **Geometric Restriction Manager** by selecting **Geometric Restriction->Manager** from the main menu bar.)
   - Click the  tool in the Optimization module toolbox.

2. From the **Create Geometric Restriction** dialog box that appears, enter the name of the geometric restriction.
3. Select **Growth (Bead)** from the list of geometric restrictions, and click **Continue**.
4. From the viewport, select the faces to which the growth restrictions will be applied. For more information, see *Using the face curvature method to select multiple faces*.

   If you would rather select from a list of existing face sets, do the following:

   a. Click **Sets** on the right side of the prompt area.

      Abaqus/CAE displays the **Region Selection** dialog box containing a list of available sets.

   b. Select the set of interest, and click **Continue**.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

5. When you have finished selecting faces, click **Done** in the prompt area.

   The **Edit Geometric Restriction** dialog box appears.

6. Toggle on **Maximum in shrink direction**, and enter a positive value specifying the maximum inward displacement of a node. You can specify the maximum inward displacement of a node only for a general bead optimization.
7. Toggle on **Maximum in growth direction**, and enter a positive value specifying the maximum outward displacement of a node relative to the initial location.
8. Click **OK** to create the growth geometric restriction and to exit the editor.

Additional information

- *Creating a geometric restriction in a bead optimization*

Creating a penetration check restriction

A penetration check geometric restriction in a bead optimization results in an optimized model with faces that cannot penetrate selected regions.

1. From the main menu bar, select **Geometric Restriction->Create**.

   The **Create Geometric Restriction** dialog box appears.

   Tip: You can initiate the **Create** procedure in two other ways:

   - Click **Create** in the **Geometric Restriction Manager**. (You can display the **Geometric Restriction Manager** by selecting **Geometric Restriction->Manager** from the main menu bar.)
   - Click the tool in the Optimization module toolbox.

2. From the **Create Geometric Restriction** dialog box that appears, enter the name of the geometric restriction.
3. Select **Penetration check (Bead)** from the list of geometric restrictions, and click **Continue**.
4. From the viewport, select the faces to which the penetration check will be applied. For more information, see *Using the face curvature method to select multiple faces*.

   If you would rather select from a list of existing face sets, do the following:

   a. Click **Sets** on the right side of the prompt area.

      Abaqus/CAE displays the **Region Selection** dialog box containing a list of available sets.

   b. Select the set of interest, and click **Continue**.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

5. When you have finished selecting faces, click **Done** in the prompt area.

   The **Edit Geometric Restriction** dialog box appears.

6. Select the regions that cannot be penetrated by faces of the optimized model.
7. Click **OK** to create the penetration check geometric restriction and to exit the editor.

Additional information

- *Creating a geometric restriction in a bead optimization*

Creating a planar symmetry restriction

You can specify a planar symmetry geometric restriction for a condition-based bead optimization. A planar symmetry geometric restriction forces the optimized model to be symmetric about a specified plane. You specify the plane of symmetry by selecting the axis of a coordinate system that is the normal to the plane of symmetry. You can use the global coordinate system, or you can create a datum coordinate system (see *Methods for creating a datum coordinate system*, for more information). You can choose to remove frozen regions from the symmetry restriction.

1. From the main menu bar, select **Geometric Restriction->Create**.

   The **Create Geometric Restriction** dialog box appears.

   Tip: You can initiate the **Create** procedure in two other ways:

   - Click **Create** in the **Geometric Restriction Manager**. (You can display the **Geometric Restriction Manager** by selecting **Geometric Restriction->Manager** from the main menu bar.)
   - Click the tool in the Optimization module toolbox.

2. From the **Create Geometric Restriction** dialog box that appears, enter the name of the geometric restriction.
3. Select **Planar symmetry (Bead)** from the list of geometric restrictions, and click **Continue**.
4. From the viewport, select the region in which the planar symmetry will be enforced or click **Done** to apply the planar symmetry restriction to the entire model.

   By default, Abaqus/CAE allows you to select all of the model. To select faces or cells, use the **Selection** toolbar to change the type of object that you can select to **Face** or **Cells**. For more information, see *Filtering your selection based on the type of object*.

   If you would rather select from a list of existing sets, do the following:

   a. Click **Sets** on the right side of the prompt area.

      Abaqus/CAE displays the **Region Selection** dialog box containing a list of available sets.

   b. Select the set of interest, and click **Continue**.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

5. When you have finished selecting the geometric restriction region, click **Done** in the prompt area. For more information on selecting objects, see *Selecting objects within the viewport*."

   The **Edit Geometric Restriction** dialog box appears.

6. Select the coordinate system, and select the axis of the coordinate system that represents the normal to the plane of symmetry.
7. Click **OK** to create the planar symmetry geometric restriction and to exit the editor.

Additional information

- *Creating a geometric restriction in a bead optimization*

Creating a point symmetry restriction

You can specify a point symmetry geometric restriction for a condition-based bead optimization. A point symmetry geometric restriction forces the optimized model to be symmetric about a specified point. You specify the point of symmetry by selecting a coordinate system (the point of symmetry is assumed to be the origin of the coordinate system). You can use the global coordinate system, or you can create a datum coordinate system (see *Methods for creating a datum coordinate system*, for more information).

1. From the main menu bar, select **Geometric Restriction->Create**.

   The **Create Geometric Restriction** dialog box appears.

   Tip: You can initiate the **Create** procedure in two other ways:

   - Click **Create** in the **Geometric Restriction Manager**. (You can display the **Geometric Restriction Manager** by selecting **Geometric Restriction->Manager** from the main menu bar.)
   - Click the tool in the Optimization module toolbox.

2. From the **Create Geometric Restriction** dialog box that appears, enter the name of the geometric restriction.
3. Select **Point symmetry (Bead)** from the list of geometric restrictions, and click **Continue**.
4. From the viewport, select the region in which the point symmetry will be enforced or click **Done** to apply the point symmetry restriction to the entire model.

   By default, Abaqus/CAE allows you to select all of the model. To select faces or cells, use the **Selection** toolbar to change the type of object that you can select to **Face** or **Cells**. For more information, see *Filtering your selection based on the type of object*.

   If you would rather select from a list of existing sets, do the following:

   a. Click **Sets** on the right side of the prompt area.

      Abaqus/CAE displays the **Region Selection** dialog box containing a list of available sets.

   b. Select the set of interest, and click **Continue**.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

5. When you have finished selecting the geometric restriction region, click **Done** in the prompt area. For more information on selecting objects, see *Selecting objects within the viewport*."

   The **Edit Geometric Restriction** dialog box appears.

6. Select the coordinate system. The point of symmetry is assumed to be the origin of the selected coordinate system.
7. Click **OK** to create the point symmetry geometric restriction and to exit the editor.

Additional information

- *Creating a geometric restriction in a bead optimization*

Creating a rotational symmetry restriction

You can specify a rotational symmetry geometric restriction for a condition-based bead optimization. A rotational symmetry geometric restriction forces the optimized model to be symmetric about a specified axis of a coordinate system. You can use the global coordinate system, or you can create a datum coordinate system (see *Methods for creating a datum coordinate system*, for more information).

1. From the main menu bar, select **Geometric Restriction->Create**.

   The **Create Geometric Restriction** dialog box appears.

   Tip: You can initiate the **Create** procedure in two other ways:

   - Click **Create** in the **Geometric Restriction Manager**. (You can display the **Geometric Restriction Manager** by selecting **Geometric Restriction->Manager** from the main menu bar.)
   - Click the tool in the Optimization module toolbox.

2. From the **Create Geometric Restriction** dialog box that appears, enter the name of the geometric restriction.
3. Select **Rotational symmetry (Bead)** from the list of geometric restrictions, and click **Continue**.
4. From the viewport, select the region in which the rotational symmetry will be enforced or click **Done** to apply the rotational symmetry restriction to the entire model.

   By default, Abaqus/CAE allows you to select all of the model. To select faces or cells, use the **Selection** toolbar to change the type of object that you can select to **Face** or **Cells**. For more information, see *Filtering your selection based on the type of object*.

   If you would rather select from a list of existing sets, do the following:

   a. Click **Sets** on the right side of the prompt area.

      Abaqus/CAE displays the **Region Selection** dialog box containing a list of available sets.

   b. Select the set of interest, and click **Continue**.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click **Select in Viewport** or **Sets** on the right side of the prompt area.

5. When you have finished selecting the geometric restriction region, click **Done** in the prompt area. For more information on selecting objects, see *Selecting objects within the viewport*."

   The **Edit Geometric Restriction** dialog box appears.

6. Select the coordinate system, and select the axis of the coordinate system that represents the axis of symmetry.
7. Enter the **Repeating segment size**, which is the angle (in degrees) specifying the size of the repeating segment. The value must be greater than or equal to 2°.
8. Click **OK** to create the rotational symmetry geometric restriction and to exit the editor.

Additional information

- *Creating a geometric restriction in a bead optimization*

Creating local stop conditions

A local stop condition is an optional setting that indicates to the Optimization module when your optimization has converged on a solution. For example, you can specify that an optimization is complete when the change in an optimization function drops below a specified value between iterations. You can choose the variable that will be compared, such as displacement or equivalent stress. You can choose the comparison operator—greater than, equal, to, less than, etc. The change in optimization function can be calculated from the previous iteration (default) or from the first iteration.

In addition, when you create an optimization process in the Job module, you can enter the global stop condition—the maximum number of optimization cycles that should be completed before the optimization process ends. For more information, see *Creating and editing optimization processes*. In most optimization problems you will use only the global stop condition. Local stop conditions are supported by only shape optimization and are rarely required.

1. From the main menu bar, select **Stop Condition->Create**.

   The **Create Stop Condition** dialog box appears.

   Tip: You can initiate the **Create** procedure in two other ways:

   - Click **Create** in the **Stop Condition Manager**. (You can display the **Stop Condition Manager** by selecting **Stop Condition->Manager** from the main menu bar.)
   - Click the  tool in the Optimization module toolbox.

2. From the **Create Stop Condition** dialog box that appears, enter the name of the stop condition and click **Continue**.
3. From the viewport, select the region to which the stop condition will be applied or click **Done** to apply the stop condition to the entire model.

   By default, Abaqus/CAE allows you to select all of the model. To select faces or cells, use the **Selection** toolbar to change the type of object that you can select to **Face** or **Cells**. For more information, see *Filtering your selection based on the type of object*.

   If you would rather select from a list of existing sets, do the following:

   a. Click **Sets** on the right side of the prompt area.

      Abaqus/CAE displays the **Region Selection** dialog box containing a list of available sets.

   b. Select the set of interest, and click **Continue**.

   Note:

   The default selection method is based on the selection method you most recently employed. To revert to the other method, click the button—**Select in Viewport** or **Sets**—on the right side of the prompt area.

4. When you have finished selecting the stop condition region, click **Done** in the prompt area. For more information on selecting objects, see *Selecting objects within the viewport*."

   The **Edit Stop Condition** dialog box appears.

5. Choose one of the following operators for calculating the objective function:

   - **Maximum value**
   - **Minimum value**
   - **Sum of values**

- **Number of values**

6. Select the variable that will be used by the stop condition. You can choose either a displacement or an equivalent stress for a shape optimization.
   - The displacement of each node from the original shape. You can select the overall displacement, only the displacement due to the addition of material, or only the displacement due to the reduction of material. In addition, you can select the relative value of the displacement or the absolute value.
   - The equivalent stress in a shape optimization. You can select the equivalent stress of the whole model or the equivalent stress calculated from the following:
     - Only the nodes in the region selected for the task.
     - Only restricted nodes in the region selected for the task. Restricted nodes are restrained by a constraint or an Abaqus boundary condition.
     - Only free or unrestricted nodes in the region selected for the task. Free or unrestricted nodes are unconstrained.
     - Only surface nodes.
7. Select the comparison operator.
8. Select the iteration that will be used to define the reference value. The Optimization module compares the current value of the optimization function with the reference value.
9. If desired, enter a value and the operation that will be used to modify the reference value. In effect, you are normalizing the value of the variable that is defining the stop condition. For a discussion of the reference value, see *Objectives and Constraints*.
10. Click **OK** to save your data and to exit the editor.

The Job module

You can use the Job module to create and manage analysis jobs and to view a basic plot of the analysis results. You can also use the Job module to create and manage adaptivity analyses and co-executions.

See the tutorial in *Creating and Analyzing a Simple Model in Abaqus/CAE* for examples of how to submit and monitor a job.

In this section:

- *Understanding the role of the Job module*
- *Understanding analysis jobs*
- *Understanding adaptivity processes*
- *Understanding co-executions*
- *Understanding optimization processes*
- *Restarting an analysis*
- *Creating, editing, and manipulating jobs*
- *Using the job editor*
- *Creating, editing, and manipulating adaptivity processes*
- *Using the adaptivity process editor*
- *Creating, editing, and manipulating co-executions*
- *Creating, editing, and manipulating optimization processes*

Understanding the role of the Job module

Once you have finished all of the tasks involved in defining a model (such as defining the geometry of the model, assigning section properties, and defining contact), you can use the Job module to analyze your model. The Job module allows you to create a job, to submit it for analysis, and to monitor its progress. If desired, you can create multiple models and jobs and run and monitor the jobs simultaneously.

In addition, you have the option of creating only the analysis input file for your model. This option allows you to view and edit the input file before submitting it for analysis. For an Abaqus/Standard or Abaqus/Explicit analysis, you can also view and edit the analysis keywords for a model by selecting **Model->Edit Keywords->*model name*** from the main menu bar.

You can create and submit a job based on an existing input file instead of an Abaqus/CAE model; for example, if you have created an input file outside Abaqus/CAE but would like to run the analysis, monitor its progress, and view the results in Abaqus/CAE. Jobs can be created only for input files that do not contain references to other results files; for example, you cannot create a job based on an input file that contains a restart analysis.

If you have defined adaptive remeshing rules in the Mesh module, you can submit a mesh adaptivity process. Abaqus/CAE submits a succession of jobs, each of which attempts to improve solution accuracy and reduce error indicators over the previous job.

For an Abaqus co-simulation, you can create a co-execution to execute two analysis jobs in synchronization with one another.

Understanding analysis jobs

This section provides an overview of the Job module.

In this section:

- *Basic steps for analyzing a model*
- *Entering and exiting the Job module*
- *The Job Manager*
- *The job editor*
- *Selecting a job type*
- *Monitoring the progress of an analysis job*
- *Submitting a job remotely*

Basic steps for analyzing a model

After you have defined your model, you are ready to analyze it.
Analyzing a model involves the following steps, each of which can be performed using either the **Job** menu on the main menu bar or the **Job Manager**:

Create and configure an analysis job

You create an analysis job by selecting **Job->Create** from the main menu bar. Abaqus/CAE asks you to name the new job and to associate it with a model selected from the model database or with an existing input file. You can select any model that exists in the database; you are not limited to the current model. The job editor allows you to configure the job settings.

Write the input file

When you submit a job associated with a model for analysis, Abaqus/CAE first generates an input file representing your model and then Abaqus/Standard or Abaqus/Explicit performs the analysis using the contents of this file. Alternatively, you can ask Abaqus/CAE to generate only the input file; Abaqus/CAE writes the input file in ASCII format, and you can view and edit it in your working directory.

Warning:

If you edit the input file for a model using a text editor outside Abaqus/CAE and then submit the job for that model in the Job module, your changes to the input file will be lost. Instead, you must submit the modified input file directly for analysis by creating a new job and selecting **Input file** as the job **Source**. However, if you use the **Keywords Editor** to modify the generated keywords for a model, those modifications are retained in the model and apply to any jobs associated with that model.

Submit the job for analysis

You submit the job for analysis by selecting **Job->Submit** from the main menu bar. As the analysis progresses, Abaqus/CAE displays information from the status, data, log, and message files in the job monitor dialog box. After your job is completed, you can display results from the output database in the Visualization module by selecting **Job->Results** from the main menu bar.

Additional information

- *Understanding analysis jobs*
- *Creating, editing, and manipulating jobs*
- *Using the job editor*

Entering and exiting the Job module

You can enter the Job module at any time during a session by clicking **Job** in the **Module** list located in the context bar. The **Job** menu appears in the main menu bar.

To exit the Job module, select any other module from the main menu. If your job completed successfully, you can also exit the Job module by selecting **Job**->**Results** from the main menu bar; you will enter the Visualization module, and the output database for your analysis job will be opened automatically.

You need not save your job before exiting the module; it will be saved automatically when you save the entire model by selecting **File**->**Save** or **File**->**Save As** from the main menu bar.

The Job Manager

The **Job Manager**, which is similar to other managers in Abaqus/CAE, allows you to do the following:

- Create an analysis job and associate the new job with a selected model or input file.
- Edit the selected analysis job.
- Copy, rename, or delete the selected analysis job.

Note:

A job associated with a model can be copied only to a job associated with a model. A job associated with an input file can be copied only to a job associated with an input file.

In addition, the **Job Manager** allows you to do the following:

- *Write* an input file for a model-based job without submitting it for analysis.
- Perform a *data check* on a model.
- *Submit* a job for analysis.
- *Continue* an analysis to completion after performing a data check.
- *Monitor* the analysis as it progresses.
- View the *results* from a job.
- *Terminate* a job that is currently running.

You can display the **Job Manager** by selecting **Job->Manager** from the main menu bar. *Figure 1* shows the layout of the **Job Manager**.

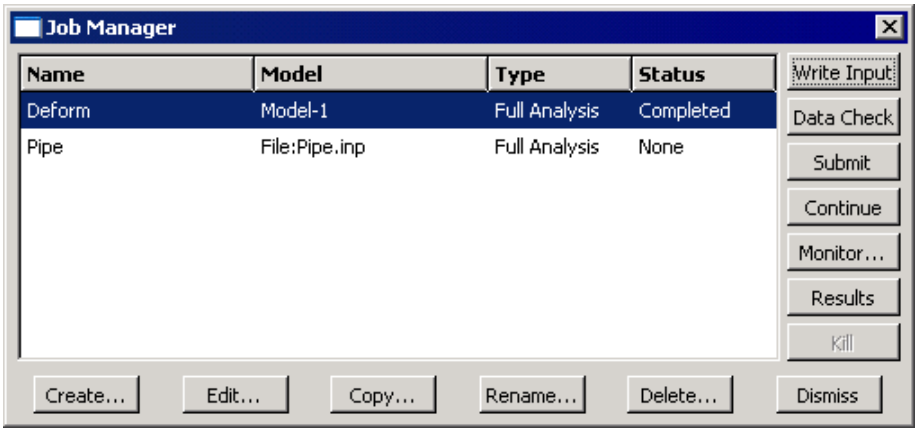

Figure 1: The Job Manager.

The four columns of the **Job Manager** display the following:

Name

The **Name** column displays the name of the job. Click **Rename** to rename the selected job.

Model

The **Model** column displays the name of the model or input file associated with the job.

Type

The **Type** column displays the job type that you selected when you configured the job using the job editor. The job type can be one of the following:

- **Full Analysis**
- **Recover**
- **Restart**

(See *Selecting a job type* for more information.) You can use the job editor to change the job type as long as the job is not running.

Status

The **Status** column displays the current status of the analysis job and is updated continually while your job is running. The status can be one of the following:

None

The job has not been submitted for analysis.

Check Submitted

The input file has been written, and the model is being submitted for a data check.

Check Running

The data check of the model is running.

Check Completed

The data check of the model has completed successfully; you can now continue with the full analysis.

Submitted

The input file has been written, and the job is being submitted for a full analysis.

Running

The job has been submitted for a full analysis and is running.

Completed

The analysis is complete. You can click **Results** to view the contents of the output database and graphically verify your results.

Aborted

The job has been aborted due to problems such as fatal errors in the input file or lack of disk space.

Terminated

The job has been killed by the user.

For detailed instructions on using the **Job Manager** to create, edit, and manipulate jobs, see the following sections:

- *Creating a new analysis job*
- *Writing the input file only*
- *Performing a data check on a model*
- *Submitting an analysis job*
- *Continuing an analysis job after a data check*
- *Terminating an analysis job*
- *Viewing the results of your job*

Additional information

- *Understanding analysis jobs*
- *Creating, editing, and manipulating jobs*
- *Using the job editor*

The job editor

You use the job editor to customize the settings for a new job or to edit the settings for an existing job. You can display the job editor by selecting **Job->Create** or **Job->Edit->*job name*** from the main menu bar. (You can also click **Create** or **Edit** in the job manager.)

The job editor contains the following tabbed pages:

Submission

Use the **Submission** tabbed page to configure the submission attributes of your job, such as job type, license type for the SimUnit license model, run mode, and submit time. You can also use the submission tabbed page to specify that the job is to be submitted to remote queues that have been configured by your local Abaqus environment file or by your system administrator.

General

Use the **General** tabbed page to configure job settings such as the analysis input file processor printout, the name of the directory used for scratch files, and the output format of the results.

Preprocessor printout options are not available for a job associated with an input file; you must specify these options in the input file itself.

Memory

Use the **Memory** tabbed page to configure the amount of memory allocated to an Abaqus analysis.

Parallelization

Use the **Parallelization** tabbed page to configure the parallel execution of an Abaqus analysis job, such as the number of processors to use.

Precision

Use the **Precision** tabbed page to specify either single or double precision for Abaqus/Explicit analyses. You can also choose the precision of nodal output that is written to the output database during the analysis.

For detailed instructions on using the job editor to define jobs, see the following sections :

- *Navigating the job customization options*
- *Configuring job submission attributes*
- *Choosing the job type*
- *Choosing the job run mode*
- *Setting the job submit time*
- *Specifying general job settings*
- *Controlling job memory settings*
- *Controlling job parallel execution*

- *Controlling job precision*

Additional information

- *Understanding analysis jobs*
- *Using the job editor*

Selecting a job type

The **Submission** tabbed page in the job editor allows you to choose between the following job types:

Full analysis

Submit a job with this option selected to generate (or regenerate) the input file (if the job is associated with a model), perform a complete analysis of your model, and write the results to the output database. This option is the default.

Recover (Explicit)

This option is available only when you are running Abaqus/Explicit. Submit a job with this option selected to complete your analysis after Abaqus/Explicit stopped unexpectedly; for example, after filling a disk or after a network problem.

You cannot use this job type to recover an Abaqus/Standard job that terminated prematurely. Instead, you should use the Abaqus/Standard restart capabilities as described in *Recovering an Abaqus/Standard analysis*.

Restart

Submit a job with this option selected to start the analysis using data from a previous analysis of a specified model. You must use the **Edit Model Attributes** dialog box to specify the job to read data from and to specify the step from which to restart the analysis. When you create a job that refers to a model with restart data attributes, Abaqus/CAE by default selects the job type to be **Restart**.

Restart analyses are described in more detail in *Restarting an analysis*. You cannot create a restart job for a job that was associated with an input file.

The **Job Type** settings are analogous to parameters of the Abaqus execution procedure; for more information, see *Abaqus/Standard and Abaqus/Explicit Execution*. For detailed instructions on choosing a job type, see *Choosing the job type*.

Additional information

- *Restarting an analysis*
- *Understanding analysis jobs*
- *Using the job editor*

Monitoring the progress of an analysis job

The **Job Manager** and **Co-execution Manager** continually update the status of analysis jobs in the model database. In addition, Abaqus/CAE prints error messages from the analysis products to the message area and creates diagnostic files in your current working directory.

You can monitor information concerning a submitted job by selecting **Job->Monitor->*job of your choice*** from the main menu bar or by selecting the job of your choice and clicking **Monitor** in the **Job Manager**. The job monitor dialog box for that job appears, as shown in *Figure 1*. You can display as many job monitors as necessary to view information on multiple jobs.

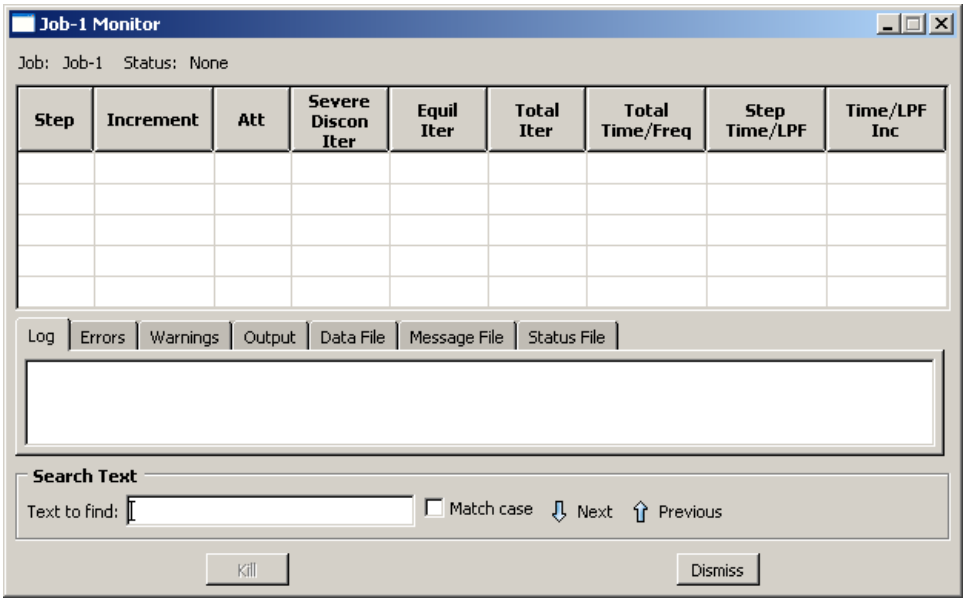

Figure 1: The job monitor.

The jobs submitted for a co-execution appear in the Model Tree in the **Jobs** container under the co-execution in the **Co-executions** container. You can monitor these jobs by clicking mouse button 3 on the job in the Model Tree and selecting **Monitor**.

The top half of the job monitor dialog box displays the information available in the status file that Abaqus creates for the analysis. The table headings are customized for each job based on the settings sent from the analysis. The bottom half of the dialog box displays the following information:

- Click the **Log** tab to display the start and end times that appear in the log file for the analysis.
- Click the **Errors** and **Warnings** tabs to display the errors or the warnings associated with the analysis. Abaqus/CAE indicates the presence of errors or warnings by prepending an exclamation point before the **Errors** and **Warnings** tab. If a particular region of the model is causing the error or warning, a node or element set will be created automatically that contains that region. The name of the node or element set appears with the error or warning message, and you can view the set using display groups in the Visualization module. (For more information on display groups, see *Using display groups to display subsets of your model*.)

  Abaqus/CAE may not perform all consistency checks when it creates an input file, which can result in warnings or error messages during an analysis. If your analysis generates warning or error messages, consider running a data check analysis (see *Performing a data check on a model*) to diagnose and fix possible problems in your model.

  The number of error and warning messages that appear in the job monitor is limited by the environment parameters **cae_error_limit** and **cae_warning_limit**, respectively (see *Job customization parameters*, for details). If the number of errors or warnings exceeds the job monitor limit, consult the data, message, or status file for a complete list of messages.

- Click the **Output** tab to display a record of each output data entry as it is written to the output database. In addition, if you requested that Abaqus monitor the values of a degree of freedom of a particular node to the message and status files, the **Output** tabbed page records each time this information is written and the value of the degree of freedom at that point of the analysis. (For more information, see *Understanding output requests*, and *Degree of freedom monitor requests*.)
- As the analysis proceeds, Abaqus creates the following files:
  - Abaqus/Standard: Data file, message file, and status file
  - Abaqus/Explicit: Data file, message file, and status file

  Abaqus/CAE activates the **Data File**, **Message File**, and **Status File** tabs accordingly. You can click any of these tabs to browse or search the corresponding file for additional error and warning messages.

  Note:

  Abaqus/CAE populates the **Data File**, **Message File**, and **Status File** tabbed pages only for locally submitted analyses; this information will not be displayed in the job monitor for remote jobs. In addition, although Abaqus/CAE updates the contents of these pages periodically as the analysis runs, the data might not always be synchronized with the latest data in the files.

For detailed information on the different output files that Abaqus creates during an analysis, see *About Output*.

You can search for specific error or warning messages within any of the files displayed in tabbed pages in the job monitor. Select the desired file tab, enter a search string in the **Text to find** field, and click **Next** or **Previous** to step through the file from one hit to the next. Toggle on **Match case** to perform a case-sensitive search.

The information presented in the job monitor dialog box is updated continually as the analysis progresses. If the job fails, the **Errors** tabbed page appears in front of the other tabbed pages automatically to help you determine the cause of the failure. In addition, an exclamation point appears on the tab if any error or warning messages are output.

If you start monitoring a job and then exit Abaqus/CAE, close the current model database, or open a new model database, Abaqus/CAE will stop updating the job monitor. The job will continue to run; however, the job monitor will not report the status of the job or update the increment information.

If you requested **DOF Monitor** output on a particular degree of freedom for a particular node, Abaqus/CAE provides another opportunity to monitor the job by plotting the values of the degree of freedom over time. The plot appears in a new viewport that is generated automatically when you submit the job. If the visible part of the canvas is already filled with one or more viewports, the new viewport may be placed on a part of the canvas that is not visible; in this case you should tile or cascade the viewports or enlarge the canvas to bring the viewport into view. (For information on requesting output for a particular degree of freedom for a particular node, see *Degree of freedom monitor requests*.)

If necessary, you can terminate the analysis job by clicking **Kill** at the bottom of the job monitor dialog box.

Additional information

- *Understanding analysis jobs*
- *Understanding co-executions*
- *Creating, editing, and manipulating jobs*
- *Creating, editing, and manipulating co-executions*

Submitting a job remotely

When you configure a job, you can request that Abaqus/CAE route the job to a specified queue on a remote Linux host computer. You can specify the remote queue by selecting an associated queue name in the **Submission** tabbed page of the job editor.

Note: The job editor displays default settings for memory usage, parallelization, and precision based on the environment files effective for the current session on the local machine. When you submit a job to a remote machine, Abaqus replaces the default settings with those from the environment files on the remote machine. Nondefault settings in the job editor are saved with the job and will be used regardless of where you run the analysis.

Each queue name that appears in the job editor refers to an entry in your Abaqus environment file in which you specify how you want the job to be run on the host computer. In other words, when you select a queue name in the job editor, you specify not only the desired queue on the host computer but also other options, such as the directory on the host computer in which you want to run the job and the files you want copied back to your local directory when the job is complete.

You can specify your preferences for running a job remotely by adding the following to your Abaqus environment file:

```
def onCaeStartup():
    import os

    def makeQueues(*args):
        session.Queue(name,
                      queueName,
                      hostName,
                      fileCopy,
                      directory,
                      driver,
                      remotePlatform,
                      filesToCopy,
                      deleteAfterCopy,
                      description)

    addImportCallback('job', makeQueues)
```

This entry is written using the Abaqus command language. The following list describes each argument in the entry above.

name

The queue name that you want to appear in the job editor.

queueName

The name of an existing queue on the host computer. (For information on creating queues on the host computer, refer to the *Abaqus Configuration Guide*.)

hostName

The name of the host computer. The default is an empty string.

fileCopy

When the analysis is complete, the value of this argument determines whether or not the analysis files will be copied back to the directory from which the job was submitted. The default value is `ON`.

directory

The name of the directory on the host computer where you want the job run. You must have write privileges to this directory. The default is an empty string.

driver

The name of the command on the host computer to execute Abaqus/Standard or Abaqus/Explicit. The default is `abaqus`.

remotePlatform

The platform on the remote machine. The default is `UNIX` (for Linux).

filesToCopy

The extensions of the analysis files that you want copied back to the local directory when the job is complete or `ALL`. By default, all of the files generated during job execution are copied.

Note:

The restart (`.res`) file, the Abaqus/Explicit state (`.abq`) file, and the packaging (`.pac`) file are platform-dependent; if your local platform and remote platform settings differ, you will not be able to use these files without some kind of translation. All of the other files can be copied across platforms without any difficulty.

deleteAfterCopy

The value of this argument determines whether remote files are to be deleted after they are copied to the local machine. The default value is `OFF`.

description

A short description of the queue.

The `name` and `queueName` arguments must be included in each queue definition. However, if you do not include any of the other arguments in a queue definition, default values will be supplied automatically. An example queue definition is shown below:

```
def onCaeStartup():
    import os

    def makeQueues(*args):
        session.Queue(name='long',
                      queueName='aba_long',
                      hostName='jobserver',
                      directory='/scratch/' + os.environ['USER'])
    addImportCallback('job', makeQueues)
```

The commands in the example above configure the following:

name

The queue name displayed in the job editor is `long`.

queueName

The queue name on the host computer is `aba_long`.

hostName

The name of the host computer is `jobserver`.

directory

The directory on the host computer where Abaqus will store the input file and all other files associated with the job is `/scratch/`*your user name*.

Since the *fileCopy*, *driver*, *remotePlatform*, *filesToCopy*, and *deleteAfterCopy* arguments have been left out of the entry above, the default options for these parameters are assigned to this queue automatically.

If you want to create two or more queues, you can repeat the line containing the `session.Queue` command as many times as necessary. For example, the following Abaqus environment file entry specifies two queues, one named `long` and the other named `job`:

```
def onCaeStartup():
    import os

    def makeQueues(*args):
        session.Queue(name='long',
                      queueName='aba_long',
                      hostName='jobserver',
                      directory='/scratch/' + os.environ['USER'])
        session.Queue(name='job',
                      queueName='aba_job',
                      hostName='jobserver',
                      fileCopy=OFF)

    addImportCallback('job', makeQueues)
```

The monitoring functions described in *Monitoring the progress of an analysis job*, are available for jobs run remotely just as they are for jobs run locally. However, the output database for the job, like any other analysis files that you may have requested, is not copied to your local directory until after the job is complete. As a result, you must create and start a network output database connector if you want to use the Visualization module to view the results being generated by an analysis running on a remote system. For more information, see *Accessing an output database on a remote computer*.

Additional information

- *Environment File Settings*
- *Abaqus Scripting User's Guide*

Understanding adaptivity processes

This section provides an overview of adaptivity processes.
You use an adaptivity process to control a succession of analysis jobs that are adaptively remeshed by Abaqus/CAE based on the contents of your remeshing rules. For more information about adaptive remeshing and the other adaptivity techniques that are available in Abaqus, see *About Adaptivity Techniques*.

In this section:

- *What is an adaptivity process?*
- *When will my mesh adaptivity stop iterating?*
- *Manual mesh adaptivity*
- *Using a combination of automatic and manual mesh adaptivity*
- *The Adaptivity Process Manager*

What is an adaptivity process?

An adaptivity process is a succession of analysis jobs where Abaqus/CAE remeshes selected regions of the model between each job. Abaqus/CAE modifies the mesh to be used in each analysis job in response to error estimates that were computed during the previous analysis and written to the output database. For more information, see *About Adaptive Remeshing*.

You have considerable flexibility in how you execute this succession of jobs. Adaptivity processes are stored in the model database and are maintained between sessions.

When will my mesh adaptivity stop iterating?

When you create an adaptivity process, you define a sequence of jobs to be run successively. You can specify the number of jobs in the sequence by specifying the maximum number of analysis iterations allowed, $iter_{max}$. The maximum number of remeshing operations will be $iter_{max}-1$, because no remeshing will be performed after the final analysis job is run. When you submit the remesh process, Abaqus/CAE runs each job in the sequence until one of the following conditions is met:

- All active remeshing rules are satisfied. For more information, see *What are remeshing rules?*.
- All jobs are completed, indicating that Abaqus/CAE has reached the maximum number of analysis iterations that you specified.
- A job fails to complete. This failure can be due to convergence difficulties or to machine resource problems.

Manual mesh adaptivity

As an alternative to automatic mesh adaptivity, you can submit a job using the Job manager. When you define a remeshing rule in the Mesh module, you request error indicator output variables that are written to the output database when the job executes. After the job has completed, you can return to the Mesh module and ask Abaqus/CAE to create a new mesh using a combination of your remesh rules and the error indicators in the output database. You can perform this process indefinitely to adapt your mesh successively until the goals of the remesh rules are met. For more information, see *What is the difference between automatic adaptive remeshing and manual adaptive remeshing?*.

Using a combination of automatic and manual mesh adaptivity

In many cases you will want to transition between automatic and manual use of adaptive remeshing. Some examples include:

- You must keep the current Abaqus/CAE session active for automatic remeshing to occur between analysis jobs. If you exit Abaqus/CAE and start a new session, you must use manual remeshing to remesh the model.
- You start an automatic sequence of jobs, but a machine problem (such as a full disk) interrupts the analysis prematurely. You can restart the analysis manually and then continue it in a fully automatic manner. Variations of this case include an analysis ending because it failed to converge or an analysis ending because you terminated the job during a particular iteration.
- You can experiment with sizing function parameters and remesh your model manually until you find a set of remeshing rules that creates a mesh that appears to be responding actively to your variables of interest. When you are comfortable with your remeshing rules, you can switch to automatic mesh adaptivity and complete a specified number of analysis iterations.
- The mesh generated by the automatic mesh adaptivity procedure converges to an acceptable configuration. You can now modify the loads applied to the model and perform an additional manual iteration that makes a minor meshing adjustment to compensate for the new load.

You can transition directly between automatic and manual mesh adaptivity. To transition from automatic to manual mesh adaptivity, you enter the Mesh module and select **Adaptivity->Manual Adaptive Remesh** from the main menu bar and remesh the model. You then return to the Job module and submit the job for analysis. Conversely, to transition from manual to automatic mesh adaptivity, you create an adaptivity process in the Job module and submit it for analysis.

The Adaptivity Process Manager

The **Adaptivity Process Manager**, which is similar to other managers in Abaqus/CAE, allows you to do the following:

- Create an adaptivity process and associate the process with a selected model.
- Edit the selected adaptivity process.
- Copy, rename, or delete the selected adaptivity process.

In addition, the **Adaptivity Process Manager** allows you to do the following:

- Perform a *data check* on a model before submitting an adaptivity process.
- *Submit* an adaptivity process.
- *Continue* an adaptivity process after performing a data check.

You can display the **Adaptivity Process Manager** by selecting **Adaptivity->Manager** from the main menu bar. *Figure 1* shows the layout of the **Adaptivity Process Manager**.

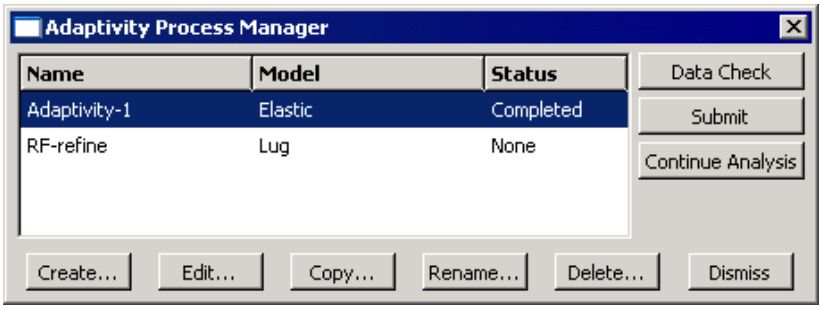

Figure 1: The Adaptivity Process Manager.

The three columns of the **Adaptivity Process Manager** display the following:

Name

The **Name** column displays the name of the adaptivity process. Click **Rename** to rename the selected process.

Model

The **Model** column displays the name of the model associated with the adaptivity process.

Status

The **Status** column displays the current status of the adaptivity process and is updated continually while the process is running. The status can be one of the following:

None

The process has not been submitted for analysis.

Check Submitted

The model is being submitted for a data check.

Check Running

The data check of the model is running.

Check Completed

The data check of the model completed successfully; you can now continue the adaptivity process.

Submitted

The process is being submitted for execution.

Running

The process has been submitted for analysis and is running.

Completed

The process has run to completion.

Aborted

The process has been aborted due to problems such as fatal errors in the model or lack of disk space.

Terminated

The process has been terminated by the user.

For detailed instructions on using the **Adaptivity Process Manager** to create, edit, and manipulate adaptivity processes, see the following sections :

- *Creating a new adaptivity process*
- *Performing a data check on an adaptivity process*
- *Submitting an adaptivity process*
- *Continuing an adaptivity process after a data check*
- *Terminating an adaptivity process*

Additional information

- *Understanding adaptivity processes*
- *Creating, editing, and manipulating adaptivity processes*
- *Using the adaptivity process editor*

Understanding co-executions

This section provides an overview of co-executions.

In this section:

- *What is a co-execution?*
- *The Co-execution Manager*
- *The co-execution editor*

What is a co-execution?

A co-execution is the co-simulation execution of two analysis jobs that are executed in Abaqus/CAE in synchronization with one another using the same functionality as described in *Understanding analysis jobs*. For more information on this analysis technique, see *Structural-to-Structural Co-Simulation*.

The Co-execution Manager

The **Co-execution Manager**, which is similar to other managers in Abaqus/CAE, allows you to do the following:

- Create a co-execution and associate it with selected analyses.
- Edit the selected co-execution.
- Copy, rename, or delete the selected co-execution.

In addition, the **Co-execution Manager** allows you to do the following:

- Perform a *data check* on the models before submitting a co-execution.
- *Submit* a co-execution.
- *View* the results of a co-execution.
- *Terminate* a co-execution that is currently running.

You can display the **Co-execution Manager** by selecting **Co-execution->Manager** from the main menu bar. *Figure 1* shows the layout of the **Co-execution Manager**.

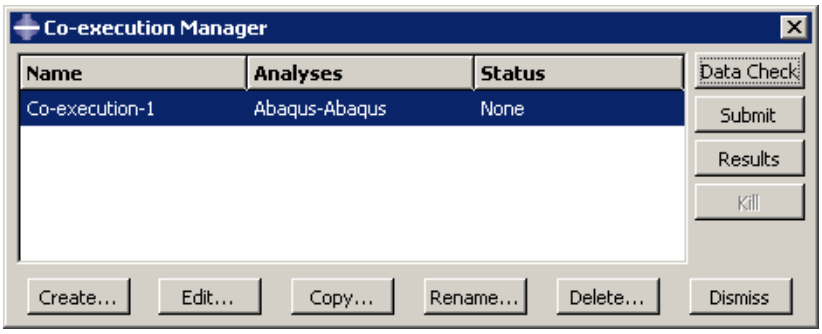

Figure 1: The Co-execution Manager.

The three columns of the **Co-execution Manager** display the following:

Name

The **Name** column displays the name of the co-execution. Click **Rename** to rename the selected co-execution.

Analyses

The **Analyses** column displays the type of analyses associated with the co-execution; for example, **Abaqus-Abaqus**.

Status

The **Status** column displays the status of the jobs in the co-execution and is updated continually while the co-execution is running. The status can be one of the following:

None

The co-execution has not been submitted for analysis.

Check Submitted

The analyses are being submitted for a data check.

Check Running

The data check of the analyses are running.

Check Completed

The data check of the analyses completed successfully; you can now continue the co-execution.

Submitted

The co-execution is being submitted.

Running

The co-execution has been submitted and is running.

Completed

The co-execution has run to completion.

Aborted

The co-execution has been aborted due to problems such as fatal errors in one of the models or lack of disk space.

Terminated

The co-execution has been terminated by the user.

Additional information

- *Understanding co-executions*
- *Creating, editing, and manipulating co-executions*

The co-execution editor

You use the co-execution editor to select the models, define the initial job parameter settings in the individual job editors, and change the co-execution timeout value. After the co-execution is created, the job parameters in the co-execution editor are unavailable for editing; you must edit the individual jobs.

You can display the co-execution editor by selecting **Co-execution->Create** or **Co-execution->Edit->*co-execution name*** from the main menu bar. (You can also click **Create** or **Edit** in the co-execution manager.)

The co-execution editor contains the following tabbed pages for specifying the job parameters:

Submission

Use the **Submission** tabbed page to configure the submission attributes of your job, such as job type, run mode, and submit time. You can also use the submission tabbed page to specify that the job is to be submitted to remote queues that have been configured by your local Abaqus environment file or by your system administrator.

General

Use the **General** tabbed page to configure job settings such as the analysis input file processor printout and the name of the directory used for scratch files.

Memory

Use the **Memory** tabbed page to configure the amount of memory allocated to an Abaqus analysis.

Parallelization

Use the **Parallelization** tabbed page to configure the parallel execution of an Abaqus analysis job, such as the number of processors to use.

Precision

Use the **Precision** tabbed page to specify either single or double precision for Abaqus/Explicit analyses. You can also choose the precision of nodal output that is written to the output database during the analysis.

Understanding optimization processes

This section provides an overview of optimization processes.

In this section:

- *What is an optimization process?*
- *Understanding the files generated by an optimization process*
- *Postprocessing an optimization*
- *The Optimization Process Manager*
- *The optimization process editor*

What is an optimization process?

Figure 1 illustrates how an optimization process iteratively updates the design variables, modifies the finite element model, and runs Abaqus analyses while it searches for an optimized solution.

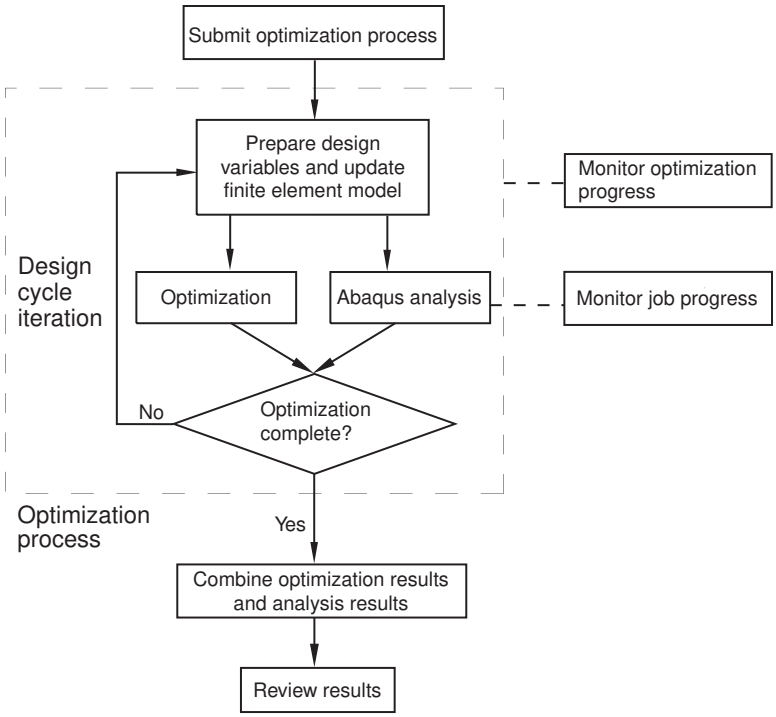

Figure 1: An optimization process iteratively searches for an optimized solution.

An optimization process reads an optimization task that you defined in the Optimization module and iteratively searches for an optimized solution based on the objective functions and constraints that you defined in the optimization task. Each iteration is called a design cycle. During each design cycle the optimization modifies the finite element model and an Abaqus analysis is performed on the modified model. The optimization process reads the results of the analysis and decides whether to end the optimization because either the solution is optimal or a specified stop condition has been reached or whether to continue the optimization and iterate on another design cycle.

An optimization process generates optimization results and analysis results. You must combine the optimization results and analysis results into a single output database file to view the results of the optimization in the Visualization module, as described in *Postprocessing an optimization*. The Optimization module does not support the use of parts and assemblies in the Abaqus input file. When you run an optimization task, the Optimization module generates a flattened input file that does not use parts and assemblies, regardless of your Abaqus model attributes.

An optimization process appears in the **Analysis** section of the Model Tree and contains the Abaqus jobs that were run during the optimization, as shown in *Figure 2*.

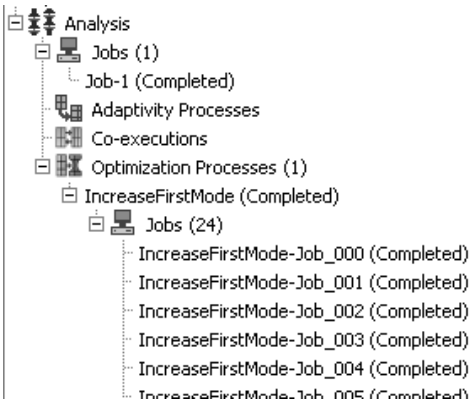

Figure 2: An optimization process in the Model Tree.

You can check the validity of your optimization process; however, the validation does not check your Abaqus model. You should run a complete analysis of your model and make sure that it runs to completion before you attempt to run an optimization process.

Understanding the files generated by an optimization process

When an optimization process is executing, it creates two types of data that are saved in separate files—optimization results and analysis results.

Optimization results

The optimization results consist of the optimization variables and the optimization values. The optimization variables depend on the type of optimization you are performing.

Topology optimization

The optimization variable is the normalized material distribution variable (MAT_PROP_NORMALIZED).

Shape optimization

The optimization variables are the displacement variables:

- DISP_OPT: a vector indicating the direction in which the nodes were moved during the shape optimization. Because of mesh smoothing and filtering, the vector may not be coincident with the node normal vector.
- DISP_OPT_VAL: the magnitude of the DISP_OPT vector with a sign indicating the direction of the displacement—positive for growth and negative for shrinkage.
- CTRL_INPUT: the value of the objective function at each node (stress, for example).

Sizing optimization

The optimization variables are the shell thickness and the change in shell thickness (THICKNESS and DELTA_THICKNESS).

Bead optimization

The optimization variables are the displacement variables:

- DISP_NORMAL_VAL: the magnitude of a vector indicating the direction in which the nodes were moved during the bead optimization along the node normal vector.
- DISP_OPT: a vector indicating the direction in which the nodes were moved during the bead optimization. Because of mesh smoothing and filtering, the vector may not be coincident with the node normal vector.
- DISP_OPT_VAL: the magnitude of the DISP_OPT vector with a sign indicating the direction of the displacement—positive for growth and negative for shrinkage.

The optimization variables are saved in separate optimization (`.onf`) files after every design cycle. In addition, the optimization values, such as the value of the objective and the constraints, are written to a comma-separated text file (`.csv`) after each design cycle. (You are viewing the optimization values when you monitor the progress of an optimization process, as described in *Monitoring your optimization process*.)

Analysis results

The analysis results are the field and history data generated by Abaqus during the analysis. During each design cycle a new output database file is created. In the initial design cycle, Abaqus writes both field and history data to the new output database file; however, during subsequent design cycles, Abaqus writes only field data. Abaqus

also generates data (`.dat`), message (`.msg`), and status (`.sta`) files during each design cycle. To conserve disk space and to speed up postprocessing, the output database file and the data, message, and status files are saved only at specified intervals; by default, after the initial, first, and final design cycles. (You specify the rate at which the files are saved when you create the optimization process, as described in *Creating and editing optimization processes*.) In addition, Abaqus saves the new input file that is generated during each design cycle.

Postprocessing an optimization

To view the results of an optimization process in the Visualization module, you must combine the optimization results and the analysis results into a single results output database file, as described in *Combining optimization results*.

Creating the base results output database file

The output database file that you choose to be the base results becomes the starting point for the combined results output database file.

Choosing between the initial and the final design cycle

You can specify that the base results be taken from the output database file generated by the initial design cycle or from the output database file generated by the final design cycle. In most cases you will select the initial design cycle and view the progression of the optimization from the initial design cycle to the final design cycle; for example, to follow the change in stiffness. Select the final design cycle if you performed a frequency optimization and want to view the frequency and the mode shape of the first few modes. If you performed a shape optimization, you should take the base results from the output database file generated by the first design cycle.

Choosing the original model

The Optimization module modifies the material definitions and the section assignments before running the initial design cycle of the optimization process. The original model is the model that existed before any modifications were made by the Optimization module.

You can specify that the base results be taken from the output database file generated by the original model. However, the optimization process does not run an Abaqus analysis of the original model. Therefore, you must run the analysis manually before you can choose the original model as the base results. (The Abaqus input file for the original model is stored, along with all the input files generated by the optimization process, in the *optimization process name*`\SAVE.inp` directory. The name of the input file for the original model is *optimization process name*`_org.inp`.)

The output database file that you use for the base results must be generated without parts and assemblies, as described in *Writing input files without parts and assemblies*. The input files generated by the Optimization module do not include parts and assemblies, regardless of any user settings in Abaqus/CAE. However, if you create the base results from an input file that was not generated by the Optimization module or by executing a job from Abaqus/CAE, you must ensure that the resulting output database file does not contain parts and assemblies.

Appending to the base results

After you have specified the output database file that will be used as the source of the base results, Abaqus/CAE appends the optimization results and the Abaqus analysis results to the combined output database file.

Appending the optimization results

Abaqus/CAE appends the optimization variables as field data to the combined output database file after every design cycle, and each design cycle appears as a frame in the combined output database file. Similarly, Abaqus/CAE appends the optimization values as history data to the combined output database file.

Appending the analysis results

You can do the following to specify which analysis results data are written to the combined results output database file:

- Specify from which design cycles the analysis results should be written.
- Specify from which models the analysis results should be written. Abaqus/CAE creates a combined results output database file for each model in your optimization process.
- Specify for a selected model from which steps within the model the analysis results should be written.
- Specify which analysis field variables should be written.

History data are not written to the combined database file during the combine process. The combined output database file contains only the history data from the base results output database file.

It is recommended that you save the analysis results after the initial and final design cycle when you create the optimization process. After the optimization is complete, you can select the output database file generated during the initial design cycle as the base results. You can then combine the base results output database file with the optimization results from every design cycle along with the analysis results from the final design cycle, as illustrated in *Table 1*.

Table 1: Saving optimization and analysis results in the combined output database file.

	Design Cycle				
	Initial	**First**	**Second**	**Third**	**Fourth (Final)**
Data saved	Analysis results (field and history data)	Optimization results	Optimization results	Optimization results	Optimization results and analysis results (field data only)
Action	Create base results	Append to base results	Append to base results	Append to base results	Append to base results

For example, if you executed a topology optimization, you can then do the following:

- View the initial state of your model; for example, the initial geometry and the loads and boundary conditions.
- View the change in the optimization variables—normalized material distribution variable (MAT_PROP_NORMALIZED)—during each design cycle to observe the progression of the optimization.
- View the final state of your model; for example, the optimized geometry and the displacements and the stresses and strains.
- Create a history plot that tracks the change in the objective and constraints.

You can apply similar conditions to view the beginning and ending state and the progression of the shape and sizing optimizations.

Combining optimization results is supported only for optimizations that you configured with the following analysis cases:

- Simple analysis (a single model, a single step, and a single load case)
- Frequency or modal analysis
- Linear perturbation analysis with multiple load cases

- Optimization with multiple models

The Optimization Process Manager

The **Optimization Process Manager** allows you to create and configure an optimization process and to edit, copy, rename or delete the selected optimization process.

In addition, the **Optimization Process Manager** allows you to do the following:

- Write copies of the TOSCA parameter (`.par`) file and the Abaqus input (`.inp`) file to your working directory.
- Validate the optimization before submitting an optimization process to ensure that the optimization task has been configured correctly and the Abaqus model exists.
- Submit an optimization process.
- Restart an optimization process that has failed because of a problem external to the optimization or the Abaqus analysis, such as a failure to obtain an Abaqus license.
- Monitor the progress of an optimization process.
- Extract a smooth isosurface meshed representation of the optimized model surface in the form of a file that can be transferred to a CAD system or back into Abaqus/CAE.
- Combine the optimization results and the analysis results created by an optimization process into a single results output database file that can be displayed by the Visualization module.
- View the results of an optimization process.

You can display the **Optimization Process Manager** by selecting **Optimization Process Manager->Manager** from the main menu bar. *Figure 1* shows the layout of the **Optimization Process Manager**.

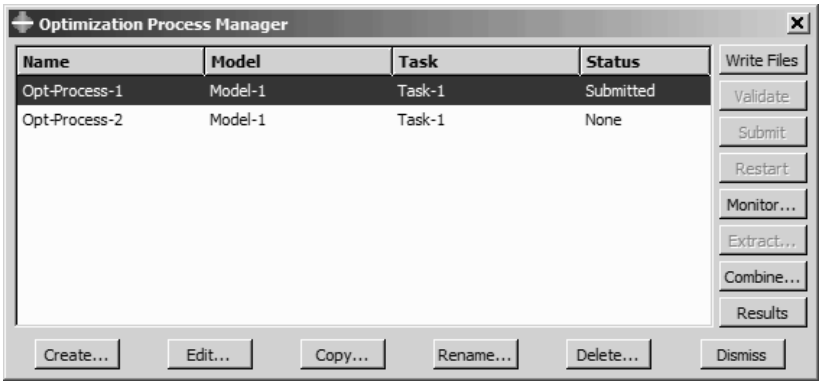

Figure 1: The Optimization Process Manager.

The four columns of the **Optimization Process Manager** display the following:

Name

The **Name** column displays the name of the optimization process. Click **Rename** to rename the selected optimization process.

Model

The **Model** column displays the Abaqus/CAE model associated with the optimization process.

Task

The **Task** column displays the optimization task associated with the optimization process.

Status

The **Status** column displays the status of the jobs in the optimization process and is updated continually while the optimization process is running. The status can be one of the following:

None

The optimization process has not been submitted for analysis.

Submitted

The optimization process is being submitted.

Running

The optimization process has been submitted and is running.

Completed

The optimization process has run to completion.

Aborted

The optimization process has been aborted due to problems such as fatal errors in one of the models or lack of disk space.

Terminated

The optimization process has been terminated by the user.

The optimization process editor

You use the optimization process editor to select the Abaqus/CAE model and the optimization task that will be included in the optimization process. You can also configure the optimization settings, such as the maximum number of optimization iterations.

You can display the optimization process editor by selecting **Optimization Process->Create** or **Optimization Process->Edit->*optimization process name*** from the main menu bar. (You can also click **Create** or **Edit** in the **Optimization Process Manager**.)

The optimization process editor allows you to configure the following:

Optimization

Use the **Optimization** tabbed page to specify the maximum number of optimization iterations that should be run before the process terminates and the frequency at which data are saved. For more information, see *Creating and editing optimization processes*.

Submission

Use the **Submission** tabbed page to configure the submission attributes of your optimization process, such as the submit time and whether the process is to be submitted to remote queues that have been configured by your local Abaqus environment file or by your system administrator. For more information, see *Configuring job submission attributes*.

Memory

Use the **Memory** tabbed page to configure the amount of memory allocated to the Abaqus jobs during the optimization process. For more information, see *Controlling job memory settings*.

Parallelization

Use the **Parallelization** tabbed page to configure the parallel execution of the Abaqus analysis jobs during the optimization process, such as the number of processors to use. For more information, see *Controlling job parallel execution*.

Restarting an analysis

This section describes the restart capability in Abaqus/CAE.
If your model contains multiple steps, you do not have to analyze all of the steps in a single analysis job. Indeed, it is often desirable to run a complex analysis in stages. This allows you to examine the results and confirm that the analysis is performing as expected before continuing with the next stage. The restart files generated by an Abaqus analysis allow you to continue the analysis from a specified step. For more information, see *Restarting an Analysis*.

In this section:

- *Controlling a restart analysis*
- *Files required to restart an analysis*
- *Rules governing a restart analysis*
- *The relationship between the model and the restart analysis*
- *Restarting after adding more analysis steps to the model*
- *Restarting after modifying existing analysis steps*
- *Restarting from the middle of a step*
- *Visualizing results from restart analyses*
- *Recovering an Abaqus/Standard analysis*
- *Remote submission of restart jobs*

Controlling a restart analysis

By default, no restart information is written for an Abaqus/Standard analysis and restart information is written only at the beginning and end of each step for an Abaqus/Explicit analysis.
You can use the Step module to change the frequency at which restart information is written. For more information, see *Restart output requests*.

After an analysis has generated restart information, you can control the following aspects of the subsequent restart analysis:

Model attributes

To configure a restart analysis, you must specify whether the model should reuse data from a previous analysis of the same model. You can specify the step and the increment or time interval of the previous analysis from which the new analysis should start. You can also choose one of the following:

- Allow the selected step to continue to completion.
- Terminate the selected step at the specified increment and begin a new step.

For more information, see *Specifying model attributes*.

Job type

You use the job editor to specify the job type. If you edit the model attributes to specify that the model should reuse data from a previous analysis and you create a job that refers to this model, Abaqus/CAE sets the job type to **Restart**. For more information, see *Selecting a job type*. You cannot create a restart job that refers to a job that was associated with an input file.

Files required to restart an analysis

To restart an analysis, various files that were created by the previous analysis must be available in the directory from which you started the Abaqus/CAE session.

Abaqus/Standard

- Output database (`.odb`)
- Restart file (`.res`)
- Model file (`.mdl`)
- Part file (`.prt`)
- State file (`.stt`)

Abaqus/Explicit

- Output database (`.odb`)
- Restart file (`.res`)
- Model file (`.mdl`)
- Package file (`.pac`)
- Part file (`.prt`)
- State files (`.abq` and `.stt`)
- Selected results file (`.sel`)

The restart analysis generates an error if any of these files are not available in the current directory.

Rules governing a restart analysis

Defining the restart information for models and jobs is straightforward using Abaqus/CAE; however, you should understand the following before you use the analysis restart capability:

- The model used in the restart analysis must be the same as the model used in the original analysis up to the restart location. Specifically,
  - For the new model do not modify or add any geometry, mesh, materials, sections, beam section profiles, material orientations, beam section orientations, interaction properties, or constraints.
  - Similarly, do not modify any steps or prescribed conditions (loads, boundary conditions, fields, interactions, or output requests) at or before the restart location.
- Keyword editing is not supported for restart analyses. If you used the keyword editor to edit the original model, Abaqus/CAE ignores those changes when you restart the analysis.

Warning:

Abaqus/CAE does not perform any checks to ensure that the restart data stored for the original job are consistent with the model used in the restart analysis. In some cases the analysis will terminate with error messages. In other cases the analysis will run, but the results may not correspond with your intent. A specific example of a case that will result in an error message is one where you define a coupling constraint and its accompanying reference node in the original model and then suppress the constraint prior to the original analysis submission. In this example Abaqus/CAE maintains the reference node definition but Abaqus/Standard or Abaqus/Explicit may remove it from the model definition if it is not attached to other elements or constraints. Your subsequent Abaqus/CAE restart analysis in this example will be seen as inconsistent with the original analysis. In many cases like this example you can manually modify the restart analysis input file to correct the discrepancy.

The relationship between the model and the restart analysis

When you first submit a job based on a model for analysis, Abaqus/CAE generates an input file based on the definition of your model; and that input file, in turn, is submitted for analysis. The input file contains the element and node definitions generated by the Mesh module along with the materials, steps, output requests, loads, interactions, etc. that you specified using Abaqus/CAE.

To run a restart analysis of a job associated with a model, it is recommended that you copy the model to a new model. The new model contains all the element and node definitions from the original model along with all the materials, steps, output requests, loads, interactions, etc. To request a restart analysis, you edit the new model's attributes and specify that the analysis continue from a specified step of the original analysis. When you create a new restart job that refers to the new model, Abaqus/CAE sets the job type to **Restart**.

When you submit the new job for analysis, Abaqus/CAE generates an input file based on the restart information. No part, assembly, or property data are written to the restart input file. Only the following data are written:

- Steps that appear after the analysis is restarted.
- Data from step-dependent objects that are associated with steps that appear after the restart step; for example, loads, boundary conditions, fields, and output requests.
- New regions and amplitudes that are used by step-dependent objects that are associated with steps that appear after the restart step.

Abaqus reads the part, assembly, and property data, along with data from steps that appear before the restart step from the restart files that were generated by the original analysis. As a result, although the model contains all this information, the information is not written to the input file that is submitted to Abaqus/Standard or Abaqus/Explicit. This is an important consideration. Some changes that you make to the model in a restart analysis, say a material property, will not appear in the input file that is analyzed.

Restarting after adding more analysis steps to the model

The most common use of the restart capability is to analyze your model and then add one or more steps to the model and continue the analysis. This section describes an example of this usage.

Assume that you have done the following:

- Created a model called `Model-A` that has two analysis steps, `Step-1` and `Step-2`.
- Used the **Edit Restart Requests** dialog box in the Step module to output the restart information at the end of each step.
- Created a job called `Job-A` that uses `Model-A`.
- Analyzed the model.

After studying the results of the analysis, you decide to add another step, `Step-3`, to the model. The restart capability allows you to compute the results for `Step-3` without having to repeat the computations for `Step-1` and `Step-2`. The following steps describe a recommended procedure to follow:

1. Copy `Model-A` to a new model, say `Model-A-restart`, and make `Model-A-restart` the current model.
2. Add the new `Step-3` to `Model-A-restart`.
3. Add new prescribed conditions (loads, boundary conditions, interactions, fields, or output requests) in `Step-3`, or modify the prescribed conditions propagated from `Step-2`.
4. From the main menu bar, select **Model->Edit Attributes->Model-A-restart**. From the **Edit Model Attributes** dialog box that appears, do the following:
   - Enter `Job-A` as the job from which the restart data will be read.
   - Set the restart location:
     - Enter `Step-2` to indicate the step from which the restart data will be read.
     - Choose **Restart from the end of the step**. `Step-3` will continue the analysis after the end of `Step-2`.
5. Copy `Job-A` to a new job, say `Job-A-restart`, that uses `Model-A-restart`.
6. From the main menu bar, select **Job->Edit->Job-A-restart**. From the **Edit Job** dialog box that appears, choose a job type of **Restart**.
7. Submit `Job-A-restart` for analysis.

Restarting after modifying existing analysis steps

You can use the restart capability to analyze your model and then modify an existing step before continuing the analysis. This section describes an example of this usage.

Assume that you have done the following:

- Created a model called `Model-A` that has two analysis steps, `Step-1` and `Step-2`.
- Used the **Edit Restart Requests** dialog box in the Step module to output the restart information at the end of each step.
- Created a job called `Job-A` that uses `Model-A`.
- Analyzed the model.

After examining the results of `Job-A`, you realize that you need to make changes to `Step-2`, to an output request in `Step-2`, or to a prescribed condition in `Step-2`, such as a load or boundary condition. You may also want to add some new steps with additional output requests and loads and with changes to the boundary conditions. You know that you can still use the results from `Step-1`; however, you realize that the results from `Step-2` are no longer valid. The restart capability allows you to recompute the results for `Step-2` without having to repeat the computations for `Step-1`. The following steps describe a recommended procedure to follow:

1. Copy `Model-A` to a new model, say `Model-A-restart`, and make `Model-A-restart` the current model.
2. Do the following:
   - Make the desired changes to `Step-2`.
   - Add new steps after `Step-2`.
   - Create new prescribed conditions in `Step-2` and subsequent steps.
3. From the main menu bar, select **Model->Edit Attributes->Model-A-restart**. From the **Edit Model Attributes** dialog box that appears, do the following:
   - Enter `Job-A` as the job from which the restart data will be read.
   - Set the restart location:
     - Enter `Step-1` to indicate the step from which the restart data will be read.
     - Choose **Restart from the end of the step**. `Step-2` will continue the analysis after the end of `Step-1`.
4. Copy `Job-A` to a new job, say `Job-A-restart`, that uses `Model-A-restart`. Abaqus/CAE sets the job type to `Restart`.
5. Submit `Job-A-restart` for analysis.

Restarting from the middle of a step

You can use the restart capability to continue the analysis from the middle of a completed step or from the middle of a partially completed step. The restarted analysis uses a new step that continues the analysis from a specified increment of the previous step. This section describes an example of this usage.

Assume that you have done the following:

- Created a model called `Model-A` that has two Abaqus/Standard analysis steps, `Step-1` and `Step-2`.
- Used the **Edit Restart Requests** dialog box in the Step module to output the restart information every 10 increments.
- Created a job called `Job-A` that uses `Model-A`.
- Analyzed the model.

You suspected that the loading is too severe for the structure and might lead to instabilities or collapse of the structure and, hence, to numerical convergence difficulties. As a result, you used the Step module to save the restart information every 10 increments of each step. When you ran the analysis, you found that the analysis terminated before the end of `Step-2`, at increment `25`. You used the Visualization module to look at the results of the analysis and realized that the negative eigenvalue messages confirmed your suspicion that the structure might have become unstable. Now that you have some idea of the collapse load level, you want to restart the analysis at increment `20` of `Step-2` with lower levels of loading and more frequent output of results data. The following steps describe a recommended procedure to follow:

1. Copy `Model-A` to a new model, say `Model-A-restart`, and make `Model-A-restart` the current model.
2. Add the new `Step-3` to `Model-A-restart`.
3. Modify the load levels and output requests in `Step-3`. For example, if the load at `Step-2`, increment `25` was `260` and the load at `Step-2`, increment `20` was `250`, you might change the load level for the end of `Step-3` to `262`. In addition, you can increase the frequency at which data are written to the output database so that you can follow the progression of the collapse of the structure. You can also reduce the size of the maximum increment to control the resolution of the data that are generated by the analysis. For more information, see *Restarting an Analysis*.
4. From the main menu bar, select **Model->Edit Attributes->Model-A-restart**. From the **Edit Model Attributes** dialog box that appears, do the following:
   - Toggle on **Read data from job** and enter `Job-A` to indicate the job from which the restart data will be read.
   - Set the restart location:
     - Enter `Step-2` to indicate the step from which the restart data will be read.
     - Choose **Restart from increment, interval, iteration, or cycle**, and enter `20` to indicate the increment from which the restart data will be read.
     - Choose **and terminate the step at this point** to indicate that `Step-2` should terminate at increment `20`. `Step-3` will continue the analysis from this location.
5. Copy `Job-A` to a new job, say `Job-A-restart`, that uses `Model-A-restart`. Abaqus/CAE sets the job type to `Restart`.
6. Submit `Job-A-restart` for analysis.

Visualizing results from restart analyses

Each restart analysis creates a new output database. Consider the example described in *Restarting after adding more analysis steps to the model*, where you did the following:

- Ran an analysis of `Job-A` that referred to `Model-A` that contains `Step-1` and `Step-2`. As a result, the output database generated by the analysis, `Job-A.odb`, contains results from `Step-1` and `Step-2`.
- Ran a restart analysis of `Job-A-restart` that referred to `Model-A-restart`. Although `Model-A-restart` contains `Step-1`, `Step-2`, and `Step-3`, the output database generated by the restart analysis, `Job-A-restart.odb`, contains results from only `Step-3`.

You can use the Visualization module to create deformed, contour, and symbol plots of field data; however, you can plot the results from only one output database at any time. You must change the output database if you are looking at the results from `Step-1` or `Step-2` and want to look at the results from `Step-3`.

If you want to create an animation of results from all three steps, you must combine the two output databases. Abaqus provides an execution procedure for this purpose. For more information, see *Joining Output Database (.odb) Files from Restarted Analyses*.

Alternatively, you can create a history plot of a variable over all three steps using the following technique:

- Create one *X–Y* data object for the variable from the original output database—`Job-A.odb`.
- Create a second *X–Y* data object from the output database generated by the restart analysis—`Job-A-restart.odb`.
- Create an *X–Y* plot of the two *X–Y* data objects. Alternatively, you can create a new *X–Y* data object using the **Operate on XY data** option, append the first two *X–Y* data objects, and create an *X–Y* plot of the result.

For more information, see *X–Y plotting*.

You should take care that your *X–Y* data objects are not referring to the same step. For example, consider the restart analysis described in *Restarting after modifying existing analysis steps*, where you modified an existing step and added a new step before continuing the analysis. The first output database contains data from `Step-1` and `Step-2`. The second output database contains data from a modified `Step-2` and the new `Step-3`. The first *X–Y* data object that you create should use only the data from `Step-1` and should exclude the data from the original `Step-2`. The second *X–Y* data object should use the data from the modified `Step-2` and the new `Step-3`.

Recovering an Abaqus/Standard analysis

Abaqus/Explicit has a recovery mechanism for analysis jobs that terminate prematurely; for example, because of disk space or power failures. For more information, see *Selecting a job type*. However, unlike Abaqus/Explicit, Abaqus/Standard does not have a recovery mechanism. The following example describes how you can use the restart capabilities of Abaqus/Standard to continue an analysis that terminated prematurely. Assume the following:

- You analyzed `Model-A` containing `Step-1`, `Step-2`, and `Step-3`.
- Because of a power outage, the analysis ended prematurely at `Increment 17` of `Step-2`.
- You requested that restart information be saved every 10 increments. As a result, the last restart information was saved at `Increment 10` of `Step-2`.

The following procedure describes how you can recover the analysis using the last restart information that was saved:

1. Copy `Model-A` to a new model, say `Model-A-recover`, and make `Model-A-recover` the current model.
2. From the main menu bar, select **Model->Edit Attributes->Model-A-recover**. From the **Edit Model Attributes** dialog box that appears, do the following:
   - Toggle on **Read data from job**, and enter `Job-A` to indicate the job from which the restart data will be read.
   - Set the restart location:
     - Enter `Step-2` to indicate the step from which the restart data will be read.
     - Choose **Restart from increment, interval, iteration, or cycle**, and enter `10` to indicate the increment from which the restart data will be read.
     - Choose **and complete the step**. `Step-2` will continue the analysis after increment `10` and run to completion.
3. Copy `Job-A` to a new job, say `Job-A-recover`, that uses `Model-A-recover`. Abaqus/CAE sets the job type to `Restart`.
4. Submit `Job-A-recover` for analysis.

Remote submission of restart jobs

If you submit a job to a remote machine for analysis, by default Abaqus copies the files required for a restart analysis back to your local directory when the job is complete. For more information, see *Submitting a job remotely*. If the remote job terminates prematurely, you may have to copy the files back to your local directory manually.

Most of the files required for a restart analysis are platform-dependent binary files. As a result, you will not be able to continue a restart analysis on a Windows machine after starting the analysis on a Linux machine, or vice versa. The part (`.prt`) file contains ASCII text and can be copied across platforms.

The lack of portability across platforms with different binary formats does not preclude you from restarting an analysis on a machine that is different from the machine on which the original analysis was run. However, the two machines must be binary compatible, and it is recommended that the original analysis and the restart analysis both be executed on the same platform. Abaqus does not test cross-platform compatibility of restart files.

Creating, editing, and manipulating jobs

This section describes how you create, edit, and manipulate jobs using either the main menu or the **Job Manager**.

In this section:

- *Creating a new analysis job*
- *Writing the input file only*
- *Performing a data check on a model*
- *Submitting an analysis job*
- *Continuing an analysis job after a data check*
- *Terminating an analysis job*
- *Viewing the results of your job*

Creating a new analysis job

To create a new analysis job, select **Job->Create** from the main menu bar. Analysis jobs are stored in the model database and are maintained between sessions.

1. From the main menu bar, select **Job->Create**.

   The **Create Job** dialog box appears.

   Tip: You can also create a new analysis job by clicking the icon in the module toolbox or by clicking **Create** in the **Job Manager**.

2. Type the name of the new job in the **Name** text field. The name that you specify must adhere to the file name rules of your operating system.
3. Click the arrow to the right of the **Source** field to choose the source for the job.

   - Select **Model** to create a job based on a model created in Abaqus/CAE.

     The **Model** list displays all the models defined in the model database. From this list, select the model to associate with the new job.

   - Select **Input file** to create a job based on an input file that may or may not have been created in Abaqus/CAE.

     Click ; Abaqus/CAE lists all the files in the selected directory with the file extension `.inp`. Select the input file to associate with the new job, and click **OK**.

     Note:

     You cannot create a job based on an input file that contains references to other results files, such as a restart analysis, an import analysis, or a submodel analysis.

4. Click **Continue**.

   The job editor appears.

5. If desired, enter the job description. When you submit the job for analysis, Abaqus/CAE writes the job description immediately following the input file header. The job description is not written to the output database and is not retained upon import into Abaqus/CAE. For more information, see *Importing descriptions*.
6. In the editor, enter all data necessary to define the job and click **OK**. (For more information, see *Using the job editor*.)

Additional information

- *Understanding analysis jobs*
- *Creating, editing, and manipulating jobs*

Writing the input file only

By default, when you submit a job associated with a model for analysis, Abaqus/CAE generates an input file representing your model and then Abaqus analyzes that input file. However, sometimes you may prefer to generate the input file and then view or edit it before performing the analysis.

To write the input file without immediately performing the analysis, select **Job->Write Input->*job of your choice*** from the main menu bar. The input file *job name* **.** `inp` is written to the directory from which you started Abaqus/CAE. You can also write an input file by selecting the job of your choice and then clicking **Write Input** in the **Job Manager**.

The input file is written in ASCII format and can be viewed and edited using a text editor. If you are familiar with Abaqus keywords, you can check the input file for errors and check that the keywords, parameters, and data were generated as expected. Keep in mind that Abaqus/CAE processes your input to the graphical user interface, performing additional calculations when needed, to determine the keywords that accurately reflect your modeling intent. You can also modify the contents of the input file. For example, you can change a material property or the magnitude of a load.

Warning:

If you edit the input file for a model using a text editor outside Abaqus/CAE and then submit the job for that model in the Job module, your changes to the input file will be lost. Instead, you must submit the modified input file directly for analysis by creating a new job and selecting **Input file** as the job **Source**. However, if you use the **Keywords Editor** to modify the generated keywords for a model, those modifications are retained in the model and apply to any jobs associated with that model. (You can display the **Keywords Editor** by selecting **Model->Edit Keywords** from the main menu bar.)

Additional information

- *Adding unsupported keywords to your Abaqus/CAE model*
- *Understanding analysis jobs*
- *Creating, editing, and manipulating jobs*

Performing a data check on a model

A data check runs the input file through the analysis input file processor to ensure that the model is consistent and that all the required model options have been set.
This option generates (or regenerates) the input file for the job if the job source is an Abaqus/CAE model.

To perform a data check on a model, select **Job->Data Check->*job of your choice*** from the main menu bar. You can also perform a data check by selecting the job of your choice and then clicking **Data Check** in the **Job Manager**.

To see the results of a data check analysis, review the data (`.dat`) file in your working directory. You can also review the results of a data check by selecting **Job->Monitor->*job of your choice*** to display the job monitor dialog box. For more information on the job monitor, see *Monitoring the progress of an analysis job*.

A data check also creates an output database. You can view the output database in the Visualization module to verify model information such as face labels, surface normals, and material orientations. For more information on viewing an output database, see *Viewing results*.

Additional information

- *Understanding analysis jobs*
- *Creating, editing, and manipulating jobs*

Submitting an analysis job

To submit a job for analysis, select **Job**->**Submit**->***job of your choice*** from the main menu bar. You can also submit a job for analysis by selecting the job name in the **Job Manager** and clicking **Submit**. Abaqus/CAE submits the job for analysis using the job settings defined in the job editor.

For information on monitoring a job that you have submitted, see *Monitoring the progress of an analysis job*.

When you start an Abaqus/CAE session and submit an analysis job, Abaqus sends messages to Abaqus/CAE indicating the current status of the job, and Abaqus/CAE updates the **Status** column in the **Job Manager** accordingly.

Additional information

- *Understanding analysis jobs*
- *Creating, editing, and manipulating jobs*

Continuing an analysis job after a data check

When you perform a data check analysis (see *Performing a data check on a model*), Abaqus creates and saves all the files necessary to continue the full analysis at a later time. To continue an analysis, select **Job->Continue->*job of your choice*** from the main menu. You can also continue an analysis by selecting the job name in the **Job Manager** and clicking **Continue**. Abaqus/CAE continues the analysis using the job settings defined in the job editor.

For information on monitoring a job that you have submitted, see *Monitoring the progress of an analysis job*.

Additional information

- *Understanding analysis jobs*
- *Creating, editing, and manipulating jobs*

Terminating an analysis job

You can use one of the following methods to terminate an analysis job:

- From the main menu bar, select **Job->Kill->*job of your choice***.
- In the **Job Manager**, select the job name and then click **Kill**.
- In the job monitor dialog box for that particular job, click **Kill**. (For more information, see *Monitoring the progress of an analysis job*.)

Abaqus/CAE asks you for confirmation, terminates the job, and updates the status of the job in the **Job Manager** to `Terminated`.

Additional information

- *Understanding analysis jobs*
- *Creating, editing, and manipulating jobs*

Viewing the results of your job

Once your analysis job is completed, Abaqus/CAE stores the results of the analysis in an output database. You can use the Visualization module to view these results graphically. Using the **Results** command from the **Job** menu starts the Visualization module and gives you a basic plot of your model.

1. From the main menu bar, select **Job->Results->*job of your choice***.

   Tip: You can also select the job name in the **Job Manager** and click **Results**.

   The Visualization module starts and presents you with a plot of the model.

   Note:

   Using the **Results** command exits the Job module. To reenter the Job module, select **Job** from the **Module** list located in the context bar.

2. Use the Visualization module to create and customize different plots of your results. For more information on using the Visualization module, see *Viewing results*."

Additional information

- *Understanding analysis jobs*
- *Creating, editing, and manipulating jobs*

Using the job editor

This section describes how you use the job editor to configure the settings of a job.

In this section:

- *Navigating the job customization options*
- *Configuring job submission attributes*
- *Choosing the job type*
- *Setting the license type for the SimUnit license model*
- *Choosing the job run mode*
- *Setting the job submit time*
- *Specifying general job settings*
- *Controlling job memory settings*
- *Controlling job parallel execution*
- *Controlling job precision*

Navigating the job customization options

Use the job editor to customize a job's settings before submitting it for analysis. To locate the job editor, select **Job->Edit->*jobname*** from the main menu bar. The job editor contains the following tabbed pages:

Submission

Use the **Submission** tabbed page to configure the basic attributes of your job, such as the job type, the run mode, and the run time. You can also use the submission page to submit jobs to a *remote queue*.

General

Use the **General** tabbed page to configure preprocessor printout and to specify a scratch directory. Preprocessor printout options are not available for a job associated with an input file; you must specify these options in the input file itself. You also use the **General** tabbed page to specify any user subroutines that are referred to by the model and the output format of the results.

Memory

Use the **Memory** tabbed page to configure the amount of memory allocated to an Abaqus analysis.

Parallelization

Use the **Parallelization** tabbed page to configure the parallel execution of an Abaqus analysis job, such as the number of processors to use.

Precision

Use the **Precision** tabbed page to specify either single or double precision for Abaqus/Explicit analyses. You can also choose the precision of nodal output that is written to the output database during the analysis.

You can also use the Abaqus environment file (`abaqus_v6.env`) to control the default value of many of the settings in the job editor tabbed pages. For more information, see *Environment File Settings*.

Additional information

- *Understanding analysis jobs*
- *Using the job editor*
- *Abaqus/Standard and Abaqus/Explicit Execution*

Configuring job submission attributes

To locate the job editor, select **Job->Edit->*jobname*** from the main menu bar. Use the **Submission** tabbed page in the job editor to configure attributes related to job submission. You can do the following:

- Choose the type of analysis. (For more information, see *Choosing the job type*.)
- Choose the type of license. (For more information, see *Setting the license type for the SimUnit license model*.)
- Choose the run mode. (For more information, see *Choosing the job run mode*.)
- Choose the submit time. (For more information, see *Setting the job submit time*.)

Additional information

- *Understanding analysis jobs*
- *Using the job editor*
- *Creating, editing, and manipulating co-executions*
- *Abaqus/Standard and Abaqus/Explicit Execution*

Choosing the job type

To locate the job editor, select **Job->Edit->*jobname*** from the main menu bar.
Use the **Job Type** options in the **Submission** tabbed page to choose the type of job that Abaqus will run. You can choose one of the following options:

Full analysis

Select this option to submit a complete model or input file for analysis.

Recover (Explicit)

Select this option to resubmit an Abaqus/Explicit analysis that has previously terminated prematurely. This option is not valid for Abaqus/Standard analyses.

Restart

Select this option to submit an analysis of a model that uses saved data from a previous analysis of the same model. The model attributes must specify the location of the saved data.

The available job types are covered in more detail in *Selecting a job type*.

1. In the job editor, click the **Submission** tab to display the **Submission** tabbed page.
2. From the **Job Type** options at the top of the tabbed page, select the job type of your choice.

Additional information

- *Understanding analysis jobs*
- *Using the job editor*
- *Creating, editing, and manipulating co-executions*

Setting the license type for the SimUnit license model

To locate the job editor, select **Job->Edit->*jobname*** from the main menu bar. Use the **SIM Unit Licensing** options in the **Submission** tabbed page to choose license options for your analysis job execution.

The **SIM Unit Licensing** options are enabled when you use the SimUnit license model or when Abaqus/CAE is launched by the **3D**EXPERIENCE Platform Connector for Abaqus/CAE. For all other cases, these options are disabled. If you are using the Abaqus Learning Edition, this option is not available.

1. In the job editor, click the **Submission** tab to display the **Submission** tabbed page.
2. When using the SimUnit license model, from the **SIM Unit Licensing** options in the middle of the page, choose one of the following:

Default

The job executes with the default license type in the Abaqus environment file. The **license_type** parameter value is used, if applicable. If you do not specify the parameter in an Abaqus environment file, tokens are used.

Tokens

The job executes using tokens. This selection overrides the **license_type** parameter in the Abaqus environment file.

Credits

The job executes using credits. This selection overrides the **license_type** parameter in the Abaqus environment file.

3. If Abaqus/CAE is launched by the **3D**EXPERIENCE Platform Connector for Abaqus/CAE, you see an additional option to choose the License Server:

3DExperience On-Cloud

The job executes using the ***3D****EXPERIENCEPlatform* license server.

Local

The job executes using the locally installed license server.

Additional information

- *Understanding analysis jobs*
- *Using the job editor*
- *Creating, editing, and manipulating co-executions*

Choosing the job run mode

To locate the job editor, select **Job->Edit->*jobname*** from the main menu bar. Use the **Run Mode** options in the **Submission** tabbed page to choose the mode in which Abaqus will run your job. You can choose one of the following options:

- **Background** to run your job locally in the background.
- **Queue** to submit your job to a named local or remote batch queue; select the batch queue from the pull-down list. (You must define the queue in the Abaqus environment file. For more information, see *Defining analysis batch queues*. You must also make the queue available to Abaqus/CAE. For more information, see *Submitting a job remotely*.)

The **Run Mode** setting is analogous to parameters of the Abaqus execution procedure.

1. Locate the job editor.

   From the main menu bar, select **Job->Edit->*jobname***.

   Abaqus/CAE displays the **Edit Job** dialog box.
2. Click the **Submission** tab to display the **Submission** tabbed page.
3. From the **Run Mode** options in the middle of the page, select either **Background** or **Queue**.

Additional information

- *Understanding analysis jobs*
- *Submitting a job remotely*
- *Using the job editor*
- *Creating, editing, and manipulating co-executions*
- *Abaqus/Standard and Abaqus/Explicit Execution*
- *Environment File Settings*

Setting the job submit time

To locate the job editor, select **Job->Edit->*jobname*** from the main menu bar. Use the **Submit Time** options in the **Submission** tabbed page to choose when your analysis job will execute.

1. In the job editor, click the **Submission** tab to display the **Submission** tabbed page.
2. From the **Submit Time** options at the bottom of the page, choose one of the following options:

Immediately

The job executes in the background of your local machine immediately or is submitted to the batch queue immediately.

Wait

The job executes in the background of your local machine after a waiting period. Type the waiting period in the hours and minutes fields. (This option is available only on Linux platforms. In addition, it is not available if the job is being submitted to a batch queue.)

At

The job executes at a time that you specify in either the background of your local machine or in a batch queue. Click  to the right of the **At** field for information on what syntax to use when specifying a time. If you want the job to run in a batch queue at the specified time, you must configure the queue to accept a time variable using the **after_prefix** queue parameter in the Abaqus environment file. For more information, see *Defining analysis batch queues*. (The **At** option is available for jobs that run in either the background or in a batch queue on Linux platforms. However, the **At** option is available only for jobs that execute in a batch queue on Windows platforms.)

Additional information

- *Understanding analysis jobs*
- *Using the job editor*
- *Creating, editing, and manipulating co-executions*

Specifying general job settings

To locate the job editor, select **Job->Edit->*jobname*** from the main menu bar. Use the **General** tabbed page to configure miscellaneous job settings. You can configure the following:

Preprocessor Printout

The **Preprocessor Printout** options allow you to control whether Abaqus prints an echo of the input data, contact constraints, model definition data, and history data to the data (`.dat`) file. By default, each of these options is toggled on.

Preprocessor printout options are not available for a job associated with an input file; you must specify these options in the input file itself.

Scratch directory

The **Scratch directory** option allows you to specify the name of the directory used for scratch files. On Linux systems the default scratch directory is the value of the `$TMPDIR` environment variable or `/tmp` if the variable is not defined. On Windows systems the default scratch directory is the value of the `TEMP` environment variable or `\TEMP` if the variable is not defined. To specify a scratch directory, you can do one of the following:

- Click in the **Scratch directory** text field, and type the directory path.
- Click  to display the **Select Scratch Directory** dialog box, and select the directory of your choice.

User subroutine file

Provide the name of the file containing all user subroutines that are referred to by the model. To specify a user subroutine file, you can do one of the following:

- Click in the **User subroutine file** text field, and type the file path.
- Click  to display the **Select User Subroutine File** dialog box, and select the file of your choice.

If your model refers to a user subroutine but you do not specify the name of the subroutine file in the **General** tabbed page, Abaqus generates an error that is reported by the job monitor dialog box. (You can display the job monitor dialog box by selecting **Job->Monitor->*job of your choice*** from the main menu bar.) For more information on subroutines, see *About User Subroutines and Utilities*.

Results Format

The **Results Format** options allow you to write the results from an Abaqus analysis in ODB format or SIM format. For an Abaqus/Standard or Abaqus/Explicit analysis, you can also write the results to both formats. For more information, see *The Output Database*.

Note: If you select the ODB format, a `.sim` file may still be created; however, it will not contain the analysis results.

You can use the Abaqus environment file (`abaqus_v6.env`) to control the default value of most of the settings in the **General** tabbed page; for more information, see *Environment File Settings*.

Additional information

• *Understanding analysis jobs*

- *Using the job editor*
- *Creating, editing, and manipulating co-executions*

Controlling job memory settings

To locate the job editor, select **Job->Edit->*jobname*** from the main menu bar. Use the **Memory** tabbed page to control the amount of memory allocated to an Abaqus/Standard or Abaqus/Explicit analysis. Abaqus/CAE initially populates the settings in the **Memory** tabbed page with the values specified in the Abaqus environment file (`abaqus_v6.env`), and you can edit the environment file if you want to change the default memory settings. For more information about customizing the memory settings, see *Environment File Settings*.

If no memory values are specified in the Abaqus environment file, Abaqus automatically detects the physical memory on the machine and allocates a percentage of this available memory. The default percentages are platform specific, but they typically represent a large portion of the available physical memory. You should check the memory allocation values that Abaqus selects upon your next submission of the job to confirm that the allocation is appropriate for your system and for the job. For details on the default memory allocation settings, refer to the Dassault Systèmes Knowledge Base at *http://support.3ds.com/knowledge-base/*.

Smaller jobs may use less memory than the maximum available amount. You might want to reduce the memory allocation for your jobs or adjust the default allocation if you usually run multiple jobs at the same time. You can control the following:

- The **Memory allocation units** for the memory size specification. You can allocate memory as a **Percent of physical memory** or in **Megabytes** or **Gigabytes**.
- The **Maximum preprocessor and analysis memory** value. This option specifies either the percentage of physical memory or the number of megabytes or gigabytes of physical memory that will be allocated as a maximum for the analysis.
- The **Increase memory allocation based on analysis estimates** option. This setting enables you to use the memory allocation setting that Abaqus determines to be suitable for this job, with an additional amount of memory as a buffer, as the memory allocation settings for all future submissions of this job. The job memory value will be updated only if the estimate is higher than the value you specified.

For more information about memory settings, see *Managing Memory and Disk Resources*.

Additional information

- *Understanding analysis jobs*
- *Using the job editor*
- *Creating, editing, and manipulating co-executions*

Controlling job parallel execution

To locate the job editor, select **Job->Edit->*jobname*** from the main menu bar. Use the **Parallelization** tabbed page to control the parallel execution of an Abaqus analysis job, as follows:

- Select the number of processors to use for the analysis if parallel processing is available.
- For an Abaqus/Standard analysis, you can choose to use GPGPU acceleration of the direct sparse solver and specify the number of GPGPUs. For more information, see *Parallel Execution in Abaqus/Standard*.
- For an Abaqus/Explicit analysis, you can choose the following:
  - The number of domains. If you choose domain-level parallelization, the number of domains must be equal to or a multiple of the number of processors.

    When the number of domains is a multiple of the number of processors, you can toggle on **Activate dynamic load balancing** if desired. This option may improve the performance of your analysis job. If you have 4 processors and choose 8, 12, 16, etc. domains, for example, the dynamic load balancing feature becomes available. Dynamic load balancing is turned off by default. This option is equivalent to the `dynamic_load_balancing` option in the Abaqus/Explicit execution procedure. For more information, see *Abaqus/Standard and Abaqus/Explicit Execution*.

    Dynamic load balancing is most likely to improve the computational speed and efficiency in applications with a strongly time-dependent and/or spatially varying computational load. Most imbalanced problems will see an optimal performance improvement when the number of domains is two to four times the number of processors. For more details, see *Domain Decomposition*.
  - Whether the parallelization method should be **Domain** (default) or **Loop**. The domain-level method splits the model into a number of topological domains that are distributed evenly among the available processors. The loop-level method parallelizes low-level loops in the code that are responsible for most of the computational cost.

    If you select **Loop** for the parallelization method, you must select **Default** for the multiprocessing mode. For more information, see *About Parallel Execution*.

  For more information, see *Parallel Execution in Abaqus/Explicit*.
- For both an Abaqus/Standard and an Abaqus/Explicit analysis, you can choose whether the multiprocessing mode should be **Default**, **Threads**, **MPI** (Message Passing Interface), or **Hybrid**. The default multiprocessing mode is dependent on the platform on which the analysis product executes.
  - For the **Hybrid** multiprocessing mode, you can choose the number of threads per MPI process.
  - You cannot choose the number of threads per MPI process for all other multiprocessing modes. For **MPI** and **Default**, the number of threads per MPI process has value of 1. For **Threads**, the number of threads per MPI process is equal to the number of processors.

Note:

You use the Step module to choose between the Abaqus/Standard iterative and direct sparse solvers. For more information, see *Using the step editor*.

Additional information

- *Understanding analysis jobs*
- *Using the job editor*
- *Creating, editing, and manipulating co-executions*
- *Parallel Execution*

Controlling job precision

To locate the job editor, select **Job->Edit->*jobname*** from the main menu bar. Use the **Precision** tabbed page to control the precision of the Abaqus/Explicit analysis or the precision of nodal output for an Abaqus/Standard or Abaqus/Explicit analysis. You can do the following:

- Select the single, forced single (override environment variable **double_precision** setting if necessary), or double (analysis only, constraints only, or analysis and packager) setting for Abaqus/Explicit precision. This option is equivalent to the `double` option in the Abaqus/Explicit execution procedure.
- Select either single or full nodal output precision. This option is equivalent to the `output_precision` option in the Abaqus execution procedure.

For more information, see *Abaqus/Standard and Abaqus/Explicit Execution*, and *Environment File Settings*.

Additional information

• *Understanding analysis jobs*
• *Using the job editor*
• *Creating, editing, and manipulating co-executions*
• *Abaqus Execution Guide*

Creating, editing, and manipulating adaptivity processes

This section describes how you create, edit, and manipulate adaptivity processes using either the main menu or the **Adaptivity Process Manager**.

In this section:

- *Creating a new adaptivity process*
- *Performing a data check on an adaptivity process*
- *Submitting an adaptivity process*
- *Continuing an adaptivity process after a data check*
- *Terminating an adaptivity process*

Creating a new adaptivity process

An adaptivity process is a succession of analysis jobs. Abaqus/CAE modifies the mesh in each analysis job in response to error estimates that were computed from data written to the output database during the final increment of the previous analysis. For more information, see *What is an adaptivity process?*. To create a new adaptivity process, select **Adaptivity->Create** from the main menu bar.

1. From the main menu bar, select **Adaptivity->Create**.

   The **Edit Adaptivity Process** dialog box appears.

   Tip: You can also create a new adaptivity process by clicking the icon in the module toolbox or by clicking **Create** in the **Adaptivity Process Manager**.

2. Type the name of the new adaptivity process in the **Name** text field. The name that you specify must adhere to the file naming rules for your operating system.
3. Select the model to associate with the adaptivity process from the **Model** field.
4. If desired, type the description of the adaptivity process in the **Description** text field. The description is stored in the model database and the output database, and you can use this description to help you manage your adaptivity processes.
5. Enter the job prefix in the **Job Prefix** text field. The job name for each iteration of the adaptivity process will start with this prefix. The prefix that you specify must adhere to the file naming rules for your operating system. If you do not provide a job prefix, Abaqus/CAE uses the name of the adaptivity process.
6. In the editor, enter all data necessary to define the process and click **OK**. (For more information, see *Using the adaptivity process editor*.)

Additional information

- *Understanding adaptivity processes*
- *Creating, editing, and manipulating adaptivity processes*

Performing a data check on an adaptivity process

A data check runs the input file for a model through the analysis input file processor to ensure that the model is consistent and that all the required model options have been set. Performing a data check on an adaptivity process will create a job and verify model information for the first iteration of the overall adaptivity process.

To perform a data check on an adaptivity process, select **Adaptivity**->**Data Check**->***adaptivity process name*** from the main menu bar. You can also perform a data check by selecting the process name in the **Adaptivity Process Manager** and clicking **Data Check**.

The job created by the data check appears in the **Jobs** container using the naming conventions discussed in *Creating a new adaptivity process*. To see the results of a data check, review the data (`.dat`) file for this job in your working directory. You can also review the results of a data check by selecting **Job**->**Monitor**->***created job*** from the main menu bar to display the job monitor dialog box.

Additional information

- *Monitoring the progress of an analysis job*
- *Understanding adaptivity processes*
- *Creating, editing, and manipulating adaptivity processes*

Submitting an adaptivity process

To submit an adaptivity process for analysis, select **Adaptivity**->**Submit**->***adaptivity process name*** from the main menu bar. (You can also submit an adaptivity process for analysis by selecting the process name in the **Adaptivity Process Manager** and clicking **Submit**.) Abaqus/CAE submits the process for analysis and remeshing using the settings defined in the adaptivity process.

When you start an Abaqus/CAE session and submit an adaptivity process, Abaqus/Standard sends messages to Abaqus/CAE indicating the current status of the process. Abaqus/CAE then updates the **Status** column in the **Adaptivity Process Manager** accordingly. You must keep the current Abaqus/CAE session active for automatic remeshing to occur between analysis jobs. If you exit Abaqus/CAE and start a new session, you must use manual remeshing to continue the adaptivity process. For more information, see *When do I need to use manual adaptive remeshing?*.

In addition, Abaqus/CAE displays status information in the message area after each iteration of the adaptivity process. The status information lists the error indicator variables in each remeshing rule and whether the remeshing rule has been satisfied for that variable.

Additional information

- *Understanding adaptivity processes*
- *Creating, editing, and manipulating adaptivity processes*

Continuing an adaptivity process after a data check

When you perform a data check on an adaptivity process, a job is created for the first iteration of the adaptivity process (as described in *Performing a data check on an adaptivity process*). In addition, Abaqus creates and saves all the files necessary to complete this job at a later time. You can also use these files to continue the full adaptivity process from the current state of the first iteration.

To complete only the job associated with the first iteration of the adaptivity process, use the procedures listed in *Continuing an analysis job after a data check*. Remeshing and further iterations will not occur.

To continue the full adaptivity process, select **Adaptivity->Continue Analysis->*adaptivity process name***. You can also continue the adaptivity process by selecting the process name in the **Adaptivity Process Manager** and clicking **Continue Analysis**. The adaptivity process proceeds as described in *Submitting an adaptivity process*.

The **Continue Analysis** option can be used only in conjunction with a data check; it is not used to continue remeshing after an adaptivity process is complete. Once an adaptivity process runs to completion, you can continue to remesh a model by resubmitting the full process. You can also consider using the combination remeshing techniques described in *Using a combination of automatic and manual mesh adaptivity*.

Additional information

- *Understanding adaptivity processes*
- *Creating, editing, and manipulating adaptivity processes*

Terminating an adaptivity process

To terminate an adaptivity process, you should use the Job Manager to display the analysis job that is running and to end the job. Ending the job will terminate the adaptivity process. For more information, see *Terminating an analysis job*.

Additional information

- *Understanding adaptivity processes*
- *Creating, editing, and manipulating adaptivity processes*

Using the adaptivity process editor

This section describes how you use the adaptivity process editor to configure the settings of an adaptive remeshing process.

In this section:

- *Navigating the adaptivity process customization options*
- *Configuring adaptivity process attributes*
- *Specifying general adaptivity process settings*
- *Controlling adaptivity process memory settings*
- *Controlling adaptivity process parallel execution*
- *Controlling adaptivity process precision*

Navigating the adaptivity process customization options

Use the adaptivity process editor to customize your adaptivity processes before submitting them. The settings are analogous to parameters of the Abaqus execution procedure. For more information, see *Abaqus/Standard and Abaqus/Explicit Execution*.

To locate the adaptivity process editor, select **Adaptivity->Edit->*adaptivity process name*** from the main menu bar. The adaptivity process editor contains the following tabbed pages:

Adaptivity

Use the **Adaptivity** tabbed page to specify the maximum number of analysis iterations and to select the run mode. For more information, see *Configuring adaptivity process attributes*.

General

Use the **General** tabbed page to configure preprocessor printout and to specify a scratch directory. You also use the **General** tabbed page to specify any user subroutines that are referred to by the model and the output format of the results. For more information, see *Specifying general adaptivity process settings*.

Memory

Use the **Memory** tabbed page to configure the amount of memory allocated to each of the adaptivity analyses. For more information, see *Controlling adaptivity process memory settings*.

Parallelization

Use the **Parallelization** tabbed page to configure the parallel execution of an Abaqus analysis job, such as the number of processors to use and the parallelization method. For more information, see *Controlling adaptivity process parallel execution*.

Precision

Use the **Precision** tabbed page to specify the precision of nodal output that is written to the output database during each analysis. For more information, see *Controlling adaptivity process precision*.

The settings that you specify in the adaptivity process editor apply to each of the analyses that runs after each iteration of the adaptive remesh.

You can also use the Abaqus environment file (`abaqus_v6.env`) to control the default value of many of the settings in the adaptivity process editor tabbed pages. For more information, see *Environment File Settings*.

Additional information

- *Understanding adaptivity processes*
- *Using the adaptivity process editor*
- *About Adaptive Remeshing*

Configuring adaptivity process attributes

To locate the adaptivity process editor, select **Adaptivity->Edit->*adaptivity process name*** from the main menu bar. Use the **Adaptivity** tabbed page in the adaptivity process editor to specify the maximum number of iterations and to select the run mode.

Choose either of the following to specify the run mode:

- **Background** to run your job locally in the background.
- **Queue** to submit your job to a named local or remote batch queue; select the batch queue from the pull-down list. (You must define the queue in the Abaqus environment file. For more information, see *Defining analysis batch queues*. You must also make the queue available to Abaqus/CAE. For more information, see *Submitting a job remotely*.)

Additional information

- *Understanding adaptivity processes*
- *Using the adaptivity process editor*
- *About Adaptive Remeshing*

Specifying general adaptivity process settings

To locate the adaptivity process editor, select **Adaptivity->Edit->*adaptivity process name*** from the main menu bar. Use the **General** tabbed page to configure miscellaneous adaptivity process settings. You can configure the following:

Preprocessor Printout

The **Preprocessor Printout** options allow you to control whether Abaqus prints an echo of the input data, contact constraints, model definition data, and history data to the data (`.dat`) file. By default, each of these options is toggled off.

Scratch directory

The **Scratch directory** option allows you to specify the name of the directory used for scratch files. On Linux systems the default scratch directory is the value of the `$TMPDIR` environment variable or `/tmp` if the variable is not defined. On Windows systems the default scratch directory is the value of the `TEMP` environment variable or `\TEMP` if the variable is not defined. To specify a scratch directory, you can do one of the following:

- Click in the **Scratch directory** text field, and type the directory path.
- Click  to display the **Select Scratch Directory** dialog box, and select the directory of your choice.

User subroutine file

Provide the name of the file containing all user subroutines that are referred to by the model. To specify a user subroutine file, you can do one of the following:

- Click in the **User subroutine file** text field, and type the file path.
- Click  to display the **Select User Subroutine File** dialog box, and select the file of your choice.

If your model refers to a user subroutine but you do not specify the name of the subroutine file in the **General** tabbed page, Abaqus generates an error that is reported by the job monitor dialog box. (You can display the job monitor dialog box by selecting **Job->Monitor->*job of your choice*** from the main menu bar.) For more information on user subroutines, see *About User Subroutines and Utilities*.

Results Format

The **Results Format** options allow you to write the results from an Abaqus analysis in ODB format, SIM format, or both formats. For more information, see *The Output Database*.

Note: If you select the ODB format, a `.sim` file may still be created; however, it will not contain the analysis results.

You can use the Abaqus environment file (`abaqus_v6.env`) to control the default value of most of the settings in the **General** tabbed page; for more information, see *Environment File Settings*.

Additional information

- *Understanding adaptivity processes*
- *Using the adaptivity process editor*
- *About Adaptive Remeshing*

Controlling adaptivity process memory settings

To locate the adaptivity process editor, select **Adaptivity->Edit->*adaptivity process name*** from the main menu bar. Use the **Memory** tabbed page to control the amount of memory allocated to an Abaqus analysis. Abaqus/CAE initially populates the settings in the **Memory** tabbed page with the values specified in the Abaqus environment file (`abaqus_v6.env`), and you can edit the environment file if you want to change the default memory settings. For more information about customizing the memory settings, see *Environment File Settings*.

If no memory values are specified in the Abaqus environment file, Abaqus automatically detects the physical memory on the machine and allocates a percentage of this available memory. The default percentages are platform specific, but they typically represent a large portion of the available physical memory. For details on the default memory allocation settings, refer to the Dassault Systèmes Knowledge Base at *http://support.3ds.com/knowledge-base/*.

Smaller jobs may use less memory than the maximum available amount. You might want to reduce the memory allocation for your jobs or adjust the default allocation if you usually run multiple jobs at the same time. You can control the following:

- The **Memory allocation units** for the memory size specification. You can allocate memory as a **Percent of physical memory** or in **Megabytes** or **Gigabytes**.
- The **Maximum preprocessor and analysis memory** value that specifies either the percentage of physical memory or the number of megabytes or gigabytes of physical memory that will be allocated as a maximum for the analysis.

For more information about memory settings, see *Managing Memory and Disk Resources*.

Additional information

- *Understanding adaptivity processes*
- *Using the adaptivity process editor*
- *About Adaptive Remeshing*

Controlling adaptivity process parallel execution

To locate the adaptivity process editor, select **Adaptivity->Edit->*adaptivity process name*** from the main menu bar. Use the **Parallelization** tabbed page to control the parallel execution of an Abaqus process job as follows:

- Select the number of processors to use for the analysis if parallel processing is available.
- Select the **Threads** multiprocessing mode. Only the linear equation solver in Abaqus/Standard will execute in parallel.

Note:

You use the Step module to choose between the Abaqus/Standard iterative and direct sparse solvers. For more information, see *Using the step editor*.

Additional information

- *Understanding adaptivity processes*
- *Using the adaptivity process editor*
- *About Adaptive Remeshing*

Controlling adaptivity process precision

To locate the adaptivity process editor, select **Adaptivity->Edit->*adaptivity process name*** from the main menu bar. Use the **Precision** tabbed page to control the precision of nodal output. You can select either single or full nodal output precision. This option is equivalent to the `output_precision` option in the Abaqus execution procedure. For more information, see *Abaqus/Standard and Abaqus/Explicit Execution*.

Additional information

- *Understanding adaptivity processes*
- *Using the adaptivity process editor*
- *About Adaptive Remeshing*

Creating, editing, and manipulating co-executions

This section describes how you create, edit, and manipulate co-executions using either the main menu or the **Co-execution Manager**.

In this section:

- *Creating and editing co-executions*
- *Performing a data check on a co-execution*
- *Submitting a co-execution*
- *Viewing the results of your co-execution*
- *Terminating a co-execution*

Creating and editing co-executions

A co-execution is the co-simulation execution of two analysis jobs. You specify job parameters in a co-execution to create both analysis jobs. After creating the co-execution, you can edit the job parameters only in the individual analysis jobs.

The jobs are executed in synchronization with one another using the same functionality as described in *Understanding analysis jobs*. For more information on this analysis technique, see *Structural-to-Structural Co-Simulation*.

1. From the main menu bar, select **Co-execution->Create** or **Co-execution->Edit->*co-execution name***.

   The **Edit Co-execution** dialog box appears.

   Tip: You can also create a co-execution by clicking the icon in the module toolbox or clicking **Create** in the **Co-execution Manager**.

2. Type the name of the new co-execution in the **Name** text field. The name that you specify must adhere to the file naming rules for your operating system.
3. If desired, type the description of the co-execution in the **Description** text field. The description is stored in the model database and the output database, and you can use this description to help you manage your co-executions.
4. In the **Models** table, select the models in the current model database to associate with the co-execution from the list in the **Model Name** column.

   The analysis product used in each of the selected models and the default job name for each model are displayed in the table.

5. If desired, click in the **Job Name** column and edit the job name.
6. Use the **Submission**, **General**, **Memory**, **Parallelization**, and **Precision** tabbed pages to define the initial job parameter settings in the individual job editors. After the co-execution is created, the job parameters in the co-execution editor are unavailable for editing; you must edit the individual jobs.

   Define the initial job parameter settings as described in the following sections:

   - *Configuring job submission attributes*
   - *Specifying general job settings*
   - *Controlling job memory settings*
   - *Controlling job parallel execution*
   - *Controlling job precision*

7. If desired, enter a different value in the **Communication time out** field to specify the time after which Abaqus/CAE terminates if it does not receive any communication from the coupled analyses. The default value is 10 minutes.
8. Click **OK**.

Additional information

- *Understanding co-executions*
- *Creating, editing, and manipulating co-executions*

Performing a data check on a co-execution

A data check runs the input files for the models through the analysis input file processor to ensure that the models are consistent and that all the required model options have been set. Performing a data check on a co-execution will verify model information in each of the jobs created for the co-execution.

To perform a data check on a co-execution, select **Co-execution**->**Data Check**->***co-execution name*** from the main menu bar. You can also perform a data check by selecting the co-execution name in the **Co-execution Manager** and clicking **Data Check**.

The jobs involved in the co-execution appear in the Model Tree in the **Jobs** container under the co-execution in the **Co-executions** container. You can review the results of a data check by clicking mouse button 3 on the job in the Model Tree and selecting **Monitor** to display the job monitor dialog box. For more information, see *Monitoring the progress of an analysis job*.

Additional information

- *Understanding co-executions*
- *Creating, editing, and manipulating co-executions*

Submitting a co-execution

To submit a co-execution, select **Co-execution->Submit->*co-execution name*** from the main menu bar. (You can also submit a co-execution by selecting the co-execution name in the **Co-execution Manager** and clicking **Submit**.) Abaqus/CAE submits the jobs for analysis using the job settings defined in the co-execution editor or the individual job editors.

The jobs involved in the co-execution appear in the Model Tree in the **Jobs** container inside the **Co-executions** container. You can monitor the jobs that you have submitted by clicking mouse button 3 on the job in the Model Tree and selecting **Monitor** to display the job monitor dialog box. For more information, see *Monitoring the progress of an analysis job*.

Additional information

- *Understanding co-executions*
- *Creating, editing, and manipulating co-executions*

Viewing the results of your co-execution

Once your co-execution is completed, Abaqus/CAE stores the results of each analysis job in an output database. You can use the Visualization module to view the combined results graphically.

1. From the **Co-execution Manager**, select the co-execution name and click **Results**.

   The Visualization module starts and presents you with an overlay plot of both models.

2. Use the Visualization module to create and customize different plots of your results. For more information on using overlay plots, see *Overlaying multiple plots*.

Additional information

- *Understanding co-executions*
- *Creating, editing, and manipulating co-executions*

Terminating a co-execution

To terminate a co-execution, you should use the **Co-execution Manager** to display the co-execution that is running and to end the analysis jobs. Ending the jobs terminates the co-execution. Abaqus/CAE asks you for confirmation, terminates the jobs, and updates the status of the co-execution in the **Co-execution Manager** to `Terminated`. Note that co-execution termination may result in various error messages written to the message area, reflecting the unpredictable manner in which co-execution inter-job messaging is terminated. These error messages occurring immediately following co-execution termination can generally be disregarded

Additional information

- *Understanding co-executions*
- *Creating, editing, and manipulating co-executions*

Creating, editing, and manipulating optimization processes

This section describes how you create, edit, and manipulate optimization processes using either the main menu or the **Optimization Process Manager**.

In this section:

- *Creating and editing optimization processes*
- *Creating the optimization files*
- *Validating an optimization process*
- *Submitting an optimization process*
- *Continuing an optimization process that terminated*
- *Monitoring your optimization process*
- *Extracting a smoothed mesh*
- *Combining optimization results*
- *Viewing the results of your optimization process*

Creating and editing optimization processes

An optimization process reads an optimization task that you defined in the Optimization module and iteratively searches for an optimized solution based on the objective functions and constraints that you defined in the optimization task.

1. From the main menu bar, select **Optimization->Create** or **Optimization->Edit->*optimization process name***.

   The **Edit Optimization Process** dialog box appears.

   Tip: You can also create an optimization process by clicking the  icon in the module toolbox or clicking **Create** in the **Optimization Process Manager**.

2. Type the name of the new optimization process in the **Name** text field. The name that you specify must adhere to the file naming rules for your operating system. A directory is created with this name, and the output from the optimization process is stored in this directory.
3. Select the model to associate with the optimization process from the **Model** field.
4. Select the optimization task to associate with the optimization process from the **Optimization Task** field.

   If desired, type the description of the optimization process in the **Description** text field. The description is stored in the model database and the output database, and you can use this description to help you manage your optimization processes.
5. Enter the maximum number of optimization design cycles that are allowed before Abaqus ends the optimization process.
6. Choose how often to write the analysis results to the output database file that is created by the Abaqus job that runs for each design cycle of the optimization process. This option also specifies how often to create the related Abaqus analysis files, such as the status file and the message file. You can choose the following:

   - **Initial**: save data after the initial cycle (n=0) . The Optimization module uses the initial cycle to prepare the model for the first design cycle; for example, by creating groups and output requests. A finite element analysis is not performed during the initial cycle.
   - **First**: save data from the first design cycle (n=1).
   - **Last**: save data from the last design cycle.
   - **Every *n* cycles**: save data every n design cycles relative to the initial (n=0) design cycle. For example, if n=3, the optimization process will save data corresponding to design cycle 2, 5, 8, etc.
   - **Every**: Save data after every design cycle, including the initial (n=0) design cycle.

     Note: Selecting this option could lead to large disk space requirements for Abaqus models that generate large output database files.

   For more information, see *Understanding the files generated by creating and analyzing a model*. To postprocess the results of an optimization, you must combine the output databases that were generated by each design cycle into a single output database. For more information, see *Combining optimization results*.
7. Use the **Submission**, **Memory**, and **Parallelization** tabbed pages to define the initial settings for each Abaqus job that runs during the optimization process, as described in the following sections:

   - *Configuring job submission attributes*

- *Controlling job memory settings*
- *Controlling job parallel execution*

8. Click **OK**.

Additional information

• *Understanding optimization processes*
• *Creating, editing, and manipulating optimization processes*

Creating the optimization files

You can create copies of the optimization parameter (`.par`) file and the Abaqus input (`.inp`) file in your working directory. The parameter file contains parameters that are used to execute the optimization and contains information about the input file that is associated with the optimization; the input file, in turn, defines the Abaqus model you are optimizing.

You can run the optimization from the command line with the following command:

```
abaqus optimization -task parameter file -job results folder
```

The parameter file and the input file must be saved in the same directory. During the optimization, Abaqus creates a folder called *results folder* in which the results of the optimization are stored.

To create the optimization files, select **Optimization->Write Files->*optimization process name*** from the main menu bar. You can also create the optimization files by selecting the process name in the **Optimization Process Manager** and clicking **Write Files**.

Additional information

- *Understanding optimization processes*
- *Creating, editing, and manipulating optimization processes*

Validating an optimization process

A validation checks the optimization process to ensure that the optimization task has been configured correctly and the Abaqus model exists. A validation does not check your Abaqus model. You should run a complete analysis of your model and make sure that it runs to completion before you attempt to run an optimization process.

To validate an optimization process, select **Optimization->Validate->*optimization process name*** from the main menu bar. You can also validate an optimization process by selecting the process name in the **Optimization Process Manager** and clicking **Validate**.

Additional information

- *Understanding optimization processes*
- *Creating, editing, and manipulating optimization processes*

Submitting an optimization process

To submit an optimization process, select **Optimization->Submit->*optimization process name*** from the main menu bar. (You can also submit an optimization process by selecting the optimization process name in the **Optimization Process Manager** and clicking **Submit**.) Abaqus/CAE submits the optimization process using the settings defined in the optimization process editor. Click **Monitor** in the **Optimization Process Manager** to monitor the optimization process. For more information, see *Monitoring your optimization process*.

The optimization process appears in the Model Tree. The **Optimization Process** container includes a **Jobs** container that includes the Abaqus jobs executed during the optimization process. You can monitor an Abaqus job that is running by clicking the **Monitor** button from the top of the optimization process monitor. If your optimization process includes multiple models, the Optimization module creates an analysis job for each model and you must select the desired job to monitor. You can also view the monitor for the Abaqus jobs that completed during previous design cycles by clicking mouse button 3 on the job in the Model Tree and selecting **Monitor**. To terminate an optimization process, you must terminate the current Abaqus job. For more information, see *Monitoring the progress of an analysis job*.

Additional information

- *Understanding optimization processes*
- *Creating, editing, and manipulating optimization processes*

Continuing an optimization process that terminated

You can restart an optimization process that has failed for a reason external to the optimization. To continue the optimization process, select **Optimization->Restart->*optimization process name***. You can also continue the optimization process by selecting the optimization process name in the **Optimization Process Manager** and clicking **Restart**.

You can restart an optimization process only if it has failed because of a problem external to the optimization or the Abaqus analysis, such as:

- A license was not available.
- The Abaqus analysis failed due to insufficient disk space or memory.
- The user terminated the Abaqus analysis job by clicking the **Kill** button from the job monitor.

If the optimization fails due to errors in your Abaqus model, performing a restart will not allow it to continue. For example, if Abaqus stops because of excessively distorted elements, the same problem will occur after you attempt to restart the optimization. Before you restart the process, you can use the optimization process editor to change the optimization task and the model referred to by the optimization process. In addition, you can change the maximum number of optimization design cycles that are allowed before Abaqus ends the optimization process.

The optimization always restarts with an Abaqus analysis using the model that was most recently modified.

Additional information

- *Understanding optimization processes*
- *Creating, editing, and manipulating optimization processes*

Monitoring your optimization process

You can monitor the progress of your optimization process while it is running by selecting **Optimization->Monitor->*optimization process name***. You can also monitor the optimization process by selecting the optimization process name in the **Optimization Process Manager** and clicking **Monitor**. In addition, you can monitor the Abaqus jobs that completed during previous design cycles by clicking mouse button 3 on the job in the Model Tree and selecting **Monitor**.

The optimization process monitor displays a table showing the optimization values after each design cycle, as described in *Understanding the files generated by an optimization process*. By default, the table includes only the objective function and any constraints in the optimization process. Abaqus/CAE adds a row to the table when a design cycle completes. You can click mouse button 3 on a cell in the table and do the following:

- Select **Hide** to remove the selected column from the table.
- Select **Edit visible columns** and choose the variables to display. *Table 1* describes the variables that can be displayed.

Table 1: Variable categories

Category	Description
Objective Function	The value of the objective function—a single design response or a weighted combination of design responses and reference values.
Objective Function-Design Response	The value of a design response that is used by the objective function.
Objective Function Term	The weighted value of a design response and its reference value.
Constraint	The value of a constraint.
Variable	The value of each design response.

See *Objectives and Constraints*, for more information about the formulation of the objective function from a combination of weighted design responses and reference values.

To view an *X–Y* plot showing the change in the value of the design responses after each design cycle, click the **Plot** button in the upper left corner of the optimization process monitor. The *X–Y* plot appears in a new viewport and includes every design response listed in the table. You can use the *X–Y* plot options to customize the appearance of the plot, as described in *X–Y plotting*.

The data that are displayed in the table or in the *X–Y* plot are read from the files `optimization_status_all.csv` and `optimization_report.csv`. The Optimization module must be able to write to these files while the optimization process is executing. For example, you cannot open the files in an application such as Microsoft Excel while the optimization process is executing.

The optimization process monitor also displays the following information:

- The **Log** tabbed page displays the start and end times for the optimization process along with a log of the progress of the process.
- The **Errors** and **Warnings** tabbed pages display the errors or the warnings associated with the optimization process. Abaqus/CAE indicates the presence of errors or warnings by prepending an exclamation point before the **Errors** and **Warnings** tab.

  The number of error and warning messages that appear in the job monitor is limited by the environment parameters **cae_error_limit** and **cae_warning_limit**, respectively (see *Job customization parameters*, for details). If the number of errors or warnings exceeds the optimization process limit, consult the data, message, or status file for a complete list of messages.

- The **Output File** tabbed page displays a detailed record of each output data entry as it is written to the output file, including status, warning, and error messages. The output file is called `atom.out`, and it is stored in the optimization process directory (the directory with the same name as the optimization process).

To monitor the Abaqus analysis job associated with the optimization process, click the **Monitor** button in the upper right corner of the optimization process monitor. (If your optimization process includes multiple models, the Optimization module creates an analysis job for each model and you must first select the desired job to monitor.) Abaqus/CAE displays the job monitor and continues to update the job monitor for each iteration of the optimization. If desired, you can terminate the Abaqus analysis job and, hence, the optimization process, from the job monitor. For more information, see *Continuing an optimization process that terminated*, and *Monitoring the progress of an analysis job*.

An optimization process outputs a large amount of information to the optimization process monitor, especially to the **Output File** tabbed page. To help you locate a particular text string, you can use the **Search Text** fields in the lower half of the optimization process monitor. Select the desired file tab, enter a search string in the **Text to find** field, and click **Next** or **Previous** to step through the output from one hit to the next. Toggle on **Match case** to perform a case-sensitive search.

The information presented in the optimization process monitor is updated continually as the optimization progresses. If the optimization fails, the **Errors** tabbed page appears in front of the other tabbed pages automatically to help you determine the cause of the failure. In addition, an exclamation point appears on the tab if any error or warning messages are output.

If you start monitoring an optimization process and then either exit Abaqus/CAE, close the current model database, or open a new model database, the optimization process will continue; but, you will no longer be able to monitor the optimization process from Abaqus/CAE.

Additional information

- *Understanding optimization processes*
- *Creating, editing, and manipulating optimization processes*

Extracting a smoothed mesh

When the optimization process has completed, you can choose to extract a smooth isosurface meshed representation of the optimized model surface in the form of a file that can be transferred to a CAD system or back into Abaqus/CAE.

You can extract a smoothed surface mesh from either a topology, shape, or bead optimization. You can extract a single file from the entire assembly, or you can extract individual files from selected part instances.

The optimized model is usually a combination of tetrahedral and hexahedral elements and can include a significant number of interior elements that are not included in the isosurface representation that will be generated. In addition, the surface of the model might be rough and irregular, depending on the element density. The smoothing operation is an iterative process that displaces the nodes at the surface and generates a smooth triangular mesh on the surface of the model.

The smoothing operation can be followed by a data reduction operation that combines adjacent triangles with nearly coincident planes and reduces the number of surface triangles. Data reduction continues iteratively until the decrease in the number of triangles reaches a specified percentage of the original number of triangles. You can specify the angle that determines if adjacent planes are coincident.

Finally, you can choose to apply an optional filtering operation to remove local irregularities. The filtering is applied before the smoothing operation.

1. From the main menu bar, select **Optimization->Extract->*optimization process name***. You can also smooth the results by selecting the optimization process name in the **Optimization Process Manager** and clicking **Extract**.

   The **Extract Surface Mesh** dialog box appears.

2. Enter the name of the output file that will be extracted.
3. Select the content of the output files that will be extracted. You can choose either of the following:

   - Create a single file from the entire assembly.
   - Create individual files from selected part instances. Abaqus/CAE names the files by appending the name of the part instance to the name of the output file.

4. Select the format of the file that will be generated. You can choose from the following:

   - **Abaqus input file** (`.inp`): file that can be imported into Abaqus/CAE.
   - **STL** (`.stl`): file that can be read by 3D CAD systems, such as CATIA V5 and SOLIDWORKS.
   - **IGES1** (`.igs`): IGES file using block 114.
   - **IGES2** (`*_2.igs`): IGES file with explicit point information.
   - **IGES3** (`*_3.igs`): IGES file using block 128.

5. In the **Design Cycle** field, enter the design cycle from which the isosurface should be extracted. By default, the **Extract Surface Mesh** dialog box displays the last design cycle. The default value will not be displayed for sensitivity-based topology optimization since the solver is called once at the beginning of the optimization procedure.
6. Enter a value between zero and one specifying the **Iso value**.

   The smoothing process determines which elements are on the surface of the model and uses the isovalue to calculate where on the interior edges of the elements new nodes are created. Increasing the isovalue leads to shifting the isosurface toward the inside of the model, which results in a decrease in the model volume. For structures with thin components, you should not enter an isovalue greater than `0.7` to prevent the structure from becoming disconnected.

7. Enter the **Reduction percentage**, which defines the percent of faces that should be removed during the data reduction operation. A value of 0 indicates that no faces should be removed. A value of 100

indicates the data reduction stops when no more faces can be removed, given the value of the reduction angle.

8. Enter a value between 0 and 90 specifying the **Reduction angle**. The reduction angle defines the maximum angle between adjacent faces at a node such that the node might be removed during the data reduction.
9. Select the number of iterative smoothing cycles. Larger values lead to smoother models but can result in an increase of the computation time. In practice, 5 to 10 smoothing cycles are usually sufficient. Further smoothing can result in the narrowing or contracting of thin components. You can turn off smoothing by selecting a value of `0`.
10. Enter a value between zero and one specifying the **Target volume**.

    The target, or relative, volume of a solid model is the ratio of the volume defined by the isosurface and the original volume (calculated from the volume of the solid elements generated by the optimization). Likewise, the target area of a shell model is the ratio of the volume defined by the isosurface and the original area (calculated from the area of the shell elements generated by the optimization). If the model contains both solid and shell elements, only the solid elements are considered. The calculated volume does not account for voids inside a solid model.

    If you specify the target volume, the data reduction process calculates the isovalue that will result in the specified volume (the value of the isovalue that you enter is ignored). The data reduction process generates an error if you enter an excessively large value for the target volume that is larger than the volume calculated with an isovalue of zero or if you enter an excessively small value for the target volume that is smaller than the volume calculated with an isovalue of one. The data reduction process also generates an error if it fails to converge before 20 iterations.
11. In some cases, the optimized model will contain small irregularities that you can choose to remove with an optional filtering operation. Filtering is applied before the smoothing operation and results in a more homogeneous material distribution. Select **Moderate** to apply a single filtering cycle, select **Full** to apply five filtering cycles.
12. Click **OK** to extract the smoothed mesh.

    The specified output file is created in the TOSCA_POST directory. For subsequent runs, a unique number is appended to the file name; for example, *name*`_002.inp`.

Note:

If you extracted the smoothed mesh in the form of an Abaqus input file, you can select **File->Import->Model** from the main menu bar to import the mesh into Abaqus/CAE. For more information, see *Importing a model*.

Additional information

- *Understanding optimization processes*
- *Creating, editing, and manipulating optimization processes*

Combining optimization results

To view the results of an optimization in the Visualization module, you must combine the optimization results and analysis results into a single results output database file, as described in *Postprocessing an optimization*. The optimization results and the analysis results are appended to the output database file you specified as the base results.

1. From the main menu bar, select **Optimization->Combine->*optimization process name***. You can also combine optimization results by selecting the optimization process name in the **Optimization Process Manager** and clicking **Combine**.

   The **Combine Optimization Results** dialog box appears.

2. The **Optimization result directory** displays the path to the directory in which the output files from the selected optimization process reside. Click  to change the path.

3. Choose the output database file that will be used to create the base results. Abaqus/CAE uses the output database file defined in the base results as the source of the combined output database file. During the combination process, Abaqus/CAE appends additional data to the base results output database file.

   - Choose **Initial** to create the base results from the output database file generated during the initial optimization design cycle.
   - Choose **Last** to create the base results from the output database file generated during the last optimization design cycle. You should not choose **Last** if you performed a shape optimization.
   - Choose **Original Model** to create the base results from the output database file generated by running a separate analysis job of the model prior to the optimization. The optimization process does not run an Abaqus analysis of the original model. Therefore, you must run the analysis manually before you can select the output database file generated by the original model as the base results. (The Abaqus input file for the original model is stored in *optimization process name*`\SAVE.inp\`*optimization process name*`_org.inp`.)

4. Choose the output database files that will be combined with the base results output database file and the optimization results. The resulting output database file may be very large, so you should select only the data that you need to view in the Visualization module.

   - Choose **All** to combine the base results with the analysis results from all the output database files that were generated by the optimization process.
   - Choose **Last** to combine the base results with the analysis results from the output database file from the last design cycle.
   - Choose **Initial and last** to combine the base results with the analysis results from the output database files from the initial and last design cycles.
   - Choose **Every n cycles** and enter a value for *n* to combine the base results with the analysis results from the output database files created at periodic intervals starting with the initial design cycle.
   - Choose **Specify** to combine the base results with the analysis results from specified output database files; for example, `1,5,7,9`.

5. Select the **Models** and the **Steps** from within the models from which data will be combined into the results output database file.
6. From the list that appears, select the **Analysis Field Variables** that will be included in the results output database file.

   Abaqus/CAE always includes the optimization variables as field variables in the results output database file. The optimization data depend on the type of optimization that was performed:

7. Click **Submit** to create the results output database file.

Abaqus/CAE displays the **Combine Optimization Results Monitor** with the status of the merge operation and a log of output database files that are being merged.

8. Click **Close** to close the **Combine Optimization Results Monitor**.
9. From the **Optimization Process Manager**, click **Results** to view the combined results output database file in the Visualization module.

Additional information

Viewing the results of your optimization process

The results from each design cycle are stored in a separate output database file. To view the results of the optimization, you must combine the separate output database files into a single output database file, as described in *Combining optimization results*.

To view the results of your optimization process, select **Optimization->Results->*optimization process name***. You can also view the results by selecting the optimization process name in the **Optimization Process Manager** and clicking **Results**. Abaqus/CAE enters the Visualization module and, if you executed a topology optimization, automatically displays a view cut superimposed on the undeformed view. The isosurface variable of the view cut is the normalized material property that the Optimization module uses to "add" or "remove" elements from the analysis. If you executed a shape optimization, Abaqus/CAE displays an undeformed view showing the new position of the surface nodes. If you executed a sizing optimization, Abaqus/CAE displays an undeformed view showing the shell thickness. You can view the results of an optimization while it is running. For more information, see *Monitoring your optimization process*.

The Sketch module

Sketches are two-dimensional profiles that are used to help form the geometry defining an Abaqus/CAE native part.

You use the Sketch module to create a sketch that defines a planar part, a beam, or a partition or to create a sketch that might be extruded, swept, or revolved to form a three-dimensional part. This chapter explains how you use the tools within the Sketch module to create, modify, and manage sketches.

In this section:

- *Understanding the role of the Sketch module*
- *Entering and exiting the Sketch module*
- *Using the Sketch module*
- *Basic Sketcher concepts*
- *Sketcher geometry*
- *Specifying precise geometry*
- *Controlling sketch geometry*
- *Modifying, copying, and offsetting objects*
- *Customizing the Sketcher*
- *Sketching simple objects*
- *Creating construction geometry*
- *Constraining, dimensioning, and parameterizing a sketch*
- *Editing dimensions*
- *Adding reference geometry*
- *Projecting edges onto a sketch*
- *Moving or copying sketch geometry*
- *Modifying objects*
- *Repairing short edges, gaps, and overlaps*
- *Creating patterns, offsetting, and deleting objects*
- *Undoing and redoing sketching actions*
- *Resetting the view*
- *Managing stand-alone sketches*

Understanding the role of the Sketch module

You use the Sketch module to create and manage two-dimensional profiles that are not associated with a feature; these profiles are known as stand-alone sketches. Stand-alone sketches can be incorporated in the current sketch, and they will overlay any existing geometry. For more information, see *Managing stand-alone sketches*.

Entering and exiting the Sketch module

You can enter the Sketch module at any time during an Abaqus/CAE session by clicking **Sketch** in the **Module** list located in the context bar. The Sketch module tools appear in the module toolbox, and the **Sketch** menu appears on the main menu bar.

To exit the Sketch module, first exit the current drawing tool by clicking mouse button 2. Then click the **Done** button that appears in the prompt area, and select any other module from the **Module** list. You need not take any specific action to save your sketches before exiting the module; they are saved automatically when you save the entire model by selecting **File->Save** or **File->Save As** from the main menu bar.

You should recognize the difference between the Sketch module and the Sketcher. When you create or edit a stand-alone sketch, the Sketch module starts the Sketcher and displays the Sketcher tools in the module toolbox. In addition, Abaqus/CAE starts the Sketcher whenever you do one of the following:

- Create or edit a feature while defining a part in the Part module.
- Sketch a partition on a face or cell while working in the Part module.
- Sketch a partition on a face or cell in the assembly while working in the Assembly module or the Mesh module.

To exit the Sketcher and incorporate your sketch into the part or assembly, first exit the current drawing tool by clicking mouse button 2. Then, click the **Done** button that appears in the prompt area. Where applicable, follow any additional prompts to extrude, revolve, or sweep the feature. Abaqus/CAE exits the Sketcher and returns to the module that invoked it. In addition, Abaqus/CAE restores the original view of the part or assembly.

Using the Sketch module

This section provides an overview of the Sketch module.

In this section:

- *Stand-alone sketches*
- *Imported sketches*

Stand-alone sketches

You use the Sketch module to create and manage sketches that are not associated with a feature; these sketches are called stand-alone sketches.

A stand-alone sketch is stored in the model; like other objects in the model, such as parts and loads, a stand-alone sketch can be edited, copied, renamed, and deleted. To create a stand-alone sketch, click the sketch create tool  in the Sketch module toolbox.

When you are using the Sketcher (for example, when you are sketching the profile of a solid extrusion in the Part module), you can save your work as a stand-alone sketch by clicking the sketch save tool  in the Sketcher toolbox.

Similarly, you can incorporate one stand-alone sketch in another sketch by clicking the sketch retrieve tool  in the Sketcher toolbox. When you retrieve a stand-alone sketch, Abaqus/CAE does the following:

- Positions the retrieved sketch so that its origin is coincident with the origin of the current sketch.
- Resizes the viewport so that both the current sketch and the retrieved sketch are displayed.
- Asks if you want to translate, rotate, mirror, or scale the retrieved sketch from the default size and position.

Additional information

• *Managing stand-alone sketches*
• *Using the Sketch module*

Imported sketches

You can import stand-alone sketches into the model by selecting **File->Import->Sketch** from the main menu bar. You can import sketches from files stored in the following industry-standard formats:

- AutoCAD (file extension `.dxf`)
- IGES (file extension `.igs`)
- ACIS (file extension `.sat`)
- STEP (file extension `.stp`)

When you import a file as a stand-alone sketch, Abaqus/CAE translates the contents of the file into a set of Sketcher entities, such as lines, arcs, and circle. Abaqus/CAE can import most planar entities from an IGES-format file. For a complete list of the IGES entities that can be imported into a sketch, see *IGES entities recognized by Abaqus/CAE when importing a part or a sketch*. When you import an AutoCAD- or ACIS-format file, Abaqus/CAE recognizes only the entities listed in *Table 1* and *Table 2*. If Abaqus/CAE finds geometry that it cannot translate, it ignores that geometry and continues importing the sketch.

Table 1: AutoCAD entities supported by the Sketcher.

AutoCAD entity	Sketcher entity
Line	Line
Circle	Circle
Arc	Arc
Vertex	Point

Table 2: ACIS entities supported by the Sketcher.

ACIS entity	Sketcher entity
Line	Line
Circle	Circle
Arc	Arc
Vertex	Point
Ellipse	Ellipse
Spline and polyline	Spline

For Abaqus/CAE to convert the file to a sketch, the file must contain a two-dimensional planar profile that can be mapped to the sketch plane. If the file contains three-dimensional geometry, Abaqus/CAE cannot import the sketch.

In some cases, when you import a sketch to create the base feature of a part, Abaqus/CAE positions the sketch relatively far from the Sketcher origin. As a result, the part will be far from its origin, and the analysis of your model can be affected by a loss of precision. To improve precision, you may have to move the part closer to its origin by moving the vertices of the sketch closer to the origin of the Sketcher grid. For more information, see *The Sketcher sheet and grid*.

Basic Sketcher concepts

You use the Sketcher to sketch the lines and curves that form the two-dimensional profile of a feature, to add constraints to the sketch, and to modify the sketch. This section describes some of the basic concepts used by the Sketcher and how these concepts influence the behavior of the Sketcher tools and appearance of the sketch.

In this section:

- *The Sketcher tools*
- *The Sketcher sheet and grid*
- *How Abaqus/CAE orients your sketch*
- *Realigning the sketch grid relative to the sketch*
- *The Sketcher cursors and preselection*
- *Using the chain method to select edges in the Sketcher*
- *How Sketcher customization options are initialized and saved*
- *Using the Query toolset in the Sketcher*

The Sketcher tools

You can access all the Sketcher tools through either the main menu bar or the toolbox. *Figure 1* shows the hidden icons for all the tools in the Sketcher toolbox.

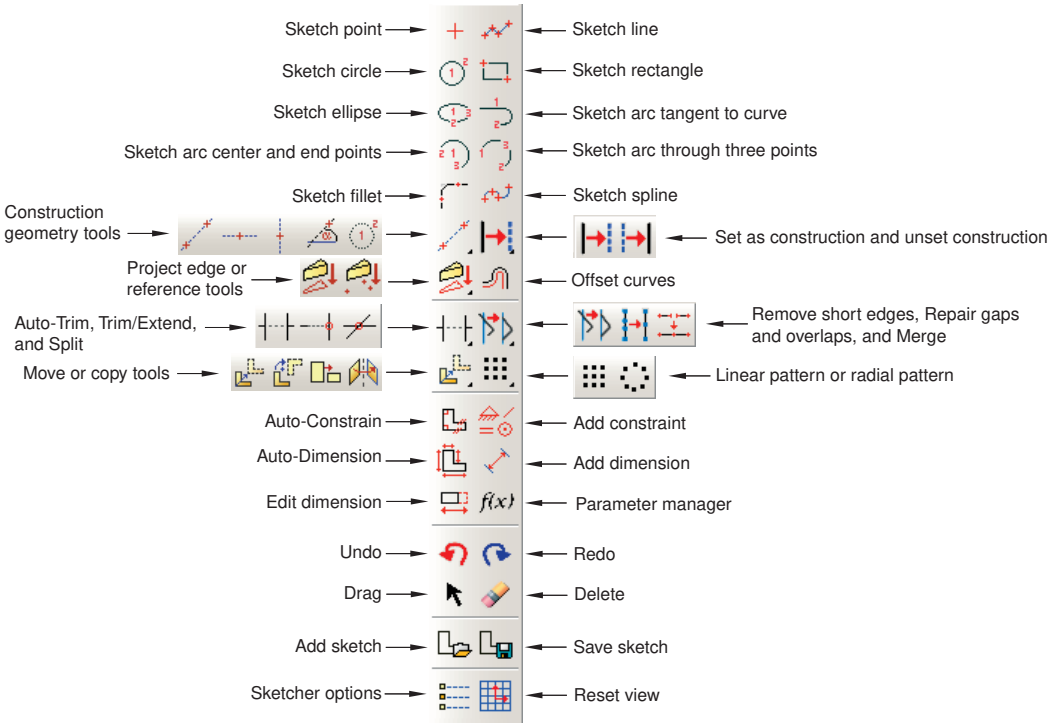

Figure 1: The Sketcher toolbox.

To see a tooltip containing a brief definition of a Sketcher tool, hold the mouse over the tool for a moment. For information on using toolboxes and selecting hidden icons, see *Using toolboxes and toolbars that contain hidden icons*.

The Sketcher tools allow you to do the following:

- Create basic sketch entities, such as lines, circles, arcs, ellipses, fillets, and splines.
- Add construction geometry to help you position and align sketch entities.
- Add constraints, dimensions, and parameters to control your sketch geometry and add precision.
- Translate, rotate, scale, or mirror sketch geometry.
- Drag, trim, extend, split, or merge sketch entities.
- Create similar objects by offsetting, creating linear patterns, or creating radial patterns.

Additional information

- *Basic Sketcher concepts*
- *Using the Sketch module*

The Sketcher sheet and grid

When you enter the Sketcher and either create a new sketch or edit an existing sketch, Abaqus/CAE displays a sheet in the current viewport on which you sketch. In addition, the triad in the lower-left corner of the viewport indicates the orientation of the part or the assembly relative to the Sketcher sheet. The sheet is always square, and its height and width are determined by the sheet size. Abaqus/CAE determines the sheet size and the location of the origin, depending on what you are sketching:

- If you are sketching the base feature of a new part, the sheet size is the same as the approximate size of the part that you provided when you created the part. The origin of the sheet is located at the origin of the part's coordinate system. Similarly, if you are creating a stand-alone sketch, the sheet size is the same as the approximate size of the sketch that you provided when you created the sketch.
- If you are adding a feature to a part or to the assembly, the default sheet size depends on the size of the face on which you are sketching. The origin of the sheet is located at the centroid of the selected face. If you selected a datum plane as the sketching plane, the origin of the sheet is located at the center of the part or assembly; the sheet size depends on the total size of the part or assembly.

You can use the Sketcher customization options to increase or decrease the sheet size if it does not correspond with the size of the geometry you are trying to sketch. To access the Sketcher customization options, select the customization tool  from the Sketcher toolbox. You may need to use the magnify tool  to view the entire Sketcher sheet within the viewport.

Abaqus/CAE overlays the sheet with a grid of invisible grid points to help you position the cursor as you draw, move, resize, or reshape objects. By default, when you move the cursor near a grid point, the cursor automatically moves, or snaps, to the point. This behavior allows you to easily position the cursor precisely on a grid point while also providing you with full control when the cursor is not close to any grid points. If it is more convenient, you can *disable* the snapping behavior so that you have full control over the cursor. To help you visualize the grid points underlying the Sketcher grid, Abaqus/CAE displays visible gridlines that pass through the grid points at a selected interval; for example, every other grid point.

For example, *Figure 1* shows a magnified view of a sheet whose spacing is set to 2 units.

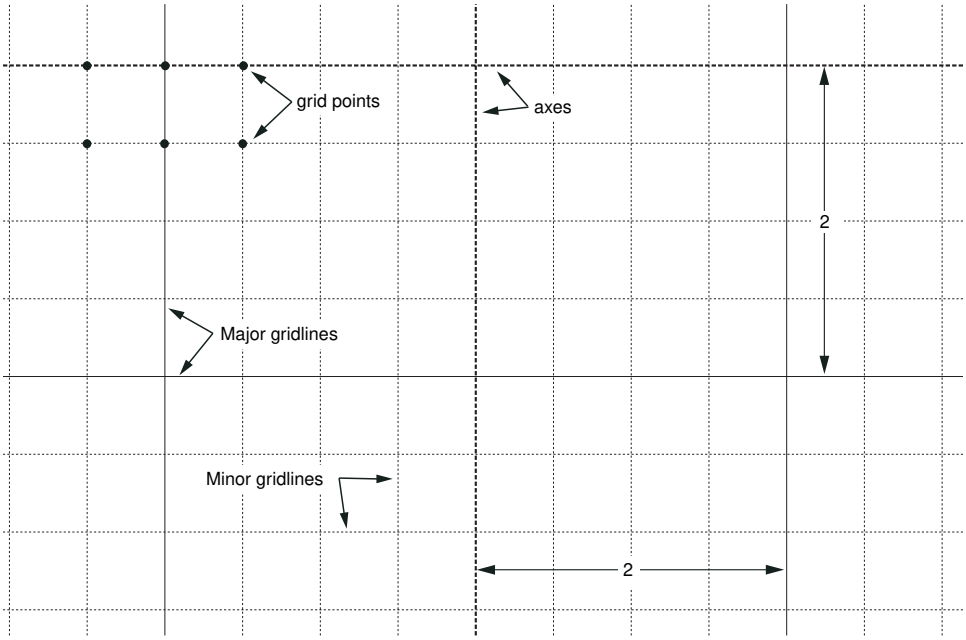

Figure 1: Magnified view of the Sketcher grid.

In this example the Sketcher displays both major gridlines (in a solid line style) and minor gridlines (in a thin, dashed line style). Minor gridlines appear in the Sketcher only when the magnification level is high. In addition, the thick dashed lines in the sheet indicate the *X*- and *Y*-axes of the sketch; the lines intersect at the origin of the sketch.

You can *customize* the appearance and behavior of the grid by choosing the spacing of grid points, the spacing of the visible gridlines that overlay the grid points, the number of minor intervals, and the sheet size. You can also realign the grid relative to the sketch by moving the origin of the grid and by rotating the grid. Your sketch can extend beyond the Sketcher grid; however, if you find that you need to sketch outside the grid, it is recommended that you increase its size to include the entire sketch. If you change the grid origin or rotation, the Sketcher displays cursor coordinates in two forms as you continue to modify the sketch. Grid coordinates indicate the cursor position using the new grid origin or rotation; sketch coordinates indicate the position based on the original grid location.

The analysis of your model can be affected by a loss of precision if the coordinates of a part are far from the origin of the part. For example, after you import a sketch to create the base feature of a part, the sketch may be relatively far from the Sketcher origin; as a result, the part will be far from its origin. To improve precision, you may have to move the part closer to its origin by moving the sketch geometry closer to the origin of the Sketcher grid using the translate tool, . You should not move the origin of the sketch closer to the geometry. Moving the origin of the Sketcher grid closer to the sketch is a graphical convenience only and has no effect on the underlying precision of the coordinates.

- *Customizing the sheet size and grid*
- *Basic Sketcher concepts*

How Abaqus/CAE orients your sketch

When the Sketcher starts, Abaqus/CAE orients the view of the part or assembly so that the face or datum plane on which you are sketching is parallel to the screen; this plane is known as the sketch plane. The orientation of the sketch plane depends on the modeling space of the part or assembly and the type of feature you are creating:

Two-dimensional or axisymmetric modeling space

When you add a planar feature to a two-dimensional or axisymmetric part or assembly, Abaqus/CAE starts the Sketcher and aligns the *X*- and *Y*-axes of the part with the axes of the Sketcher grid, regardless of the type of feature you are creating. (Abaqus/CAE derives the *X*- and *Y*-axes of the part from the axes of the sketch that defined the base feature.)

Three-dimensional modeling space

When you add a feature to a three-dimensional part or assembly, you must use the following technique to control the orientation of the view relative to the Sketcher grid:

1. Select the plane on which to sketch by selecting appropriate geometry; for example, a face of a part or a datum plane.
2. Select an edge. By default, the selected edge will appear vertical and on the right side of the Sketcher grid. Alternatively, you can choose a different orientation for the edge in the Sketcher grid before you select the edge; for example, horizontal and on the top of the Sketcher grid. You can select any edge from the part or assembly that is not perpendicular to the selected plane. You can select a datum axis, or you can select one of the axes of a datum coordinate system; but you cannot select the edge of a datum plane. You can select a curved edge, but the resulting orientation of the part or assembly is system dependent.

Abaqus/CAE highlights the selected edge, enters the Sketcher, and rotates the part until the selected edge aligns with the grid in the desired orientation. The orientation of the view on the Sketcher grid also depends on the type of feature you are creating:

- When you are sketching a cut feature in the Part module, Abaqus/CAE orients the view so that the resulting feature will cut away from you and into the screen.
- When you are sketching a feature other than a cut (for example, an extruded solid), Abaqus/CAE orients the view so that the resulting feature will protrude out of the screen toward you.
- When you are adding a swept feature, you must sketch a sweep path and sweep profile. For details of the resulting view orientation, see *Adding a swept solid feature*; *Adding a swept shell feature*; and *Creating a swept cut*.

When you are partitioning faces using the sketch method in the Partition toolset, Abaqus/CAE orients the view based upon the modeling space of the part or assembly and the type of faces you selected to partition. For more information, see *Using the sketch method to partition faces*.

If you are unsure of the part's or assembly's orientation relative to the sketch plane, use the view manipulation tools to examine the sketch plane and the object on which you are sketching. Use the reset view tool  to return to the original view.

Figure 1 illustrates how Abaqus/CAE determines the sketch plane orientation relative to a three-dimensional part after you select a face, an edge, and the orientation of the edge on the Sketcher grid.

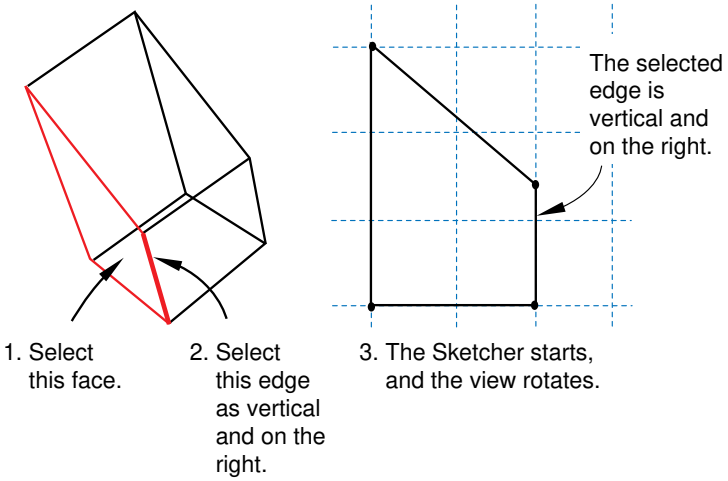

Figure 1: Determining the sketch plane orientation.

Additional information

- *Adding a swept solid feature*
- *Adding a swept shell feature*
- *Creating a swept cut*

- *Using the Sketch module*
- *Using the sketch method to partition faces*

Realigning the sketch grid relative to the sketch

When you are sketching a feature, the sketch grid does not always align with the vertices and lines of the sketch or the underlying reference geometry. You can use the following techniques to realign the grid:

- Shift the grid relative to the sketch by selecting a vertex representing the origin of the grid.
- Rotate the grid relative to the sketch by selecting a line that will be parallel to the *X*-axis of the sketch.
- Remove any realignment and reset the grid to its original orientation.

Realignment applies only to the particular sketch, and the alignment of the grid is stored along with the sketch in the model database. New and existing sketches retain their default alignment.

Changing the origin and rotating the sketch grid allows you to quickly create features that might be difficult to create using the default grid location. Rotating the grid has the following effect:

- The grid coordinates of the current cursor position are displayed in the upper-left corner of the viewport, and you can use these coordinates as a guide. The grid coordinates displayed are relative to the current alignment of the sketch grid and change if you realign the grid.
- The sketch coordinates of the current cursor position are displayed in the upper-right corner of the viewport. The sketch coordinates displayed are relative to the original alignment of the sketch grid and do not change if you realign the grid.
- When you enter the coordinates of a vertex in the prompt area, those coordinates are relative to the current alignment of the sketch grid.
- Old and new horizontal and vertical dimensions remain horizontal and vertical.
- Old horizontal and vertical construction lines remain horizontal and vertical.
- New horizontal and vertical construction lines and preselection points are aligned with the rotated grid.
- The lines generated by the rectangle tool are aligned with the rotated grid.

Additional information

• *Realigning the sketch grid*
• *Basic Sketcher concepts*
• *Using the Sketch module*

The Sketcher cursors and preselection

There are two cursors active within the Sketcher: the primary cursor and the secondary cursor. The two cursors are shown in *Figure 1*.

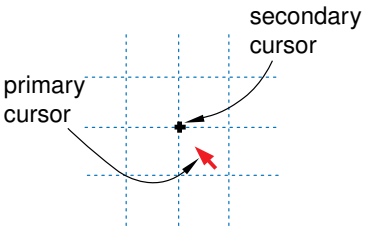

Figure 1: The Sketcher cursors.

The primary cursor is the one you use with most applications on your computer, including Abaqus/CAE. The primary cursor usually appears as an arrow pointer or a pointing hand; you position this cursor by moving the mouse. The secondary cursor is active only in the Sketcher; it appears near the primary cursor when the Sketcher prompts you to select a point. The position of the secondary cursor allows you to see exactly which point is selected before committing the selection. If you move the primary cursor near a point that is eligible for selection, the secondary cursor jumps directly to the point while the primary cursor remains fixed. This behavior is called preselection. If you click the mouse button, Abaqus/CAE selects the point under the secondary cursor.

The appearance of the secondary cursor changes as you move around the sketch. *Table 1* shows the shape assumed by the secondary cursor when the primary cursor is close to the Sketcher entity listed.

Table 1: Preselection cursors.

Preselection cursor	Sketcher entity
□	A vertex
	The midpoint of a line or curve
×	The intersection of lines and curves
×——	The projection of a line onto other lines and curves
	Points along existing lines or curves
+	The intersection of gridlines with each other or with other lines and curves

The secondary cursor works in conjunction with other preselection symbols in the sketch to indicate special points that you can select. *Table 2* shows the other preselection symbols used in the Sketcher and the meaning of each symbol.

Table 2: Preselection symbols.

Preselection symbol	Location and Meaning
□	At the starting point of a new line segment when the line starts on existing sketch, reference, or construction geometry. The new line segment is perpendicular to the existing geometry.
‖	Near the starting point when creating a new line starting on an existing edge; the symbol is aligned with the existing edge. The new line segment is tangent to the existing edge.
H	Near the secondary cursor when creating a new line. The new line segment is horizontal.
V	Near the secondary cursor when creating a new line. The new line segment is vertical.

The preselection cursors and symbols also indicate constraints that Abaqus/CAE will apply to the sketch if you choose the preselected point. Constraints such as coincidence, perpendicularity, and tangency help control sketch geometry and preserve your design intent.

Preselection applies to any entity that is a valid selection in the sketch. For example, as you move the cursor around the sketch, preselection highlights the following to indicate a valid selection:

- Vertices, intersections, projections, and points of tangency highlight when you are sketching a line, as shown in *Table 1*.
- Sketch, construction, and reference geometry highlight when you are adding a dimension.
- Dimensions highlight when you are modifying a dimension.

You can customize the cursor's behavior as follows:

- By default, the secondary cursor snaps to grid points that are close to the primary cursor. If you turn off this snapping, the secondary cursor follows the primary cursor and can be positioned anywhere on the Sketcher sheet.
- You can turn off preselection.

For more information on customizing the secondary cursor, see *Turning snapping on or off*, and *Turning preselection on or off*. The secondary cursor is available only in the Sketcher, but you can use another form of preselection to help you select viewport objects in other Abaqus/CAE modules. For more information on selecting viewport objects, see *Selecting and unselecting individual objects*.

Additional information

- *Controlling sketch geometry*
- *Customizing the Sketcher*
- *Using the Sketch module*
- *Basic Sketcher concepts*

Using the chain method to select edges in the Sketcher

When offsetting or copying edges in a sketch, you can select a "chain" of connected edges. A chain is a connected group of edges in which each edge may be connected to, at most, one other edge at each endpoint—like the links in a chain. The chain method is available only in the Sketcher, and it allows you to select a chain of edges as if they were a single entity.

When you are performing a task that allows you to pick more than one edge from a sketch, Abaqus/CAE displays a field in the prompt area. The field allows you to choose between the two selection methods—**individually** and **by chain**, as shown in *Figure 1*.

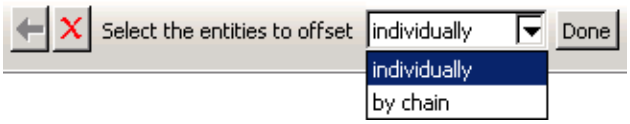

Figure 1: Choose the selection method from the field in the prompt area.

After you use the chain method, you can click the **individually** method in the prompt area and **[Shift] + Click** on individual edges to append them to your selection. You can also **[Ctrl] + Click** on edges to unselect them. In addition, you can continue to use the chain method and use **[Shift] + Click** to append more chains to your selection.

- *Selecting objects within the current viewport*

How Sketcher customization options are initialized and saved

Sketcher customization options are grouped into the following settings:

Sketcher options

- Snapping
- Preselection behavior
- Whether to display construction geometry, dimensions, parameter names, and constraints
- The types of constraints and dimensions that Abaqus/CAE can add automatically

Sketch options

- Sheet size, grid spacing, and grid display
- The origin of the grid and the alignment of the axes
- The text height and decimal places of dimensions and text height of parameter names

Sketcher options control the interactive behavior of the Sketcher, while Sketch options control the appearance of individual sketches. Abaqus/CAE stores and uses your Sketcher customization settings only for the duration of the session. In contrast, Abaqus/CAE stores your Sketch customization settings along with each sketch in the model database. As a result, if you exit the Abaqus/CAE session and return to the sketch at a later date, the Sketch customization options are retained.

When you create a new part or stand-alone sketch, Abaqus/CAE always uses the default Sketch options. The sheet size and grid spacing are recalculated based on the approximate size of the part or the selected sketch plane, the origin of the sketch is at `0,0` , the grid is displayed and aligns with the 1- and 2-axes, and the text height and decimal places are at their default settings.

Additional information

• *Using the Sketch module*
• *Customizing the Sketcher*

Using the Query toolset in the Sketcher

You can use the Query toolset to request either general information or module-specific information.

For a discussion of the information displayed by general queries, see *Obtaining general information about the model*.

Select **Tools->Query** from the main menu bar, or click the  tool in the Query toolset to start the Query toolset.

The following queries are specific to the Sketcher:

Constraint

Abaqus/CAE displays the constraint type and the names of the constrained entities in the message area and highlights the entities in the sketch.

Detail

Abaqus/CAE displays the number of geometries, vertices, constraints, dimensions, and unconstrained degrees of freedom in the message area.

Additional information

- *Basic Sketcher concepts*
- *The Query toolset*

Sketcher geometry

This section describes the different types of geometry available in the Sketcher.

In this section:

- *Reference geometry*
- *Construction geometry*

Reference geometry

When you sketch the profile of a feature, Abaqus/CAE projects onto the sketch sheet all the edges and vertices of the part or assembly that are in the same plane as the sketch plane. Abaqus/CAE also projects all datum points and datum axes onto the sketch sheet, regardless of their location in the part or assembly. These projected points and lines are called reference geometry, and you can use them for reference while sketching.

You typically use reference geometry to position your sketch accurately by specifying a dimension between a sketched entity, such as a line or a vertex, and the reference geometry. You can also use reference geometry to realign the sketch grid. The sketch retains any reference geometry that is used to position or dimension the sketch—the reference geometry reappears when you use the Sketcher to edit the feature again. Abaqus/CAE discards any reference geometry that is not used in the sketch.

If your part is complex, projecting only the edges, vertices, and datum points in the sketch plane onto the sketch sheet reduces the amount of clutter on the screen and makes the selection procedure more straightforward. However, your selection will be limited to only edges, vertices, and datum points that are in the sketch plane. If you want to use other edges, vertices, or datum points–including orphan element edges and nodes—as references, you must project them onto the sketch plane as reference geometry by using the **Project References** tool . Alternatively, if you want to create new sketch edges from existing model edges or orphan element edges, you can use the **Project Edges** tool  (for more information, see *Projecting edges onto a sketch*).

When you sketch a new feature, you can constrain the position of the sketch to the underlying reference geometry using one of the following methods:

- Select entities from the reference geometry while sketching the new feature; for example, select a projected vertex to define the center of a circle or one end of a line.
- Create a constraint, dimension, or parameter between the sketch and any projected reference geometry. For more information, see *Controlling sketch geometry*.

Constraining the sketch defines how it is positioned relative to the reference geometry and how it will be repositioned if you modify and regenerate the part or assembly.

When you exit the Sketcher, Abaqus/CAE determines whether you have constrained the sketch to the reference geometry. If a constraint is found, Abaqus/CAE creates a parent-child relationship between the new feature (the child) and the selected reference geometry (the parent). If no constraints are found, Abaqus/CAE displays the following message in the message area: `No sketch placement constraints specified on feature feature name`. You do not have to constrain the sketch; but if you do not, its position relative to the underlying geometry of the part or assembly may change if you modify and regenerate the part or assembly.

If you save a stand-alone sketch, Abaqus/CAE saves only the sketch and does not save any underlying reference geometry. As a result, if the sketch includes a dimension between a sketch line and a reference line, the dimension is not saved with the stand-alone version of the sketch.

The order in which you create features influences the available reference geometry. Feature-based modeling allows a child feature to be dependent on a parent feature but does not allow a parent to be dependent on a child. As a result, if a feature was created after the feature you are editing, the edges and vertices of the newer feature cannot be projected onto the sketch sheet. You can use the Query toolset to determine the order in which features were created; for more information, see *Using the Model Tree to obtain feature information*.

Additional information

- *The Feature Manipulation toolset*
- *Using the Sketch module*

Construction geometry

You create construction geometry in the Sketcher to help you position and align the geometry in your sketch; objects that you might need to position include holes, arcs, slots, or gear teeth.

The Sketcher allows you to add construction lines and circles to your sketch; in addition, points that you create using the isolated point tool  are considered construction geometry. Construction lines, circles, and points do not appear in the feature you are creating or modifying.

While you are adding construction geometry and moving the cursor around the sketch, Abaqus/CAE displays preselection symbols at the following locations:

- The intersection of the new construction geometry and sketched lines or curves.
- The intersection of the new construction geometry and existing construction geometry.
- The intersection of the new construction geometry and reference geometry. Abaqus/CAE displays preselection symbols only when the reference geometry was created before the feature being edited. (See *Reference geometry*, for more information about the behavior of reference geometry.)

The preselection symbols generated by construction geometry allow you to align objects precisely; for example, along an oblique line or around a circle. For example, you could create an oblique construction line and several vertical construction lines to help align a group of circles, as illustrated in *Figure 1*.

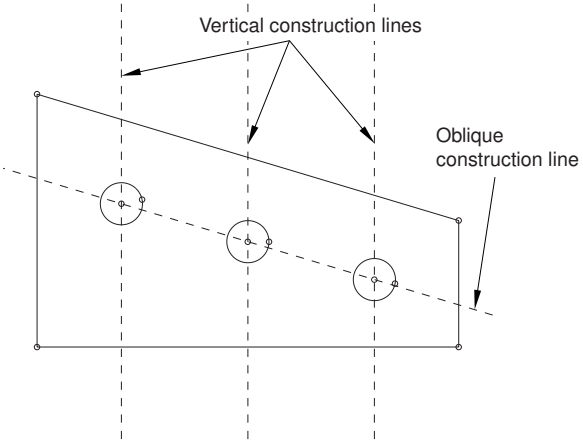

Figure 1: Using construction lines to align sketch geometry.

Construction lines also define the axis of rotation when sketching revolved solids and surfaces. For more information about the relationship between construction lines and the axis of revolution, see *Defining the axis of revolution for axisymmetric parts and for revolved features*.

Construction geometry is shown using dashed lines to distinguish it from sketched geometry. Construction geometry is visible only while you are working on a sketch; as soon as you exit the Sketcher, the construction geometry disappears. Abaqus/CAE saves construction geometry with the original sketch; if the Sketcher is invoked to modify a sketch that included construction geometry, the construction geometry reappears along with the sketch.

To create construction geometry, select one of the construction geometry tools from the Sketcher toolbox or select **Add->Construction** from the main menu bar.

You can also convert components of your sketch into construction geometry, and you can reverse this process for items that had been converted to construction geometry. To convert a component to construction geometry, select the

component and select **Edit->Set as Construction** from the main menu bar; to reverse this process, select the construction geometry component and select **Edit->Unset Construction**.

Specifying precise geometry

When you are using the Sketcher to sketch features, you can use the underlying grid and preselection to position the cursor and create or modify sketch geometry. In addition, you can use the following techniques to position the geometry precisely:

Entering coordinates

When you are using the Sketcher to create a feature and Abaqus/CAE asks you to position a point (for example, to define the endpoint of a line or the center of a circle), you can do one of the following:

- Select a point on the sketch using the Sketcher grid, existing vertices, or preselection.
- Enter the desired *X*- and *Y*-coordinates of the point in a text box in the prompt area.

  To help you determine the coordinates to provide, the *X*- and *Y*-axes of the sketch are indicated by dashed lines, which intersect at the origin of the sketch. The coordinates that you specify are relative to this origin. In addition, when you select a Sketcher tool, the coordinates of the current cursor position are displayed in the upper-left corner of the viewport, and you can use these coordinates as a guide.

For detailed instructions, see *Sketching simple objects*.

Creating and modifying dimensions

After you have created the geometry, the Sketcher allows you to add dimensions between lines and vertices and other pieces of geometry in the sketch. You can then refine the sketch by replacing these dimensions with precise dimensions, and the sketch changes to reflect the new dimensions. In addition, dimensions allow you to annotate sketches for future reference.

You add dimensions by selecting the dimension tool  in the Sketcher toolbox or by selecting **Add->Dimension** from the main menu bar—editing the dimension value is the final step in creating a new dimension. To modify an existing dimension, select the modify dimension tool  from the Sketcher toolbox or select **Edit->Dimension** from the main menu bar. For detailed instructions, see *Editing dimensions*.

- *Using the Sketch module*

Controlling sketch geometry

Controlling sketch geometry helps you prevent unintended changes by creating relationships between sketch entities. If all the geometry in a sketch is controlled, the sketch is fully constrained—the entities in the sketch cannot be modified without violating the controls, and you cannot add another control without creating a conflict with one that already exists.

The following section describes how you can use constraints, dimensions, and parameters to control sketch geometry. All three types of controls can be considered constraints since they all work to restrict the degrees of freedom in a sketch, but each control creates a different type of relationship between the selected entities.

In this section:

- *Using constraints to control sketch geometry*
- *Using dimensions to control sketch geometry*
- *Using parameters to control sketch geometry*
- *Fully constrained geometry*

Using constraints to control sketch geometry

Constraints create logical relationships that control the position or size of geometry. Constraints are defined without using numerical values. The other types of geometry controls, dimensions and parameters, are specialized constraints that use values or evaluated expressions to define numerical relationships in a sketch. Constraints are not required in Abaqus/CAE sketches; however, they can help you preserve the design intent. When you modify a constrained sketch, you must either work within the existing controls, modify them, or delete them to complete your changes.

Table 1 lists each constraint type, its symbol, and a brief description of its use.

Table 1: Sketcher constraints.

Constraints	Symbol	Description
Coincident	o	Abaqus/CAE moves the selected entities so that they share a common point. The point may be a point on both entities or a projected point that would exist only if one of the entities was extended. If two straight lines are selected, they become colinear.
Concentric	⊙	Abaqus/CAE moves the selected arcs or circles to share a common center.
Equal length	/	Abaqus/CAE makes the selected lines all the same length.
Equal radius	—	Abaqus/CAE makes the selected arcs or circles the same radius.
Fixed	△	Abaqus/CAE fixes the radius of an arc or circle, the angle of a line, or the position of a vertex.
Horizontal	H	Abaqus/CAE aligns the selected line with the *X*-axis of the sketch. The horizontal constraint is not affected by grid orientation.
Equal distance	|o|	Abaqus/CAE moves the selected vertex so that it is the same distance from the two vertices or lines used to define the constraint.
Parallel	//	Abaqus/CAE makes the selected lines parallel.
Perpendicular	□	Abaqus/CAE makes the selected lines perpendicular.
Symmetry	o|o	Abaqus/CAE makes the selected entities symmetrical about your chosen line of symmetry.
Tangent	‖	Abaqus/CAE makes the selected entities tangent at their nearest point. At least one of the entities must be curved.
Vertical	V	Abaqus/CAE aligns the selected line with the *Y*-axis of the sketch. The horizontal constraint is not affected by grid orientation.

Note:

The behaviors described in *Table 1* assume that no other constraints are applied to the selected entities. The presence of other constraints and the constraint solution method selected in the **Sketcher Options** may affect how Abaqus/CAE moves entities to comply with the constraints.

You can create multiple instances of the same type of constraint in a sketch. You can use the sketch module queries to locate the geometries controlled by a constraint or to list the constraint details for the entire sketch (for more information, see *The Query toolset*).

You can use the following techniques to add constraints to a sketch:

Preselecting geometry

If preselection is active, Abaqus/CAE can add some constraints while you create geometry. Coincident, horizontal, perpendicular, tangent, and vertical constraints can be added using the preselection cursor. For more information, see *The Sketcher cursors and preselection*.

Selecting midpoints of lines or curves

If you select the midpoint of a line or curve as the vertex for additional sketch geometry, Abaqus/CAE also creates an equal distance constraint between the midpoint and the endpoints of the line or curve.

Adding constraints automatically

After you create a sketch, you can use the auto-constrain tool  to add constraints to the entire sketch or to a selected group of entities. Use the sketch options to control the constraint types that Abaqus/CAE can add automatically and the allowable tolerances for adding a constraint. For more information, see *Customizing the use of constraints in the Sketcher*.

Adding individual constraints

After you create sketch geometry, you can select the constraint type and pick the entities to apply the constraint. This method gives you the most control, but it is also the most time consuming. For more information, see *Adding individual constraints*.

When you add constraints, you must not overconstrain the sketch geometry. Geometry is overconstrained when multiple controls are applied to a single degree of freedom (for more information, see *Fully constrained geometry*). Abaqus/CAE colors conflicting constraints magenta to indicate an overconstraint condition. You must resolve any overconstraints before you can use a sketch to create a feature or save it with the model database.

Additional information

- *Customizing the Sketcher*
- *Constraining, dimensioning, and parameterizing a sketch*

Using dimensions to control sketch geometry

Dimensions are a type of constraints that use numerical values to define sizes, angles, or distances in a sketch. Dimensions control sketch geometry by preventing changes to the dimensioned quantities. To change a dimensioned quantity, you must modify the associated dimension.

The following dimension types are available in the Sketcher:

- horizontal
- vertical
- oblique
- angular
- radial

The first three dimension types correspond to linear distances between two points (including the endpoints of a single line), two lines, or a point and a line. Angular dimensions always indicate the angle, in degrees, between two lines. Radial dimensions indicate the radius of a circle, arc, or fillet or the major and minor radii of an ellipse.

You can use the following techniques to add dimensions to a sketch:

Adding dimensions automatically

After you create a sketch, you can use the auto-dimension tool  to add dimensions to the entire sketch or to a selected group of entities. Use the sketch options to control the dimension types that Abaqus/CAE can add automatically. For more information, see *Customizing the format and use of dimensions in the Sketcher*.

Adding individual dimensions

After you create sketch geometry, you can add individual dimensions. This method gives you the most control, but it is also the most time consuming. For more information, see *Adding individual dimensions*.

You can modify any dimension in a sketch. When you edit an existing dimension, you can modify it in several ways. You can

- edit the numerical value to modify the sketch,
- convert the dimension to a reference dimension, or
- link the dimension to a parameter.

Reference dimensions annotate quantities that are already controlled elsewhere in the sketch or quantities such as projected reference geometry that cannot be controlled within the current sketch. Reference dimension values are enclosed in parentheses, and Abaqus/CAE updates them automatically to match changes in the associated geometry. Dimensions that have been linked to parameters are assigned a variable name for use in creating mathematical expressions (parametric equations) to define other parameters in the sketch. For detailed instructions on editing dimensions, see *Editing dimensions*.

When you add or modify dimensions, you must not overconstrain the sketch geometry. Geometry is overconstrained when multiple controls are applied to a single degree of freedom (for more information, see *Fully constrained geometry*). Abaqus/CAE colors conflicting constraints magenta to indicate an overconstraint condition. You must resolve any overconstraints before you can use a sketch to create a feature or save it with the model database.

Additional information

• *Modifying objects by changing dimensions or adding parameters*

- *Customizing the Sketcher*
- *Constraining, dimensioning, and parameterizing a sketch*

Using parameters to control sketch geometry

Parameters are dimensions or numerical constants that have been given a variable name and are used to create parametric equations between pieces of geometry. While dimensions always have a numerical value, parameters may have a numerical value or a value resulting from a mathematical expression. For example, you can parameterize the radius dimension of a circle so it will always be half the size of another dimension in the sketch, but you must first associate both dimensions with parameters to create the expression. You can use the sketch options to control whether Abaqus/CAE displays the names or values of parameters in a sketch (for more information, see *Customizing the format and use of dimensions in the Sketcher*).

Parameters must be defined within a single sketch—you cannot define parameters in one sketch and use them to create expressions in another sketch. Defining a parameter adds it to the **Parameter Manager** for the sketch. The order of parameters in the manager indicates the order in which they can be used in expressions. *Figure 1* shows two parameters; the *length* parameter is used to define the *width* parameter. If you instead wanted to define the length in terms of the width, the width parameter would need to appear first in the manager. You can use the buttons on the right side of the dialog box to create parameters by selecting dimensions from the viewport or to insert, move, or delete parameters from the manager. For detailed instructions, see *Adding and editing parameters*.

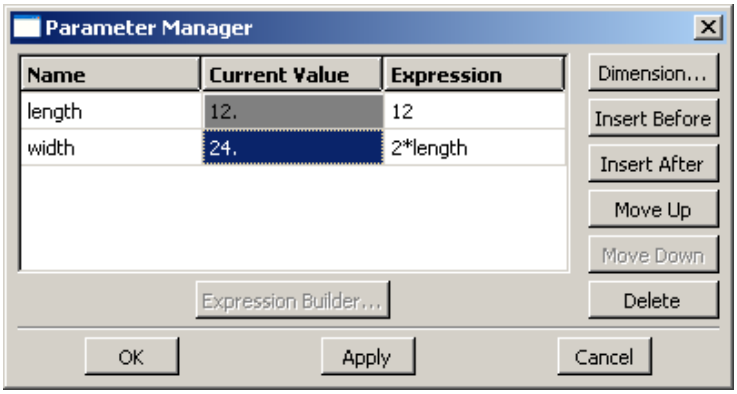

Figure 1: The Parameter Manager.

- *Modifying objects*

Fully constrained geometry

Constraints, dimensions, and parameters are all used to create relationships that control, or constrain, Sketcher geometry. Geometry is constrained by the removal of degrees of freedom from the sketch. For example, if you apply a perpendicular constraint to two lines, you remove the angular degree of freedom between those lines. If you drag one of the lines, the other line must also move to maintain the perpendicular constraint.

If geometry is controlled such that you cannot change it without redefining the relationships—changing constraints, dimensions, or parameters—the geometry is fully constrained. Abaqus/CAE colors fully constrained geometry green to indicate that it cannot be changed. If you add too many constraints to a sketch, the geometry becomes overconstrained. Abaqus/CAE colors conflicting constraints magenta to indicate the overconstraint condition. To resolve an overconstraint, you can

- undo the last modification or constraint addition,
- delete constraints or dimensions, or
- convert unnecessary dimensions to reference dimensions.

If you intend to fully constrain an entire sketch, you can use the **Detail** query to list sketch information—including the number of unconstrained degrees of freedom—in the message area. For more information, see *Using the Query toolset in the Sketcher*.

Modifying, copying, and offsetting objects

The following section describes the techniques you can use to modify your sketch and to copy or offset Sketcher objects.

In this section:

- *Modifying a sketch by dragging objects*
- *Modifying objects by changing dimensions or adding parameters*
- *Modifying or copying objects by selecting edges*
- *Modifying edges by trimming, extending, splitting, or merging*
- *Copying sketch objects to create patterns*
- *Offsetting objects*

Modifying a sketch by dragging objects

You can drag vertices, edges, construction geometry, and dimension text to new locations in a sketch. You can drag only one object at a time, and the object you drag will snap to gridlines when the **Snap to grid** option in the **Sketcher Options** dialog box is toggled on. This option is toggled on by default.

When you drag a vertex or an edge, Abaqus/CAE repositions the selection and uses the **During drag** constraint solution method to modify any connected edges (for more information, see *Customizing the use of constraints in the Sketcher*). Sketch constraints may cause multiple objects to move along with the one you select. Constraints may also restrict or prevent dragging some objects. For example, consider the sketch shown in *Figure 1*.

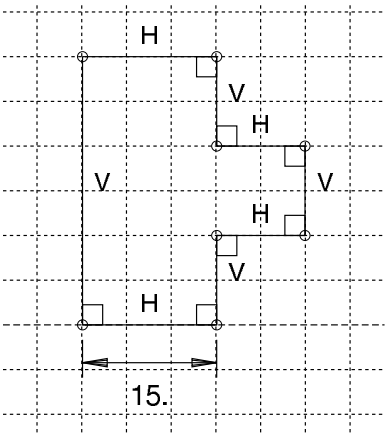

Figure 1: The original sketch.

The sketch includes the default horizontal, vertical, and perpendicular constraints created by Abaqus/CAE during the sketching process and one added length dimension. With these constraints in place, dragging the left edge of the sketch has the same effect as dragging the vertex at either end of the left edge, as shown in *Figure 2*.

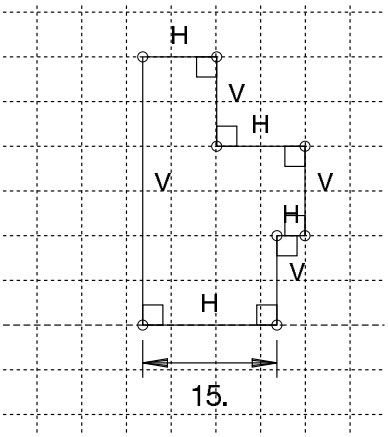

Figure 2: Dragging the left edge or vertices with constraints.

With the constraints and dimension removed, dragging the edge produces similar results to those shown in *Figure 2*, but dragging a vertex modifies the sketch as shown in *Figure 3*. The result in *Figure 3* is achieved using the default **Minimum move** constraint solution method. For this sketch, dragging the vertex using any of the other constraint solution methods repositions the entire sketch.

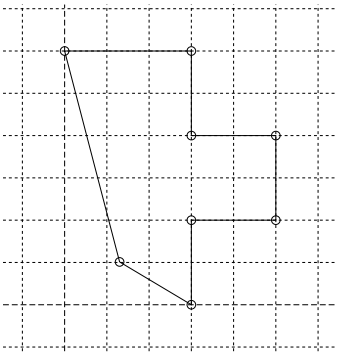

Figure 3: Dragging the lower left vertex without constraints.

Dragging edges and vertices is a quick, but imprecise, method of moving them since the motion is based on the cursor position as opposed to an exact numerical change. To move objects more precisely, use the methods described in *Modifying objects by changing dimensions or adding parameters*, and *Modifying or copying objects by selecting edges*.

Dragging dimension text is one way to clean up the sketch after using the **Auto-Dimension** tool. The lack of precision does not matter since the exact location of dimension text is not important. When you drag dimension text, you can make the following changes:

- Move a linear dimension closer to, farther from, or to the opposite side of the dimensioned quantity.
- Move an angular dimension closer to or farther from the angle's vertex.
- Move an angular dimension across one of the edges that define the angle to dimension a supplement of the original angle.

Possible locations for dragging an angular dimension are shown in *Figure 4*.

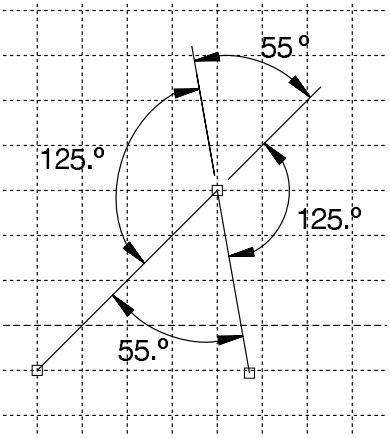

Figure 4: Four possible positions for an angular dimension.

Dimension text is not controlled by any constraints other than the attachment to the dimensioned object. The constraint solution methods also do not affect dragging dimension text in a sketch.

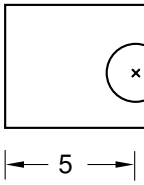
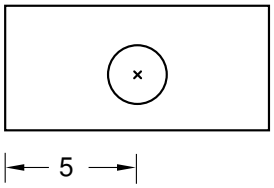
Modifying objects by changing dimensions or adding parameters

Use dimensions between lines and vertices to define and maintain dimensional relationships between features. Dimensions can be applied between lines and vertices from any of the following:

- Sketch geometry
- Reference geometry
- Construction geometry

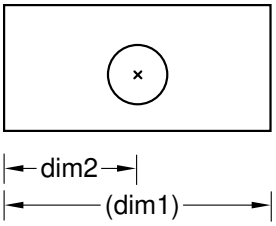


Parameters are dimensions or constants that have been associated with a name so you can use them to create functions and to define relationships between features. For example, consider a three-dimensional shell with an extruded circular post, as shown in the following figure:



This part was created in two steps:

1. Create a part consisting of only the shell.
2. Extrude a solid feature from the face of the shell (the circular post).



If you want to keep the distance between the left edge of the shell and the center of the post constant, you can edit the post and add a dimension between the center of the sketched circle and the left edge of the reference geometry that represents the shell, as shown in the following figure:

If you move either the left or the right edge of the shell, the distance between the center of the circle and the left edge remains constant, as shown in the following figure:

If you want to keep the post centered between the left and right edges of the shell, you must add two dimensions and associate them with parameters. You can then define a parametric equation, *dim2*=(*dim1*)/2, to set the distance from the left edge to the post at half the width of the shell, as shown in the following figure:

Note:

The distance dimension associated with the parameter *dim1* is defined in the sketch of the shell feature and cannot be edited in the sketch of the post. When you dimension reference geometry, Abaqus/CAE colors the dimension magenta to indicate an overconstraint. To clear the overconstraint, you must make *dim1* a reference dimension. Abaqus/CAE places parentheses around the value of reference dimensions (or around the parameter name if the dimension is associated with a parameter) and automatically updates their values if the dimensioned quantity changes. For more information, see *Editing dimensions*.

You can modify any dimension or parameter in a sketch. For detailed instructions, see *Editing dimensions*, and *Adding and editing parameters*, respectively.

Modifying or copying objects by selecting edges

When you move edges, Abaqus/CAE repositions the selected edges and uses the **During edit** constraint solution method to modify any connected edges (for more information, see *Customizing the use of constraints in the Sketcher*). The sketch constraints and constraint solution method may restrict the types of moves that you can make or cause Abaqus/CAE to reposition edges that you did not select. When you copy edges, the copies are positioned according to the copy method—the copied edges are not affected by any existing sketch constraints. You cannot copy objects between sketches. Abaqus/CAE provides the following methods for moving or copying selected edges:

Translate

You can translate selected edges by specifying the start and end coordinates of a translation vector. The translation vector can start from any point; however, you may find it more meaningful to start the vector from the vertex at one end of a selected edge and end it at the vertex's new location. *Figure 1* shows the selected edges, the translation vector, and the result of the translation. To achieve the results shown, **Fixed** constraints were added to prevent the two vertices of the upper rectangle from moving.

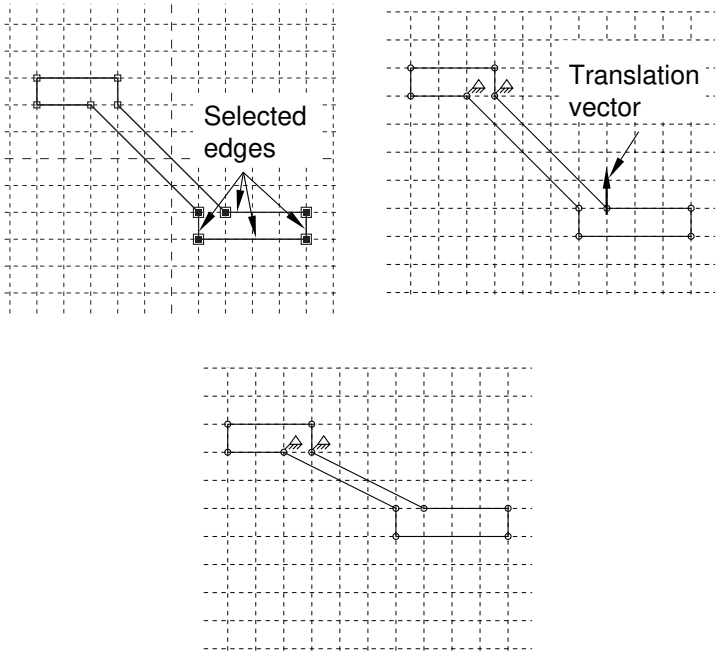


Figure 1: Translating selected edges.

Rotate

You can rotate selected edges by specifying the coordinates of the center of rotation and entering the angle of rotation; a positive angle indicates a counterclockwise rotation. *Figure 2* shows the selected edges, the selected center of rotation, and the result of a 90° rotation. The selected edges are not connected or otherwise constrained to other edges in the sketch, so the constraint solution method has no effect on the rotation.

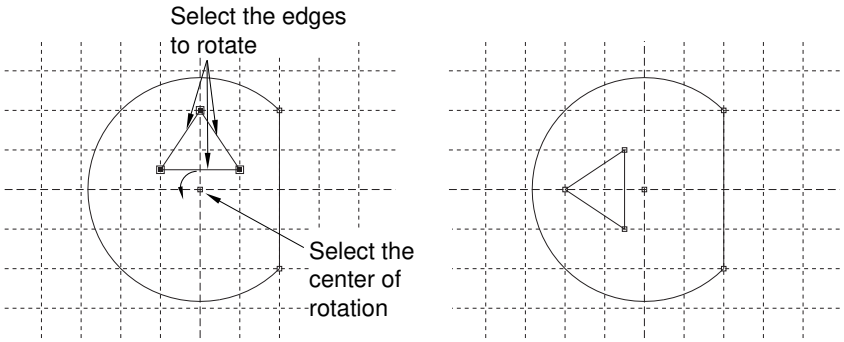

Figure 2: Rotating selected edges.

Mirror

You can mirror selected edges by selecting a straight line in the sketch as the mirror line. *Figure 3* shows the selected edges, the mirror line, and the resulting copy including a mirror constraint for each of the four selected edges. The mirror line may be any straight object line or construction line in the sketch.

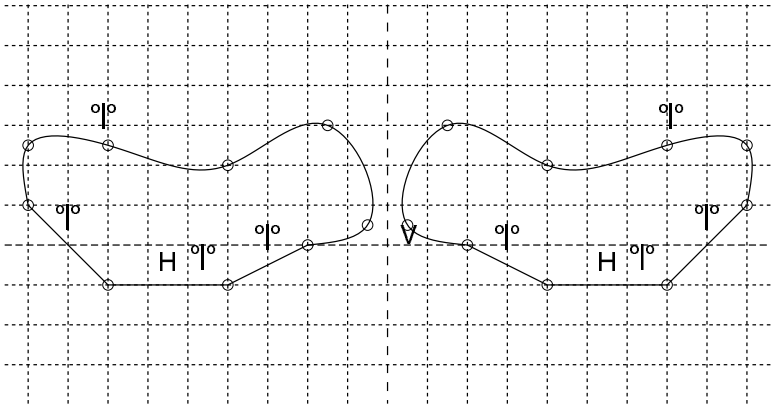

Figure 3: Mirroring selected edges.

Scale

You can scale selected edges by specifying a center point and a scale factor. A scale factor less than 1.0 decreases the spacing between the edges, and a scale factor greater than 1.0 increases the spacing between the edges. *Figure 4* shows the selected edges, the selected center point, and the result for a scale factor of 1.5.

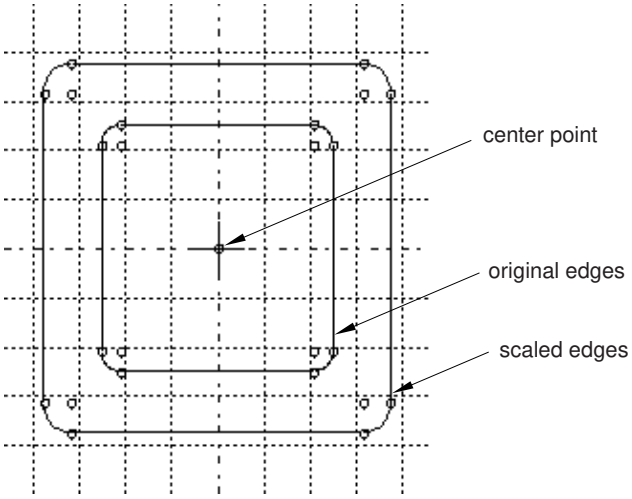

Figure 4: Scaling selected edges.

Additional information

• *Modifying objects*

Modifying edges by trimming, extending, splitting, or merging

When you are modifying a sketch, you can implement your changes by modifying a dimension, by moving selected vertices, or by trimming, extending, splitting, or merging edges. Abaqus/CAE provides the following methods for trimming, extending, splitting, and merging edges:

Trim/Extend

You can trim or extend one end of a line or arc; you can also trim a spline curve, but spline curves cannot be extended. To trim or extend an edge, first select the edge near the end that you want to modify and then select a second edge to define an intersection point. The second edge may be any object in the sketch, including construction geometry. The intersection point may lie beyond the current endpoints of either selected edge. Abaqus/CAE trims or extends the first edge at the intersection point. If you want to trim or extend the second edge to the same point, repeat the process, reversing the selection order (see *Figure 1*).

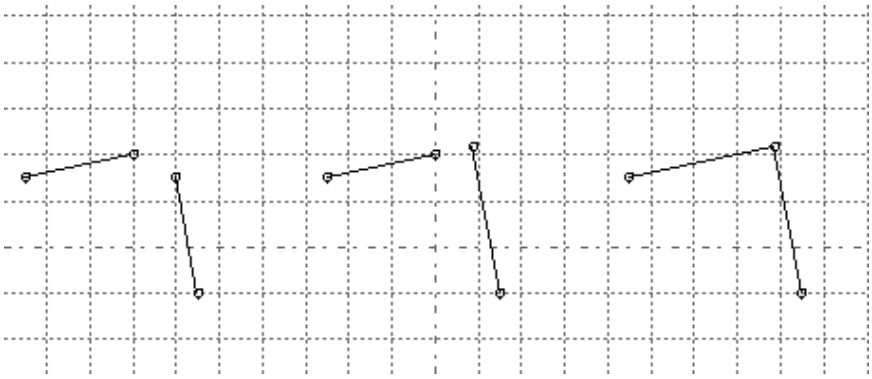

Figure 1: Extending two edges to create a corner.

For detailed instructions on trimming and extending edges, see *Modifying Sketcher objects by trimming or extending edges*.

Auto-trim

You can trim an intermediate or end segment from a line, arc, circle, or spline curve. **Auto-trim** is the fastest method you can use to remove unwanted edge segments from a sketch. Abaqus/CAE uses preselection to highlight edges that you can remove. Preselection is based on cursor proximity and the two nearest "trim points." Trim points include intersection points, endpoints, vertices, and the picked points that define the edges of circles. Unlike when you use **Trim/Extend**, Abaqus/CAE does not split the intersecting edges. *Figure 2* shows several possible trim combinations based on the circle and line shown in the upper left corner.

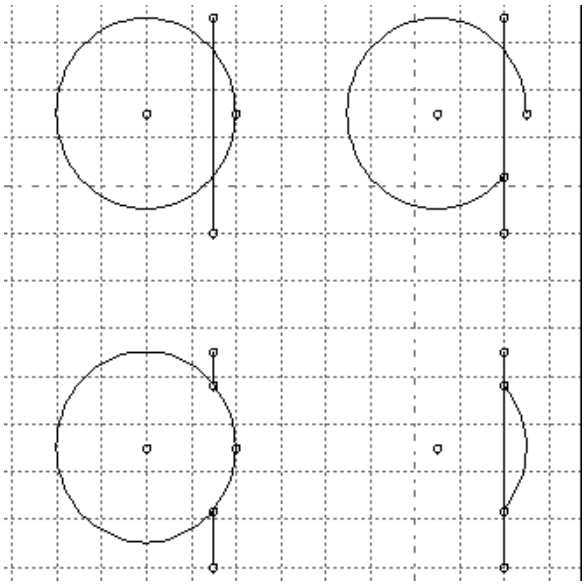

Figure 2: Auto-trim selections.

For detailed instructions on automatically trimming edges, see *Modifying Sketcher objects by automatically trimming edges*.

Split

You can split edges, creating separate pieces with a common vertex, where they intersect in the sketch. Select the first edge to be broken, then select a second edge that intersects the first at the desired split point. As you move the cursor near the second edge, a circle appears around the split point that you would create. If there is more than one intersection point between the two edges, Abaqus/CAE highlights the intersection closest to the cursor. Abaqus/CAE splits the first edge at the indicated point. *Figure 3* shows an intersecting line and spline on the left, indicates the split point in the center image (the cursor is not shown), and shows the three resulting edges on the right. In this case the spline was selected first, so the straight line remains unbroken.

Note:

Spline curves retain their exact shape when you split or trim them, but the control points are removed so you can no longer edit the shape of the curves.

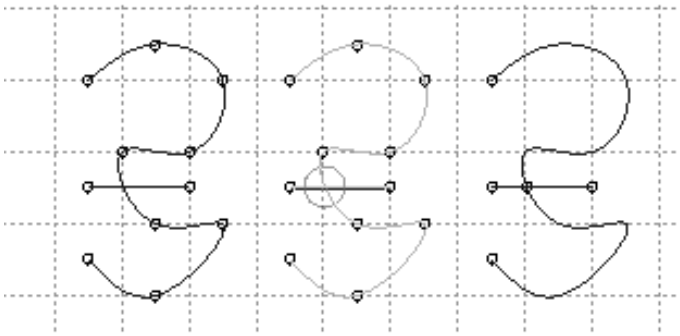

Figure 3: Splitting a line and a spline.

For detailed instructions on splitting edges, see *Modifying Sketcher objects by splitting edges*.

Merge

The Merge tool enables you to close small gaps in a sketch. These gaps commonly occur in the following situations:

- When you use the **Project Edges** tool on edges that are not in a plane parallel to the sketch plane, the endpoints may be created in a slightly different location from other selected edges.
- When you import sketch geometry into an existing sketch, the edges may not line up exactly.

The Merge tool is intended only for closing small gaps. Merging edges to close larger gaps may change the sketch geometry significantly. If you want to move elements in a sketch over a large distance, use the drag tool from the Sketcher toolbox to move vertices in your sketch to a new location. For more information, see *Dragging Sketcher objects*.

For detailed instructions on merging edges, see *Modifying Sketcher objects by merging edges*.

Additional information

• *Modifying objects*

Copying sketch objects to create patterns

You can copy objects in your sketch and create a pattern of copied objects; for example, *Figure 1* illustrates radial patterns of gear teeth and holes on a solid part.

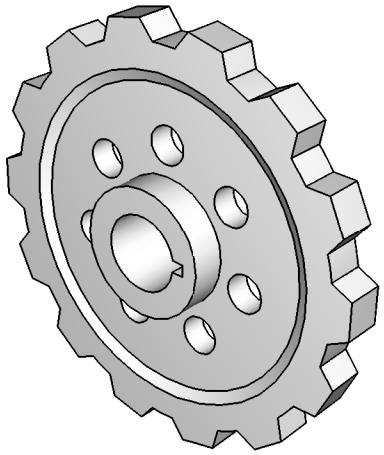

Figure 1: Radial patterns of gear teeth and holes.

You can choose either of the following methods to define the pattern:

Linear pattern

A linear pattern positions copies of selected objects along a direction; for example, the *X*-direction. You can specify the number of copies and the spacing between the copies; and you can choose to position the copies in a positive direction or a negative direction. In addition, you can change the orientation of the linear pattern. *Figure 2* shows how you can create different linear patterns in a single direction.

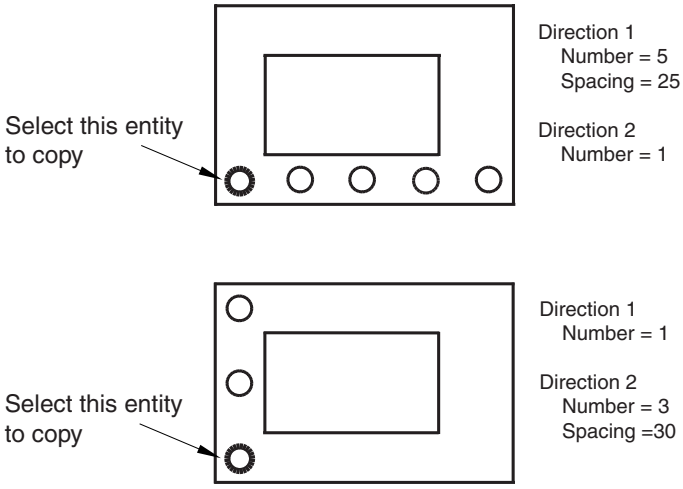

Figure 2: Linear patterns in a single direction.

You can create a matrix of copied objects by creating copies in a second direction; for example, the *Y*-direction. The options are the same as for the first direction; you can control the number of copies, the direction, and the angle. *Figure 3* shows how you can create different linear patterns in two directions.

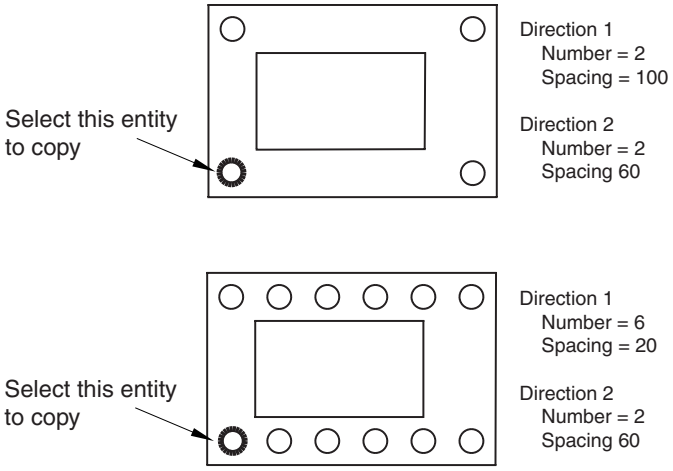

Figure 3: Linear patterns in two directions.

By default, the first direction is the *X*-axis and the second direction is the *Y*-axis. However, you can change the orientation of the first direction or the second direction by selecting a line from the sketch that represents the new orientation. *Figure 4* shows a linear pattern oriented along a selected line.

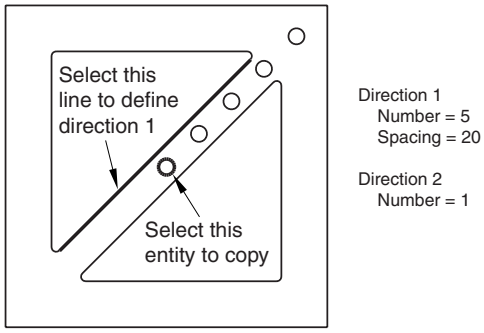

Figure 4: A linear pattern oriented along a line.

By default, Abaqus/CAE creates the pattern in a positive direction; however, you can reverse the direction. For example, *Figure 5* shows the same linear pattern as in *Figure 4* but with the direction reversed.

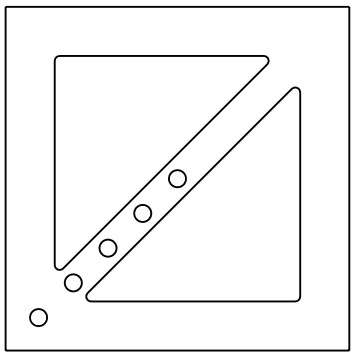

Figure 5: The effect of reversing the direction of a linear pattern.

For detailed instructions on creating linear patterns, see *Creating linear patterns of objects*.

Radial pattern

A radial pattern positions copies of selected objects in a circular pattern. You can specify the number of copies, and you can specify the angle between the first and last copy, where a positive angle corresponds to a counterclockwise direction. In addition, you can select a point from the sketch that defines the center point of the circular pattern. *Figure 6* shows how you can create different radial patterns.

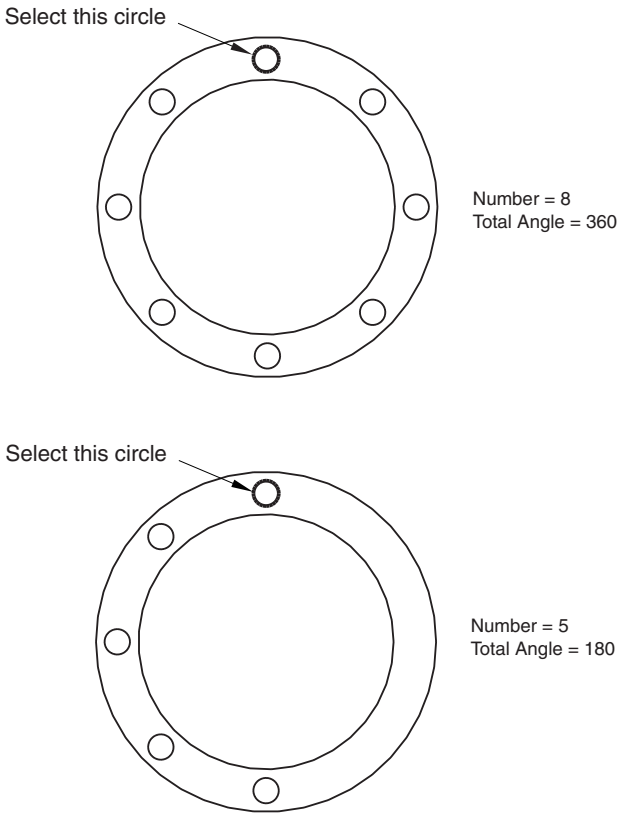

Figure 6: Radial patterns.

For detailed instructions on creating radial patterns, see *Creating radial patterns of objects*.

By default, Abaqus/CAE displays a preview of the linear and radial pattern as you enter the settings. In most cases the preview will help you decide on the settings that will create the desired pattern. However, if you are creating a large number of copies, the preview may slow down the generation of the sketch. In this case you should toggle off the **Preview** button.

Several methods are also available for creating individual copies of sketch objects. These methods are discussed in *Modifying or copying objects by selecting edges*.

Offsetting objects

You can offset objects in your sketch to create similar objects of a larger or smaller size. You select the edges to offset and the offset distance; Abaqus/CAE displays a preview so that you can choose the offset direction. You can offset any continuous open or closed loops that do not contain branches. *Figure 1* shows the two possible offsets that can be created for several edge selections. (For clarity, vertices and datum points are not shown in the figure.)

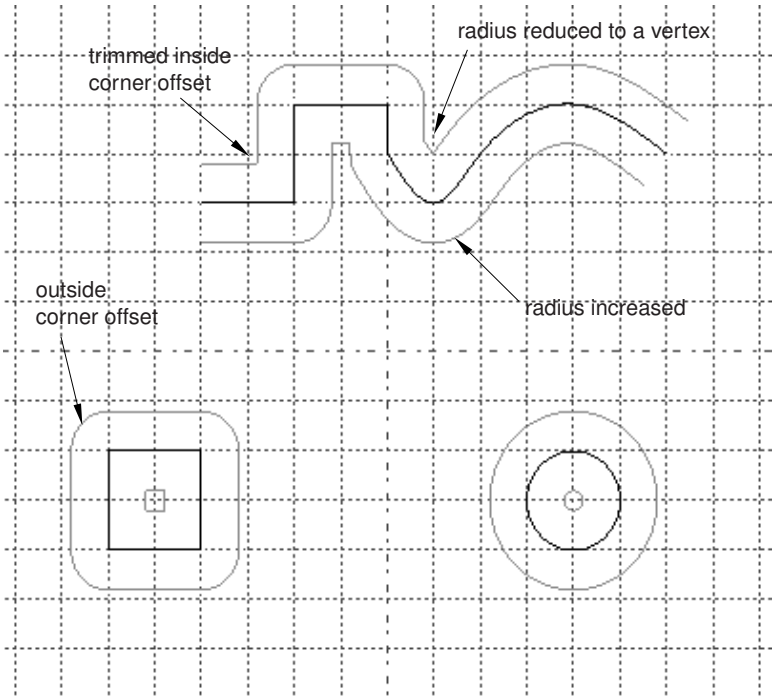

Figure 1: Offsets of a spline curve, a square, and a circle.

Abaqus/CAE offsets each object in the same way that you would offset edges on paper with a drafting compass. Using a compass, you would draw the compass point along the original edge tracing a new edge with the pencil at the required perpendicular (offset) distance. At any sharp corners, you would rotate the compass to make it perpendicular to the second edge at the corner. At the end of this process, you would trim any offset edges that intersected with other offset edges.

As shown in *Figure 1*, Abaqus/CAE completes a similar process:

- Straight edges are copied.
- Offset edges that overlap, such as corners offset toward the “inside,” are trimmed to make new corners.
- Where corners are offset toward the “outside,” you can choose to create sharp corners or fillets with radii equal to the offset distance.
- Radii of existing curves are increased or decreased by the offset distance.

If the radius of a curve would be decreased to zero or less by the offset, Abaqus/CAE creates a new vertex joining the surrounding edges that were previously connected by the curve. For detailed instructions, see *Offsetting the edges of Sketcher objects*.

Customizing the Sketcher

This section describes how you customize the behavior and the appearance of the Sketcher.

In this section:

- *Using Sketcher customization options*
- *Turning snapping on or off*
- *Turning preselection on or off*
- *Customizing the sheet size and grid*
- *Realigning the sketch grid*
- *Displaying and hiding construction geometry*
- *Limiting the projection of coplanar entities*
- *Setting the maximum number of recorded sketching operations*
- *Customizing the format and use of dimensions in the Sketcher*
- *Customizing the use of constraints in the Sketcher*
- *Managing images in the Sketcher background*

Using Sketcher customization options

Use the Sketcher customization options to control the appearance and behavior of the Sketcher.

The following options control the behavior of the Sketcher throughout the Abaqus/CAE session:

- Whether the cursor *snaps* to the grid.
- Whether *preselection* is active.
- Whether dimensions are displayed.
- Whether names or values of parameters are displayed.
- Limiting the number of coplanar entities that are projected.
- The types of dimensions and constraints available for use with the **Auto-Dimension** and **Auto-Constrain** tools.
- The *constraint solution method* for use while editing or dragging objects.
- Whether *sketch constraints* are displayed.
- Whether implied constraints are added during entity creation.
- Whether *construction geometry* is displayed.
- Whether a *background image* is displayed.

The following options are stored with each sketch; they control the behavior and appearance of the current sketch and new sketches that you create:

- The sheet size, the *grid* spacing, and the number of gridlines to display.
- Whether the sheet size and grid spacing are controlled automatically.
- Whether the grid is *visible*.
- The text font size and the number of decimal places displayed in *sketch dimensions*.

The origin of the sketch grid and the alignment of the *X*-axis are also stored with each sketch. However, the grid origin and alignment settings control only the behavior and appearance of the current sketch; they are reset to their default values for any new sketch that you create.

1. From the bottom of the Sketcher toolbox, select the Sketcher customization tool .
   The **Sketcher Options** dialog box appears.
2. Set the desired customization options on each of the tabbed pages. For detailed help, request context-sensitive help on individual items in the dialog box.

    **Tip:** You can also click **Defaults** to revert all Sketcher options to their default settings.
3. Click **OK** to apply your changes and to close the **Sketcher Options** dialog box.

Additional information

- *Customizing the Sketcher*
- *How Sketcher customization options are initialized and saved*

Turning snapping on or off

Snapping to the grid helps you position the cursor when you want to select a Sketcher grid point or drag an object to a specific point on the grid. When snapping is enabled and you move the cursor near a grid point, the secondary cursor jumps, or snaps, to the grid point. Toggle **Snap to grid** in the **Sketcher Options** dialog box to enable or disable snapping. (By default, snapping is enabled when you start the Sketcher.) The behavior you choose for snapping applies to all sketches in the Abaqus/CAE session. Sketcher preselection overrides snapping if a preselection point and a grid point are both close to the cursor position.

1. From the bottom of the Sketcher toolbox, select the Sketcher customization tool .

   The **Sketcher Options** dialog box appears.
2. From the **General** tabbed page, toggle **Snap to grid**.

   When **Snap to grid** is on, the secondary cursor snaps to nearby grid points as you move around the sketch. Depending on the grid size, magnification of the viewport, and whether preselection is active, you may also be able to select other points in addition to the grid points and the existing sketch geometry.

   When **Snap to grid** is off, the secondary cursor aligns with the primary cursor as you move around the sketch. You can select anywhere on the sheet.
3. After you have chosen the desired customization options, click **OK** to apply your changes and to close the **Sketcher Options** dialog box.

Additional information

- *The Sketcher sheet and grid*
- *The Sketcher cursors and preselection*
- *Customizing the Sketcher*
- *Turning preselection on or off*

Turning preselection on or off

Preselection helps you select reference geometry or Sketcher objects, such as lines, vertices, and dimensions. When preselection is enabled and you move the cursor near one of these objects, Abaqus/CAE highlights the object so that you can more easily select it. Preselection also helps constrain your sketch by indicating selections that will create horizontal, vertical, colinear, perpendicular, and coincident constraints while you sketch. For a list of the preselection symbols displayed by different Sketcher objects as you move the cursor around the sketch, see *The Sketcher cursors and preselection*.

Toggle **Preselect geometry** in the **Sketcher Options** dialog box to enable or disable preselection. (By default, preselection is enabled when you start the Sketcher.) Preselect customization is stored for the duration of the Abaqus/CAE session and applies to all sketches. Preselection overrides snapping to the grid if a preselection point and a grid point are both close to the cursor position.

1. From the bottom of the Sketcher toolbox, select the Sketcher customization tool .

   The **Sketcher Options** dialog box appears.

2. From the **General** tabbed page, toggle **Preselect geometry**.

   When **Preselect geometry** is on, Abaqus/CAE highlights valid selections, such as vertices, midpoints, and dimensions, as you move around the sketch.

   When **Preselect geometry** is off, Abaqus/CAE does not highlight valid selections.

3. After you have chosen the desired customization options, click **OK** to apply your changes and to close the **Sketcher Options** dialog box.

Additional information

- *The Sketcher cursors and preselection*
- *Customizing the Sketcher*
- *Turning snapping on or off*
- *How Sketcher customization options are initialized and saved*

Customizing the sheet size and grid

Use the **Sketcher Options** dialog box to control the sheet size and the grid.

You can customize the following:

Sheet size

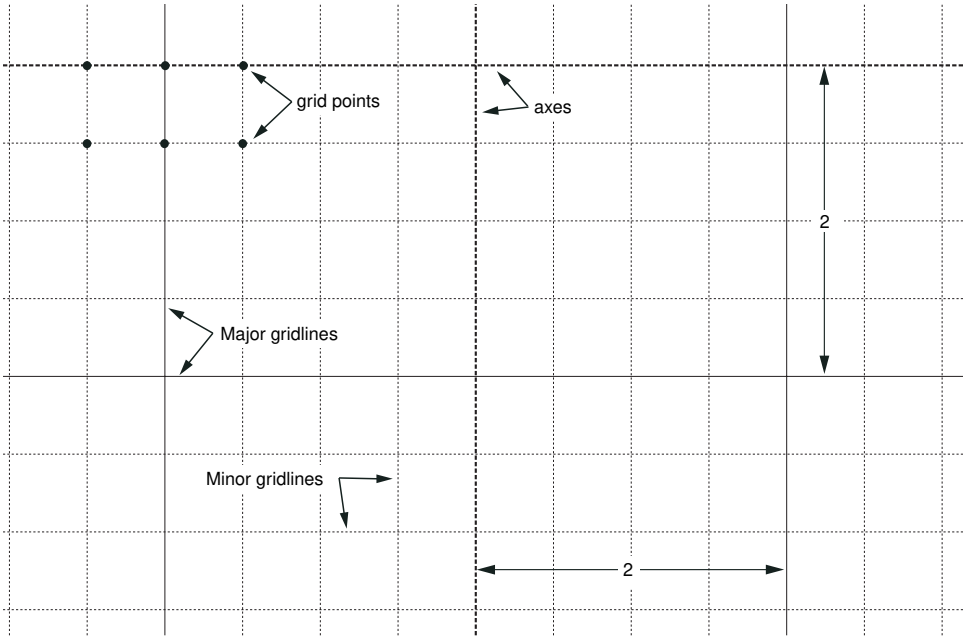
The boundary of the sheet is always square, and its height and width are equal to the sheet size. If you find that the sheet size is too large or too small, you can use the **Sketcher Options** dialog box to change the size.

When you create a part or a stand-alone sketch, you define the approximate size of the new part or sketch; Abaqus/CAE bases the initial sheet size on the approximate size that you provide. The approximate size must be between 10^{-3} and 10^{4} units for a part and between 10^{-3} and 10^{5} units for a sketch. Abaqus/CAE does not use specific units, but the units must be consistent throughout the model. The **Auto** toggle next to the **Sheet size** field unlocks the field and controls whether or not Abaqus/CAE can automatically change the sheet size in the current sketch and in new sketches that you create.

Grid spacing

You can use this option to change the grid spacing for major gridlines using the same units that define the **Sheet size**. If ***Snap to grid*** is enabled, the cursor will snap to each grid point. The **Auto** toggle next to the **Grid spacing** field unlocks the field and controls whether or not Abaqus/CAE can automatically change the grid size in the current sketch and in new sketches that you create.

Minor intervals



Minor gridlines subdivide the space between major gridlines into intervals and enable you to position items in your sketch with greater precision when you have the Sketcher set to a high magnification level. You can use this option to change the number of minor intervals between each major gridline.

The display of minor gridlines is dynamic: Abaqus/CAE hides these lines at the default magnification level and reveals them as you zoom in.

Show gridlines

You can toggle the display of major gridlines and minor gridlines in the Sketcher. Minor gridlines can be displayed only when major gridlines are displayed as well.

The following figure shows the relationship between the grid spacing, major gridlines, and minor gridlines:

Sheet size and grid customization options apply to the current sketch and are stored along with the sketch. When you create a new sketch, Abaqus/CAE uses the most recent settings to determine whether or not to recalculate the sheet size and grid spacing and whether to display the grid.

1. From the bottom of the Sketcher toolbox, select the Sketcher customization tool .

   The **Sketcher Options** dialog box appears.
2. From the **General** tabbed page, toggle off **Auto** next to the **Sheet size** text box.
3. In the text box, type the dimension of the square sheet that will contain the feature being created or edited.

   Specify the sheet size in units consistent with those used to describe the rest of the model.
4. Toggle off **Auto** next to the **Grid spacing** text box.
5. In the text box, type the desired spacing between grid points.

   Specify the grid spacing in the same units that you used to define the sheet size.
6. Click the arrows to the right of the **Minor intervals** field to increase or decrease the number of minor grid intervals displayed between each major gridline.
7. Toggle **Major** to show or hide the major gridlines.

   If major gridlines are displayed, you can also toggle **Minor** to show or hide the minor gridlines.
8. After you have chosen the desired customization options, click **OK** to apply your changes and to close the **Sketcher Options** dialog box.

Additional information

- *The Sketcher sheet and grid*
- *Customizing the Sketcher*
- *How Sketcher customization options are initialized and saved*

Realigning the sketch grid

In some circumstances the sketch grid does not align with the vertices and lines of the sketch or the underlying reference geometry. You may find it easier to create the desired sketch if you use Sketcher customization options to realign the sketch grid. If you add an existing sketch to a new blank sketch (such as for a new part), Abaqus/CAE automatically realigns the sketch grid. The customization options allow you to do the following:

- Shift the grid relative to the sketch by selecting a vertex representing the origin of the grid. To help you locate the origin of the sketch, the *X*- and *Y*-axes of the sketch are indicated by dashed lines that intersect at the origin.
- Rotate the grid relative to the sketch by selecting a line from the sketch that will be parallel to the *X*-axis of the grid.
- Reset the grid to the original sketch coordinates.

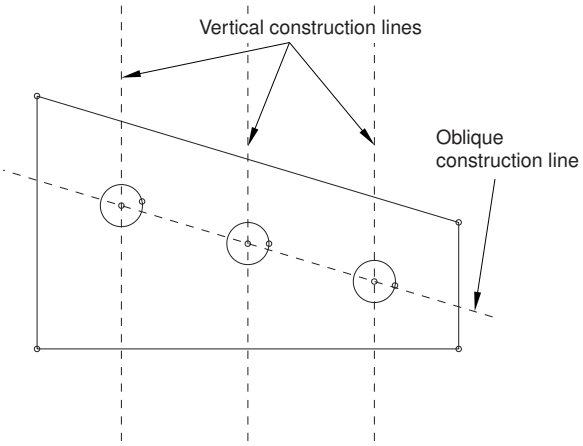
Realigning the grid does not change existing features in the sketch. However, the change is applied to any new sketch entities. For example, if you rotate the grid, an existing horizontal construction line will not change; however, a new horizontal construction line will be parallel with the new *X*-axis. Dimensions are an exception; horizontal and vertical dimensions—new and existing—align with the default grid rotation.

When you change the grid origin or rotation and create new sketch geometry, Abaqus/CAE displays two sets of cursor coordinates. The grid coordinates are relative to the current alignment of the sketch grid; they are displayed in the upper-left corner of the viewport. The sketch coordinates are relative to the original alignment of the sketch grid; they are displayed in the upper-right corner of the viewport and do not change if you realign the grid. When both sets of coordinates are the same, Abaqus/CAE displays a single coordinate set in the upper-left corner of the viewport.

1. From the bottom of the Sketcher toolbox, select the customization tool .

   The **Sketcher Options** dialog box appears.
2. From the buttons across the center of the **General** tabbed page, do the following:
   - Click **Origin** to move the origin of the sketch grid relative to the part. Select the new origin from the sketch or type the coordinates of the origin in the prompt area.
   - Click **Angle** to rotate the sketch grid relative to the part. Select a line that will be parallel to the *X*-axis of the sketch.
   - Click **Reset** to restore the original sketch origin and to restore the original alignment of the *X*-axis. Resetting the grid aligns the grid coordinates with the sketch coordinates.

   Your grid alignment changes are applied to the sketch immediately.
3. Click **OK** to apply any other customizations that you made and to close the **Sketcher Options** dialog box.



Additional information

- *Realigning the sketch grid relative to the sketch*
- *Customizing the Sketcher*
- *How Sketcher customization options are initialized and saved*

Displaying and hiding construction geometry

You can create to help you position and align objects in your sketch.

For example, the following figure shows a series of holes aligned along an oblique construction line. The holes are centered where the vertical construction lines intersect the oblique construction line:

If the construction geometry becomes distracting, you can use the **Show construction geometry** option in the **Sketcher Options** dialog box to hide it. (By default, construction geometry is displayed when you start the Sketcher.) If preselection is enabled, the cursor will still snap to items associated with hidden construction geometry, such as the intersection of a line with a construction line. Customization of the display of construction geometry applies to the current sketch and is stored along with the sketch.

1. From the bottom of the Sketcher toolbox, select the customization tool .
   The **Sketcher Options** dialog box appears.
2. From the **General** tabbed page, toggle **Show construction geometry**.
   When **Show construction geometry** is on, Abaqus/CAE displays construction geometry in the sketch.
3. After you have chosen the desired customization options, click **OK** to apply your changes and to close the **Sketcher Options** dialog box.

Additional information

- *Construction geometry*
- *Creating construction geometry*
- *Customizing the Sketcher*
- *How Sketcher customization options are initialized and saved*

Limiting the projection of coplanar entities

When a sketch-based feature is created or edited, you can set a limit for the number of coplanar entities that Abaqus/CAE automatically projects from the background. By default, Abaqus/CAE automatically projects 300 coplanar entities. The limit you choose for projected coplanar entities applies to all sketches in the Abaqus/CAE session.

1. From the bottom of the Sketcher toolbox, select the customization tool .
   The **Sketcher Options** dialog box appears.
2. From the **General** tabbed page, enter a value in the **Max coplanar entities to project** text field.
   If this value is exceeded, a warning message is issued and no entities are automatically projected.
3. After you have chosen the desired customization options, click **OK** to apply your changes and to close the **Sketcher Options** dialog box.

Additional information

- *Customizing the Sketcher*
- *How Sketcher customization options are initialized and saved*

Setting the maximum number of recorded sketching operations

Abaqus/CAE records your changes to the current sketch in a cache that enables you to undo and redo several consecutive sketching changes. By default, the undo cache supports up to 10 levels of undo, but you can increase or decrease this number. You might want to increase the number of levels if your sketching operations require large-scale changes, and you might want to decrease this number to improve system performance for large, complex sketches.

The maximum number of undo levels applies to all sketches in the Abaqus/CAE session. Abaqus/CAE clears the undo cache each time you change the current sketch or switch to a different module.

1. From the bottom of the Sketcher toolbox, select the customization tool .

   The **Sketcher Options** dialog box appears.
2. From the **General** tabbed page, enter a value from 0 to 100 in the **Max level for sketch undo** text field.
3. After you have chosen the desired customization options, click **OK** to apply your changes and to close the **Sketcher Options** dialog box.

Additional information

- *Customizing the Sketcher*
- *Undoing and redoing sketching actions*

Customizing the format and use of dimensions in the Sketcher

When you add *dimensions* to your sketch, the default dimension text height is 12 points. You can change the text height by using the arrows in the **Dimension text height** field on the **Dimensions** tabbed page of the **Sketcher Options** dialog box. The dimension text is independent of the current sheet size and zoom settings; that is, the text remains at the size you chose regardless of the apparent size of the dimensioned feature.

In addition, you may want to change the number of decimal places to match the dimensions of the feature you are creating. You can use the **Decimal places** field to control the number of decimal places displayed in each dimension. To reduce clutter while editing a sketch, you can use the **Show dimensions** option to hide the dimensions. You can also use the **Show parameter names** option to display the names of dimensions that have been converted to parameters instead of their numerical values. Displaying parameter names allows you to view dimensions that have been replaced by parametric expressions and helps you to create relationships between various sketch dimensions. Finally, you can select the types of dimensions that can be created automatically with the **Auto-Dimension** tool.

Dimension text height and decimal place settings apply to the sketch you are working on and are stored along with the sketch. When you create a new sketch, Abaqus/CAE uses the default dimension text height and number of decimal places for the new sketch. All other dimension options are stored for the remainder of the current Abaqus/CAE session.

1. From the bottom of the Sketcher toolbox, select the Sketcher customization tool .

   The **Sketcher Options** dialog box appears.
2. Click on the **Dimensions** tab.

   Abaqus/CAE displays the **Dimensions** tabbed page.
3. If desired, toggle **Show dimensions**.

   When **Show dimensions** is on, Abaqus/CAE displays dimensions in the sketch.
4. If desired, toggle **Show parameter names**.

   When **Show parameter names** is on, Abaqus/CAE shows the names of dimensions that have been converted to parameters. (For more information, see *Adding and editing parameters*.)
5. Next to the **Dimension text height** label, click the arrows to increase or decrease the height of the dimension text.

   Specify the height in points; the height can vary from 8 to 30.
6. Next to the **Decimal places** label, click the arrows to increase or decrease the number of decimal places that will be included in the dimension text.

   The number of decimal places displayed can vary from one to six.
7. In the lower portion of the page, toggle the dimension types available for use with the **Auto-Dimension** tool. (For more information, see *Automatically dimensioning a sketch*.)
8. After you have chosen the desired customization options, click **OK** to apply your changes and to close the **Sketcher Options** dialog box.

Customizing the use of constraints in the Sketcher

Constraints create non-numerical relationships that control the geometry of a sketch. As you edit a sketch, Abaqus/CAE applies solution methods to avoid violating the constraints. Several methods are available for use either when entities are *dragged* or when they are edited using other sketcher tools.

Note:

The constraint solution method does not prevent sketch modification tools from overriding applied constraints. For example, you can use the **Translate** tool to move a line that has a **Fixed** constraint.

In addition, you can use the **Show constraints** option to hide the constraints and reduce clutter in the sketch and the **Add constraints during entity creation** option to add the constraints that are implied during sketching. You can select the linear and angular tolerance and the types of constraints that can be created automatically with the **Auto-Constrain** tool.

Constraint customization options apply to the entire Abaqus/CAE session. They are not saved with individual sketches or with the current model.

1. From the bottom of the Sketcher toolbox, select the Sketcher customization tool .

   The **Sketcher Options** dialog box appears.
2. Click on the **Constraints** tab.
3. Select the desired constraint solution methods for use while dragging sketch entities or during other types of editing. The following selections are available:

Standard

This is the default solution method for editing. Abaqus/CAE moves or modifies the geometry by the minimum amount to satisfy the constraints and dimensions. Abaqus/CAE also attempts to maintain a rigid body appearance of the uninvolved geometries during the move.

Weighted

Abaqus/CAE moves or modifies the geometry by the minimum amount to satisfy the constraints and dimensions. The rigid body appearance of the uninvolved geometries are not considered during the move.

Minimum move

This is the default solution method for dragging. Abaqus/CAE moves the minimum number of entities to satisfy the constraints.

Relaxation

Abaqus/CAE moves the geometry using a numerical solution technique to minimize the sum of the squares of the movements. This solution method results in more geometries being moved compared to other methods.

4. If desired, toggle **Show constraints**.

   When **Show constraints** is on, Abaqus/CAE displays constraint symbols in the sketch.
5. If desired, toggle **Add constraints during entity creation**.

When **Add constraints during entity creation** is on, Abaqus/CAE adds the constraints that are implied during sketching. For example, if you are sketching a line for which the preselection symbol indicates Abaqus/CAE will apply a horizontal constraint and **Add constraints during entity creation** is on, the horizontal constraint is added to the line.

6. In the lower portion of the page, toggle the constraint types available for use with the **Auto-Constrain** tool. (For more information, see *Automatically constraining a sketch*.)
7. After you have chosen the desired customization options, click **OK** to apply your changes and to close the **Sketcher Options** dialog box.

Additional information

- *How Sketcher customization options are initialized and saved*
- *Customizing the Sketcher*
- *Constraining, dimensioning, and parameterizing a sketch*

Managing images in the Sketcher background

You can display an image in the background of the Sketcher to help you draw and align objects in your sketch. This image can be positioned in any location in the Sketcher background and can be stretched or compressed horizontally or vertically. When you resize the viewport, Abaqus/CAE resizes the background image proportionally.

The Sketcher background image appears in the Sketch module only. You can also display a different image that appears in the viewport background in every Abaqus/CAE module, including the Sketch module; see *Working with background images and movies in viewports* for more information. When both the Sketcher and the module-wide background images are toggled on, Abaqus/CAE displays the Sketcher background image on top when you enter the Sketch module.

Before you can display an image in the background of the Sketch module or any other module, you must add the image to your Abaqus/CAE session. To add an image from the **Sketcher Options** dialog box, click **Create**; then enter a name for the image and provide its location. Images in your session are available in all modules and persist for your session only; they are not saved to the model database or output database.

Abaqus/CAE supports background images in the following formats: Bitmap (`.bmp`), PNG (`.png`), TIFF (`.tif`), XPM (`.xpm`), PCX (`.pcx`), ICO (`.ico`), TGA (`.tga`), and RGB (`.rgb`).

1. From the bottom of the Sketcher toolbox, select the Sketcher options tool .

   The **Sketcher Options** dialog box appears.
2. Click the **Image** tab.
3. Toggle **Show image** to display or hide the Sketcher background image.
4. Select an image file to display:
   - To display an image that has been defined in your session, expand the **Image name** list and select the image name.
   - To add a new image, click **Create**; then enter a name and specify a file location in the dialog box that appears. You can either enter the file location directly in the **File Name** field or click  to navigate to it in the **Select Image File** dialog box.
5. Stretch or compress the background image using one of the following techniques:

Scaling the image along either axis

You can stretch or compress the Sketcher background image by specifying **X scale** and **Y scale** values. When these scale values are equal to 1 (the default value), the image retains its original scale. You can increase the scale value to stretch the Sketcher background image along the selected axis, or you can decrease the value to compress the image along the selected axis.

Calibrate image size

You can scale the size of the Sketcher background image by calibrating the distance between two points on the image. Click **Calibrate**, click two points in the viewport; then enter in the Prompt area the desired distance between the two points.

After you calibrate an image, Abaqus/CAE reflects the changes in the **X scale** and **Y scale** fields.

6. Reposition the Sketcher background image using one of the following techniques:
   - Enter the Sketch coordinates to which you want to move the lower left corner of the Sketcher background image into the **Origin X** and **Origin Y** fields.

- Click **Pick**, then click a point on the Sketcher background image.

  Abaqus/CAE moves this point of the image to the grid origin and populates the **Origin** fields with the new origin location.

Note:

The lower left corner of the image is used to fix the position of the background image. If you change the scaling after positioning the background image, the center of the image will move.

7. Drag the **Translucency** slider to the level of translucency with which you want to display the Sketcher background image. Background images are opaque by default, and you can select a value from 0.00 (transparent) to 1.00 (opaque).
8. Click **OK** to apply your changes and to close the **Sketcher Options** dialog box.

Additional information

- *Working with background images and movies in viewports*
- *Customizing the Sketcher*

Sketching simple objects

This section describes how to use the Sketcher tools to draw simple objects.

In this section:

- *Sketching an isolated point*
- *Sketching lines and polygons*
- *Sketching rectangles*
- *Sketching circles*
- *Sketching arcs using a center point and two endpoints*
- *Sketching arcs through three points*
- *Sketching arcs tangent to a line*
- *Sketching ellipses*
- *Sketching fillets between two lines*
- *Sketching splines*

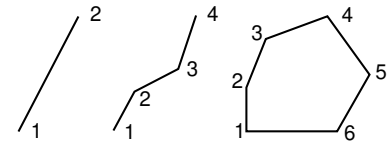
Sketching an isolated point

Use the point tool from the Sketcher toolbox to draw a single isolated point. You can use the resulting point as a reference, and you can create dimensions between the point and vertices on your sketch.

1. From the Sketcher toolbox, select the point tool . For a diagram of the tools in the Sketcher toolbox, see *The Sketcher tools*.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.
2. Click at the desired location of the point.

   The point appears.
3. To create more points, repeat the previous step.
4. When you have finished creating points, do one of the following:
   - Click mouse button 2 anywhere in the Abaqus/CAE window.
   - Select any other tool in the Sketcher toolbox.
   - Click the cancel button  in the prompt area.



Additional information

- *Sketching simple objects*
- *Creating construction geometry*
- *Modifying objects*
- *Undoing and redoing sketching actions*

Sketching lines and polygons

Use the line tool from the Sketcher toolbox to draw lines, connected lines, or polygons.

The following figure shows how you draw lines, connected lines, and polygons by clicking the locations shown, in the order indicated below:

You should take care positioning points while sketching because this positioning can affect the quality of your mesh. Points in the sketch become vertices of the part you are creating or modifying. In turn, when you mesh your model in the Mesh module, Abaqus/CAE converts these vertices into fully constrained seeds and places nodes at their location. For information on how to subsequently move vertices, see *Dragging Sketcher objects*.

1. From the line tools in the Sketcher toolbox, select the connected lines tool . For a diagram of the tools in the Sketcher toolbox, see *The Sketcher tools*.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

2. To construct a simple line, click the two end points. To construct a connected line or a polygon, click each vertex.

   Tip: If necessary, you can use the text box in the prompt area to enter the precise coordinates of the vertices of the line. For more information on precisely defining the line, see *Specifying precise geometry*.

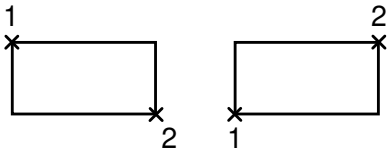
   The line or polygon appears as you click a vertex or enter the coordinates.

3. To complete the line or polygon, click mouse button 2.

   Tip: If you make a mistake while constructing a connected line or a polygon, click the **Undo** tool  in the Sketcher toolbox to delete the most recent line segment. If you make a mistake in an earlier segment, you can delete the incorrect segments using the **Delete** tool  and redraw them with the line tool.

4. To create more lines or polygons, repeat the above steps beginning with Step 2.
5. When you have finished creating lines and polygons, do one of the following:
   - Click mouse button 2 anywhere in the Abaqus/CAE window.
   - Select any other tool in the Sketcher toolbox.
   - Click the cancel button  in the prompt area.

Additional information



- *Sketching simple objects*
- *Creating construction geometry*

- *Modifying objects*
- *Undoing and redoing sketching actions*

Sketching rectangles

Use the rectangle tool from the Sketcher toolbox to draw rectangles.

To draw a rectangle, click at any two opposite corners as indicated by the numbering in the following figure.

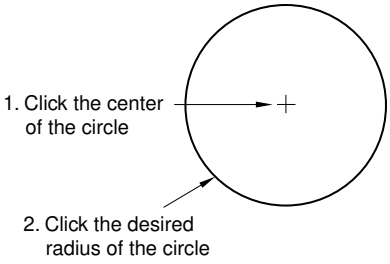
You should take care positioning points while sketching because this positioning can affect the quality of your mesh. Points in the sketch become vertices of the part you are creating or modifying. In turn, when you mesh your model in the Mesh module, Abaqus/CAE converts these vertices into fully constrained seeds and places nodes at their location. For information on how to subsequently move vertices, see *Dragging Sketcher objects*.

1. From the line tools in the Sketcher toolbox, select the rectangle tool . For a diagram of the tools in the Sketcher toolbox, see *The Sketcher tools*.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.
2. Click the desired locations of any two opposite corners of the rectangle.

   Tip: If necessary, you can use the text box in the prompt area to enter the precise coordinates of the corners of the rectangle. For more information on precisely defining the rectangle, see *Specifying precise geometry*.

   The rectangle appears, aligned with the current Sketcher grid, as you move the cursor or enter the coordinates.
3. To create more rectangles, repeat the previous step.
4. When you have finished creating rectangles, do one of the following:
   - Click mouse button 2 anywhere in the Abaqus/CAE window.
   - Select any other tool in the Sketcher toolbox.
   - Click the cancel button  in the prompt area.



Additional information

- *Realigning the sketch grid*
- *Sketching simple objects*
- *Creating construction geometry*
- *Modifying objects*
- *Undoing and redoing sketching actions*

Sketching circles

Use the circle tool from the Sketcher toolbox to draw circles based on a center point and any arbitrary point on the circumference of the circle.

An example of using the circle tool from the Sketcher toolbox is shown here:

You should take care positioning points while sketching because this positioning can affect the quality of your mesh. Points in the sketch become vertices of the part you are creating or modifying. In turn, when you mesh your model in the Mesh module, Abaqus/CAE converts these vertices into fully constrained seeds and places nodes at their location. For information on how to subsequently move vertices, see *Dragging Sketcher objects*.

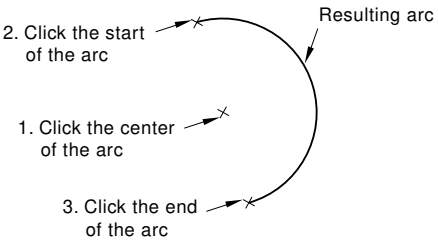
1. From the Sketcher toolbox, select the circle tool . For a diagram of the tools in the Sketcher toolbox, see *The Sketcher tools*.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.
2. Click at the desired location of the center of the circle.
3. Move the cursor to a point on the circumference of the circle.

   Abaqus/CAE displays a preview of the circle that would be created using the current cursor position.
4. Click any point on the circumference of the desired circle.

   Tip: If necessary, you can use the text box in the prompt area to enter the precise coordinates of the center and the point on the circumference of the circle. For more information on precisely defining the circle, see *Specifying precise geometry*.

   Abaqus/CAE draws the circle.
5. To create more circles, repeat the above steps beginning with Step 2.
6. When you have finished creating circles, do one of the following:
   - Click mouse button 2 anywhere in the Abaqus/CAE window.
   - Select any other tool in the Sketcher toolbox.
   - Click the cancel button  in the prompt area.



Additional information

- *Sketching simple objects*
- *Creating construction geometry*
- *Modifying objects*
- *Undoing and redoing sketching actions*

Sketching arcs using a center point and two endpoints

Use the Center with Two Endpoints arc tool from the Sketcher toolbox to draw arcs using a center point and two endpoints.

The following figure shows the resulting arc:

An arc that forms part of an analytical *rigid surface* cannot subtend an angle greater than 180°. If necessary, append two arcs to create an arc that subtends an angle of more than 180°. There is no such limitation for deformable bodies or discrete rigid surfaces.

You should take care positioning points while sketching because this positioning can affect the quality of your mesh. Points in the sketch become vertices of the part you are creating or modifying. In turn, when you mesh your model in the Mesh module, Abaqus/CAE converts these vertices into fully constrained seeds and places nodes at their location. For information on how to subsequently move vertices, see *Dragging Sketcher objects*.

1. From the arc tools in the Sketcher toolbox, select the Center with Two Endpoints arc tool . For a diagram of the tools in the Sketcher toolbox, see *The Sketcher tools*.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.
2. Click at the center of the desired arc.
3. Click the first endpoint to define the radius of the arc.

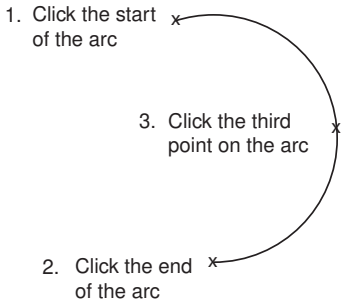
   Tip: If necessary, you can use the text box in the prompt area to enter the precise coordinates of the center and the endpoints of the arc. For more information on precisely defining the arc, see *Specifying precise geometry*.

   Abaqus/CAE draws a circle showing the radius of the arc as you move the cursor from the center of the arc to its first endpoint.
4. Move the cursor clockwise from the first endpoint to draw the arc in a clockwise direction. Move the cursor counterclockwise from the first endpoint to draw the arc in a counterclockwise direction. Click the second endpoint to define the length of the arc. If you start drawing the arc and then decide to change its direction, you must return to the first endpoint and move the cursor in the desired direction toward the second endpoint.

   Step 2 and Step 3 define the center of the arc and the radius of the arc, respectively. The point that you select in Step 4 defines only the length of the arc, and the point may not lie on the arc. If you want the arc to pass through a vertex of the sketch, you should select that vertex when you click the first endpoint in Step 3.

   Tip: If necessary, click the **Previous** button  to reverse the selection of the endpoints.
5. To create more arcs, repeat the above steps beginning with Step 2.

6. When you have finished creating arcs, do one of the following:
   - Click mouse button 2 anywhere in the Abaqus/CAE window.
   - Select any other tool in the Sketcher toolbox.
   - Click the cancel button  in the prompt area.



Additional information

- *Sketching simple objects*

- *Undoing and redoing sketching actions*

Sketching arcs through three points

Use the Through Three Points arc tool from the Sketcher toolbox to draw arcs through three noncolinear points.

The following figure shows the resulting arc:

When you draw an arc using the Through Three Points method, you should consider the same angle size and point selection prerequisites as described in *Sketching arcs using a center point and two endpoints*.

1. From the arc tools in the Sketcher toolbox, select the Through Three Points arc tool . For a diagram of the tools in the Sketcher toolbox, see *The Sketcher tools*.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

2. Click the two points that you want to use as the endpoints of the arc.

   Tip: If necessary, you can use the text box in the prompt area to enter the precise coordinates of the endpoints. For more information on precisely defining the arc, see *Specifying precise geometry*.

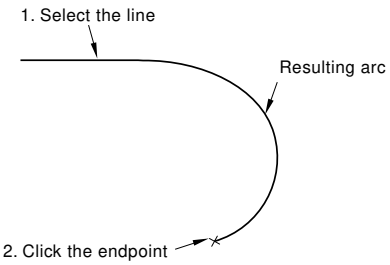
   Abaqus/CAE draws a sample arc with a predetermined radius as you select the second endpoint of the arc. You change this sample radius when you select the third point.

3. Move the cursor to the third point on the arc, and click mouse button 1.

   Abaqus/CAE draws an arc joining the endpoints and passing through the selected point.

   Tip: If necessary, click the **Previous** button  to reverse the selection of either endpoint. Clicking one enables you to reverse the selection of the second endpoint; clicking twice reverses the selection of the first endpoint as well.

4. To create more arcs, repeat the above steps beginning with Step 2.
5. When you have finished creating arcs, do one of the following:
   - Click mouse button 2 anywhere in the Abaqus/CAE window.
   - Select any other tool in the Sketcher toolbox.
   - Click the cancel button  in the prompt area.



Additional information

- *Sketching simple objects*

- *Creating construction geometry*
- *Modifying objects*
- *Undoing and redoing sketching actions*

Sketching arcs tangent to a line

Use the tangent arc tool from the Sketcher toolbox to draw an arc that is tangent to a line or curve at a selected point and ends at a second selected point, as illustrated in the following figure:

You should take care positioning points while sketching because this positioning can affect the quality of your mesh. Points in the sketch become vertices of the part you are creating or modifying. In turn, when you mesh your model in the Mesh module, Abaqus/CAE converts these vertices into fully constrained seeds and places nodes at their location. For information on how to subsequently move vertices, including those that define arcs, see *Dragging Sketcher objects*.

1. From the arc tools in the Sketcher toolbox, select the tangent arc tool . For a diagram of the tools in the Sketcher toolbox, see *The Sketcher tools*.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

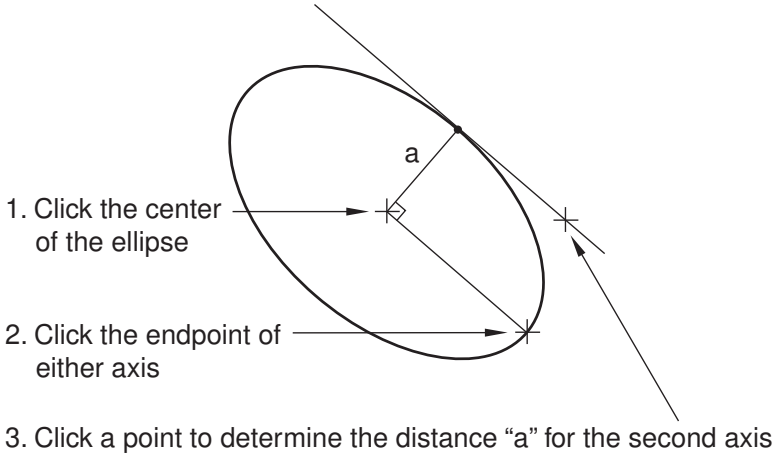
2. Select the point along the line or curve. The arc will be tangent-continuous at this point.

   If you start the arc at the endpoint of a line, a spline, or a second arc, the new arc is tangent-continuous at the endpoint. If you start the arc at a point in space (where there is no endpoint), the arc is tangent to the positive *X*-axis. If more than one line or curve meets at the point, the arc will be tangent to the one that was created first.

3. The radius of the arc changes as you move the cursor. Click at the desired endpoint.

   Tip: If necessary, you can use the text box in the prompt area to enter the precise coordinates of the tangent point and the endpoint of the arc. For more information on creating the desired arc, see *Specifying precise geometry*.

4. To create more arcs, repeat the above steps beginning with Step 2.
5. When you have finished creating tangent arcs, do one of the following:
   - Click mouse button 2 anywhere in the Abaqus/CAE window.
   - Select any other tool in the Sketcher toolbox.
   - Click the cancel button  in the prompt area.



Additional information

- *Sketching simple objects*
- *Creating construction geometry*
- *Modifying objects*
- *Undoing and redoing sketching actions*

Sketching ellipses

Use the ellipse tool from the Sketcher toolbox to draw ellipses based on a center point, an axis endpoint, and an arbitrary point whose distance from the first axis determines the length of the second axis.

An example of using the ellipse tool from the Sketcher toolbox is shown here:

You should take care positioning points while sketching because this positioning can affect the quality of your mesh. The center point and the first axis point in the sketch become vertices of the part you are creating. In turn, when you mesh your model in the Mesh module, Abaqus/CAE converts these vertices into fully constrained seeds and places nodes at their location. For information on how to subsequently move vertices, see *Dragging Sketcher objects*.

You cannot edit the size of an ellipse by moving its vertices. To edit the size of an ellipse, create a radial dimension and then edit that dimension. The radial dimension for an ellipse includes both the major and minor radius.

1. From the Sketcher toolbox, select the ellipse tool . For a diagram of the tools in the Sketcher toolbox, see *The Sketcher tools*.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.
2. Click at the desired location of the center of the ellipse.
3. Move the cursor to the endpoint of the first axis of the ellipse.

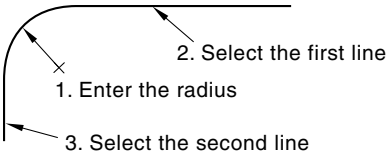
   Abaqus/CAE displays an ellipse that could be created using the current cursor position to define the major axis and rotation.
4. Click a point to define the endpoint of one axis. The point that you select can be either the major or minor axis endpoint.

   Tip: If necessary, you can use the text box in the prompt area to enter the precise coordinates of the center and the first axis endpoint of the ellipse. For more information on precisely defining geometry, see *Specifying precise geometry*.

   Abaqus/CAE sets the rotation of the ellipse and the endpoint of the first axis.
5. Click a point to define the length of the second axis. The point you select defines the distance from the first axis to the end of the second axis. The point does not need to lie on the second axis, and it cannot lie along the first axis since this would create a second axis of length 0.

   Abaqus/CAE creates the ellipse.
6. To create more ellipses, repeat the above steps beginning with Step 2.

7. When you have finished creating ellipses, do one of the following:
   - Click mouse button 2 anywhere in the Abaqus/CAE window.
   - Select any other tool in the Sketcher toolbox.
   - Click the cancel button  in the prompt area.



Additional information

- *Sketching simple objects*

- *Undoing and redoing sketching actions*

Sketching fillets between two lines

Use the fillet tool from the Sketcher toolbox to draw fillets between two lines or circles.

Enter the radius of the fillet and select the two lines or circles as shown here:

Construction geometry illustrates how you can create a fillet tangent to two construction circles.

You should take care positioning points while sketching because this positioning can affect the quality of your mesh. Points in the sketch become vertices of the part you are creating or modifying. In turn, when you mesh your model in the Mesh module, Abaqus/CAE converts these vertices into fully constrained seeds and places nodes at their location. For information on how to subsequently move vertices, see *Dragging Sketcher objects*.

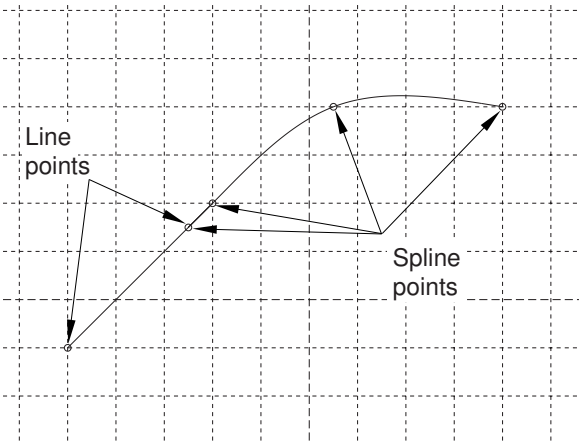
If you create a fillet and subsequently move the selected lines or circles, Abaqus/CAE will move the fillet and maintain the tangency.

1. From the Sketcher toolbox, select the fillet tool . For a diagram of the tools in the Sketcher toolbox, see *The Sketcher tools*.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.
2. In the text box that appears in the prompt area, enter the radius of the desired fillet.
3. Select the two lines or circles (not arcs) to which the fillet must remain tangent.

   The fillet appears between the two lines or circles.

   Tip: When you select a line or circle from the sketch, Abaqus/CAE uses the cursor position to determine the location of the fillet. To create the desired fillet, you should position the cursor close to the expected location of the fillet when making a selection.
4. To create more fillets of the same radius, repeat the previous step.
5. When you have finished creating fillets, do one of the following:
   - Click mouse button 2 anywhere in the Abaqus/CAE window.
   - Select any other tool in the Sketcher toolbox.
   - Click the cancel button  in the prompt area.



Additional information

- *Sketching simple objects*
- *Creating construction geometry*
- *Modifying objects*
- *Undoing and redoing sketching actions*

Sketching splines

Use the spline tool from the Sketcher toolbox to draw a spline curve connecting a series of points. Abaqus/CAE calculates the shape of the curve using a cubic spline fit between all points along the spline; in addition, the first and second derivatives of the spline are continuous. As you create the spline, you can influence the shape of the curve by placing the vertices closer or farther apart. However, you cannot add or remove vertices from a spline after you have drawn it; you must delete the spline and create a new one with the desired number of vertices. You can use the **Modify** tools to move the original vertices. Only the endpoints of a spline become vertices of the part you are creating or modifying; intermediate points of the spline do not appear outside the Sketcher.

If you want the spline to start tangent to an existing line, at the start of the spline create two adjacent vertices that are colinear with the line. This method is useful for creating smooth rigid surfaces, as illustrated in the following figure:

When you create an analytical *rigid surface*, you sketch a sequence of lines, arcs, and parabolas to define its profile. To create a parabolic curve, sketch a spline defined by only three vertices.

1. From the Sketcher toolbox, select the spline tool . For a diagram of the tools in the Sketcher toolbox, see *The Sketcher tools*.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

2. To construct a spline, click each vertex.

   Tip: If necessary, you can use the text box in the prompt area to enter the precise coordinates of each vertex of the spline. For more information on creating the desired spline, see *Specifying precise geometry*.

   The spline appears as you click each vertex or enter each coordinate, and Abaqus/CAE adjusts the curve to maintain a cubic spline between all points.

   Tip: If you make a mistake while constructing a spline, you can click the **Previous** button  to step back to the previous vertex. Alternatively, you can click the **Undo** button in the Sketcher toolbox to delete the entire spline.

3. To complete the spline, click mouse button 2.
4. To create more splines, repeat the above steps beginning with step 2.
5. When you have finished creating splines, do one of the following:

- Click mouse button 2 anywhere in the Abaqus/CAE window.
- Select any other tool in the Sketcher toolbox.
- Click the cancel button  in the prompt area.

Additional information

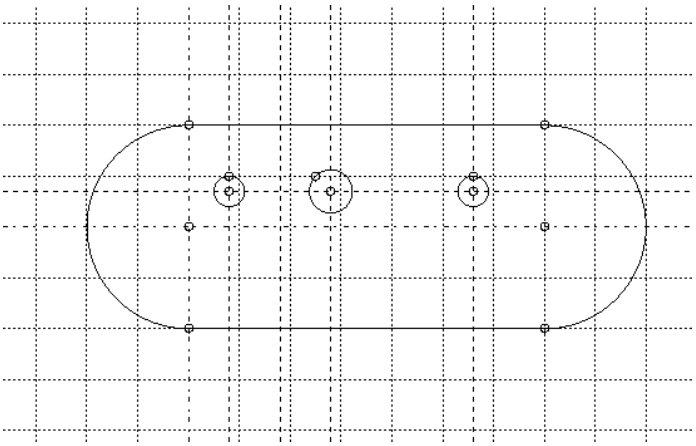
- *Creating construction geometry*
- *Modifying objects*
- *Undoing and redoing sketching actions*

Creating construction geometry

This section describes each of the Sketcher tools used to create construction geometry. Construction geometry is used to help you create and align objects in your sketch and to define the axis of rotation for revolved solids and surfaces.



In this section:

- *Creating a horizontal construction line*
- *Creating a vertical construction line*
- *Creating an oblique construction line*
- *Creating angled construction lines*
- *Creating a construction circle*
- *Setting sketch components as construction geometry*

Creating a horizontal construction line

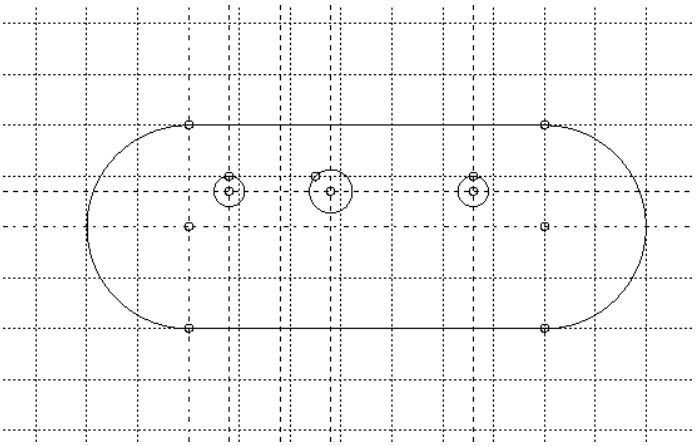
Use the horizontal construction line tool from the Sketcher toolbox to help position and align objects along a horizontal line.

Horizontal construction lines are created parallel to the *X*-axis of the Sketcher grid. Rotating the Sketcher grid does not affect existing horizontal construction lines, but new horizontal construction lines are aligned with the rotated grid. The following figure illustrates how a horizontal construction line and a set of vertical construction lines can be used to align circle centers. (Dashed lines indicate construction geometry.)

You can also use a horizontal construction line to define the axis of rotation for revolved solids and surfaces.

1. From the construction tools in the Sketcher toolbox, select the horizontal construction tool . For a diagram of the tools in the Sketcher toolbox, see *The Sketcher tools*.

   The horizontal construction line moves vertically as you move the cursor around the Sketcher sheet. Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.
2. Click a point that will lie on the horizontal construction line. Alternatively, you can type its *X*–*Y* coordinates in the text field that appears in the prompt area. (The *X*-coordinate is arbitrary since it is ignored.)
3. To create additional horizontal construction lines, repeat the previous step.
4. When you have finished creating horizontal construction lines, do one of the following:
   - Click mouse button 2 anywhere in the Abaqus/CAE window.
   - Select any other tool in the Sketcher toolbox.
   - Click the cancel button  in the prompt area.



Additional information

- *Construction geometry*
- *Realigning the sketch grid*
- *Sketching simple objects*
- *Creating construction geometry*
- *Modifying objects*
- *Undoing and redoing sketching actions*

Creating a vertical construction line

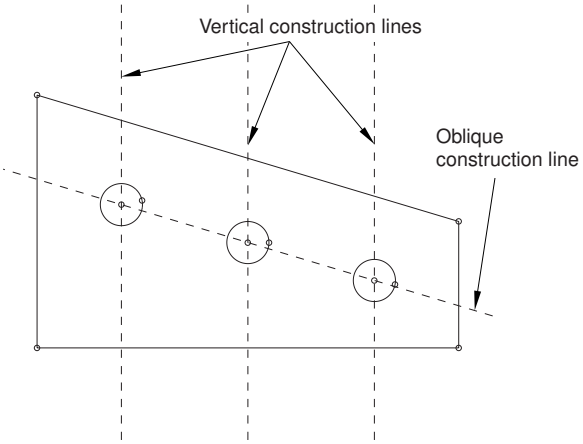
Use the vertical construction line tool from the Sketcher toolbox to help position and align objects along a vertical line.

Vertical construction lines are created parallel to the *Y*-axis of the Sketcher grid. Rotating the Sketcher grid does not affect existing vertical construction lines, but new vertical construction lines are aligned with the rotated grid. The following figure illustrates how a horizontal construction line and a set of vertical construction lines can be used to align circle centers. (Dashed lines indicate construction geometry.)

You can also use a vertical construction line to define the axis of rotation for revolved solids and surfaces.

1. From the construction tools in the Sketcher toolbox, select the vertical construction tool . For a diagram of the tools in the Sketcher toolbox, see *The Sketcher tools*.

   The vertical construction line moves horizontally as you move the cursor around the Sketcher sheet. Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.
2. Click a point that will lie on the vertical construction line. Alternatively, you can type its *X*–*Y* coordinates in the text field that appears in the prompt area. (The *Y*-coordinate is arbitrary since it is ignored.)
3. To create additional vertical construction lines, repeat the previous step.
4. When you have finished creating vertical construction lines, do one of the following:
   - Click mouse button 2 anywhere in the Abaqus/CAE window.
   - Select any other tool in the Sketcher toolbox.
   - Click the cancel button  in the prompt area.



Additional information

- *Construction geometry*
- *Realigning the sketch grid*
- *Sketching simple objects*
- *Creating construction geometry*
- *Modifying objects*
- *Undoing and redoing sketching actions*

Creating an oblique construction line

Use the oblique construction line tool from the Sketcher toolbox to help position and align objects along an arbritrary oblique line defined by two points.

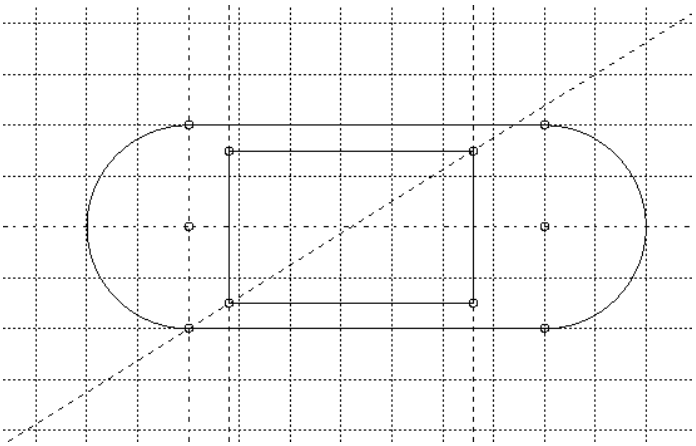
The following figure illustrates how an oblique construction line and a set of vertical construction lines can be used to align circle centers:

You can also use an oblique construction line to define the axis of rotation for revolved solids and surfaces.

1. From the construction tools in the Sketcher toolbox, select the oblique construction tool . For a diagram of the tools in the Sketcher toolbox, see *The Sketcher tools*.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.
2. Click two points that will lie on the oblique construction line. Alternatively, you can type their *X*–*Y* coordinates in the text field that appears in the prompt area.

   The oblique construction line appears when you select the first point. The line rotates about this point until you select the second point.
3. To create additional oblique construction lines, repeat the previous step.
4. When you have finished creating oblique construction lines, do one of the following:
   - Click mouse button 2 anywhere in the Abaqus/CAE window.
   - Select any other tool in the Sketcher toolbox.
   - Click the cancel button  in the prompt area.



Additional information

- *Construction geometry*
- *Sketching simple objects*
- *Creating construction geometry*
- *Modifying objects*
- *Undoing and redoing sketching actions*

Creating angled construction lines

Use the angled construction line tool from the Sketcher toolbox to help position and align objects along a line running at a specified angle to the *X*-axis of the Sketcher grid.

Rotating the Sketcher grid does not affect existing angled construction lines, but new angled construction lines are measured from the *X*-axis of the rotated grid. The following figure illustrates how an angled construction line and a pair of vertical construction lines can be used to position the vertices of a rectangle. (Dashed lines indicate construction geometry.)

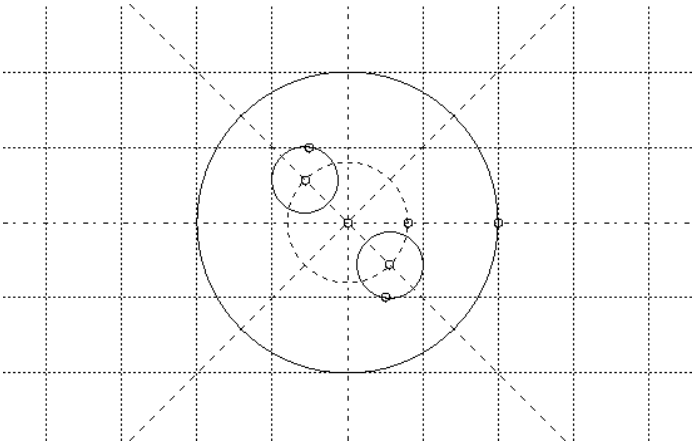
You can also use an angled construction line to define the axis of rotation for revolved solids and surfaces.

1. From the construction tools in the Sketcher toolbox, select the angled construction line tool . For a diagram of the tools in the Sketcher toolbox, see *The Sketcher tools*.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.
2. In the text box that appears in the prompt area, enter an angle value in degrees. Positive angles are measured counterclockwise from the horizontal axis, and negative angles are measured clockwise from the horizontal axis.

   The construction line moves as you move the cursor around the Sketcher sheet.
3. Click a point that will lie on the angled construction line. Alternatively, you can type its *X*–*Y* coordinates in the text field that appears in the prompt area.
4. To create additional angled construction lines, repeat the above steps beginning with Step 2.
5. When you have finished creating angled construction lines, do one of the following:
   - Click mouse button 2 anywhere in the Abaqus/CAE window.
   - Select any other tool in the Sketcher toolbox.
   - Click the cancel button  in the prompt area.

Additional information



- *Construction geometry*
- *Realigning the sketch grid*
- *Sketching simple objects*
- *Creating construction geometry*

- *Modifying objects*
- *Undoing and redoing sketching actions*

Creating a construction circle

Use the construction circle tool from the Sketcher toolbox to help position and align objects around a circle.

The following figure illustrates how a construction circle and a pair of angled construction lines can be used to position the centers of two circles. (Dashed lines indicate construction geometry.)

1. From the construction tools in the Sketcher toolbox, select the construction circle tool . For a diagram of the tools in the Sketcher toolbox, see *The Sketcher tools*.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.
2. Click at the desired location of the center of the construction circle. Alternatively, you can type the *X*–*Y* coordinates of the circle center in the text field that appears in the prompt area.

   The radius of the construction circle changes as you move the cursor around the Sketcher sheet.
3. Click a point that will lie on the circumference of the construction circle, or type its *X*–*Y* coordinates in the prompt area.

   Abaqus/CAE creates the construction circle using the point you specified.
4. To create more construction circles, repeat the above steps beginning with Step 2.
5. When you have finished creating construction circles, do one of the following:
   - Click mouse button 2 anywhere in the Abaqus/CAE window.
   - Select any other tool in the Sketcher toolbox.
   - Click the cancel button  in the prompt area.

Additional information

- *Construction geometry*
- *Sketching simple objects*
- *Creating construction geometry*
- *Modifying objects*
- *Undoing and redoing sketching actions*

Setting sketch components as construction geometry

Use the **Set as Construction** tool from the Sketcher toolbox to convert a component of your sketch into construction geometry. The **Unset Construction** tool reverses this process for items that had been converted to construction geometry. You can unset construction geometry components only if they were converted to construction geometry using the **Set as Construction** tool; items that were added to the sketch as construction geometry cannot be unset.

Additional information

- *Construction geometry*
- *Sketching simple objects*
- *Creating construction geometry*
- *Modifying objects*
- *Undoing and redoing sketching actions*

Set items in a sketch as construction geometry

1. From the construction tools in the Sketcher toolbox, select the **Set as Construction** tool . For a diagram of the tools in the Sketcher toolbox, see *The Sketcher tools*.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.
2. Select the sketch item or items that you want to set as construction geometry. You can drag-select, **[Shift] + Click**, or **[Ctrl] + Click** to select multiple items.

   Abaqus/CAE indicates the items you select by coloring them red.
3. To complete the conversion, click **Done** in the prompt area or click mouse button 2 anywhere in the Abaqus/CAE window.

   Abaqus/CAE displays the items you selected with dashed lines, indicating that they are now construction geometry.
4. When you have finished selecting geometry to convert to construction geometry, do one of the following:
   - Click mouse button 2 anywhere in the Abaqus/CAE window.
   - Select any tool in the Sketcher toolbox.
   - Click the cancel button  in the prompt area.

Unset construction geometry items

1. From the construction tools in the Sketcher toolbox, select the **Unset Construction** tool . For a diagram of the tools in the Sketcher toolbox, see *The Sketcher tools*.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.
2. Select one or more construction geometry items. You can drag-select, **[Shift] + Click**, or **[Ctrl] + Click** to select multiple items. All construction geometry is displayed in the sketch with dashed lines.

   Abaqus/CAE indicates the items you select by coloring them red.
3. To complete the conversion, click **Done** in the prompt area or click mouse button 2 anywhere in the Abaqus/CAE window.

   Abaqus/CAE displays the items you selected with solid lines, indicating that they are not construction geometry.

4. When you have finished selecting construction geometry items that you want to revert, do one of the following:
   - Click mouse button 2 anywhere in the Abaqus/CAE window.
   - Select any tool in the Sketcher toolbox.
   - Click the cancel button  in the prompt area.

Constraining, dimensioning, and parameterizing a sketch

This section describes each of the Sketcher tools used to add constraints, dimensions, and parameters to sketches. You can use these tools to create relationships between individual entities in a sketch or to create a fully constrained and parametric sketch.

In this section:

- *Automatically constraining a sketch*
- *Automatically dimensioning a sketch*
- *Adding individual constraints*
- *Adding individual dimensions*
- *Adding and editing parameters*
- *Creating parametric equations*

Automatically constraining a sketch

Adding constraints to a sketch helps you finalize the shape of a sketched feature. Abaqus/CAE can apply constraints to your sketch automatically. You can use the sketcher options to select the types of constraints that Abaqus/CAE can add to the sketch. (For more information, see *Customizing the use of constraints in the Sketcher*.)

1. From the tools in the Sketcher toolbox, select the auto-constrain tool . For a diagram of the tools in the Sketcher toolbox, see *The Sketcher tools*.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

2. Select the entities to be constrained.

    **Note:**

   You can select the entire sketch; Abaqus/CAE will not duplicate any existing constraints.

3. Click **Done** in the prompt area.

   Abaqus/CAE creates the constraints on the sketch. Sketch modification tools such as translate, rotate, scale, and mirror can override constraints.

4. If desired, use the Delete tool to remove any unwanted constraints. For more information, see *Deleting Sketcher objects*.

Additional information

- *Controlling sketch geometry*
- *Constraining, dimensioning, and parameterizing a sketch*
- *Customizing the use of constraints in the Sketcher*

Automatically dimensioning a sketch

Adding dimensions to a sketch helps you finalize the size and shape of a sketched feature. Abaqus/CAE can apply dimensions to your sketch automatically. You can use the sketcher options to select the types of dimensions that Abaqus/CAE can add to the sketch. (For more information, see *Customizing the format and use of dimensions in the Sketcher*.)

1. From the tools in the Sketcher toolbox, select the auto-dimension tool . For a diagram of the tools in the Sketcher toolbox, see *The Sketcher tools*.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.
2. Select the entities to be dimensioned.

   Note:

   You can select the entire sketch; Abaqus/CAE will not duplicate any existing dimensions.
3. Toggle on **Auto-Constrain** if you also want Abaqus/CAE to create constraints automatically for the selected entities.
4. Click **Done** in the prompt area.

   Abaqus/CAE creates the dimensions—and constraints, if selected—on the sketch.
5. If desired, use the drag tool to move dimensions that appear within the sketched feature and use the delete tool to remove any unwanted dimensions or constraints. For more information, see *Dragging Sketcher objects*, and *Deleting Sketcher objects*, respectively.

Additional information

- *Controlling sketch geometry*
- *Constraining, dimensioning, and parameterizing a sketch*
- *Customizing the format and use of dimensions in the Sketcher*
- *Customizing the use of constraints in the Sketcher*

Adding individual constraints

A constraint is a logical relationship between entities in a sketch. Constraints control Sketcher geometry by removing degrees of freedom from the sketch. The various constraint types are described in *Using constraints to control sketch geometry*. To change constrained geometry, you must either work within the defined constraints or modify the constraints to accept your changes. You can also constrain a sketch automatically using the **Auto-Constrain** tool. For more information, see *Automatically constraining a sketch*.

1. From the tools in the Sketcher toolbox, select the constraint tool . For a diagram of the tools in the Sketcher toolbox, see *The Sketcher tools*.

   Abaqus/CAE opens the **Add Constraint** dialog box.
2. Select the type of constraint that you want to add to the sketch, and click **Apply**.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.
3. Select the entity or entities to create the constraint.

   Abaqus/CAE creates the constraint and displays the appropriate constraint symbol on the sketch. Sketch modification tools such as translate, rotate, scale, and mirror can override constraints.
4. To create additional constraints, repeat the above steps beginning with Step 2.
5. When you have finished creating constraints, click **Cancel** to close the **Add Constraint** dialog box.

Additional information

- *Using constraints to control sketch geometry*
- *Constraining, dimensioning, and parameterizing a sketch*
- *Customizing the use of constraints in the Sketcher*

Adding individual dimensions

Dimensions are a specialized form of constraints; where constraints create a logical relationship between Sketcher entities, dimensions create a numerical relationship. Dimensions add clarity to your sketches and allow you to position objects precisely. Use the dimension tool from the Sketcher toolbox to add individual dimensions to a sketch. You can also dimension a sketch automatically using the **Auto-Dimension** tool. For more information, see *Automatically dimensioning a sketch*.

The dimension tool is interactive; Abaqus/CAE uses preselection and the Sketcher entities that you select to display a preview of the dimension that will be created. If the dimension type shown is not the type that you want to create, move the cursor to another location. Once you accept the dimension type and position, you can enter a new dimension value.

Note:

The interactive function of the dimension tool is available only if preselection is active. Preselection is toggled on by default in the **Sketcher Options** dialog box. (For more information , see *The Sketcher cursors and preselection*.)

1. From the tools in the Sketcher toolbox, select the dimension tool . For a diagram of the tools in the Sketcher toolbox, see *The Sketcher tools*.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.

2. Select the first entity to dimension.

   Abaqus/CAE prompts you according to your selection:

Vertex

Abaqus/CAE prompts you to select another vertex or line for the dimension. Select a line to dimension the distance between the vertex and the line. Select a vertex to dimension the horizontal, vertical, or oblique distance between the selected points—the type of dimension Abaqus/CAE creates is based on the position of the second vertex and the cursor position.

Abaqus/CAE creates a preview of the dimension that will be created and its location based on the cursor position. Horizontal or vertical dimensions values between two vertices are preceded by an H or V, respectively.

Line

Abaqus/CAE prompts you to select a location for the default length dimension. To create a different type of dimension, move the cursor over other entities in the sketch; Abaqus/CAE creates a preview of the appropriate dimension type for the relation between the selected line and the preselected entity. Click on the desired entity to accept the displayed type of dimension.

Circle or circular arc

Abaqus/CAE prompts you to select a location for the radial dimension. No other entity selections are available.

3. Move the cursor to the location where you would like the dimension to appear; click when you are satisfied with the appearance of the dimension.
4. If desired, edit the dimension value in the prompt area; press `Enter` or click mouse button 2 to accept the dimension value.

Abaqus/CAE creates the dimension on the sketch. If necessary, vertices are moved to comply with the edited dimension value and any other constraints in the sketch.

5. To create additional dimensions, repeat the above steps beginning with Step 2.
6. When you have finished creating dimensions, do one of the following:
   - Click mouse button 2 anywhere in the Abaqus/CAE window.
   - Select any tool in the Sketcher toolbox.
   - Click the cancel button  in the prompt area.

Additional information

- *Controlling sketch geometry*
- *Constraining, dimensioning, and parameterizing a sketch*
- *Editing dimensions*
- *Specifying precise geometry*
- *Modifying objects by changing dimensions or adding parameters*
- *Customizing the format and use of dimensions in the Sketcher*

Adding and editing parameters

Parameters are constraints that have variable names. They can have either numerical values or values based on the result of mathematical expressions involving other parameters—parametric equations. Parameters can be associated with dimensions in the current sketch, or they can be numerical constants and expressions independent of the sketch. The value of parameters associated with dimensions directly affect the sketch, whereas independent parameters affect the sketch only if you use them to create expressions for parameters that are in the sketch.

You add and edit parameters using the **Parameter Manager**. You can use the **Dimension** button to create new parameters by selecting dimensions, or you can add independent parameters by typing them in blank lines in the manager.

1. From the tools in the Sketcher toolbox, select the **Parameter Manager** tool $f(x)$. For a diagram of the tools in the Sketcher toolbox, see *The Sketcher tools*.

   The **Parameter Manager** appears.

   Tip: You can also open the **Parameter Manager** by selecting **Edit->Parameter Manager** from the main menu bar or by using the **f(x)** button in the **Edit Dimension** dialog box.

2. Click **Dimension**, and select dimensions from the sketch to associate them with new parameters.

   Abaqus/CAE adds the new parameters to the **Parameter Manager** using default names of the form `dimension_x`.

3. Click on a cell in the **Name** column to edit an existing name, or add a new parameter name by editing a blank cell.

   If the selected parameter is associated with a dimension, Abaqus/CAE highlights the parameter in the sketch.

4. Click on a cell in the **Expression** column to edit it directly in the cell or to select it for editing with the **Expression Builder**.

   You must define all the parameters that you want to use in an expression prior to defining the expression.

   Tip: Use the buttons on the right side of the manager to insert, rearrange, or delete rows.

5. If desired, use the **Expression Builder** to edit the expression. For detailed instructions, see *Creating parametric equations*.
6. Click **Apply** in the **Parameter Manager** to implement your changes in the sketch.

   Abaqus/CAE updates the sketch with any new expression values and, if **Show parameter names** is toggled on in the **Sketcher Options**, displays the revised parameter names.

Creating parametric equations

Parametric equations are mathematical expressions relating different quantities in a sketch. The **Expression Builder** helps you create parametric equations using the parameters in your sketch. For example, if you want the width of a Sketcher object to be twice its length, you can *associate the dimensions* with parameters and use the **Expression Builder** to create the parametric equation $width = 2 * length$.

You can use the following operators to create parametric equations:

Mathematical operations:

+	Add.
–	Subtract.
*	Multiply.
/	Divide.
1/A	Divide 1 by the parameter, value, or expression.
abs(A)	Take the absolute value of the parameter, value, or expression.
sqrt(A)	Take the square root of the parameter, value, or expression.

Trigonometric operations:

cos(A)	Take the cosine of the parameter, value, or expression.
acos(A)	Take the arccosine of the parameter, value, or expression.
cosh(A)	Take the hyperbolic cosine of the parameter, value, or expression.
sin(A)	Take the sine of the parameter, value, or expression.
asin(A)	Take the arcsine of the parameter, value, or expression.
sinh(A)	Take the hyperbolic sine of the parameter, value, or expression.
tan(A)	Take the tangent of the parameter, value, or expression.
atan(A)	Take the arctangent of the parameter, value, or expression.
tanh(A)	Take the hyperbolic tangent of the parameter, value, or expression.

Logarithmic and exponential operations:

exp(A)	Take the exponential of the parameter, value, or expression.
log(A)	Take the natural log of the parameter, value, or expression.
log10(A)	Take the base 10 log of the parameter, value, or expression.

1. With an expression highlighted in the **Parameter Manager**, click **Expression Builder**. Abaqus/CAE opens the **Expression Builder** dialog box.
2. From the **Operators** list, select the desired operation.
   The operator appears within the expression window.

3. From the **Parameter Name** choices, click the name of the parameter on which to operate and click **Add to Expression**. You can choose from all parameters that appear above the parameter that you are defining in the **Parameter Manager**.

   The parameter name appears within the expression window.

4. Repeat Steps 2 and 3 as needed to complete the expression. In some cases you may need to reposition the cursor to correctly place the next portion of the expression.
5. When you are finished, click **OK** to save your changes and to close the dialog box.

   Abaqus/CAE updates the expression and the current value in the **Parameter Manager**.

Editing dimensions

Dimensions in Abaqus/CAE are used to precisely control sizes and distances, to annotate reference values, and to create parameters that are, in turn, used to define equations relating different pieces of geometry. You can edit any dimension in a sketch as follows:

- Change the dimension value. Changing a dimension value modifies the associated Sketcher geometry.
- Designate the dimension as a reference dimension. Reference dimensions indicate quantities whose values are controlled elsewhere in the same sketch or dimensions of reference geometry that are controlled in another sketch.
- Associate the dimension with a parameter. Parameters control Sketcher geometry by defining relationships between different pieces of geometry, including reference geometry.

The effects of modifying a dimension depend on how the dimension is used in the sketch. For example, if a radius has an equal radius constraint, editing the radius dimension will change all of the constrained radii. Likewise, if a dimension is associated with a parameter, editing its value will change the value of all the parameters that refer to it. For more information on constraints, dimensions, and parameters, see *Controlling sketch geometry*.

1. From the tools in the Sketcher toolbox, select the dimension modification tool . For a diagram of the tools in the Sketcher toolbox, see *The Sketcher tools*.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.
2. Select the dimension you want to change.

   Abaqus/CAE highlights the selected dimension and opens the **Edit Dimension** dialog box.
3. Enter a new value for the dimension.

   Note:

   You cannot edit the value field for reference dimensions or for parameters whose values are defined using an equation.
4. Toggle **Reference** to switch between a standard dimension whose value is used to control the sketch geometry and a reference dimension that reads the current value from the geometry.
5. Click **f(x)** to associate the dimension with a new parameter or to edit a previously associated parameter.

   Abaqus/CAE opens the **Parameter Manager** for editing. For more information, see *Adding and editing parameters*.
6. When you are finished, click **Apply** in the **Edit Dimension** dialog box to update the sketch.

   Abaqus/CAE updates the dimension and geometry as required. If your edits result in an overconstraint, the conflicting constraints, dimensions, and parameters are indicated in magenta (for more information, see *Fully constrained geometry*).
7. To edit more dimensions, repeat the above steps beginning with Step 2.
8. When you have finished editing dimensions, do one of the following:
   - Click mouse button 2 anywhere in the Abaqus/CAE window.
   - Select any tool in the Sketcher toolbox.
   - Click the cancel button  in the prompt area.

Adding reference geometry

When you sketch the profile of a feature, Abaqus/CAE projects onto the sketch sheet the part edges and vertices that are in the same plane as the sketch plane. In addition, Abaqus/CAE projects all datum axes and datum points onto the sketch sheet. These projected lines and points are called reference geometry, and you can use them for reference while sketching. If you want to use other edges and vertices, including orphan element edges and orphan nodes, you must project them onto the sketch plane as reference geometry by selecting **Add->References** from the main menu bar. Alternatively, if you want to create new sketch edges from existing model edges, you can select **Add->Edges** from the main menu bar (for more information, see *Projecting edges onto a sketch*).

1. From the Sketcher toolbox, select the **Project References** tool . For a diagram of the tools in the Sketcher toolbox, see *The Sketcher tools*.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.
2. Select the edges, vertices, orphan element edges, and orphan nodes you want to project onto the sketch plane as reference geometry.
3. Click mouse button 2 when you have finished making selections.

   Abaqus/CAE creates isolated points for the projected reference vertices and nodes and creates reference edges for the geometric and orphan element edges.

Projecting edges onto a sketch

When you sketch the profile of a feature, you can create new edges by projecting existing edges from the part onto the sketch sheet. You can use projected edges to duplicate the shapes of existing features as they appear from the current sketch plane. To project part edges, including orphan element edges, onto your sketch; select **Add->Edges** from the main menu bar.

1. From the Sketcher toolbox, select the **Project Edges** tool . For a diagram of the tools in the Sketcher toolbox, see *The Sketcher tools*.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.
2. If desired, toggle off **Constrain to background** in the prompt area to project the edges as independent objects.

   If projected edges are constrained to the background, their shape and position depend on the original feature edges. If projected edges are unconstrained, changes to the original feature do not affect them—you can edit the projected edges and vertices independently from the original feature.
3. Select the edges you want to project into the sketch plane.
4. Click mouse button 2 to indicate you have finished selecting edges.

   Abaqus/CAE creates the new edges in the sketch.

Moving or copying sketch geometry

This section describes how to use the translate, rotate, mirror, and scale tools to move or copy Sketcher geometry.

In this section:

- *Translating Sketcher objects along a vector*
- *Rotating Sketcher objects about a point*
- *Enlarging or reducing Sketcher objects*
- *Moving or copying Sketcher objects about a mirror line*

Translating Sketcher objects along a vector

Use the translate tool from the Sketcher toolbox to move or copy Sketcher objects—lines, arcs, circles, ellipses, fillets, or splines—along a specified vector. You can define the beginning and the end of the translation vector by selecting from the sketch or by typing the *X*- and *Y*-coordinates of each end.

1. From the move and copy tools in the Sketcher toolbox, select the translate tool . For a diagram of the tools in the Sketcher toolbox, see *The Sketcher tools*.
2. Select **Copy** or **Move** in the prompt area.

   Abaqus/CAE displays prompts in the prompt area to guide you through the procedure.
3. Select all the objects that you want to translate. You can select sketch and construction geometry to move, or you can select sketch, construction, and reference geometry to copy; dimensions cannot be translated.

   Tip: To select more than one object, hold down the **[Shift]** key as you click each object or drag a rectangle around the objects. To unselect an object, use **[Ctrl] + Click**. For more information, see *Selecting objects within the viewport*."
4. Click mouse button 2 to indicate that you have finished selecting objects.
5. Select a start position for the translation vector, or enter coordinates in the prompt area.
6. Select an end position for the translation vector, or enter coordinates in the prompt area.

   Abaqus/CAE moves or copies the selected objects as specified.
